Organized by International Computer Chess Association
Important Times and Places

Opening Reception and Lunch
Thursday 25 May 1995, 12 Noon - 2 pm
Royal Park Hotel, Shatin, New Territories.

Rules Meeting
Thursday 25 May 1995, 3 pm - 4 pm
Room 603, Ho Sin Hang Engineering Building, The Chinese University of Hong Kong.

Championship Rounds
Round 1 Thursday 25 May 1995, 4 pm-10 pm
Round 2 Friday 26 May 1995, 4 pm-10 pm
Round 3 Saturday 27 May 1995, 4 pm-10 pm
Round 4 Sunday 28 May 1995, 4 pm-10 pm
Round 5 Monday 29 May 1995, 4 pm-10 pm
(All rounds are in Room 603, Ho Sin Hang Engineering Building, The Chinese University of Hong Kong.)

The Saitek Challenge (Humans v Computers Match)
Sunday 28 May 1995, 10 am-3 pm,
Room 603, Ho Sin Hang Engineering Building, The Chinese University of Hong Kong.
(A match over 6 boards between a team of computers and a team of the best human chess players living in Hong Kong. The games will be played at the rate of 40 moves in two hours followed by either adjudication or the remainder of the moves in 30 minutes.)

Computer Strategy Games Programming Workshop
Friday 26 May 1995, 10 am - 3 pm
Room 503, Ho Sin Hang Engineering Building, The Chinese University of Hong Kong.

Awards Ceremony and Closing Lunch
Tuesday 30 May 1995, 12 noon - 2 pm
SCR Clubhouse, The Chinese University of Hong Kong.
(Trophies will be awarded to first, second and third places.)

ICCA Triennial Meeting
Saturday 27 May 1995, 3 pm - 4 pm
Room 603, Ho Sin Hang Engineering Building, The Chinese University of Hong Kong.

Other Information
Exhibits by Saitek and Novag will be in Room 601, H.S.H Building, CUHK.
Refreshments are available to participants & officials in Room 606, H.S.H Building, CUHK.

Officials
Tournament Director: Mike Valvo (IM)
Tournament Organizers: Monty Newborn, Tony Marsland and David Levy.
Local Arrangements: Hon Tsang (Tel. 2609-8254)
A Hong Kong Welcome
by Tony Marsland, ICCA President.

The International Computer Chess Association welcomes participants, guests and members of the public to the Eighth Triennial World Computer Chess Championship. For the first time the event is being held outside Europe or North America. This new development reflects not only the growing technical importance of the Orient in an increasingly interconnected world, but also the interest of our principal sponsor, the IBM Corporation, which is to open a research laboratory in China this year.

This championship brings together the strongest group of entrants ever assembled, and we can expect vigorous competition for the coveted Shannon Trophy. Amongst the competitors I am pleased to recognize first the six professionals: Chess Genius from England, Fritz from The Netherlands, the Deep Blue prototype—a reworked version of the 1989 world computer-chess champion—from IBM-America, W-chess and M-chess, also from the US; and a welcome newcomer, VirtuaChess from France. These professionals have their reputations on the line to compete against some very tough amateurs from major universities using powerful multiprocessor systems: Zugzwang from Paderborn, Hitech from CMU, Star-Socrates from MIT, Frenchess from Paris and Phoenix from Alberta. In addition, there are thirteen PC or SPARC based programs - dark horses that have no doubt been worked on for innumerable hours over the past three years, and that are likely to provide some strong challenges. Inevitably not all programs will fare as well as their designers would like—after all, in this field one has to run just to stand still - but every one, I feel sure, will benefit from the experience.

We would not be here today without the help and co-operation of many people. Thanks, first, to the Chinese University of Hong Kong, which through its Dean of Engineering, Professor Omar Wing, greeted the initial proposal with enthusiasm and provided a beautiful tournament hall—the view from the window will be difficult to equal. Dr. Hon Tsang of the Department of Electronic Engineering, and the current Hong Kong chess champion, has given outstanding leadership in handling local arrangements, with the especially able assistance of Ms. Maxi Hui and Ms. Au Din Zee. Their efforts in locating and bringing together all the necessary computing and communication equipment, and in corresponding with local companies and the media, are to be highly commended.

Second, this event has been made possible by the support of our major financial sponsors, IBM, Compunetics and the Association for Computing Machinery, together with local sponsors including Sun Microsystems, Saitek, Varitronics, and Yorter Electronics. Saitek is also sponsoring today's reception and prizes for Sunday's match between computers and humans. Our thanks to all of them.

Last, but certainly not least, special thanks to my volunteer co-workers on the ICCA executive: Monty Newborn, who put in so much time negotiating with IBM, and David Levy who regularly shared with me his experience and who spent many hours coordinating with applicants. I must also add my thanks to the Computer Science Department at the University of Hong Kong, (the other one!), who made it possible for me to extend my stay and so take in this event.

Following the tradition of earlier championships we have invited an honoured guest. I welcome Robert Byrne, well-known chess correspondent for the New York Times. For nearly two decades Mr. Byrne has written about computer chess activities; he was one of the first reporters to recognize the growing strength of computer chess programs, and to perceive the contribution of computer chess to science and technology in general. We express our appreciation to him for this interest and enthusiasm for our endeavours.

The ICCA is pleased to secure once again the services of Mike Valvo as Tournament Director. Competitors always respect Mike for his experience and his calm manner, which give them confidence in his decisions. We can therefore, as always, look forward to a professionally run event under his direction.

Most participants here probably cherish a secret hope that theirs may be the first program to meet the human World Chess Champion for a regular match. Two competitors, Chess Genius and Fritz, have already won rapid-play games against Gary Kasparov, but it is still by no means certain that the occasional loss by the best human players in high-speed games represents the thin end of the wedge, the beginning of the end of human domination over computers in chess. By the end of this week, however, there may be concrete evidence to support the perennial prediction that within five years the human world champion will lose a match to a computer, and we may even know which computer that might be. Let the championship begin!
The Anatomy of Chess Programs

T.A. Marsland
Professor of Computing Science
University of Alberta
Edmonton, Canada

Introduction

Logically, chess is a trivial game: at every move, simply follow through each possible reply and its consequences until either a mate or a draw position is reached. In practical terms, however, this strategy is not workable, since an astronomically large number of chess positions would have to be examined. Thus both human players and computers rely on simplification to build an approximate model of the game. Human players have centuries of tradition and at least two hundred years of chess literature to draw on in building their personal model, but computer chess is less than fifty years old. Significant among the early ideas in computer chess is Claude Shannon's 1949-50 distinction between a brute force (type-A) strategy for looking at every combination of moves, and the use of chess knowledge to select and examine only a subset of the available moves (type-B strategy). Although some electro-mechanical systems to play a subset of chess had been built prior to Shannon's work, it was the programming of his ideas that led to the development of today's computer chess machines.

Current chess programs view the game as a tree search in which each position corresponds to a node in the game-tree, and each move is a branch (a transition from one node to the next). Thus the tree is made up of alternating layers or levels of moves for each side. (The term "ply" is used to denote each layer, and refers to one move by one player.) A three-stage tree model is popular with computer chess programmers. The first stage uses a brute force (Shannon type-A) approach, the second a selective (type-B) search, and the third a strategy known as a quiescence search, designed to resolve the problems and conflicts that remain. In this final stage the program evaluates sequences of capturing moves, assesses pawn promotion potentials, examines checking sequences and considers other highly constrained tactical issues. All programs use the same underlying depth-first alpha-beta search algorithm. What varies from program to program is the length (or "depth", to keep the layer analogy) of search assigned to each of these stages. Ultimately the stage length is not fixed, but varies by small amounts depending on the current sequence of moves being examined. For example, a search path may be locally lengthened because one side has attacked the King (given check), leaving the opponent with only a few alternatives to consider. There are so many options here that even programs using the same basic model can achieve a radically different style and speed of play.

Tree Searching

While the human method of analyzing alternatives seems to involve selecting a few promising lines of play and exploring them, computers are necessarily exhaustive rather than selective, so refinement techniques have been developed. In a technique called "iterative deepening", instead of embarking on a single search of a certain ply (which might not be completed in the given time) the computer performs a series of increasingly deeper searches (starting then at ply N+1, then N+2, etc.) until the allotted time runs out. Thus it is able to produce the best move that the time constraint allows - a computer-chess situation that has many parallels in real-time applications. The computer can combine iterat-
tive deepening with various memory functions, particularly refutation and transposition tables, to reorder moves, so that at the next iteration its selected "principal variation" (best sequence of moves found during the previous iteration) is explored first. Another move-reordering technique is to keep a short list of "killer" moves, which are tried first. Killer moves are those that have successfully "cut off" or pruned the search elsewhere. Often these killer moves are captures, so a simplification involves considering capture moves before all others. This technique is nicely generalized in the "history heuristic table" that many programs use. In its most elementary form a history table has 64x64 entries, each containing a value that measures the frequency with which the corresponding possible move has recently pruned the search.

Move-reordering mechanisms enhance the efficiency of the depth-first alpha-beta search algorithm. Three other improvements - Pearl's Scout algorithm and the related NegaScout and Principal Variation Search (PVS) methods - share a common theme: once a principal variation has been found it is sufficient to show that each alternative is inferior. Any that is not inferior must be re-searched, since it now constitutes the preferred path. Another technique for curtailing the search is called aspiration alpha-beta search. In this approach the value of the tree from the current position is estimated and a narrow search window (customarily plus and minus the value of half a pawn around that estimate) is used. Aspiration searching is a popular and better understood alternative to the Principal Variation Search method, although not as efficient.

It is difficult to be precise about the advantages that more searching provides. The size of the chess tree for any position is highly variable. In many endgames there are only about 8 moves for each side, while in complex middle game positions each side might have close to 80 moves. With today's technology programs exhaustively search 7 to 10 ply in the middle game, while at least one programmer claims to extend searches selectively to 40 ply! Selective extensions are based on heuristics devised by individual programmers to explore the sphere of influence associated with a key move: to examine the moves that might defend against a mate threat, or that might provide a counter attack and thus indirectly avoid some imminent loss. Selective extensions are not to be confused with singular extensions. The latter technique re-examines any move that looks singularly good relative to the others. The search depth is increased to determine whether the singular move remains best. In some sense this is a way of extending the principal variation in the small. It is a potentially costly but interesting method.

More popular and more widely used is the null move heuristic, where one side provisionally makes two successive moves. If the value of the position remains poor even with the benefit of two moves in a row, then the line of play is abandoned. This is one way to identify situations where an inevitable loss is otherwise being pushed out of sight beyond the search horizon. While many forward pruning methods fail too often to be useful, null move forward pruning is usually beneficial.

Transposition Table

A transposition table serves as a cache memory and is used to store information about positions that have been visited before, usually during an earlier part of an iterative deepening search. It is so called because it can be used to recognize transpositions in the order of moves. Stored in the entry associated with a position are important items like the "value" of the position, the best move from there, and the length of the previous search. "Value" is computed by applying an evaluation function at the terminal nodes of the tree (the nodes on the horizon where the search is stopping). This evaluation function often includes a quiescent search to help resolve existing capture sequences and other uncertainties in the position, such as pending pawn promotions. Transposition tables are also invaluable as a means of extending search in the endgame, where only a few new moves emerge at each node, the others leading through transposition to positions that have been seen before. These tables do not increase program size or complexity, since the total space allocated to them is simply a matter of cost. Each transposition-table entry requires about 10 bytes of memory, and most programs have tables in the range from 32 thousand to 1 million entries, though in 1993 one Supercomputer program boasted a table with 1,000 million entries. This wide range simply reflects the memory available to the programmer.

Program Performance and Rating

Despite the underlying similarity in methods there is wide variation in performance among the programs, even in machines using identical hardware. In some cases this merely reflects the effort put into the program's development. For example, although every program has an opening book, there is no basic book for them to use. Each team develops its own. At present these books vary in size from about 10,000 chess positions to about 500,000 positions, although one experimental program has 1.7 million book entries. Conversely, only a few people use Ken Thompson's CD-ROM database of 5 and 6-piece endgames. This is partly for technical reasons related to relatively slow access to the database, but also because most games finish before reaching these known endings. Perhaps programmers are just
being realistic about how to spend their time!

When it comes to speed of execution, contemporary programs examine between 3,000 and 500,000 positions per second on a single processor. Big differences in speed exist even for programs using identical machines. There are many explanations. Those who program in assembler tend to have faster programs, but even for the same programming language, not all compilers (translators) produce equally fast executable code. Much depends too on the relative sizes of the brute force, the selective and the quiescent search stages. Extra time is required in the selective stage to assess and identify which moves will be examined. The extent of this slow, knowledge-based process accounts for much of the speed difference. One other factor that influences the speed and strength of a program is the size of its transposition table.

Although many chess programs are similar to each other, their relative playing strength can still differ greatly. Determining that strength is no easy matter, since programs can be tuned to perform well on any standard test suite. For this reason the group who produce the Swedish Rating List use a more traditional approach. All commercially available programs continually and automatically play games against each other, leading to hundreds of statistically valid results. From these data an ELO rating is computed, much like the rating system used for chess players in America and elsewhere. In the US the average club player has a rating over 1500, while experts are in the range 2000-2200 and masters are rated 2200-2400. Above that come the super elite players called Grand Masters, of whom about 300 are active worldwide. At the Eighth World Computer Chess Championships most programs have an ELO rating in the range 2100-2500. The current Swedish rating list is published in each issue of the International Computer Chess Association Journal.

The Future

These days the top chess machines are challenging the Grandmasters, especially in rapid play where the stand-alone PC-based machines have an advantage over multiprocessor-based systems. Stand-alone machines are especially fast, because they don’t need the services of a computer network to transmit their moves. Multiprocessor machines using 10 to 100 processors are often better at the standard competition rate of play of 40 moves in 2 hours. Soon systems with 1000 processors, each as powerful as a high-performance PC, will be with us. Even if their efficiency is only at the 50% level, they will be able to search 2 or 3 ply deeper in a typical middle-game position than any single-processor system. By then computers will be clearly out-searching humans. Whether this will be enough to compensate for the human’s proven strength in long-term planning remains to be seen. Human chess players are especially skilled at simplifying complex situations and identifying the fundamental issues. They are also adept at provoking long-term weaknesses in their opponent’s position, until it becomes indefensible. Despite these advantages, each year we draw closer to realizing the perennial prediction that computers will beat the best humans at chess within 5 years. It could certainly take another decade to achieve that, but the inevitability is clear!

Program Descriptions

Cheiron by Ulf Lorenz (Germany)
In Greek mythology, Cheiron was the wisest of all centaurs and the teacher of many heroes. The program Cheiron is written in C. It is an alpha-beta program using most of the known state-of-the-art heuristics including transposition table and selective deepening but not null moves. The quiescence search is quite large focusing on mating and promotion threats. The evaluation function examines the pawn structure, king's security, static positions of the pieces, everlasting knights etc. as well as special situations in the endgame. On a Pentium 90MHz the program will search about 10,000 nodes per second. Cheiron relies more on positional playing than tactics. The opening book contains about 12,000 positions. On a 50MHz 486 PC, Cheiron has an estimated rating of 2100 ELO based on tournament results against humans.

Chess Genius by Richard Lang (UK)

Dark Thought by Peter W. Gillgasch, Markus Gille and Ernst Heinz (Germany)
Dark Thought is a brute-force program employing sophisticated move ordering techniques and search extensions backed by a selective quiescence search. On a DEC 3000-600 (175MHz Alpha 21064 CPU, 64MB RAM) Dark Thought visits up to 60,000 nodes per second and reaches a non-selective, brute-force search depth of at least 8 plies in 1 minute. Its opening book contains 250,000 positions. On-line access to Thompson's endgame databases is handled by a greatly enhanced version of the public domain software by Beuckens and Hoekstra. Peter Gillgasch, the main brain behind the chess engine, wrote a prototype version of Dark Thought in Pascal in 1992. Today the program compiles and runs from the same ANSI C source files on a variety of platforms. Markus Gille and Ernst Heinz are responsible for fine-tuning the evaluation function and databases and Peter Gillgasch still maintains the chess engine. During the World Championships, Darkthought will run on the most powerful DEC Alpha workstation available.

Deep Blue Prototype by Feng-Hsiung Hsu, Murray Campbell and A Joseph Hoane (USA)
The Deep Blue Prototype consists of an IBM RS/6000 workstation with 14 chess search engines as slave processors. Each processor contains a VLSI chip for move generation, as well as additional hardware for search evaluation. Each processor searches about 500,000 positions per second standalone, or about 400,000 positions per second as a slave processor. (This is about 1/10th of the projected speed of the Deep Blue single-processor currently in fabrication.) The 14-processor prototype typically searches between 3 and 5 million positions per second. When conducting a search, the search tree near the root position is processed on the host workstation, and includes selective search extension algorithms such as singular extensions. The deepest nodes in the search tree are handled by the slave search engines which usually do 4-ply alpha-beta searches.

Ferret by Bruce Moreland and James Parker (USA)
Ferret is a "normal" brute-force program that runs under Windows NT. Techniques and tools used by the program include alpha-beta pruning, selective search extensions, quiescence search limited by a static exchange evaluator, null-move forward pruning, a 50,000-positions opening book, several hash tables and a few simple endgame databases. The program consists of about 20,000 lines of C code and has been compiled using Microsoft Visual C 2.0. Ferret searches approximately 18,000-32,000 nodes per second on a Pentium 66. It was written during off-hours over a period of about 4 years, for fun. Ferret finished fifth in Don Beal's uniform platform tournament last September. It has also played several hundred games of blitz chess on the Internet Chess Server, where it has been shown to be competitive among strong human players and various commercial programs.

Frenchess by M.F. Baudot, J.C. Weill, J.L. Serret (IM) and Michel Gondran (EDF) (France)
Frenchess is a parallel chess program which runs on a CRAY T3D computer (128 Alpha processors, owned by the Commissariat à l'Energie Atomique located in Grenoble, France). It is written in C and is based on the parallel algorithm described by Jean Christophe Weill in his PhD thesis: Alpha-Beta Distribue Avec Droit d'Ainesse (ABDADA). The evaluation relies mostly on an Oracle approach, which introduces a strategy and is designed to be
rewritten in the CHEVAL (CHESS EVAluation Language) evaluation function description language currently under development (but CHEVAL will probably not be ready for the World Championships). Frenchies is written with the support of the "Direction des Etudes et Recherches (DER) d'Electricite de France (EDF)" as a research project on parallel computing.

Fritz by Frans Morsch and Cok de Gorter (The Netherlands) and Mathias Feist (Germany)
Fritz is built around a selective search technique known as null-move search. As part of its search, Fritz allows one side to move twice (the other side does a null-move). If the position after the null-move does not return a high value in the evaluation function, then clearly the first of the two moves did not contain a threat. This applies to 95% of the moves in a search. Detecting such moves before they are searched to the full depth is an excellent method to speed-up the search. In its latest version, Fritz manages a 10-times speed-up over a version without the null-move search. Selective search unavoidably introduces oversights, but these are few. In tournaments against humans and other programs, Fritz has proven to be a tough opponent when defending difficult positions.

Gandalf by Steen Suurballe (Denmark)
Gandalf is a PC program developed over the last ten years. The program performs highly selective searches, combining a one-ply brute-force search with selective search and search extensions. The search does not use standard techniques like the null-move method, but instead uses a rule-based method involving a calculation for every node to decide which moves are good. Development of the program was an extremely difficult and time consuming task. Gandalf searches about 1500 nodes per second on a 486/66. Gandalf has considerable chess knowledge and plays aggressively, which is unusual for a highly selective search program. Gandalf uses an opening book containing about 500,000 positions.

Junior by Shay Bushinsky and Amir Ban (Israel)
Junior is a leading Israeli chess playing PC program. It was developed as a hobby by Amir Ban and Shay Bushinsky. Junior's breakthrough occurred during August 1994: The program scored a remarkable equal fourth place (with GM Alon Greenfeld) in the Kfar-Saba Open national chess tournament. The games were conducted under normal tournament time control. In the final round, Junior amazingly defeated GM Leonid Gopstein. During November 1994, Junior participated in the strongest international blitz tournament ever held in Israel. It beat GM Ilya Smirin and drew with GM Lev Psakhis and GM Alon Greenfeld. Amongst others, Junior reached a completely won position against GM Judit Polgar. Since then Junior has established itself as a well respected player.

Hitech by Hans Berliner, Chris McConnell et al. (USA)
Hitech is a chess machine with special purpose hardware that is capable of evaluating 120,000 positions per second. The hardware is controlled by a SUN 4 workstation running either a brute force or selective search engine. Originally built in 1985 at Carnegie Mellon University, Hitech has since won several computer-computer and human-computer tournaments. Its primary purpose is supporting research into new search techniques. Active research includes a new selective search algorithm and techniques for automatically constructing better evaluation functions.

Lchess by Lex Loep and Ger Neef (The Netherlands)
The first version of LCHESS was written in 1987. In 1988 it participated for the first time in the Dutch Computer Chess Championship, ending 13th in a field of 16; the best result was in 1990 when it shared 3rd place. Lex Loep has steadily worked on the chess engine and the version which is playing in the WCCC has been ported to Windows NT. Techniques used by the chess engine include alpha-beta search, iterative deepening, PVS, null moves for pruning and threat detection, history tables, killer heuristics, transposition tables and refutation tables. Tactically the program plays very well, and is particularly good in finding mate threats. Positionally there is still a lot of work to do. On the Reinfeild test set it scores more than 80% with 1 minute CPU time on a Pentium 90. Search speed is 30,000-50,000 nodes/second. Ger Neef wrote the user interface.

M-Chess Pro by Martin Hirsch (USA)
knowledge of a number of endgame, while being tactically powerful. M-Chess Professional is commercially available with an excellent interface and an extensive set of features. It is currently ranked second in the Swedish Computers Rating List.

**Nightmare by Reinhold Gellner and Gaby von Rekouwski (Germany)**
Completely written in C, work on Nightmare started in 1989 as a non-commercial project. It is a brute force program searching up to 7-ply in the middle-game with a selective search depth of up to 40 ply. Modified null-move searches, modified singular extensions, part-ply extensions and a new idea of hashing related meaningful subtrees are special features of Nightmare. The program also uses well known techniques like killer-moves, history heuristic, principal variation search and hash tables of 64,000 entries per side. The tournament opening book consists of about 40,000 moves. Endgame databases are NOT used. Last year, Nightmare was transferred to 32-bit under extended DOS and it can now search 12,000 moves per second. The program’s rating is about 2000 ELO (German) on a 486-50.

**Pandix by Gyula Horvath, Szuzsa Horvath and Csaba Szus (Hungary)**
Gyula Horvath started writing chess programs in 1985. His program won the Amateur World Chess Championship in 1987 and the Personal Computer Chess Champion title in 1988 and 1989. His wife, Szuzsa, joined the development in 1986. She is mainly active in testing the program and in designing and programming the graphics of the commercial versions of the program. Both of them pursue chess programming as a hobby - Gyula works as a marketing researcher and Szusza works as a telemarketing assistant. They have participated in various computer chess events since 1986. In 1993 their team increased to three members when Csaba Szus began to implement a new 100,000 moves opening book. The program is written in C and uses a 400KB hash table. It measures the move interest and incrementally updates the attack map. The program uses principal variation search, advanced time control and special limited quiescence search.

**Phoenix by Jonathan Schaeffer (Canada)**
The Phoenix program was an active participant in the 1980’s computer chess tournaments and tied for first place in the 1986 World Championship. The program competing this year is essentially the same as that which competed in the 1989 World Computer Chess Championship. Phoenix’s participation in the 1995 championship will serve as a benchmark for measuring improvements in the field. Phoenix will be running on a 20 processor SPARC 2000 server. Therefore the primary difference will be in the hardware. Expectations are that the software advances in the last 6 years will allow the other programs to move past Phoenix 89 in the final standings.

**Schach 3 by Matthias Engelbach (Germany) and Tom Kreitmeir (The Netherlands)**
Schach 3 is the PC version of Schach 2.x one of the earliest German chess programs. It is a non-commercial project developed and maintained by two former students. Work on Schach started in 1978 and after some surprisingly good results in computer chess tournaments, the authors could not stop working on the program. Even the distance - one of the programmers (Kreitmeir) lives in the Netherlands and the other in Germany - is no real handicap. The program is a more or less simple Shannon-A program with all the known extensions (the authors believe in the brute-force method for computer chess). The program is written in 486-assembler and can search nine or ten plies in the middle-game. Schach participated in the 1980, 1983 and 1986 World Championships, in the ACM events in the period 1981-1985 and in the German and Dutch Championships since 1992. Best results were a 6th place in Linz 1980 and New York 1983, a 3rd place in the 1994 Dutch Championship and a first place in the 1994 German Championship (Zugzwang was absent, but we all need some good luck!)

**SOS by Rudolf Huber (Germany)**
SOS is a conventional chess program. It uses depth first minimax tree search with quiescence search, alpha-beta enhancement, minimal window search and null-move pruning. To improve the search efficiency, the history heuristic and a transpositional table is used. The search is extended to deeper plies on those move sequences which have a high probability of being part of the principal variation. For SOS, those sequences are recaptures and check evasions. Leaf node evaluation considers only material, piece placement and pawn structure and only about 10% of the CPU time is spent on this (not including the quiescence search which is capture only, but extends on “losing” captures which are checks and on checking sequences). The evaluation parameters are dynamic and continuously updated during tree search. SOS’s weakest part is probably endgame knowledge. SOS actively plays a wide range of openings, but most of those lines are not very deep. With autoplay games against itself, the opening book is tuned to favour those lines which harmonize with SOS’s style of play.
StarSocrates by D. Bailey, C. Joerg, B. Kuszmaul, C. Leiserson, R. Blumofe, M. Frigo, L. Kaufman (IM), K. Randall, Rolf Riesen and Yidi Zhou (USA)

The StarSocrates 2.0 chess program developed at the MIT Laboratory for Computer Science, will be running on the 1824 node Intel Paragon parallel supercomputer located at Sandia National Laboratories. The lead programmers are Don Bailey and Christiano F. Joerg and the project team is lead by Prof. Leiserson. Heuristic Software provided the chess engine on which StarSocrates was originally based. The Paragon is about 50 feet long and weighs about 30,000 pounds. Each node consists of two 50MHz 1860 processors with either 16 or 32MB of memory. The program currently runs on both the Connection Machine CM-5 and the Intel Paragon. More information about StarSocrates can be found on the web at http://theory.lcs.mit.edu/~clik/starso.html.

Ulysses by Ulf Lorenz and Valentin Rottmann (Germany)

Ulysses was the legendary conqueror of Troy and on his adventurous journey home to Athens he made many wanderings. The program is written in C and uses a new searching technique called ‘Controlled Conspiracy Number Search’ (CCNS). The algorithm is described in Lorenz’s and Rottmann’s master thesis. CCNS takes up McAllester’s 1988 Conspiracy Number scheme. Unlike Schaeffer’s 1989 “Conspire” system, which was only a tactical player, Ulysses also exhibits good positional play. Conspiracy search achieves consistency in the plain search algorithm without any domain dependent (i.e. chess specific) knowledge. In the evaluation of leaf-nodes a CCNS algorithm is able to use quiescence searches with initial windows. Positional play thus becomes possible. The program’s speed is attributed to the use of big memory tables, and from not wasting resources computing an upper bound for the value of the best move. All chess specific knowledge used in the static evaluation function which in turn uses a small quiescence search. Using a Sparc 10 60MHz, UlyssesCCN searches about 8000 nodes per second, about 350 of them are Conspiracy Number nodes. The opening book consists of 11,000 positions. After 300 seconds at each position, Ulysses solves 28 positions of WinAtChess test set, consisting of 300 positions. To our knowledge, this is the first chess program based on Conspiracy Numbers which achieves acceptable results in computer chess competitions.

VirtuaChess by M.F. Baudot and Jean Christophe Weill (France)

VirtuaChess is the commercial version of the Ecume and Cumulus 2 chess programs (which finished second in the blitz tournament in Munich and which tied 2nd/3rd in the 7th World Championships in Madrid). It runs on a PC with MSDOS and can use all available memory for its hash tables. It has a splendid graphical interface written by the French firm Titus. Most of the chess engine is written in 32 bit assembler, and the program includes dynamic evaluation of king safety and pawn structure. It is based on PVS and uses null-move pruning. The program has perfect knowledge of KPK endgames. The evaluation function attempts to build plans whenever it recognizes important features in a position. VirtuaChess runs at 20,000 nodes per second on a Pentium 90.

WCChess by Dave Kittinger and James Parker (USA)

WCChess received worldwide attention after it scored 5 out of 6 against some of the strongest American grandmasters in the Intel Harvard Cup Man v Machine tournament held in October 1994. The program consolidated its position as one of the top micro-computer chess programs by winning the 1990 Uniform Platform Computer Chess Tournament held in London. WCChess uses an iterative, depth-first alpha-beta search with forward pruning and a tactical swap-off evaluation to limit the growth of the search tree. The evaluator is somewhat primitive and is not currently as dynamic as the author would like. Positional information is communicated to the search mainly by piece value tables. The current version only implements end game databases for KPK although the author is looking into adding more databases.

Woodpusher by John Hamlen (UK)

Woodpusher is a small chess program (<64K) of conventional design. It uses an iterative deepening alpha-beta search with PVS and aspiration window enhancements. The first version of Woodpusher was born in 1989 as part of a university project looking into null-move search techniques. True to its origins, this new version of the program still uses the null-move throughout the search to recognize threats and to forward prune branches of the search tree. A database of attacks from and to all the squares on the board is maintained by using CHESS 4.5’s bitboard implementation. These data structures are used for both generating moves and making positional evaluations. Woodpusher’s position evaluation is maintained almost entirely incrementally while making and un-making moves during the search, with very little work done at the terminal nodes. The evaluation is therefore necessarily simple, but does include true measures of mobility rather than relying on piece-square evaluations.
Zeus 3.0 by Gerardo Castano (Spain)

Gerardo Castano works as a medical doctor and writes computer chess programs as a hobby. Zeus 1.0 was written in basic and finished fifth out of seven in the first Spanish Computer Chess Championships in 1993. The program was rewritten in C in 1994 and uses the standard techniques of alpha-beta search, selective extensions, minimal PVS, transposition tables, killer heuristic, history heuristic, null-move pruning and quiescence search. Capturing moves, checks, promotions, mate threats are all considered in the search. Zeus 2.0 used 256KB hash tables and searched 3000 nodes per second. It won the second Spanish Computer Chess Championships in 1994 with 7/7. Zeus 3.0 uses massive hash tables (32MB), and contains extensive chess knowledge (pawn structure, strong squares, bad bishop etc). The opening book contains about 300,000 positions and recognizes move and color transpositions. The endgame database is being developed and the evaluation function, although large, has produced good results.

Zugzwang by R.Feldman and P.Mysliwietz (Germany)

Zugzwang made its first moves in 1989. It won the bronze medal in the 1990 Computer Olympiad, and won the Paderborn (human) Championships in 1991. In the last Computer World Championships in Madrid 1992, Zugzwang, running on a system consisting of 1023 T800 transputers, finished second and was undefeated without playing the eventual Champion, Chess Machine Schroeder. In 1993 Zugzwang had its first victory over a grandmaster. In 1994 Zugzwang was completely rewritten from OCCAM to C (about 20,000 lines of code) and is now portable to a large spectrum of machines including SPARC, SGI, DEC Alpha, I860, 486 and PowerPC. In this year’s Championships, Zugzwang will run on a GC-Powerplus distributed system (based on the Power PC) with at least 96 processors. The opening book contains about 130,000 moves and 1MB transposition tables are used per processor. Zugzwang uses brute force alpha-beta search with history tables and killer heuristics. The program searches about 3000 nodes per second on processors on a PowerPC. The search is performed by distributed processors using a distributed algorithm based on the Young Brothers Wait Concept, which gives good results even if as many as 1000 processors are used. In this case the machine calculates moves more than 400 times faster than a sequential system.
Recent Games of Note Played by the Top Programs
Monty Newborn and David Levy

In the last two years, the top programs have played some very strong games. We include here a sampling of seven of them. Six of them are computer versus human games. The remaining one is between two of the leading contenders here, Deep Blue and Star Socrates. The seven games thus cover five of the leading participants in the Eighth World Computer Chess Championship.

August 1993: Yorktown Heights, New York
The following two games were played at IBM's T.J. Watson Research Center in Yorktown Heights, New York on August 20, 1993. They were played at a speed of all moves in 30 minutes per player per games. IBM had invited Judit Polgar to their world-famous research center for the encounter.

Game 1: White: Deep Blue Prototype                Black: Judit Polgar [2630 FIDE]
1 e4 c5 2 Nf3 e6 3 d4 d5 4 Nbd2 Nf6 5 Nc3 Qc7 6 b3 a6 7 O-O Bb4 8 Nc6 b6 9 Qd4 Bd6 10 Qg7 Bh2+ 11 Kh1 Be5 12 Bf4 Bg7 13 Be7 d5 14 Rad1 Ne7 15 Na4 Ra7 16 Bb6 Ra8 17 e3 Ng6 18 Bc7 Ra7 19 Bb8 Rb7 20 Bg3 O-O 21 cd5 cd5 22 Rf1 f5 23 Bb6 Rb8 24 Bb5 c5 25 Bb4 Rc8 26 Ba5 Rb8 27 Bb6 Rf7 28 Kg1 f4 29 h3 Bb7 30 Bb5 Rf7 31 Kf1 Ke7 32 e4 Rc8 33 Ba5 d4 34 Nb6 Rb8 35 Nd7 Rc8 36 Bd4 c3 37 NB4 c5 38 Nb3 Rb8 39 Ng4 Ke7 40 Rfd1 a5 41 Ra4 Be6 42 Ra5 Rb3 43 Ra7+ Kf6 44 Rf7 Nf4 45 g3 Bb5+ 46 Kg1 Nh3+ 47 Kg2 Ng5 48 Rh6+ Kg7 49 Re5 Bc6+ 50 Kh1 Rh1 51 Re1 Rh2 52 Be2 Ne4 53 Rd1 Bd5 54 Re1 Nd2+ 55 Ke1 Ne4 56 Ra1 Nec 57 Bd3 Na2 58 Kh1 Nb4 59 Bf5 Ne6 60 Rd1 Be4 61 Bd3 Bb3 62 Rh1 Bb1 63 Bb1 Bd5 64 Rh7+ Kf6 65 Rh4 Ne5 66 Ke2 Bf3 67 Ke3 Bc6 68 f4 Nf7 69 g4 e5 70 g5+ Kg7 71 Rh7+ Kg8 72 g6 ef4 73 Kf4 1-0

Hsu observed that "17. c3 might be questionable, although White does have some compensation for the material deficit. At move 49, the machine had a completely winning position, but 49. ... Ra2? gave Judit some counter-chances and 50. ... Ra2?? surrendered the win. It needed 10 seconds of thinking time, which it did not have to avoid the draw."
May 1994: Munich, Germany
The following game was played in the Intel World Chess Express Challenge tournament in Munich in May 1994. In this event the program was allowed five minutes per game for all of its moves while the 17 grandmasters each had six minutes. But the Grandmasters had to play the program from a PC screen, using a mouse to make the moves. The result of the tournament was a phenomenon! Fritz shared first place with Garry Kasparov, ahead of 16 top class Grandmasters. (In the play-off that followed Kasparov scored a convincing victory.) Kasparov erred on $35...e4$ but nevertheless had the advantage when he lost on time.

**White: Fritz**

**Black: Garry Kasparov**

June 1994: Cape May, New Jersey
Deep Thought II played at the ACM’s 24 International Computer Chess Championship at Cape May, New Jersey June 25-27, 1994. It won its first round game against Zarkov, but an electrical storm in Yorktown caused the program to default its second round game. In the third round, it bested WChess and then played the crucial game of the tournament in the next round against Star Socrates. Star Socrates castled long on move 8 and found itself on the defensive shortly thereafter. On move 40, Star Socrates went down an exchange, and with Deep Thought II keeping up the pressure, resigned twenty-one moves later. At the end of four rounds, Deep thought II and Star Socrates each had three points. In the final round Deep Thought II defeated M-Chess Pro while Star Socrates was defeated by Zarkov. Despite forfeiting its first round game, Deep Thought II won the five-round event with a 4-1 score.

Figure 7. Position after 20. Bc4

Figure 8. Position after 35. Rb6

On August 31, 1994 chess history was written when Pentium Genius defeated Gary Kasparov in a PCA Grand-Prix tournament in London. The games were played at a speed of all moves in 25 minutes per player per game. This event was a knock-out tournament involving many of the world's top grandmasters. Richard Lang's Pentium Genius program was paired against the World Champion in the first round and by winning the match 1.5-0.5 the program knocked Kasparov out of the tournament. In the second round Pentium Genius scored another dramatic victory, winning both games against Grandmaster Predrag Nikolic from Bosnia. It was only in the semi-final round that the program was to meet its match - the cool Vishy Anand of India who strategically outplayed it for a 2-0 victory.

Game 1: White: Garry Kasparov Black: Pentium Genius

Figure 9. Position after 14. ... Ne4

Figure 10. Position after 34. ... Kf7

By move 20, Kasparov had acquired a strong position, but trades over the coming moves reduced his advantage. Frederic Friedel, when writing this match up in the September 1994 ICCA Journal, noted that "Instead of 35.Qd4 with an easy draw he played 35.Qb3+? for a win. The resulting position was one in which computers reveal, and Genius had found all the tactical resources it required."

Friedel noted that "The second game saw Kasparov, playing Black, sacrifice a Pawn and then go on to entrap White positionally and gain a winning advantage. But the computer defended stubbornly and the inevitable moment of inattention came. 55...Qd4?? allows 56.Qd1 and the double threat 57.g4 and 57.Qb5, so that Black has lost the extra Pawn for nothing. A horrified Kasparov submitted to a draw."
Game 2: White: Pentium Genius
Black: Garry Kasparov

October 1994: Boston, Massachusetts
Another startling result was achieved in the Fifth Harvard Cup tournament, played in Boston on October 1–2, 1994, which pitted six Grandmasters against eight computer programs, each grandmaster playing one game against each of the programs. The outstanding success of the event was WCChess, which scored four wins and two draws, for a performance rating of 2895. WCChess' success included victories over Alexander Yermolinsky, current US Co-champion and Patrick Wolff, former US Champion. The Yermolinsky versus WCChess game follows.

White: Alexander Yermolinsky
Black: WCChess

Danny Kopec annotated the game in the December 1994 issue of the ICCA Journal and several of his comments are given here. Kopec observed that after 13...Qc7 "Rh8 is still recommended [Kopec had earlier recommended this move instead of 10.Bd2]." White's 14.Ne4 "removes Black's only kingside defender — but with every exchange Black gets closer to his goal of exploiting White's doubled pawns and three pawn islands". After 21...g6, Kopec said that "Black clearly has better pieces and central control. White's Bishop is a poor piece." He noted that 26...Qd8 prevents Qb8 mate and that after 27...Nb2, "white's King is now fully exposed." Following 31...Ne5, Kopec noted that "Black is still better centralised and co-ordinated. Here if 32.Rc1 then Qb8 defends and threatens the Pawn on h6." With 40...Nb3+, Kopec credits Black with simplifying because it evidently sees a forced win.

**WORLD MICROCOMPUTER CHAMPIONS**
A Multipoint Conferencing Unit for Voice, High Speed Data and Video that is so advanced we refuse to call it a BRIDGE.

Contex... The sum of twenty four years experience in designing advanced teleconferencing systems for the military and aerospace industries.

Contex... A true digital system, designed and manufactured to rigid military standards.

Contex... An advanced design that meets or exceeds every requirement for central office or customer premise operation.

Contex... Offers triple redundant processors, dual redundant power, space division multiplex architecture, automatic maintenance diagnostics, and hot-card maintenance. MTBF up to 1 million hours. MTTR, 15 minute.

Contex... Provides patented digital voice leveling and the use of DSPs to eliminate line and background noise to produce superior quality voice, data and video signals.

Contex... Accommodates multiple (almost unlimited) operators. N/2 conferences, N-talker full duplex. Non-blocking port usage. Advanced scheduling, reservations and billing administration software. 24 to 480+ Ports.

Contex... Multiple choice full function commercial or military type operator consoles. The commercial system utilizes IBM compatible 386 PC's with a Microsoft Windows™ 3.0 platform.

Contex... Bandwidth: 2.048 Megabit per port. Allows the Contex to be used as a multi-point control unit for both Audio and Video or high speed data at full, or sub T1 rates.

SAITEK CHESS COMPUTERS
the only choice for a challenging game of chess.

SAITEK is proud to be a major sponsor of this event. Since 1979, Saitek has been at the forefront of innovative chess computer development. Its internationally-renowned Kasparov and Mephisto brands enable this technology to be shared with consumers worldwide.
First the facts. Sun ships more UNIX systems worldwide than anyone, in terms of both dollars and units. Sun ships more workstations. More UNIX commercial desktop systems. And more UNIX technical systems. Solaris, Sun's UNIX operating environment, is the world's leading volume UNIX operating system. Not surprisingly, Sun is also the leading UNIX platform for relational database software*.

Now that you know the facts, the figures should prove especially meaningful. Consider that being number one means we have more than 16,000 UNIX experts ready to help you with service and support. More than 9,000 UNIX applications. And more UNIX know-how than any of our competitors. So why should you care? Because being number one means that when it comes to UNIX, nobody has more to offer you than Sun.

Tournament Rules

1. Each entry is a computing system and one or more human operators. A listing of all chess-related programs running on the system must be available on demand to the Tournament Director, Mike Valvo. Each entry requires at least one full-time operator.

2. Participants must attend an organizational meeting at 15:00 in the tournament hall on May 25th for the purpose of officially registering for the tournament. Rules will be finalized at that meeting.

3. The tournament will be a 5 round Swiss system event.

4. Trophies will be awarded to the first three finishers. The winner of the tournament will be awarded the Shannon Trophy and the title of World Computer Chess Champion, both until 1998. The order of finish will be determined by the total number of points earned. If two or more teams have equal points, a tie-break system will be used. The first tie-break will be by sum of opponents' scores. If there is still a tie it will be broken on the basis of the sum of the respective programs' cumulative scores after each round (i.e. score after round 1 + score after round 2 + .... + score after round 5).

5. Unless otherwise specified, rules of play are identical to those of “human” tournament play. In disputes, the Tournament Director has the right to make the final decision.

6. Games are played at a rate of 40 moves per player in the first two hours and 40 moves/player per hour thereafter.

7. The Tournament Director has the right to adjudicate a game after six hours of total clock time. The adjudication will be made on the premise of perfect play by both sides from the final position.

8. An operator may ask the Tournament Director to stop clocks at most twice during a game because of technical problems. The operator can ask the Tournament Director for permission to restart the program. When restarting after a failure of any kind, the operator must reset all parameters to their values at the time the game was interrupted. Play must resume after at most a fifteen-minute delay. If an operator using a remote computer can clearly establish that the problems are in the communication network, the Tournament Director can permit additional time-outs.

9. An operator error made when starting a game or in the middle of a game can be corrected only with the approval of the Tournament Director. If an operator enters an incorrect move, the Tournament Director must be notified immediately. Both clocks will be stopped. The game must then be backed up to where the error occurred. Clocks will be backed up to their settings when the error occurred using whatever information is available. Both sides may then adjust program parameters with the approval of the Tournament Director. The Tournament Director may not allow certain parameters (e.g., contempt factor) to be changed.

10. Terminals at the tournament site must communicate directly with remote computers, i.e., there cannot be any human intermediary at the remote location.

11. Each team that uses a terminal must position the terminal in such a way that the opponent has a good view of it. An operator can only (1) type in moves and (2) respond to request from the computer for clock information. If an operator must type in any other information, it must be approved ahead of time by the Tournament Director. (This might happen if there is noise on the communication line and, for example, a CR must be typed to clear the line.) The operator cannot query the system to see if it alive without permission of the Tournament Director.

12. A team must receive the approval of the Tournament Director to change from one computing system to another.

13. Each game is played with a chess board and clock both provided by the Tournament Committee.

14. At the end of each game, each team must hand in a game listing to the Tournament Director.

The Association for Computing Machinery is pleased to be a sponsor of the Championships

THE FIRST SOCIETY IN COMPUTING
International Computer Chess Association

Established at the Second World Computer Chess Championship in Toronto in 1977, this international association has about five hundred members from all over the world. Its journal is published four times a year. The International Computer Chess Association (ICCA) is an international organization that represents the computer chess world, not only to the computer science community (such as ACM, IEEE, and IFIP), but also to the world chess federation (FIDE). The most visible benefit of membership is the quarterly ICCA Journal. Each issue contains roughly 60 pages outlining the latest in computer chess research, news, tournament results, book reviews, conferences, games, etc.: something for researchers, chess program hobbyists, and chess players.
