TO: see "TO" DISTRIBUTION

DATE: MON 23 SEP 1985 10:18 AM EDT

FROM: WIN HINDLE

DEPT: CORPORATE OPERATIONS

EXT: 223-2338

LOC/MAIL STOP: ML10-2/A53

MESSAGE ID: 5286162852

SUBJECT: VISIT BY RESEARCH BOARD

Most of you have met Naomi Seligman and Ernie von Simson who run the Research Board (which is comprised of some 40 MIS Directors from Fortune 100 companies.) They have visited DEC several times and are generally friendly and helpful to us.

They would like to visit DEC once again to understand our current operations and strategies, and have asked to discuss your area of responsibility. They can visit November 4, 5, 13, 14 or 15. My secretary will be in touch with your office to see if we can decide which days we should invite them to visit.

A copy of the Research Board Membership List is being sent to you under separate cover.

SUBJECT: RESEARCH BOARD SCHEDULE

Naomi Seligman and Ernie von Simson from the Reseach Board will be visiting Digital on Tuesday, November 5th and Wednesday, November 13th.

The meetings will take place in Win's sitting room, ML10-2. The schedule is as follows:

November 5th

8:45 - 10:00 a.m. Jim Osterhoff
10:00 - 11:15 a.m. Bill Strecker
11:15 - 12:30 p.m. Don Zereski
12:30 - 2:00 p.m. Lunch with Bob Glorioso
2:00 - 3:15 p.m. Bill Hanson
3:15 - 4:30 p.m. Bill Johnson

November 13th

8:45 - 10:00 a.m. Sam Fuller
10:00 - 11:15 a.m. Don Busiek

11:15 - 12:30 p.m. Jack Smith
12:30 - 2:00 p.m. Rose Ann Glordano
2:00 - 3:15 p.m. Bill Heffner
3:15 - 4:30 p.m. Pete Smith

Dear David:

The members of the Policy Board have asked me to thank you for joining us last Wednesday. Needless to say, you made an unusually favorable impression on this often prickly group of veteran pragmatists. Your provocative efforts to reexamine basic industry preconceptions, and position seriously for 1992 (while avoiding crystal ball gazing) was gratifying to us all. Any unease reflected the difficulty of grappling with the unknown. But no whining dogs here!

All of us hope to see more of you in the future in the Big Apple, Geneva, Maynard ... wherever. And our friends will surely be most interested in how your ideas and programs progress. Thanks again for your participation.

Sincerely,

Naomi

Subject: RECENT ISSUES FROM THE RESEARCH BOARD, FYI

At Win's request, I did a presentation recently to the Research Board in the UK focusing on 1992 and its impact on major companies and their MIS strategies.

The following is a list of particular concerns which they brought up :

1 - Global pricing

We had about 15 minutes discussion on how global pricing would work. In the end, we agreed that a single price by account worldwide was essentially what people wanted for any given product. This included products and services. All of those present (about 15) were in favor of such a policy.

- 2 - There was a substantial interest in software development environment standards such as for example IPSE and PCTE.
- 3 - There was a substantial interest in organizational consulting skills and our ability as a company to help them with the "implementability" issues they all faced in their companies.
- 4 - They expressed some concern about the process of sharing openly their mission and objectives with two competing companies: IBM and Digital. They knew that they had to do it. They confirmed their unanimous dislike of IBM's excessive account control techniques and "box selling" orientation.
- 5 - There was a very substantial interest in UNIX and portability standards. This was just prior to the Open Systems Foundation announcement, and they all seemed to be well briefed on our participation in OSF.

These were the most significant issues on which there was basically unanimous opinion. If I can provide more information please let me know.

Regards,
DLS/cm

Bliss E.C.

BILL JOHNSON

Dear B.J.:

First, we'd like to thank you and your colleagues for the time you spent with us during our research on network management. As you'll see from the enclosed extract, Digital wins our admiration for EMA architecture - perhaps the most comprehensive (and realistic) scheme encountered during our travels. So we're particularly delighted that you will be joining the Associate Board in New York on December 8th. You probably know that this Board has two constituencies: Senior IS executives of 20-plus major corporations; and a smaller number of key managers reporting directly to RB sponsors in the largest member companies. (A list is enclosed.) Membership is highly selective and stable; we never permit substitutes, and nearly everyone plans to attend.

We have scheduled your session for 9:15 a.m. to 10:30 a.m., split about equally between formal remarks and informal exchange with the group. I know the members will value your perspective on EMA's five key objectives, and planned capabilities - notably multiple access modules, generic functional modules, and a global repository to untangle everyone's messages and alarms. The Report may provide some ideas for your remarks: in addition to the Digital "snapshot," we've included relevant bits and pieces to indicate overall scope and thrust. However, you can certainly choose to ignore the specifics and proceed on the general track.

Will go down the night before if possible.

yes (The meeting will be held in the Wall Street area, at India House (1 Hanover Square). The prior evening, we'd love to have you join the group for dinner at Fraunces Tavern, 54 Pearl Street, at around 7:00 p.m. The members are staying nearby at the Vista International Hotel, 3 World Trade Center; we'd be happy to reserve accommodations for you, if you wish. Sarah Piper, our Director of Client Services, can assist your office with visual aid requirements and any other logistics.

Please call if you have questions, or would like to discuss your presentation in more detail. The Associate Board members very much look forward to your participation; it is extraordinarily timely. And all of us hope the discussion will be worthwhile for you as well.

Sincerely,

Catherine E. Loup

Bryan Markler*

THE RESEARCH BOARD

I had lunch today with Gerhard Friedrich, Manager of the Executive Marketing Group (works for Jim Higgins). These are my notes from that conversation:

- o TRB is a leading edge thinker in the high technology communications business. They have been compared, in their approach to business, with "Lifestyles of the Rich and Famous". They have 40-50 members, all blue ribbon companies, i.e., Pepsi, Mobil, Aetna.

- o The actual member is the Chief Information Officer (CIO). Membership is via selection and approval and sponsorship by other members. It is not done by application of the company or the individual who wants to join.

- o TRB is a very independent company that provides evaluation of vendors. No vendors belong. No vendors are permitted to belong. No funding or fees are accepted from vendors.

- o Naomi Seligman is their Vice President. Her relationship is with Win Hindle and Jack Shields. Jack Shields guards this relationship jealously and does not permit anyone else in DEC to contact TRB (except Win, I assume)

- o The actual research work of the TRB is managed by Ernst (Ernie) Von Simpson. Ernie is also the President of this company.

- o Gerhard feels that TRB strikes a good balance between vendor recommendations. They are not a true blue shop. They frequently recommend Digital solutions. The image of TRB being a big blue shop is because the majority of their members are typically IBM houses.

- o Win Hindle's office has a list of the current members and I will ask for this from Win.

- o In terms of OSF membership, Gerhard feels that we should definitely support TRB. They are a very influential group and increase the likelihood of their members becoming members of OSF.

- o Just heard back from Win Hindle's office (Donna Knowlton). He is very supportive of TRB becoming a sponsor of OSF. Have not heard back from Jack Shields office yet.

Operates from two buildings which are owned by parent, Mc Caffery, Seligman & Von Simson Inc.

ARTICLES

Cashing In On Computer Confusion.
 Computer industry market researchers are entering the business of helping companies make computer buying decisions. According to International Data Group chairman PJ McGovern, his firm can tell clients how their computer investments per

dollar of sales or assets compare with others in the same industry. Market research firms are also helping companies keep up with the increasing complexity of computer technology and the vast array of available products. For example, PepsiCo retained Gartner Group (Stamford, Connecticut) to access information it would otherwise spend a long time obtaining. IDC and Gartner have had more success than Dataquest (San Jose, California) the largest market researcher, in providing services to computer buyers. Demand for such information is growing, primarily because of increased use by corporate computer buyers and financial customers. These two groups provide 70% of Gartner's business and 60% of IDC's. But IDC is increasing the number of services it offers, and is enlarging its sales force by 40%/yr vs 30% for Gartner. Dataquest and a number of smaller companies like Yankee Group (Cambridge, Massachusetts) and Diebold Group and the Research Board (both New York) are increasing their services to corporate customers.
Business Week Industrial Edition April 20, 1987 p. 85,86

Calling On The Research Board.

The Research Board, an elite club of MIS chieftans, offers in-depth research on the latest in computer technology. The 39 full members, along with 15 associate members who are granted fewer privileges, are the execs in charge of charting the technology paths for major corporations whose appetite for computer products collectively runs in the billions of dollars. Living legends in the MIS field such as M Hopper and MD MacKinnon are members. These pioneers and the other members of the Research Board are a powerful group of MIS directors that represents many Fortune 100 companies. The group's membership is kept small so that meetings can be conducted in an intimate atmosphere.
InformationWEEK September 1, 1986

Companies with big telecommunications networks do not want the Bell System deregulated. The companies fear the formation of one or more deregulated AT&T subsids will lead to dispersal of responsibility, delays in processing of service orders and poorer quality maintenance, according to S Gordon, dir of telecommunications policy research for The Research Board (New York, NY), a consulting organization.
Computerworld June 8, 1981 p. 1,10

Calling on the Research Board.

Research Board provides members with latest information on technology and markets
The Research Board is an elite, high-powered group of MIS industry leaders located in a low profile four-story townhouse on the Upper East Side of Manhattan, New York and the group's 39 full members pay an annual membership fee of \$40,000 and the 15 associate members pay \$30,000. The workings of the group, surrounded as they are in an aura of secrecy, are criticized by some as snobbish, presumptuous or elitist, but the vendors in the computer industry, all of which are

automatically excluded from membership, take the research results of the group with great seriousness. It is, in fact, the excluded vendors and their product and marketing strategies that are frequently the topics of the Research Board's three annual reports and meetings, and the organization is headed by Naomi O. Seligman and Ernest von Simson, who conceived the idea and do most of the research that provides the substance of the meetings. The only vendor presence is in the form of invited responses to the in-depth reports produced and discussed by the Board, and the process is crucial for vendors who realize the quiet clout of the organization comprised of some of the most influential computer users in a variety of industries. Vendors who become the topic of study must manufacture quality products, have efficient sales organizations and high-powered research and development teams, and offer extensive field service options like remote-diagnostics.

How to keep customers happy captives: equip them with computers they can use to keep their books, get advice and buy what you sell. (channel systems)

IN THEIR FEROCIOUS marketing wars, the world's biggest corporations have opened battle on a new front: their customers' desktops. Companies as diverse as Inland Steel, Eastman Kodak, and First Boston are trying to increase sales and ace out the competition by placing terminals hooked to their own computers in customers' offices. Such a strategy is tricky and expensive to execute. A company can win or lose by many times what the computer systems cost--and they don't come cheap. But companies are betting heavily on the systems. Naomi Seligman, co-founder of the New York-based Research Board, an organization of top computing executives from 50 of the largest U.S. corporations, explains the systems' appeal: "They destroy your customers' interest in competitors' products."

They are called channel systems because they're meant to cure headaches for people in a company's distribution channels--commercial customers and key middlemen. Some channel systems enable customers to order instantly and better manage their inventories. Customers use others to analyze costs, control quality, lay marketing plans, and electronically seek advice. In all cases, by helping the customer solve a problem the company supplying the computer system stands to increase sales or otherwise benefit. Though the systems have been around for years, they've recently begun to multiply. Last year the Research Board's members decided channel systems were the strategic issue they most urgently needed to learn more about.

When the systems work well, they are enough to make a marketing manager's mouth water, as the example of a pioneer channel system illustrates. In 1974 American Hospital Supply installed the industry's first order-taking terminals in the stockrooms of large hospitals. Accustomed to ordering

supplies from salesmen making regular rounds, hospitals at first planned to use the system only in emergencies. But stock clerks preferred the terminals to salesmen and turned to American Hospital with routine orders for everything from tongue depressors to blood analyzers. Rival distributors filed an antitrust suit (which they lost on appeal) to keep the company from establishing exclusive supply agreements with major hospitals. Now a \$3.4-billion-a-year operation, American Hospital recently agreed to be acquired for \$3.8 billion by drug maker Baxter Travenol.

Only a few of the channel systems tie customers to a single supplier. Says James Bradley, a channel system executive at Aetna Life & Casualty, "You can't dictate to your users. If you try, they turn on you, and all the money you've invested goes down the tube." Instead, Aetna, like most channel system marketers, hopes to get business by spending heavily to pamper the system's users with versatile software, friendly telephone hot lines, and artful customer training.

At costs ranging into the hundreds of millions of dollars, channel systems are the highest-stakes game a computer executive can play. Though there's a lot that isn't known about running them, a few fundamentals of the game have become apparent. The first system to appear in a market often becomes the runaway winner. Once entrenched, it is nearly impossible to displace; it can also set a pace of innovation that keeps competitors reeling. All channel systems try to incline the user toward buying more from the supplier of the system and less from competitors, through the Research Board has trouble agreeing about how brazenly this ought to be done. Some systems, such as American Hospital Supply's, simply black the competition out, listing only the supplier's products. In Research Board parlance, such systems exhibit heavy tilt. Others use light tilt: they let customers do business with the competition, employing subtler means to boost the supplier's share.

December 13, 1988

Dear Bill:

Naomi, Cathy and I would like to thank you for taking time to join us at last week's Board meeting. As you surely know, you were a great success. The combination of Digital's architectural strength and your personal candor framed the network management issues and opportunities more forcefully than our other guests were able to do. Of course, we expected nothing less. Still, it was nice to hear the members confirm our assessment.

In substantive terms, you drew high marks for product structure. Balanced by a few gripes: Digital's position on interoperability with IBM was not fully understood. And there was considerable frustration about the pace of introduction. After all, this scale installation lived with the network management gap long before the vendor community began to grasp the nettle. Making EMA architecture and scope doubly important. But no more cheers from these tough customers until the product reaches the market. Even then, they'll grouse if customization requires more highly skilled systems software experts.

Anyway, that was the group's consensus after the session. None of which detracts from the excellence of your presentation. For us at the Research Board, it was a pleasure to see you again. And we look forward to an early repeat next week.

Sincerely,

Ernest M. von Simson

WIN;

THEY HAVE MADE A REASONABLY ACCURATE ASSESSMENT OF OUR CAPABILITY. IT'S NOT CLEAR THEY HAVE SCOPED THE MAGNITUDE OF NETWORK MANAGEMENT AS IT EVOLVES TO ENTERPRISE MANAGEMENT AND SYSTEMS MANAGEMENT (OLYP, OFFICE, CIM).

IBM IS CERTAINLY IN A STRONG POSITION (FIRST TO MARKET, LOW COST ENTRY, NAME), BUT THEY ARE ASSAILABLE. THE FEEDBACK FROM CUSTOMERS IS THAT OUR VISION IS CORRECT, BUT THEY'RE NOT ABLE TO WAIT. I VIEW THE NETWORK MANAGEMENT SOLUTIONS WILL BE THE FIGHTING GROUND IN THE 90'S AS O/S WERE IN THE 80'S.

Subject: RESEARCH BOARD

COMPANY CONFIDENTIAL RESTRICTED DISTRIBUTION

We recently received some third-hand information that the Research Board was saying some disturbing things about Digital. Bel Cross heard it from one of our close friends whose boss is a Research Board member. The message being conveyed was that Digital is "losing customer focus" and "headed into some trouble."

I called Naomi Seligman to ask what they are saying about Digital. She said they had said nothing in any formal meeting of the Research Board. However, they talk with individual members of the Research Board, some of whom express concern about Digital. She said one member asked whether Ken is still active in the company; she said he is. Others have said the "atmosphere" of dealing with Digital is different than it used to be. One client said he has been dealing with Digital for 20 years and, for the first time, is looking seriously at IBM products. I pressed her to name the sources but would not give me any names because it would breach their confidential relationship with Research Board members.

Naomi said that the Research Board staff would not have said the things we heard. She said we have done a first-rate job correcting the problems at Alcoa since she mentioned these problems to Grant Saviers and Hans Gyllstrom. She believes we have good customer focus when it is called to top management's attention. She did say that there is a gap between the messages from senior management at Digital and what our people do on the front lines. Her belief is that we are not practicing our message of customer satisfaction as customers perceive it.

There is a belief at the Research Board that we have "product problems." I think this means that our commercial software does not meet all the requirements as seen by our customers. We need to pursue this in great detail, and Naomi is very willing to meet with us in New York to discuss this. Dennis Roberson is

arranging that meeting.

Subject: Oracle at the Research Board

Larry Bagwell, Alcoa's Research Board member, stated that Oracle was presented to the RB by an officer of the company. They made 2:1 performance claims, and touted a new era where software is selected independent of the hardware vendor.

Mike Reidenbaugh, who is Larry Bagwell's key Technical resource, is a supporter of Digital and Rdb. Mike was ecstatic when I gave him a technical write-up which described Oracle's inability to cluster. I believe that Alcoa can be a entry point for flowing information back to the RB. Additionally, you will probably want to present directly to the RB. How can we help?

Grant, is it possible to perform an Rdb presentation before the Research Board? I would welcome you discussing this with Larry Bagwell, (412)766-7420.

Subject: RE: Oracle presentation to Research Board, attached.

This surprises me, as I did not think they had companies present. I'd like a shot at presenting Digital's "Information Management Strategy" in response to Oracle.

By the way, my impression of the RB is slipping badly from this and other inputs.

Win,

I advised Grant you are on vacation until April 3 and will not be able to respond to this until then. I also let him know of your meeting with the Research Board on May 1.

INTEROFFICE MEMORANDUM

TO: Jack Smith

DATE: June 15, 1989
FROM: Win Hindle
DEPT: Corporate Operations
EXT : 223-2338
LOC : ML012-1/A53

SUBJECT: RESEARCH BOARD OBSERVATIONS

VERY CONFIDENTIAL -- DO NOT COPY

This is a bit more detailed feedback than I gave the entire Executive Committee. Here it is simply:

1. The Digital message is not clear. How are you differentiating yourselves from all the rest?
2. Measure power in the commercial area by TPS, not MPS. You are coming from behind here and need to recognize it. Some feel you are arrogant.
3. Bob Glorioso oversells. He is not regarded highly in your major account base. (Note: I am meeting with Bob to give specific feedback to him.) His 30 MIP processor is not a significant product outside Digital.
4. Your two best managers from the customer perspective are BJ and Grant. They listen, they are enthusiastic, and they do not oversell. Grant has personally turned the Alcoa account from negative to positive.
5. You need a big product "win" soon. Aquarius/Aridus will not do it. It would be powerful to know Digital is working on a powerful parallel processing system.

Dave Grainger

DATE: June 15, 1989
FROM: Win Hindle
DEPT: Corporate Operations
EXT : 223-2338
LOC : MLO12-1/A53

SUBJECT: RESEARCH BOARD OBSERVATIONS

VERY CONFIDENTIAL --- DO NOT COPY

My memo on The Research Board observations was quite general. They did give me some more specific input that I will send to you but not to the entire Executive Committee. Here it is:

Major account managers must be closer to the top of the company to have the clout they need to fix problems. One customer observed his account manager is eight levels from Ken. The levels are not significant--it is their ability to get Digital to perform effectively that they need.

Our Corporate Software Agreement is a pain to them--far more complicated than IBM's. It takes three pages of text with IBM and an "entire book" with Digital. We must simplify our software licensing terms.

Use the EPPs more to relieve tension when it occurs. Let the EPPs listen to problems and then work with the account managers to fix them.

Customers want an honest, technical, experienced account manager who knows his/her way around Digital to get things done. Above all, fix the broken relationships with your top 20 accounts, like Dupont.

COMPANY CONFIDENTIAL

One issue that The Research Board brought up needs work in both engineering and service. A number of our customers have complained that we are not properly managing and supporting test sites for new products. We do not have the right people there to support the new product and receive proper customer feedback. I recommend that you appoint two people (one from each group) to look into our process for test-site support and see why some customers are upset.

SUBJECT: RESEARCH BOARD COMMENTS

VERY CONFIDENTIAL

Recently, I visited Naomi Seligman and Ernie von Simson of The Research Board at their office in New York to follow up on their concerns about Digital. None of their remarks were very specific, but it gives us flavor of what they are hearing from their members. I have attached a current list of members, and most of them are good customers of ours. Following are their comments:

Our customers find us bureaucratic, even compared to IBM. We are not easy to do business with. Digital's major account managers do not have the ability to fix obvious problems. Digital has a "nickel and dime" approach to support. Our customers and The Research Board want us to go back to being "good old Digital" that keeps customers as "number one" and fixes our own problems without charging for our services. They recommend that we put senior people on large accounts and give them the resources to fix problems.

Our message about why Digital is unique is not getting across. It sounds like every other systems integrator. What distinguishes Digital from the others must be made clear, and today it is not. Our products are great, and our networks in particular are outstanding. We must put our products together in a way that our customers can understand and support. They want to buy from Digital because they do not want to be hostage to IBM. Today we are not giving them the messages they need to sell internally.

We appear to hype our products more today than we have historically. Digital's data-base products and transaction-processing products are good but not industry leaders. We are promoting them as though we are the industry leaders, and our customers feel we are over selling. This is also true with Aquarius/Aridus which appears to be a fine 30 MIP processor, but

it will not be an industry leader when introduced. PMAX was a leadership product when it was introduced, and Digital needs another leadership product soon.

Digital should give customers the sense that that there is a strong group of middle managers who will carry on the Digital tradition after Ken and the current Executive Committee are gone. Customers want to feel the presence of strong leaders in the 35- to 45-year old age bracket who will continue to build excellent products and carry on the Digital tradition of service and concern for the users.

All of The Research Board input was presented from the point of view of wanting Digital to succeed. The customers need us, and Naomi and Ernie want Digital to be a viable competitor for IBM. They are friends wanting to be constructive, and I believe we should listen carefully.

From: TPS::ROBERSON 13-JUL-1989 08:41
To: HYEND::GLORIOSO,ROBERSON
Subj: RESEARCH BOARD

Bob,

As you know I finally connected with Ernest VonSimpson and Anne Seligman from the Research Board and closed on their TP/DB concerns. In net they have two concerns:

- 1) At our current DebitCredit TPS performance level we still don't have the capability to cover the commercial performance requirements of the largest US Customers (the Research Board's primary clients/members). Note: Aquarius will finally enable us to penetrate this exclusive club.
- 2) The Board felt that we had not been totally open and upfront with them on the stability of Rdb 3.0 at its first ship last fall. Several of the member companies had experienced significant difficulties and we didn't acknowledge these difficulties when they visited us. The heavy effort's Han's team have been applying are turning the tide to enhance Rdb 3.0's reliability.

The Board would very much like to see us again, but probably not until we have announced Aquarius and can describe its performance attributes in detail. This sounds like a late October or November session in New York. At the session they'd also like to see our long term plans, both hardware and software, and how they relate to the solution of high end customers needs. They would also like to see our Office System Strategy and how it relates to the rest of our High End Strategy.

The phone conversation was a very positive one with Ernest emphasizing the Research Board's strong support for us and they desire to see us succeed. I'll schedule the session with Anne Seligman to fit with our Aquarius plans and your calendar.

Subject: Research Board

Win,

Dennis was finally able to contact the Research Board with respect to the TP issues they had. It looks like the key issue was the feeling that we could not cover a broad range of TP user needs unless we had an Aquarius class product. This is true to some extent if people don't buy a distributed solution or understand the advantages of the DEC Distributed Transaction Architecture. So it looks like we have two problems both of which may be solved when we announce Aquarius and they then look seriously at our distributed capabilities and realize that they do not need Aquarius in all high performance TP applications. Of course there are classes of problems and customers who cannot use a distributed solution so Aquarius is very much needed by them.

See Dennis' memo on the conversation with Ernest attached for more detail.

/Bob

EXT : 223-2338
LOC : MLO12-1/A53

SUBJECT: RESEARCH BOARD MEETING

Ernie von Simsen and Ann Seligman (Naomi Seligman's daughter) of the Research Board will visit on December 18 and 19 to discuss a number of topics with us. The meetings will be held in the Sitting Room at the Mill in building 10 to make it convenient for them. Under separate cover, I am sending a list of the current members of the Research Board.

As you know, the Research Board staff prefers a "conversational" approach rather than a "marketing pitch." The last time they were here, they felt that we were trying too hard to "sell" them. They want to know that we are realistic in assessing our competitive position. Of course, they hear from their members all the time and already know how our customers evaluate us.

They do not sign non-disclosures, but I encourage you to talk about future directions as you would to any close friend of the company. They are in fact very supportive of Digital and want us to do well because they do not want IBM to be sole supplier to any of their members.

Thanks for taking part.

FOREWORD

This report was prepared solely for the use of the Research Board, which financed its completion. It contains information and attitudes expressed by individual companies that may be considered sensitive.

For this reason, and for proprietary reasons of our own, we would not want this document to be circulated so widely within Research Board organizations as to raise the possibility that it would be distributed outside these companies, in whole or in part.

I. Topologies

Network management is a research nightmare! Vast in scope, yet clogged with endless nitty-gritty. And zillions of vendors. Most making slow progress behind marketing hyperbole intended to disguise can't with cant. As everyone slows down to match the glacial pace of standards. Which aren't the whole answer.

A warm-up exercise: What's a network? Not so long ago, voice networks were WATS. While data trickled over point-to-point analog lines at 4800 baud. That's quickly changing. Today voice and data share a backbone of T1 circuits arrayed in rings or figure eights; dotted with intelligent multiplexors that break down those 1,544,000 bits per second to usable gulps. And forward the gulps to data controllers or voice PBXs. Then down the pipeline to LAN communications servers, minis or mainframes. Each LAN a constellation of workstations, each processor with baskets of software. Complex relationships among components that might have originated on different planets when it comes to coherent management.

And what's coherent network management? Ideally, a system that collects alarms and performance statistics from each and every network denizen mentioned above. Then filters and integrates those alarms to diagnose the real failure. Routes the diagnosis to the appropriate point-of-correction. Accepts corrective commands through a single "manager-of-managers" console, not one per vendor. Plus immensely useful ancillary functions: network-wide component inventory control, trouble ticket tracking, security, perhaps accounting.

All critical to RB companies building ever more complex global networks. For ever more crucial applications like CIM and EDI. When your customer's order entry port remains inactive for two weeks, should you send a salesman or a repairman? And if the downed system downs company revenues, can it ever be forgiven? Indeed, the primitive state of network management will soon stifle user innovation, if it hasn't already. Unfortunately, vendors expect that implementing the ideal system described above will take at least ten years.

For us, each supplier interview starts on a high conceptual plane: comfortable and managementy, but irrelevant. To understand the problem's impact, visit a user's network operations center. To appreciate the solution's complexity, probe the vendors about alarm formats and message routing conventions. Humdrum stuff. But vital to gauging industry progress on several deceptively simple user requirements:

1. Outage Alarms - So the right person is notified when your customer's order entry terminal fails. Before he complains. Or worse, reroutes the business.
2. Performance Monitoring - So an incubating outage can be pre-empted by replacing the unit registering soft fails. Or by adding capacity to the network route nearing saturation.
3. Diagnosis and Repair Assistance - So the root cause of related outages or performance bottlenecks is correctly identified. And so fixes can be initiated through a single console, regardless of the troublemaker's logo.
4. Configuration Management - So Operations can monitor and control the entire network from a single terminal. Maybe through a topology map. With nodal subviews (LANs and their workstations) available at the click of a mouse.
5. Equipment Inventory - So the network boss knows the location and status of every device and spare.
6. Trouble Ticket Tracking - So the appropriate service supplier is automatically alerted of a mission critical defect. And so the anxious user can monitor its resolution.
7. Security Alerts - So a node or session can be temporarily quarantined, until keyboard stumbler is incontrovertibly distinguished from potential pirate. The capability farthest from implementation.

Eminently reasonable requirements. But meeting them raises a host of many-faceted issues. Which we discuss in four separate frameworks:

- The Real World: Chapter II looks at network management in practice at several member companies: American Airlines, Bank of America, Citicorp, Federal Express, J.C. Penney, Northern Trust, Rockwell and Seafirst.
- Alliances and "Aliences": Chapter III chases consensus on standard message formats and protocols. Introduces OSI front-runners CMIP and CMIS. Plus a bevy of sometimes overlapping, often competitive consortia like Corporation for Open Systems, Forum and Alliance.
- Physical Networks: Some think voice networks less troublesome than data networks, because voice users can easily sidestep problems by redialing. Others call traditional voice/data distinctions obsolete. Better to characterize physical versus logical facilities. In which physical includes every box and wire between communicating end points. While logical adds the complexity of dueling computers and sinfully incompatible software. In Chapter IV we check out network physique, beginning with private network switches and multiplexors; then go public with MCI, Northern Telecom and Nynex.
- Logical Networks: A messy world. Chapter V visits LAN fans Microsoft, 3Com and Ungermann-Bass; plus Retix and Touch, two unsung heroes of a recent standards bash. Chapter VI questions network management fundamentals at Tandem, Hewlett-Packard and three hopeful middlemen. While Chapter VII takes on four heavy hitters: IBM, Wang, AT&T. And Digital, who wins our award for best architecture.

Several legs of this uphill trek may be arduous. But the view from the summit (Chapter VIII) will be inspiring.

II. THE REAL WORLD

A. User Environments

For RB company telecom operations, unavailability of coherent network management sometimes means several monitoring stations, fragmented problem reports, dueling repair conventions, and gaping blind spots. Challenges increase exponentially with network complexity.

1. Company A

Bank branches are connected to a statewide T1 backbone. A mix of Stratacom multiplexors, Doelz data switches and Northern Telecom voice switches delivers the goods. But that mix complicates network management. The company's control center has a separate monitor for each supplier's components. And a separate mini watching local modems. A Tandem computer tracks branch data connectivity. While a telephone company system oversees transmission trunks.

A single physical outage can trigger alarms from all. Requiring a team of human operators to isolate its precise location. If every ATM in a region signals failure, the fault must lie in the transmission network. But where? If voice traffic dies too, the culprit could be a T1 break. Or a switch. Or a branch channel bank. But which? Absent collaborative diagnosis from the autonomous component monitors, the control center is left to "micro manage the pieces," observes a bank executive. Fortunately, the Stratacom devices reroute traffic around a failed component so fast that neither voice calls nor SNA sessions are noticeably disrupted.

"But we're far from managing overall availability: viewing all these network components the way customers do, as a single window on all our services." True, downed branch circuits, crashed central data bases and cash-strapped ATMs require different responses from individuals with different skills. Yet they all affect the "availability" of customer service, a much broader perspective than today's provincial component management products can provide.

2. Company B

Voice management might seem inconsequential to some. But the company's use of communications gives the task a different weight. After all, fourteen service centers field 250,000 customer calls a day. And network availability is critical to company-wide service levels. Voice facilities are monitored constantly by a mix of management systems:

- A DEC based system generates near real-time performance statistics on Automatic Call Distributors, plus trouble reports and potential overflow warnings. Traffic rebalancing requires manual intervention, however.
- NET supplies T1 multiplexors, and their monitor. With nice graphics for fault detection. But two holes in performance tracking. First, getting throughput statistics only on request inhibits detection of deteriorating circuit quality until it's too late. Second, NET's highly automated rerouting capability can degrade throughput. So the customer's technicians must analyze and reoptimize the network map daily, but would prefer that NET software absorb the chore.
- An AT&T system monitors T1 circuits span by span. Office PBXs (administrative traffic only) are tracked box by box. Another system manages Paradyne modems. All of which leaves network operators sifting through blizzards of confusing, even conflicting alarms and statistics. Until calls from users become the only reliable and actionable indicators of an outage. "We need to integrate these systems, then automate as many network management functions as possible. You can't expect an operator left dozing before the screens all week, to handle a real crisis when every alarm goes crazy."

B. Missing Links

In Chapter I, we listed seven commonly acknowledged (certainly reasonable) user requirements for network management. Yet these experiences from members with leading edge operations show that only the first two - outage alarms and performance monitoring - are usually served. And those only in part. Console alerts are often less reliable trouble indicators than telephone calls from disrupted users. Performance measurements never reflect response times users actually experience. And end-to-end troubleshooting is impossible: today's management systems exclude key network components. "There are so many potential failure points between us and the user," observes one executive. "Problem diagnosis would improve if operators' consoles could mirror user sessions. Instead, we rely on groping over the telephone."

The other five requirements aren't addressed at all. Message consolidation and routing are left to home-grown code and third party software packages. Topology maps - when provided - show only the vendor's own components. Customers who want cross-vendor control of equipment inventories and trouble tracking must develop their own applications.

And several are. Federal is building a trouble ticket system to help operators dispatch the right technician; respond to user inquiries; and track problems from initial report to final resolution. Rockwell is developing a configuration data base, interfaced with equipment inventory systems in its decentralized user divisions. Everyone agrees such a data base is critical to effective network management. "That's the key to integrating various subsystem monitors," notes one executive.

III. STANDARDS MANAGEMENT

A. You Say Tomato, and I Say...

Coherent network management would obviously benefit from inter-vendor standards. Just as connecting two unlike devices requires prior treaties on physical terrain: (i) transmission medium; (ii) network addressing; (iii) routing protocols; and (iv) handshake conventions. And just as actual message exchange requires consensus on logical environments: (v) dialogue structure; (vi) presentation format; (vii) file transfer and message handling. Those seven layers celebrated in story and song. And in countless meetings of the International Standards Organization (ISO). Not to mention ISO hangers-on like COS, OSF, X-Open, SPAG, CCITT, etc. Many acknowledged in last winter's Report, Until the Next Millennium.

Are those muffled yawns and muttered threats from our gentle readers? Sure, vendors proclaim OSI (Open Systems Interconnection) the most important invention since the transistor. And cite customer demand as their primary motive for abandoning hallowed individuality. Yet member IS Executives seem unexcited about standards (reserving applause until the curtain rises). And suspicious that pious vendor palaver about standards minutiae is actually a ploy to delay OSI and extend the life of proprietary goodies. Are standards just a game for insiders and politicians?

B. Framing the Framework

Enough carping. Better proceed to a description of network management standards, notably the OSI Management Framework. Work's begun, with some progress. Particularly on the concepts for multi-vendor data access and message exchange. The Framework envisions that each of those seven ISO layers will participate. And seeks to provide common conventions governing communications: both vertically - within a single device's layers. And horizontally - among peer layers in different devices. Recognizing that most networks include equipment and software from more than one vendor. A messy, inherently counter-systemic world.

Next, Framework folks target six capabilities: fault management, performance management, configuration and name management, security, accounting, and directory services. The first three correlate pretty closely to the priorities raised by member companies we visit. Security also draws considerable user concern, particularly as LANs broadcast every message to every station. Standards work here is in its infancy, however. Ditto accounting, but who cares? A vocal ISO constituency of commercial service providers, no doubt. But it's difficult to imagine RB companies pricing network services on any basis besides standard charge per session minute or processing unit.

Directory services are part of a larger issue: a standard data base or repository for multi-vendor management data crossing the draft stage as X.500. But there is still disagreement on "registration" or how to identify and categorize various management domains, says the VP Engineering at Corporation for Open Systems. Elsewhere, we hear of debates over how repository entries should be structured: for each "object" represented, like a counter that gathers performance statistics, what's the appropriate format (e.g., integer versus floating point)? And how does it operate (can it trigger an alarm whenever a threshold value is exceeded)? If the ISO bees don't keep buzzing, de facto standards from IBM, AT&T and DEC could pollinate the farm.

Working out the critical definitions for every conceivable component and situation falls under the rubric of SMI, or Structure of Management Information. The effort is nowhere near complete: the number of unique SMIs keeps growing. As does their complexity. One example of the definitional rat's nest (offered by a 3Com developer) is the oscillating counter: Consider an SMI describing a counter that triggers an alarm when a preset threshold is exceeded - e.g., more than 26 concurrent users on a LAN. Sounds straightforward. But say User 27 logs on, then another user logs off, then another logs on, etc. Should the counter oscillate around its threshold value repeatedly, sounding an endless (useless) volley of alarms? Or should there be another SMI describing how to turn the damn thing off? Amidst this confusion, one hopeful sign: a new generic category for conditions like "retransmission error" that apply to many SMIs. Reducing the agenda of discussion items. Much remains to be done, however.

Enter CMIP and CMIS, the building blocks of OSI management applications: two hooks where all vendors plan to hang their hats. At least, that's the pitch for mollifying network management-hungry customers. Scratch the topic at any supplier session for a reflexive oath of eternal fealty to CMIP and CMIS "as soon as the standards are set." Which could take several years.

CMIP (Common Management Information Protocol) will allow systems from different vendors to exchange data. CMIS (Common...Services) specifies three basic types of exchange: report an event (e.g., send an alarm); request information (read a performance counter); invoke an action (set a threshold, run a test). So far, so good. But many publicly committed participants privately defer CMIP/CMIS until the SMI issues are resolved: They want concurrence on what the data is before deciding how to exchange and apply it. Sounds reasonable, though hardly ASAP. Meanwhile, CMIP/CMIS are "nothing more than an empty envelope with a stamp," says one insider.

CMIP/CMIS are just a corner of OSI network management. Which creates a dilemma for would-be implementors. The full "stack" of layer-by-layer protocols will require 500-plus kilobytes of memory, and commensurate compute capacity. (As a harbinger, see overleaf for HP's Express OSI board.) No problem for heavy-duty communications servers. But what about lesser net denizens like modems, muxes, even workstation LAN adapters? That's one concern of still another standards club, NetMan: a crew of LAN makers. NetMan champions OSI-style network management, but won't wait for full OSI. Instead, they propose two extensions to TCP/IP, a popular de facto standard: a "proxy" technique to let puny network components send simple "I'm alive" up the big pipe to the glass house. And OSI-sympathetic presentation and directory services, to facilitate eventual migration once OSI settles. A prototype is being rushed to demo as we scribble.

Not everyone believes NetMan boosts OSI goals. A ruse to prolong TCP/IP? Which backs into a storm brewing over whether formal network management standards should be compatible with pervasive in-place network protocols like MAP. Raising the remote spectre of expensive retrofits. And plenty of controversy.

Where are the users in all this? we ask COS chief Lincoln Faurer. Still lagging in participation, he replies. Thirty percent of COS members are users, up from 25 percent a year ago; but still far from Faurer's goal of 50 percent. Moreover, he knows existing user members are frustrated by their limited influence. A COS executive is on the road discussing possible remedies. But the real problem is us. The users. With few exceptions, says Faurer forthrightly, they don't take the initiative, don't work together, don't have the requisite patience to work out thorny details. "Our users are great counterpunchers - give them a proposal, and they'll react and criticize. But they're slow to take the lead. And few realize they have interests in common with users representing other industries." Something for the Research Board to discuss?

IV. PHYSICAL NETWORK MANAGEMENT

A. Nomenclature

In networking, the traditional voice/data split is replaced by a physical/logical differentiation. Where physical refers to transport components like circuits, concentrators, multiplexors, modems and switches. While logical refers to software-based network architectures like SNA, DECnet, and OSI. This new perspective also spells basta to old tussles over whether network "intelligence" would reside within common carrier facilities or on customer premises. Vendor aspirations notwithstanding, it's a draw. Logical networks thread through both realms. So do physical networks. But they don't map precisely: the same logical session needn't retrace the same physical path. A productive snarl which makes heterogeneous network management even messier.

In this chapter, we get physical. And consider network management for several layers. At the lowest, raw circuits - notably digital T1, a 1.544 megabits-per-second pipe. At the next, multiplexors and concentrators.

Semantic distinctions are fuzzy here. But concentrators (like Doelz) generally funnel several low speed data streams into a higher speed channel. While multiplexors ("muxes") do the reverse: scale T1's fire hose streams down to kitchen tap trickles. Consider that common carriers carve T1 into 23 voice channels, operating at 64 kilobits per second. Independent muxers get more - through two techniques: speech interpolation, which fits a second conversation into the natural pauses left by the first. And speech compression, which squeezes conversational bandwidth from 64 kilobits down to 32. Interpolation effectively doubles the virtual channels on a T1 line; compression doubles them again. Timeplex and Infotron muxes use interpolation to get 46 voice channels per T1. While Stratacom and NET piggyback both techniques to crank out 90 plus. For nice gains in cost and capacity over common carrier offerings. Improved reliability, too; muxes automatically reroute traffic around downed nodes or congested circuits. But not without certain pains in network management, as we discover.

VI. LOGICAL NETWORK MANAGEMENT

A. Logical Conundrum

We already agreed the voice community will have network management facilities years before that sweet suite is available in private data networks. But why? Maybe it's the difference between oligopsony and oligopoly (i.e., few buyers vs. few sellers). Telcos and inter-exchange carriers forced voice network suppliers to discover the wisdom of working together. So coordinating network management isn't an unnatural act. Whereas in the data market, the feisty few exercise almost as much clout in setting international network directions as the ever-bickering standards organizations. Which they join and effectively dominate. Oligopolists still buffered from any real interference by the fragmented, generally uninformed customer base. But perhaps any standard is better than none.

Another obvious reason for the pokier pace in data network management is that problems are more complex and far-reaching. Failed voice conversation? Hang up and try again. With a broken data connection, no such easy sidestep. And one break can disrupt business operations, require revalidation of financial controls, even necessitate reconstruction of compromised data bases.

Finally, the intricate inter-relationships of the data network. With the world of physical transmission. Between LANs and WANs, though that linkage is not yet porous to management. And between communications software (SNA, DECnet, OSI) and all the other software (computer vendor, third party or homegrown) whose failure could back into data networks. All apparent as we discuss the subject with several leading edge data communications participants.

VII. HEAVY HITTERS

A. Casting Their Nets

NetView is the system every network supplier has to meet - or beat with something much, much better. Its entrenched position appears unassailable: many times the installed base of nearest competitor Cincom. Controlling huge logical networks that utilize a wide diversity of physical communications devices, as well. NetView primacy derives partly from time-to-market; partly from IBM clout. When NetView debuted (1986), other potential contenders had barely scented the opportunity. So NetView got the gateway to the Fortune 500 market. Certainly, that's the perception of network insiders large and small. Unless one of them can hammer together a credible alternative.

In this chapter, we size up the challenge with a deeper look at IBM - which intends to hold its lead through an aggressive development program. Then consider competitive strategies at Wang, AT&T and Digital. That ordering isn't casual. Digital has the most open and realistic architecture, assimilating network components physical and logical, standard and proprietary, large and small, old and new. Could become a leader.

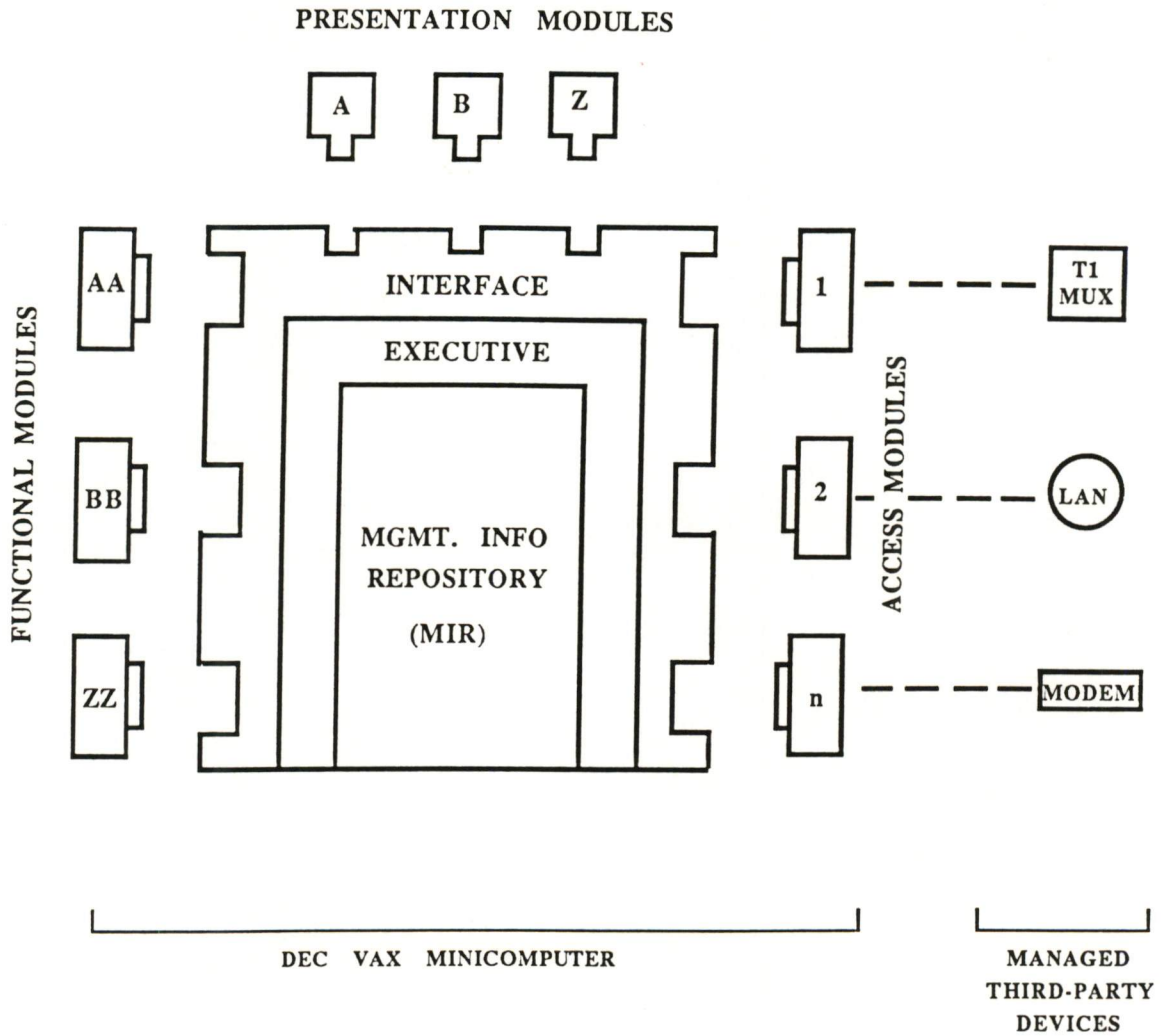

Three buttons to watch: (1) Does the vendor offer an architecture functionally attuned with the requirements described in Chapter I? (2) Can the architecture's repository handle the incredibly diverse array of network devices, services, protocols, alarms etc. that populate large customer networks? (3) Does the network management system filter and integrate alarms and statistics from the various devices to power effective diagnosis and response?

E. Digital Equipment

Flash: Digital pops span man plan. Amidst our labors, DEC finally announces the architecture mulled for three years, at least. (See 1987 RB Report Charting the Gyre.) At a preview with VP Distributed Systems Bill Johnson and chief engineer Gary Gottschalk, we learn that Enterprise Management Architecture (EMA) targets five market requirements:

- Scope must accommodate DECless protocols: whether standard or proprietary, physical or logical. After all, CMIP/CMIS, the great leveler, may arrive late. Retrofits to everyone's hardware and software products, even later. Hence multiple "access modules" as discussed below.
- Functionality must include configuration management, fault management, performance management, security and accounting. But those applications must be independent of what's being managed: a command like "display percent utilization" should be applicable across CPUs, circuits, switches etc. Full function also implies full life cycle support: network evaluation, planning, implementation and maintenance. Plus inclusion of whatever tools the customer chooses.
- Integration through a repository containing extensive information about every network component, including its alarms and performance counters. Driving functional modules that correlate, filter and route diverse messages.
- Scale must accommodate networks small and large. And network operations centralized, decentralized and distributed. "We will not dictate management philosophy."
- Modularity, in the sense of protective isolation. So a change in incoming alarm formats won't rock the repository. While functional enrichments (e.g., expert systems) slide transparently beneath the consistent user interface. Very prudent. And a better structure for mapping the messy real world than anyone else provides.

ENTERPRISE MANAGEMENT ARCHITECTURE

SOURCE: DIGITAL EQUIPMENT

The architecture itself (Exhibit) has four significant segments:

1. Access Modules - as many as necessary. A multiplicity that realistically anticipates the persistence of proprietary protocols even as international standards are implemented. So begin with a module for DECnet; add CMIP as it solidifies; encourage other vendors to contribute. Accompanying the EMA announcement were support commitments from eight component vendors including Codex, Stratacom and Timeplex. Modules for NetView and UNMA may come from third parties.
2. Functional Modules include generic routines for message handling and alarm responses. For example, a system-wide utility defines failed-circuit alarm thresholds (and rerouting instructions) for any mux-make. Here too, different modules that filter and correlate related alarms: e.g., suppress DECnet alarms triggered by a T1 break.
3. Presentation Modules are the user interface options. Fairly simple at first: ASCII terminals for DECnet, 3270 for SNA. Later on, graphics workstations. Plus third parties - like Netmaster?
4. Repository, "the cornerstone of integrated network management," will include: (a) component inventory; (b) performance trends; (c) device-specific alarms, commands etc.; (d) "meta data," or component class attributes and inter-relationships. This last category is critical to achieving the level of integration advocated throughout this report.

On balance, an extremely strong architectural concept made even sturdier by its flexible, modular structure. And by the implicit assumption that networks will remain messy tangles of heterogeneous, hetero-generational bits and boxes for many years. A world that can't be force-fit to a single protocol, even a standard one. All of which makes EMA our favorite architecture - though we've yet to see the building. Muses Bill Johnson, "This construction effort could approach the scale of our VMS operating system."

VIII. Closing The Loup

The struggle toward coherent network management is complex and grinding, thanks to a hostile environment of inter-dependent but not integrated equipment. In which the largest vendors dominate standards alliances while looking for a continuing - and proprietary - competitive advantage. The mid-scale seek alliances that don't give away the store. And the smallest hide behind players they trust won't steal their niche. For all, the technical difficulties of integrating dissimilar alarms, statistics and command sequences would be challenging enough. But the task is compounded by endless supplier wrangles over account control. Bruising for frustrated customers.

To summarize the critical issues:

- The customer problem is quite straightforward. Few network subsystem monitors work together. In fact, they often confound one another. And cause such confusion that the most reliable (if least desirable) alarm is a phone call from an irate user.
- Standards are evolving - but slowly. For the reasons suggested above.
- Forceful oligopsonists rule the public, physical network. Consequently, it's here that network management consensus will emerge first.
- Network management remains blind to LANs. Bridges and gateways open connectivity options for diverse workstations. But block the view from the top.
- Logical network management systems require solid underpinnings: architecture, repository, set of standard message protocols. Almost like a basic operating system. Little wonder progress is slow. Effectively, the lead belongs to IBM and AT&T. Artistically, the prizes go to Tandem and Digital.

III. THE GREAT AMERICAN HARDWARE BASH

A. A New Order

Until recently, old-fashioned "minicomputers" could be clearly and unfavorably distinguished from sprightlier servers on technical grounds. Minicomputers are built around idiosyncratic instruction sets proprietary to one supplier, like the Digital VAX. While servers achieve better cost/performance and capacity from engines licensed to multiple computer makers. Those engines are usually supplied by Intel, whose Pentium is now on the near horizon. But Pentium will meet five RISC contenders who hope to dent Intel's market share with a design strategy of more-is-less: RISC gets more throughput than Pentium from one-third less transistor equivalents. That makes RISC cheaper to design and fabricate. And leaves each chip with enough vacant "real estate" to house performance boosting goodies like memory, or customized logic, or built-in graphics. Streamlined chips also require less power, a critical characteristic for the "Personal Digital Assistants" in which many companies are so interested.

$\alpha \approx \frac{1}{2} \times \text{Sisley}$
as Pentium
of 2x PERP.

Industry debates over Intel vs. RISC divert attention from a more striking development. The basic capacity and performance differences between old minis and new servers will soon end; minicomputer operating systems will reside on exactly the same hardware platforms as Unix or NT, their server counterparts.

- Hewlett-Packard already uses its Precision Architecture RISC engine in both proprietary minicomputer systems and in servers running Unix.
- Tandem is using the same RISC processor (from Mips) for both proprietary Guardian systems and Unix-based Integrity servers.
- IBM will use its PowerPC RISC engine under AIX, OS/2 and (in 1995) for its AS/400 family. The same chip, also produced by Motorola, will be the engine for Apple's new servers.
- Digital's Alpha RISC engine will power both OpenVMS and the company's "standard" Unix (OSF/1).

The convergence of minicomputers and servers reflects the desperate need for volume sales in the microprocessor business. Enormous volume is needed to justify the huge cost of designing and tooling a new microprocessor. And to attract the independent software vendors, whose support (and packages) can determine whether a hardware platform flourishes or fizzles. The pressure for volume will elbow some RISC designs out of the market. It's also Intel's overwhelming advantage.

5. Digital Equipment

Once the industry's biggest minicomputer company, Steady Grey may now be its biggest question mark. So it's terrific to observe a fresh sense of managerial enthusiasm and purpose under the leadership of new CEO Bob Palmer. Whose three immediate objectives are:

- a. Making the company profitable, through headcount reductions and plant closings. One third of the company's 135,000 employees have been laid off; another 10,000 to 17,000 will go. Half in Europe through several actions: merging DEC's acquisitions; reducing sales administrators; and reeling in the countless islands of software development set afloat by Pier Carlo Falotti, former President of DEC Europe (now CEO of The ASK Group). Some of these islands were as small as 15 persons. Many were unknown to engineering management in Maynard.
- b. Restructuring the organization around Customer Business Units (CBUs) with full profit and loss responsibility. Partly to ensure that companywide and worldwide attention is focused on customer requirements. (Chapter VI.) At this point, the redrawn organization charts are still taking shape. Morale is poor among the remaining employees, no surprise. Compensation incentives and metrics must still be realigned. But these difficult issues are being addressed squarely by the executives we interview.
- c. Rationalizing the confused and fragmented product lines that evolved near the end of Ken Olsen's reign. Central to that strategy is the Alpha microprocessor, Digital's first RISC chip and the first on the market with 64-bit addressing. That gives Alpha a momentary (2-3 year) edge, but a challenge in finding the right partners. Because Digital entered the RISC contest after the other contenders already formed alliances around their older (32-bit) RISC generations. So currently, Alpha's few allies include Cray and MasPar, who can only promise small volumes. And Olivetti whose equity DEC bought last year, agreeing to take 10.2 percent for \$400 million.

Of course, Digital's product strategy would be stronger today had Alpha been introduced before the VAX/VMS market began to seriously erode. But the company was wholly preoccupied by its massive investment in developing a bipolar-based mainframe (the VAX 9000). Until insiders were hesitant to suggest RISC and workstation technology could achieve better throughput at lower cost. Meanwhile, Digital began losing the attention of its customers. And finally felt impelled to announce the DECsystem based on RISC from Mips; another distraction, unfortunately.

Ironically, Alpha's best prospect today is not Unix or VMS, but in large servers with Microsoft NT. In that arena, a tough race is shaping up with Intel, everyone's favorite NT horse in the early betting. Digital hopes Alpha will realize an early edge from the liaison with Microsoft.

*too Early to tell
could win here
also*

Meanwhile, Digital has a determined program to slash the number of distinct products. The roster had grown too large for Engineering and Manufacturing to support economically, or for the field force to understand. Items being "de-emphasized" and "stabilized" are the Mips-based DECsystem and DECstation (in favor of Alpha) and Digital's Ultrix Unix (in favor of the Open Software Foundation's "standard"). In addition, certain software will be spun out for support by independent companies; two office applications will go to a venture in the Negev desert which Digital shares with the Israeli Government, for example.

IV. THE SQUEEZE IN OPERATING SYSTEMS

C. Traditional Proprietary Systems

As previously noted, most vendors will soon use the same hardware engines for all the operating systems they support. At the same time, traditionalists and new breed alike are bringing their administrative costs to comparable levels. And both are pushing into each other's distribution channels: On the one hand, the traditionalists have discovered the lower costs inherent in indirect distribution; note that 70 percent of the AS/400 business worldwide was handled by resellers last year. On the other hand, the new suppliers of departmental servers like Apple and Compaq are discovering they need direct account presence - though they'll contain overall sales expenses by continuing to rely on computer stores as their PC distribution channel. In essence, the basic costs in the minicomputer business are being slimmed down just as those in server companies escalate.

To blur the boundaries even more, many proprietary operating systems are meeting open interface standards promulgated by the Feds (Posix) or OSF. "NT will be compliant with Posix," says Bill Gates. "We'll pass all the tests." So will/can Digital's VMS, Hewlett-Packard's MPE and Tandem's Guardian. True, those standards are not inclusive enough today to guarantee portability between suppliers. But new programs written to a single vendor's guidelines should be portable between that vendor's proprietary system and its Unix variant. And from there to other Unixes. This "latent" portability gives customers the option of either adopting Unix gradually or even waiting until (if ever?) it provides the throughput and reliability of proprietary systems. While computer vendors get the option of repositioning their proprietary systems as premium products, offering more functionality than Unix at the same price. We'll illustrate with examples from several key players:

3. Digital. The company is engaged in severely pruning its product line. In part because current margin assumptions leave 20 percent of current offerings without enough sales to make them economic for Engineering to design or Manufacturing to build. As part of this rationalization, the new chief executive has mandated a three-pronged operating system strategy:

- ✓- VMS on its new Alpha platform will be priced competitively against all comers, says President Bob Palmer. That's possible because VMS won't need much incremental investment to be ready for Alpha unless DEC decides to make 64-bit addressing available to user applications. Aggressive pricing of VMS will be aimed at two primary audiences: existing customers, who will then lose the economic incentive for a Unix migration; and downsizers, who seek the same robustness on smaller machines they enjoy on mainframes.
- OSF/1, also on Alpha, is heralded as the first 64-bit version of "standard" Unix. (Ultrix is being functionally "stabilized.") Long term, DEC senior executives want to embrace whatever industrywide version of Unix promises the lowest in-house development costs. But meanwhile, the pacesetting capabilities of OSF/1 will attract applications software developers to Alpha until competitors catch up.
- Microsoft NT, where Alpha power and the company expertise in global networking will be Digital's value-added differentiator against the mass market Intel variant. Steady Grey has high hopes for this positioning and for the Microsoft alliance, in general.

VI. FEET ON THE STREET

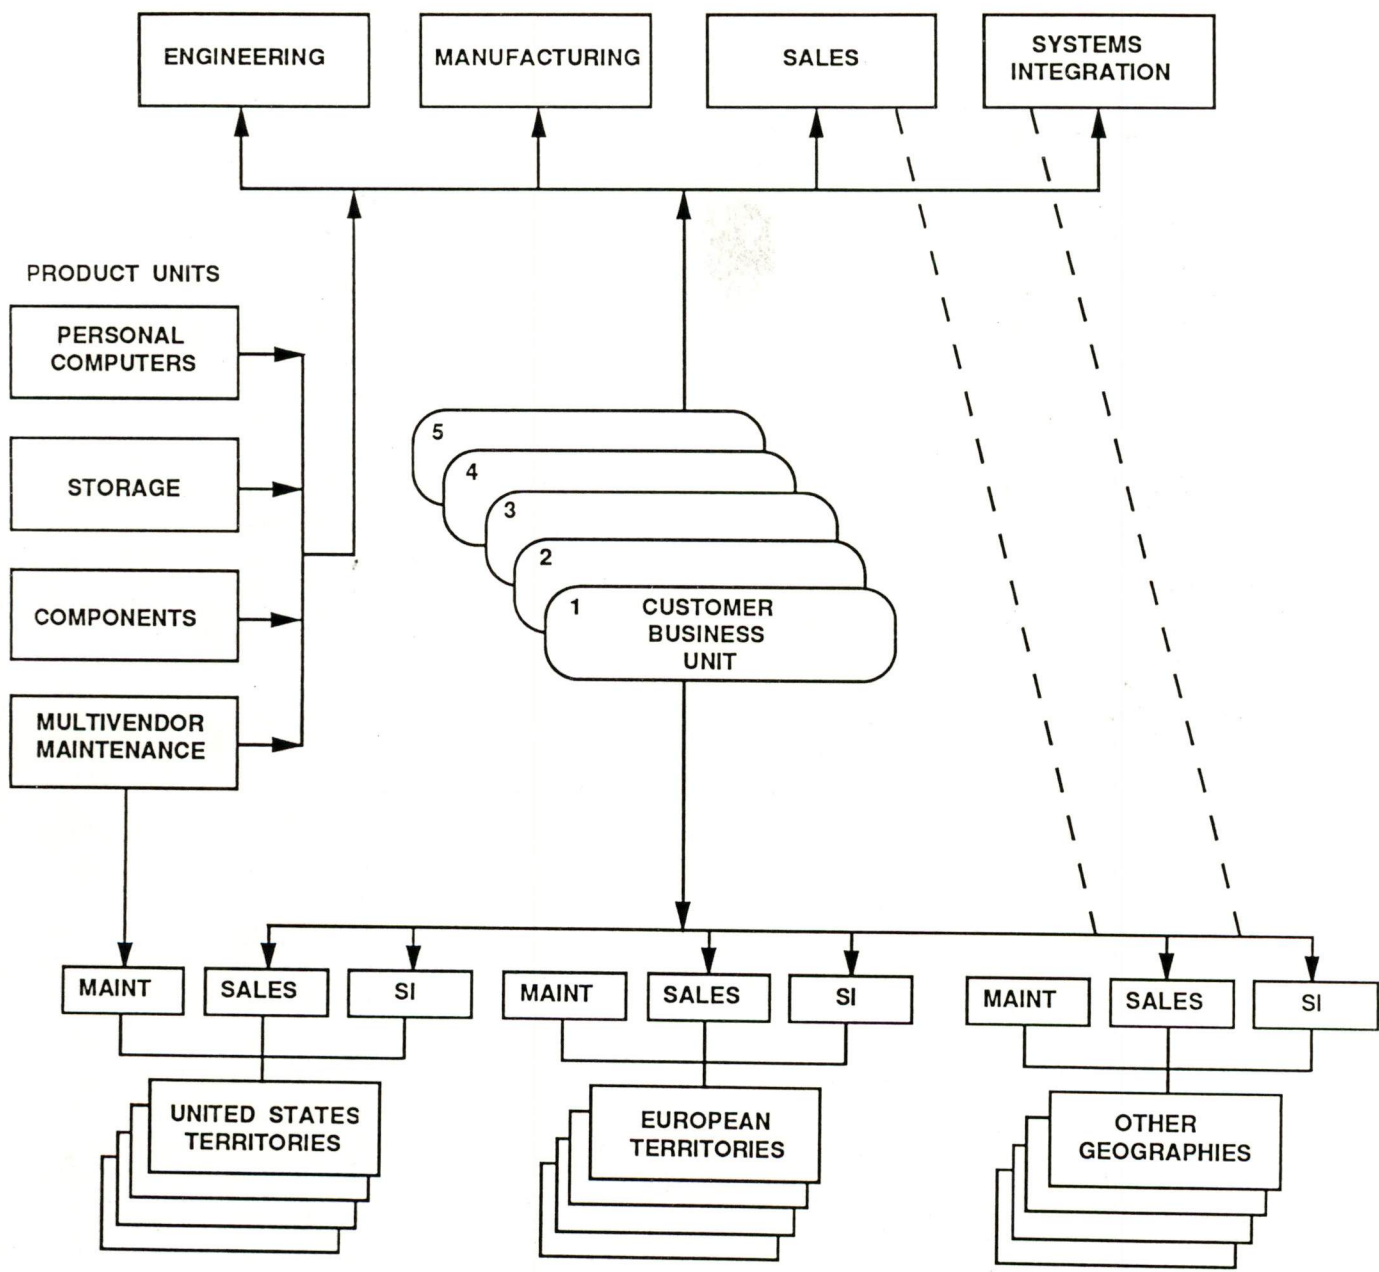

A. Street Smarts

We seem to spend half our interviewing time with the vendors discussing the proper care of RB accounts. Not surprising, since so much has changed. A few years ago, computer company success was assumed to depend on "feet on the street": the number of direct salespeople engaged in presale problem definition, closing the contract, and post-sale handholding. The advent of the personal computer overturned that assumption. Because PCs could be distributed to customers by retailers, at far less expense to the manufacturer than a direct sales force. Or by value-added resellers (VARs) whose business returns depended on applications expertise.

Recent price pressures on hardware, operating systems and applications software have simply made the traditional sales/services model unaffordable. As prices have declined, so have the gross margins once sufficient to compensate a computer company for "uncharged" services. These days, presale man-hours are carefully rationed to targeted industries and applications; post-sales support is determinedly unbundled.

Today's winners maintain their profits by holding headcount constant (or even downsizing) while increasing unit volumes and revenues. That's how successful restructurers Apple and Compaq are able to achieve over \$500,000 in revenue per employee. True, this can be a misleading metric. Lean headcount masks the possibly negative impact of bypassing software r&d or outsourcing manufacturing. These are attractive near-term tactics, but problematic if they leave the company vulnerable to competitive countermoves and product commoditization. Alternatively, bucks-per-back metrics should probably exclude activities like hardware maintenance whose margins and return on assets are very high. Though these cash cows are generally headed to the slaughterhouse.

These caveats aside, it's reasonable[?] to conclude that any computer hardware or package software company should be pushing revenue per employee towards \$300,000. (Sun is at \$280,000, Microsoft at \$279,000, but body-intensive companies sweat to reach \$150,000.) That goal can be achieved partly by pruning and targeting the sales force; partly by realizing revenue from every activity except product demonstration and contract negotiation. Prompting two survival rules for traditionalists and new breed alike: Cut headcount! And charge!

4. Digital Equipment's new organization structure (exhibit) merits a full description because it's intended to focus the entire corporation around specific markets and customer sets. One objective is to rationalize the plethora of hardware and software offerings; another is to concentrate the attentions of the field force on fewer industries and accounts. Until some customers will get little more than basic information on mainstream offerings, emphasizes the new CEO.

The control towers for this global corporate structure are the five "Customer Business Units" or CBUs: Financial Industries; Consumer and Process Manufacturing; Discrete Manufacturing and Defense Industries; Health Industries; and Communications, Education and Entertainment. Along with four product-oriented business units: Personal Computers, Storage Devices, Components and, interestingly, "Multivendor Support," or maintenance.

The CBUs are relatively small (250 people), but they have the ultimate profit and loss responsibility for every product and every account. They will control marketing and advertising; they will influence the activities of Engineering (for new product requirements) and Manufacturing (for production plans). They'll also "contract" with the various sales territories for account representatives, technical support specialists and consultants. So a Customer Business Unit can order account support from the territory manager of one country even though another country will realize revenue from the transaction. "The new organization's best feature is its approach to cross-border customers," enthuses President Palmer. Including the ability to aggregate an account's profitability and measure the quality of the relationship for all products and services; across many different countries and sales territories. Finally giving teeth to the major account program enthusiastically initiated by Pier Carlo Falotti, former President of DEC Europe. *PCF? ~~was~~*

Worth a separate mention are the four horizontal functions: Engineering, Manufacturing, Sales and Systems Integration which provide companywide support to the nine business units. Engineering and Manufacturing are both centralized line functions responsible for end results. While Sales and Systems Integration are staff functions responsible for training and practices, but apparently not for the job performance of individuals in the territories. *shared responsibility ?* That responsibility resides with the field organization, divided into three broad geographies: the U.S., Europe and the rest of the world including Canada. Each office within a geography will have three activities: sales, systems integration and maintenance. The first two also get guidance from the horizontal functions; the third reports to a specific customer business unit.

The new structure is only beginning to take shape when we visit in January 1993. Many details still await resolution, everyone acknowledges. Yet we have some immediate questions; customers may have more.

- a. How will individual customer requirements be conveyed to the new Digital? Through the sales force which has no direct connection to Engineering or Manufacturing? Or through the Customer Business Units which have no direct presence in the field?
- b. Who will lead the sales force? Will it be the CBUs whose plans drive the territories? Or the territories themselves? Or the corporate sales staff?
- c. How will the sales force react as their compensation is shifted from straight salary (a time-honored Digital tradition) to commissions and other incentives? Bob Palmer suggests the change he's going to implement will be gradual, but eventually up to half of a salesperson's compensation could be tied to performance. Customers will want to see how that influences the account rep's behavior. *Perhaps for
Box
SA/IS man
...
70/30 low
or more?*
- d. How will these business units, sales and systems integration activities mesh in terms of incentives and compensation? For example, how will the field people in one territory be compensated when their efforts produce revenues realized in another? The key is mutual dependency, responds Palmer. Each consultancy center will both serve a specific territory like Chicago and wield a specific competency like manufacturing. So the manager of the New York center will gladly supply Chicago with banking expertise because he may need manufacturing skills tomorrow. We're not totally convinced. Though we certainly applaud the heartening signs of greater focus in product lines and resource utilization.

VII. SERVICE RIBBONS

A. The Three Furies

Almost every supplier has a presentation on systems integration and consulting. Complete with foils on the multivendor alliances they'll use to deliver these discretionary services to large corporate accounts. In response, we raise the customer's natural question about quality: Who's responsible for the final results when Systems Integrator A plops Vendor B's application on Vendor C's data base on Vendor D's computer system? Simply pointing at the prime contractor is not enough. The quality of the overall relationship should concern every member of the alliance. How else can these vendors expect discretionary services to restore their faded profit margins?

Indeed, discretionary services should be a win-win for suppliers and customers alike. Vendors from Andersen to HP to Oracle to Microsoft need to sell services either as their primary revenue generator, or to help differentiate a commoditized product. RB members have suffered through five years of recessionary declines and headcount restrictions, leaving many corporate IT organizations seriously understaffed or with outdated skills. So this should be a splendid opportunity for the consultancy and contract software businesses. Yet these folks remain mired in problems they've wrestled for 25 years.

1. The calibre of their professional resources: how to attract, train and motivate the right number and level of employees as the company expands. Then how to deploy them, matching employee skills and availability with client location and project schedule. While minimizing idle time between billable assignments. For nothing chews up profits faster than time spent "on the beach."
2. More important, how to ensure customer satisfaction. Both to maximize project profitability and to increase the prospect of follow-on assignments and referenceable accounts. Thus dampening sales costs while improving staff utilization. To guarantee project quality, however, vendors need consistent and meaningful quality metrics. A subject that suppliers give barely a glimmer - beyond boasting those "Customer Satisfaction Surveys," proving only how few people will express anything hostile in writing. Unfortunately, the lack of metrics becomes even more troublesome when projects involving several "allies" have no vendor willing to take end-to-end responsibility for the results. While the customer stands frothing and frustrated in the middle. ✓

Metrics aside, the customer's best hope of getting a useable and reliable system is project replicability. This means that a systems integrator has mechanisms in place to draw on the experience, designs and even programming of prior assignments. And that a project "alliance" comprises a stable grouping of partners expert in implementing a specific set of applications for a specific industry segment - again and again. Replicability allows the lead supplier to take full responsibility for the output quality of the other participants, precisely because the same team has delivered measurably satisfactory results in the past. At least that's the dream. In reality, we found no vendor with any notion of performance metrics spanning an entire alliance. Nor any plans and incentives to promote replicability. Perhaps it's time the industry began devoting as much attention to benchmarking project performance as it does to benchmarking hardware performance. ✓

Hardware vendors have long been interested in the systems integration business, of course. But we're starting to discern a difference from the trivial pursuits of the past. Digital's Chief Technology Officer Bill Strecker positions the company strategy on a spectrum between the wholly replicable and the scarcely replicable. Where the wholly replicable refers to mass market solutions represented by the idiot-proof systems Microsoft and Apple want to load into PC and TV alike. And scarcely replicable refers to the heterogeneous components programmed or integrated by Andersen or EDS into a customer-unique system. In between is "mass customization," where Digital plans to play with standardized components its field personnel could snap together on a replicable basis to meet the requirements of many customers. In essence, the profitable systems integrator will have technology that permits its project teams to "deliver complex solutions more routinely." Sounds sensible. ✓

How should Research Board members react to the changes in sales and service? A few suggestions:

1. First and foremost, recognize that all these marketing alliances are both a necessity for the vendors and a mixed blessing for the customer.
2. Refuse to allow vendors to escape their basic responsibility for quality through alliance waffles. The lead vendor should be held fully accountable for any failure to deliver excellent products and services. ✓
3. Require suppliers to demonstrate their relevant experience or (even better) "replicability" when you're evaluating sources for applications development and systems implementation. Have the specific individuals proposed from this particular combination of suppliers achieved excellent results on similar projects? Check references, of course.
4. Ignore those "customer satisfaction" surveys every vendor proffers. Unless they were conducted by an independent party, and the vendor wasn't identified to the respondents as the sponsor. *check over*
5. Pressure the vendors to develop, and release, fathomable and credible gauges of their service quality. Both for the projects they conduct by themselves and those they undertake with their allies. Is this a pipe dream, given the infancy of the systems integration business? Perhaps. But end-to-end service quality is the most important issue of the day. And service quality can't be improved without metrics to serve as the signposts and traffic directions.
6. Do not rely on the "buddy system" as a mechanism for transferring skills and technology from outside vendors to in-house IT staff.
7. Do not contract out applications development or integration assignments that demand skills the IT organization will need for the future. To the contrary, the best activities to outsource are those requiring skills already at a dead end.

VIII. FUTURE HOPES AND HYPES

A. Towards the Next Millennium

Slouching toward the millennium, the dogged RB researchers also prospect for intriguing technologies that could radicalize the use of computing. And thus stimulate an industry renaissance comparable to those occasioned by the programmable mainframe (circa 1960), the minicomputer (1970) and, of course, the microprocessor (1980). Four promising areas surfaced repeatedly as the locus of industry r&d investment: parallel processing; object technology, with a bow to multimedia; computer miniaturization; and client/server reliability and security.

All four draw new funds because they're relevant to present needs, not a stretch towards any new conceptual frontier. Commercial parallelism is needed to record, store and correlate business transactions because their volumes grow tenfold each decade. Client/server robustness will reduce the burdensome care and feeding that distributed networks demand today. Object technology will address the need for better productivity in building and maintaining software components. And miniaturization will let our increasingly office-less office workers carry their knowledge tools like lunch pails.

Such new horizons are particularly important at a moment when the software market seems saturated by Microsoft; the hardware market by Intel. And when new offerings are too often fettered by ossified rules of engagement in existing sales channels, or by the constraints of protecting everyone's embedded product base or old code.

So investors are ready for a "relevant" prize. Though it's not clear how these four technologies will impact customer usage patterns. Will they merely increase usage, like cellular telephones? Or also attract business from competing media? Just as facsimile battered the U.S. mails, courier delivery services, image processing, intercompany e-mail, telephone, even altered the routine of ordering sandwiches from the corner delicatessen. Moreover, can these technologies open new avenues for computing - in education, information and entertainment? We'll speculate momentarily.

III. THE GREAT AMERICAN HARDWARE BASH

A. A New Order

Until recently, old-fashioned "minicomputers" could be clearly and unfavorably distinguished from sprightlier servers on technical grounds. Minicomputers are built around idiosyncratic instruction sets proprietary to one supplier, like the Digital VAX. While servers achieve better cost/performance and capacity from engines licensed to multiple computer makers. Those engines are usually supplied by Intel, whose Pentium is now on the near horizon. But Pentium will meet five RISC contenders who hope to dent Intel's market share with a design strategy of more-is-less: RISC gets more throughput than Pentium from one-third less transistor equivalents. That makes RISC cheaper to design and fabricate. And leaves each chip with enough vacant "real estate" to house performance boosting goodies like memory, or customized logic, or built-in graphics. Streamlined chips also require less power, a critical characteristic for the "Personal Digital Assistants" in which many companies are so interested.

Industry debates over Intel vs. RISC divert attention from a more striking development. The basic capacity and performance differences between old minis and new servers will soon end; minicomputer operating systems will reside on exactly the same hardware platforms as Unix or NT, their server counterparts.

- Hewlett-Packard already uses its Precision Architecture RISC engine in both proprietary minicomputer systems and in servers running Unix.
- Tandem is using the same RISC processor (from Mips) for both proprietary Guardian systems and Unix-based Integrity servers.
- IBM will use its PowerPC RISC engine under AIX, OS/2 and (in 1995) for its AS/400 family. The same chip, also produced by Motorola, will be the engine for Apple's new servers.
- Digital's Alpha RISC engine will power both OpenVMS and the company's "standard" Unix (OSF/1).

The convergence of minicomputers and servers reflects the desperate need for volume sales in the microprocessor business. Enormous volume is needed to justify the huge cost of designing and tooling a new microprocessor. And to attract the independent software vendors, whose support (and packages) can determine whether a hardware platform flourishes or fizzles. The pressure for volume will elbow some RISC designs out of the market. It's also Intel's overwhelming advantage.

5. Digital Equipment

Once the industry's biggest minicomputer company, Steady Grey may now be its biggest question mark. So it's terrific to observe a fresh sense of managerial enthusiasm and purpose under the leadership of new CEO Bob Palmer. Whose three immediate objectives are:

- a. Making the company profitable, through headcount reductions and plant closings. One third of the company's 135,000 employees have been laid off; another 10,000 to 17,000 will go. Half in Europe through several actions: merging DEC's acquisitions; reducing sales administrators; and reeling in the countless islands of software development set afloat by Pier Carlo Falotti, former President of DEC Europe (now CEO of The ASK Group). Some of these islands were as small as 15 persons. Many were unknown to engineering management in Maynard.
- b. Restructuring the organization around Customer Business Units (CBUs) with full profit and loss responsibility. Partly to ensure that companywide and worldwide attention is focused on customer requirements. (Chapter VI.) At this point, the redrawn organization charts are still taking shape. Morale is poor among the remaining employees, no surprise. Compensation incentives and metrics must still be realigned. But these difficult issues are being addressed squarely by the executives we interview.
- c. Rationalizing the confused and fragmented product lines that evolved near the end of Ken Olsen's reign. Central to that strategy is the Alpha microprocessor, Digital's first RISC chip and the first on the market with 64-bit addressing. That gives Alpha a momentary edge, but a challenge in finding the right partners. Because Digital entered the RISC contest after the other contenders already formed alliances around their older (32-bit) RISC generations. So currently, Alpha's few allies include Cray and MasPar, who can only promise small volumes. And Olivetti whose equity DEC bought last year, agreeing to take 10.2 percent for \$400 million.

Of course, Digital's product strategy would be stronger today had Alpha been introduced before the VAX/VMS market began to seriously erode. But the company was wholly preoccupied by its massive investment in developing a bipolar-based mainframe (the VAX 9000). Until insiders were hesitant to suggest RISC and workstation technology could achieve better throughput at lower cost. Meanwhile, Digital began losing the attention of its customers. And finally felt impelled to announce the DECsystem based on RISC from Mips; another distraction, unfortunately.

Ironically, Alpha's best prospect today is not Unix or VMS, but in large servers with Microsoft NT. In that arena, a tough race is shaping up with Intel, everyone's favorite NT horse in the early betting. Digital hopes Alpha will realize an early edge from the liaison with Microsoft.

Meanwhile, Digital has a determined program to slash the number of distinct products. The roster had grown too large for Engineering and Manufacturing to support economically, or for the field force to understand. Items being "de-emphasized" and "stabilized" are the Mips-based DECsystem and DECstation (in favor of Alpha) and Digital's Ultrix Unix (in favor of the Open Software Foundation's "standard"). In addition, certain software will be spun out for support by independent companies; two office applications will go to a venture in the Negev desert which Digital shares with the Israeli Government, for example.

IV. THE SQUEEZE IN OPERATING SYSTEMS

C. Traditional Proprietary Systems

As previously noted, most vendors will soon use the same hardware engines for all the operating systems they support. At the same time, traditionalists and new breed alike are bringing their administrative costs to comparable levels. And both are pushing into each other's distribution channels: On the one hand, the traditionalists have discovered the lower costs inherent in indirect distribution; note that 70 percent of the AS/400 business worldwide was handled by resellers last year. On the other hand, the new suppliers of departmental servers like Apple and Compaq are discovering they need direct account presence - though they'll contain overall sales expenses by continuing to rely on computer stores as their PC distribution channel. In essence, the basic costs in the minicomputer business are being slimmed down just as those in server companies escalate.

To blur the boundaries even more, many proprietary operating systems are meeting open interface standards promulgated by the Feds (Posix) or OSF. "NT will be compliant with Posix," says Bill Gates. "We'll pass all the tests." So will/can Digital's VMS, Hewlett-Packard's MPE and Tandem's Guardian. True, those standards are not inclusive enough today to guarantee portability between suppliers. But new programs written to a single vendor's guidelines should be portable between that vendor's proprietary system and its Unix variant. And from there to other Unixes. This "latent" portability gives customers the option of either adopting Unix gradually or even waiting until (if ever?) it provides the throughput and reliability of proprietary systems. While computer vendors get the option of repositioning their proprietary systems as premium products, offering more functionality than Unix at the same price. We'll illustrate with examples from several key players:

3. Digital. The company is engaged in severely pruning its product line. In part because current margin assumptions leave 20 percent of current offerings without enough sales to make them economic for Engineering to design or Manufacturing to build. As part of this rationalization, the new chief executive has mandated a three-pronged operating system strategy:

- VMS on its new Alpha platform will be priced competitively against all comers, says President Bob Palmer. That's possible because VMS won't need much incremental investment to be ready for Alpha unless DEC decides to make 64-bit addressing available to user applications. Aggressive pricing of VMS will be aimed at two primary audiences: existing customers, who will then lose the economic incentive for a Unix migration; and downsizers, who seek the same robustness on smaller machines they enjoy on mainframes.
- OSF/1, also on Alpha, is heralded as the first 64-bit version of "standard" Unix. (Ultrix is being functionally "stabilized.") Long term, DEC senior executives want to embrace whatever industrywide version of Unix promises the lowest in-house development costs. But meanwhile, the pacesetting capabilities of OSF/1 will attract applications software developers to Alpha until competitors catch up.
- Microsoft NT, where Alpha power and the company expertise in global networking will be Digital's value-added differentiator against the mass market Intel variant. Steady Grey has high hopes for this positioning and for the Microsoft alliance, in general.

VI. FEET ON THE STREET

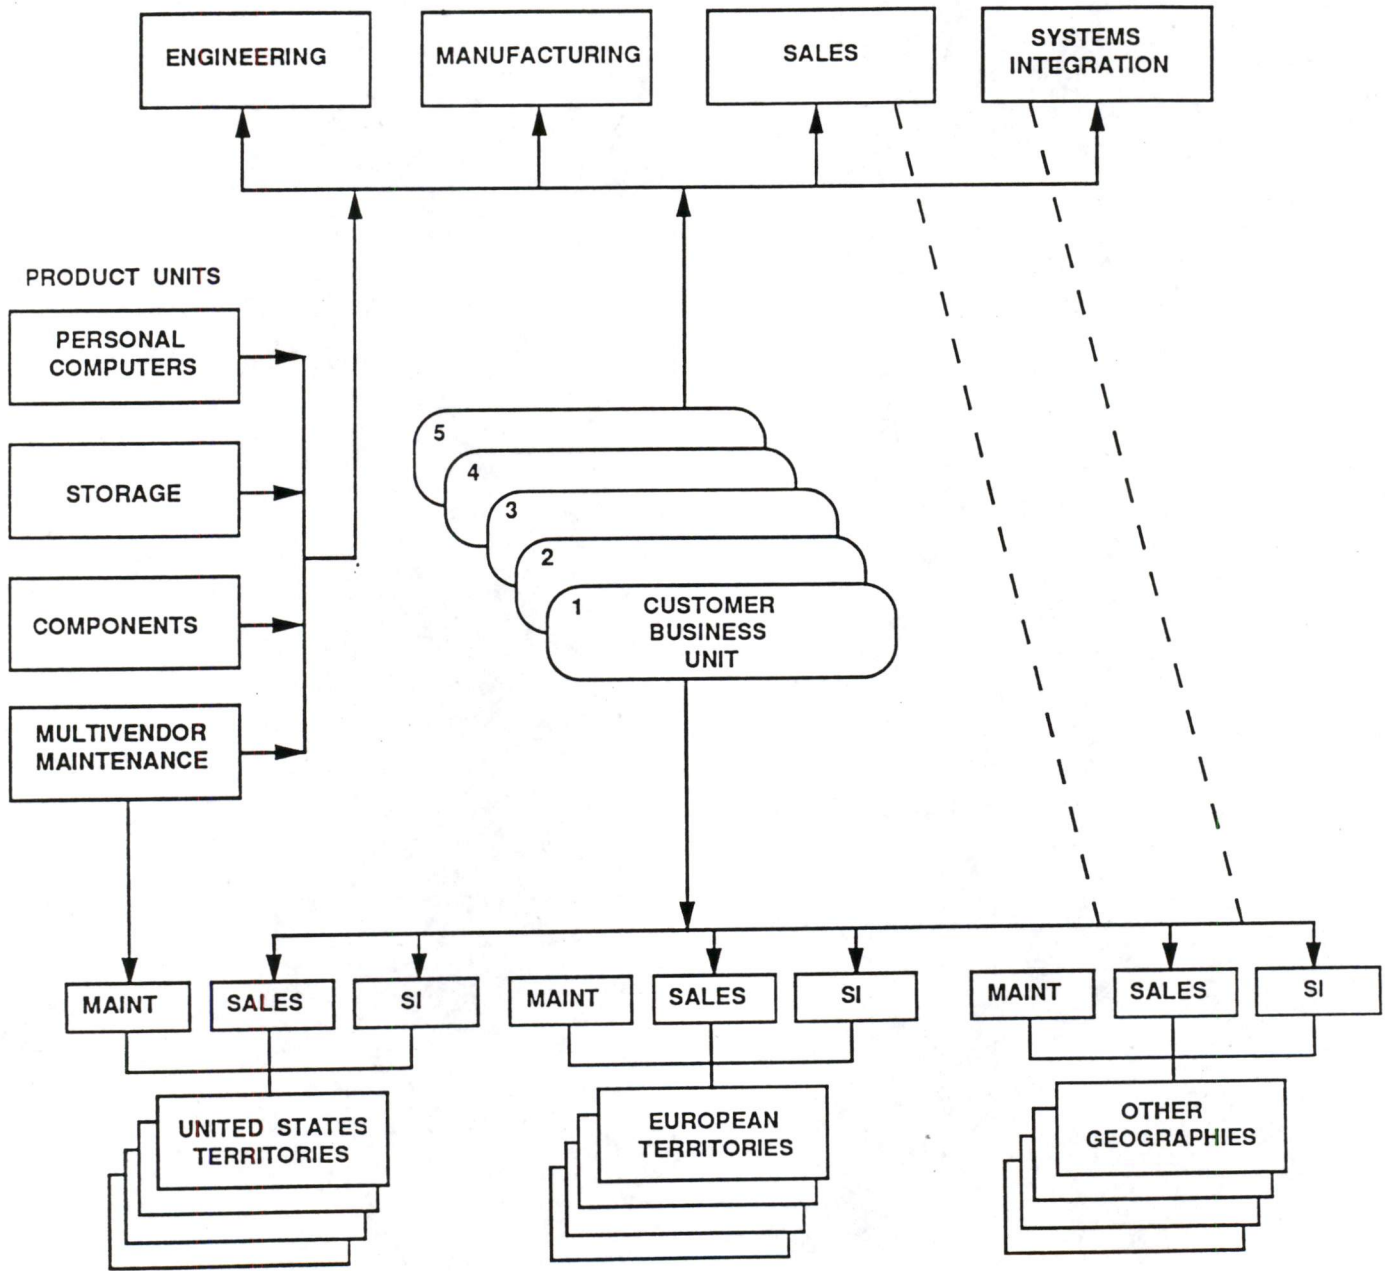

A. Street Smarts

We seem to spend half our interviewing time with the vendors discussing the proper care of RB accounts. Not surprising, since so much has changed. A few years ago, computer company success was assumed to depend on "feet on the street": the number of direct salespeople engaged in presale problem definition, closing the contract, and post-sale handholding. The advent of the personal computer overturned that assumption. Because PCs could be distributed to customers by retailers, at far less expense to the manufacturer than a direct sales force. Or by value-added resellers (VARs) whose business returns depended on applications expertise.

Recent price pressures on hardware, operating systems and applications software have simply made the traditional sales/services model unaffordable. As prices have declined, so have the gross margins once sufficient to compensate a computer company for "uncharged" services. These days, presale man-hours are carefully rationed to targeted industries and applications; post-sales support is determinedly unbundled.

Today's winners maintain their profits by holding headcount constant (or even downsizing) while increasing unit volumes and revenues. That's how successful restructurers Apple and Compaq are able to achieve over \$500,000 in revenue per employee. True, this can be a misleading metric. Lean headcount masks the possibly negative impact of bypassing software r&d or outsourcing manufacturing. These are attractive near-term tactics, but problematic if they leave the company vulnerable to competitive countermoves and product commoditization. Alternatively, bucks-per-back metrics should probably exclude activities like hardware maintenance whose margins and return on assets are very high. Though these cash cows are generally headed to the slaughterhouse.

These caveats aside, it's reasonable to conclude that any computer hardware or package software company should be pushing revenue per employee towards \$300,000. (Sun is at \$280,000, Microsoft at \$279,000, but body-intensive companies sweat to reach \$150,000.) That goal can be achieved partly by pruning and targeting the sales force; partly by realizing revenue from every activity except product demonstration and contract negotiation. Prompting two survival rules for traditionalists and new breed alike: Cut headcount! And charge!

4. Digital Equipment's new organization structure (exhibit) merits a full description because it's intended to focus the entire corporation around specific markets and customer sets. One objective is to rationalize the plethora of hardware and software offerings; another is to concentrate the attentions of the field force on fewer industries and accounts. Until some customers will get little more than basic information on mainstream offerings, emphasizes the new CEO.

The control towers for this global corporate structure are the five "Customer Business Units" or CBUs: Financial Industries; Consumer and Process Manufacturing; Discrete Manufacturing and Defense Industries; Health Industries; and Communications, Education and Entertainment. Along with four product-oriented business units: Personal Computers, Storage Devices, Components and, interestingly, "Multivendor Support," or maintenance.

The CBUs are relatively small (250 people), but they have the ultimate profit and loss responsibility for every product and every account. They will control marketing and advertising; they will influence the activities of Engineering (for new product requirements) and Manufacturing (for production plans). They'll also "contract" with the various sales territories for account representatives, technical support specialists and consultants. So a Customer Business Unit can order account support from the territory manager of one country even though another country will realize revenue from the transaction. "The new organization's best feature is its approach to cross-border customers," enthuses President Palmer. Including the ability to aggregate an account's profitability and measure the quality of the relationship for all products and services; across many different countries and sales territories. Finally giving teeth to the major account program enthusiastically initiated by Pier Carlo Falotti, former President of DEC Europe.

Worth a separate mention are the four horizontal functions: Engineering, Manufacturing, Sales and Systems Integration which provide companywide support to the nine business units. Engineering and Manufacturing are both centralized line functions responsible for end results. While Sales and Systems Integration are staff functions responsible for training and practices, but apparently not for the job performance of individuals in the territories. That responsibility resides with the field organization, divided into three broad geographies: the U.S., Europe and the rest of the world including Canada. Each office within a geography will have three activities: sales, systems integration and maintenance. The first two also get guidance from the horizontal functions; the third reports to a specific customer business unit.

The new structure is only beginning to take shape when we visit in January 1993. Many details still await resolution, everyone acknowledges. Yet we have some immediate questions; customers may have more.

- a. How will individual customer requirements be conveyed to the new Digital? Through the sales force which has no direct connection to Engineering or Manufacturing? Or through the Customer Business Units which have no direct presence in the field?
- b. Who will lead the sales force? Will it be the CBUs whose plans drive the territories? Or the territories themselves? Or the corporate sales staff?
- c. How will the sales force react as their compensation is shifted from straight salary (a time-honored Digital tradition) to commissions and other incentives? Bob Palmer suggests the change he's going to implement will be gradual, but eventually up to half of a salesperson's compensation could be tied to performance. Customers will want to see how that influences the account rep's behavior.
- d. How will these business units, sales and systems integration activities mesh in terms of incentives and compensation? For example, how will the field people in one territory be compensated when their efforts produce revenues realized in another? The key is mutual dependency, responds Palmer. Each consultancy center will both serve a specific territory like Chicago and wield a specific competency like manufacturing. So the manager of the New York center will gladly supply Chicago with banking expertise because he may need manufacturing skills tomorrow. We're not totally convinced. Though we certainly applaud the heartening signs of greater focus in product lines and resource utilization.

VII. SERVICE RIBBONS

A. The Three Furies

Almost every supplier has a presentation on systems integration and consulting. Complete with foils on the multivendor alliances they'll use to deliver these discretionary services to large corporate accounts. In response, we raise the customer's natural question about quality: Who's responsible for the final results when Systems Integrator A plops Vendor B's application on Vendor C's data base on Vendor D's computer system? Simply pointing at the prime contractor is not enough. The quality of the overall relationship should concern every member of the alliance. How else can these vendors expect discretionary services to restore their faded profit margins?

Indeed, discretionary services should be a win-win for suppliers and customers alike. Vendors from Andersen to HP to Oracle to Microsoft need to sell services either as their primary revenue generator, or to help differentiate a commoditized product. RB members have suffered through five years of recessionary declines and headcount restrictions, leaving many corporate IT organizations seriously understaffed or with outdated skills. So this should be a splendid opportunity for the consultancy and contract software businesses. Yet these folks remain mired in problems they've wrestled for 25 years.

1. The calibre of their professional resources: how to attract, train and motivate the right number and level of employees as the company expands. Then how to deploy them, matching employee skills and availability with client location and project schedule. While minimizing idle time between billable assignments. For nothing chews up profits faster than time spent "on the beach."
2. More important, how to ensure customer satisfaction. Both to maximize project profitability and to increase the prospect of follow-on assignments and referenceable accounts. Thus dampening sales costs while improving staff utilization. To guarantee project quality, however, vendors need consistent and meaningful quality metrics. A subject that suppliers give barely a glimmer - beyond boasting those "Customer Satisfaction Surveys," proving only how few people will express anything hostile in writing. Unfortunately, the lack of metrics becomes even more troublesome when projects involving several "allies" have no vendor willing to take end-to-end responsibility for the results. While the customer stands frothing and frustrated in the middle.

Metrics aside, the customer's best hope of getting a useable and reliable system is project replicability. This means that a systems integrator has mechanisms in place to draw on the experience, designs and even programming of prior assignments. And that a project "alliance" comprises a stable grouping of partners expert in implementing a specific set of applications for a specific industry segment - again and again. Replicability allows the lead supplier to take full responsibility for the output quality of the other participants, precisely because the same team has delivered measurably satisfactory results in the past. At least that's the dream. In reality, we found no vendor with any notion of performance metrics spanning an entire alliance. Nor any plans and incentives to promote replicability. Perhaps it's time the industry began devoting as much attention to benchmarking project performance as it does to benchmarking hardware performance.

Hardware vendors have long been interested in the systems integration business, of course. But we're starting to discern a difference from the trivial pursuits of the past. Digital's Chief Technology Officer Bill Strecker positions the company strategy on a spectrum between the wholly replicable and the scarcely replicable. Where the wholly replicable refers to mass market solutions represented by the idiot-proof systems Microsoft and Apple want to load into PC and TV alike. And scarcely replicable refers to the heterogeneous components programmed or integrated by Andersen or EDS into a customer-unique system. In between is "mass customization," where Digital plans to play with standardized components its field personnel could snap together on a replicable basis to meet the requirements of many customers. In essence, the profitable systems integrator will have technology that permits its project teams to "deliver complex solutions more routinely." Sounds sensible.

How should Research Board members react to the changes in sales and service? A few suggestions:

1. First and foremost, recognize that all these marketing alliances are both a necessity for the vendors and a mixed blessing for the customer.
2. Refuse to allow vendors to escape their basic responsibility for quality through alliance waffles. The lead vendor should be held fully accountable for any failure to deliver excellent products and services.
3. Require suppliers to demonstrate their relevant experience or (even better) "replicability" when you're evaluating sources for applications development and systems implementation. Have the specific individuals proposed from this particular combination of suppliers achieved excellent results on similar projects? Check references, of course.
4. Ignore those "customer satisfaction" surveys every vendor proffers. Unless they were conducted by an independent party, and the vendor wasn't identified to the respondents as the sponsor.
5. Pressure the vendors to develop, and release, fathomable and credible gauges of their service quality. Both for the projects they conduct by themselves and those they undertake with their allies. Is this a pipe dream, given the infancy of the systems integration business? Perhaps. But end-to-end service quality is the most important issue of the day. And service quality can't be improved without metrics to serve as the signposts and traffic directions.
6. Do not rely on the "buddy system" as a mechanism for transferring skills and technology from outside vendors to in-house IT staff.
7. Do not contract out applications development or integration assignments that demand skills the IT organization will need for the future. To the contrary, the best activities to outsource are those requiring skills already at a dead end.

VIII. FUTURE HOPES AND HYPES

A. Towards the Next Millennium

Slouching toward the millennium, the dogged RB researchers also prospect for intriguing technologies that could radicalize the use of computing. And thus stimulate an industry renaissance comparable to those occasioned by the programmable mainframe (circa 1960), the minicomputer (1970) and, of course, the microprocessor (1980). Four promising areas surfaced repeatedly as the locus of industry r&d investment: parallel processing; object technology, with a bow to multimedia; computer miniaturization; and client/server reliability and security.

All four draw new funds because they're relevant to present needs, not a stretch towards any new conceptual frontier. Commercial parallelism is needed to record, store and correlate business transactions because their volumes grow tenfold each decade. Client/server robustness will reduce the burdensome care and feeding that distributed networks demand today. Object technology will address the need for better productivity in building and maintaining software components. And miniaturization will let our increasingly office-less office workers carry their knowledge tools like lunch pails.

Such new horizons are particularly important at a moment when the software market seems saturated by Microsoft; the hardware market by Intel. And when new offerings are too often fettered by ossified rules of engagement in existing sales channels, or by the constraints of protecting everyone's embedded product base or old code.

So investors are ready for a "relevant" prize. Though it's not clear how these four technologies will impact customer usage patterns. Will they merely increase usage, like cellular telephones? Or also attract business from competing media? Just as facsimile battered the U.S. mails, courier delivery services, image processing, intercompany e-mail, telephone, even altered the routine of ordering sandwiches from the corner delicatessen. Moreover, can these technologies open new avenues for computing - in education, information and entertainment? We'll speculate momentarily.

NOTES
