

For the better part of a decade, Varian 620-series computers have paced the minicomputer industry. Each new model has represented a dramatic improvement in performance, and an equally dramatic reduction in the dollars paid for that performance.

Now, with the introduction of the Varian 73, Varian Data Machines has achieved a major step-function change in the power and potential of the minicomputer as a systems component.

The Varian 73 has been designed specifically to meet the new, more sophisticated demands that have developed as users have gained experience in applying minicomputers to thousands of applications.

These demands have included faster processing times, a more efficient and flexible instruction repertoire, expanded memories, a faster, more versatile input/output structure, simpler interfacing between multiple processors and memories.

The Varian 73 meets all these requirements, with performance to spare.

User-Accessible Microprogramming

The Varian 73 is a microprogrammed computer, with 64-bit control words dictating the flow of data through a 16-register processing section. This powerful combination permits the writing of exceptionally fast and efficient programs. The computer can process all previous Varian 620 programs, and with the addition of a Writable Control Store option, the microprogram can be extended to meet any special system requirements.

Extendable Architecture

The Varian 73 is available with either semiconductor or core memories, or any combination of the two. With memory mapping (a future option) up to 262K of memory can be included in the system. All memories are dual port for fast interleaving of I/O and processor functions. Built-in features allow multiple central processors to share memory, greatly simplifying the implementation of a multi-processor system.

165-Nanosecond Microinstruction Time

The Varian 73 has set a new standard for processing speed. Microinstructions are carried out in 165 nanoseconds. With semiconductor memory, register-reference instructions are

VARIAN 73 THE ALL-NEW COMPUTER FOR THE NEW COMPUTER AGE

completed in 330 nanoseconds, memory-reference instructions in 660 nanoseconds. Cycle time for semiconductor memory modules is 330 nanoseconds; cycle time for the core memory is 660 nanoseconds. Direct I/O-to-memory data transfers can take place at rates up to 3.03 million words per second.

Four Input/Output Techniques

The designer and programmer have a choice of up to four different input/ output techniques, depending on the data rate required and the number of peripherals on the interface. Dual-port memories allow for highly efficient direct-to-memory transfers.

Off-The-Shelf Software and Peripherals

The Varian 73 is an all-new computer, but it is fully supported with the extensive software and peripheral interfaces that have been developed for Varian 620-series computers. Immediately available are powerful operatingsystem software packages such as VORTEX and MOS. Varian 73 software also includes DAS macro-assemblers for programs written in Varian 620 language, higher level language compilers such as FORTRAN IV, BASIC, and RPG IV, mathematical and data-conversion packages, and editing, debugging, and diagnostic programs.

Compact, Reliable Packaging

The entire Varian central processor, including the microprogram read-only memory, is contained on a single circuit board, 15.6 inches by 19 inches. Similar boards carry up to 8K of semiconductor or core memory. All boards plug into universal slots in either a 7inch or a 14-inch chassis. A single power supply will accommodate systems with up to 32K of core memory. Two types of consoles are available: a programmer's console with a full set of controls and indicators, and an operator's console with just the switches needed to start, stop, and control the program.

The Varian 73 has set a new standard for speed and flexibility.

Data flow is controlled by hundreds of microinstructions stored in a read-only memory. Execution time per microinstruction is only 165 nanoseconds. And if that isn't enough speed and flexibility, the user can add an optional Writable Control Store to create his own microinstruction set.

Processor Microprogram — The standard Varian 73 microprogram consists of 512 microinstructions, each a 64-bit word stored in the processor ROM. The 64 bits are divided into fields which control the flow and manipulation of data throughout the machine. A single microinstruction can dictate a number of different machine functions: register, memory and I/O transfers, arithmetic and logical operations, and tests on the conditions of registers.

User-Written Microprogram — The processor microprogram can be supplemented by an optional Writable Control Store memory containing microinstructions written by the user. The standard Varian 73 microprogram is designed to decode and emulate the widely used Varian 620 instruction set. Special microprograms can also be written, using the powerful 64-bit microinstruction format, to adapt the Varian 73 to special application requirements.

Sixteen General-Purpose Registers — Further programming flexibility is provided by 16 general-purpose and 8 special-purpose 16-bit registers, all accessible to the microprogram.

Dual Memory Buses — Processors, memories, and PMA (Priority Memory Access) I/O controllers are all connected to a common bus structure for fast data transfers and ease of expansion. Two parallel buses are provided, allowing data transfer from a peripheral to a 4K or 8K memory module, for example, while the processor accesses a second memory module. Multiple processors, peripheral devices, and up to 262K words of memory can share the parallel buses. Advantages of this unique structure are detailed on the following pages.

Varian 73 Memory Expansion

THE ALL-NEW VARIAN 73... USER-ACCESSIBLE MICROPROGRAMMING FOR SPEED AND FLEXIBILITY

Varian 73 Processor Organization

The Varian 73 has added a new dimension to the architecture of computer memory systems.

Both core and MOS memories are available in 8K modules, each packaged on a single board. All share a common, dual bus structure, along with multiple processors and PMA controllers. Processors equipped with the Memory Map option will be able to address 262K of memory.

Core Memories — Cycle time for core memories is a fast 660 nanoseconds. The memories are available in 4K and 8K modules.

MOS Memories — Semiconductor memories, with a cycle time of 330 nanoseconds, are available in 1K, 2K, 4K, and 8K modules. They may be combined with core memories in any proportion. Addressing and programming are identical for the two types of memories. MOS memories are for optimum speed and throughput; core memories for optimum economy. A battery-powered Data Save option may be added to the power supply when semi-conductor memory is included in the system.

Dual Ports — Both core and MOS memories are provided with two fully implemented ports, each connected to one of two parallel memory buses. In multiple-memory systems, this means that one memory may be communicating with a processor while another is transferring data to or from another processor or an I/O device. Priorities between the buses are implemented by memory-control circuits, with Bus A having priority over Bus B.

Memory Mapping — The Memory Map option performs address relocation and memory protection for up to 262K memory locations by translating the 15bit virtual memory address and a 4-bit key into an 18-bit physical address. Up to 16 independent protection partitions may be simultaneously assigned. Any user program may employ up to 32K words of memory in 512-word blocks. Completely protected, readonly, and common memory blocks may be defined.

Memory Protect — The memory-protect option prevents the program from accessing any 512-word segment of memory that has been "protected" by a mask stored in the option. The 64-bit mask provides protection for a full 32K memory block. The mask can be applied, removed, and changed under program control.

Memory Parity — Another memory option checks the parity of every data transfer on the dual memory bus. Two parity bits are used, one for the 8 most significant bits, the other for the 8 least significant bits. This facilitates byte packing and retrieval with a parity check on each byte that is transferred.

THE ALL-NEW VARIAN 73... DUALPORT MEMORIES, CORE AND MOS, IN AN EXTENDABLE ARCHITECTURE

Memory Module

Memory Module

Memory Module

Single Processor System

Semiconductor Memory Module

The Varian 73 gives the system designer four different ways to communicate with peripherals and other data sources. The result is unprecedented flexibility in selecting the I/O technique that will provide the highest possible data transfer rate at minimum cost in processor time.

All data transfers, except PMA, are over the party-line I/O bus, with 16 bidirectional lines for addresses and for data, plus an additional 14 lines for timing, sense, and control signals. PMA transfers are direct to memory, with separate 16-line buses for addresses and data.

Priority Interrupt Structure — The Varian 73 has a true hardware priority interrupt structure, expandable at low cost to up to 64 levels, with automatic interrupt identification. External controllers can all request interrupts and specify the interrupt location via the address lines of the Varian 73 I/O bus. An optional Priority Interrupt Module (PIM) provides hardware priority arbitration and interrupt address (vector) generation for 8 levels. Up to 8 PIM's may be interfaced to the I/O bus of a Varian 73 processor. Interrupts may be enabled or disabled individually or in groups.

Programmed I/O — Programmed I/O operations are initiated by the central processor and are used primarily to control and sense the state of peripherals, to prepare controllers for other types of I/O transfers, and to communicate with low-speed devices, such as a teletype. Any peripheral controller can also initiate a data transfer (or signal its completion) by an interrupt to the processor.

Direct Memory Access (DMA) I/O — Direct data transfers between I/O bus and memory are effected in the DMA mode. The technique is implemented by a Buffer Interlace Controller (BIC) option that stores the initial and final addresses of the data words to be transferred. The transfers are made on a "cycle stealing" basis. DMA transfers can occur at rates up to 333,000 words per second.

High-Speed DMA — Special control lines are provided for peripheral controllers that are able to operate at "high speed" DMA rates, up to 1 million words per second, A similar BIC option is used to implement transfers at this higher rate.

Priority Memory Access (PMA) I/O — Data transfers at the full memory cycle rate (3.03 million words per second, in the case of a MOS memory) can be obtained through the PMA channel. A PMA controller is loaded with the initial and final addresses of the data words to be transferred. Controller data and address lines are connected directly to the memory bus.

THE ALL-NEW VARIAN 73... FOUR WAYS TO COMMUNICATE WITH PERIPHERALS

VARIAN 73 PERIPHERALS

Peripheral devices and I/O interfaces for Varian 73 systems have been field tested in hundreds of installations and have been selected to provide an optimum combination of economy and high performance.

Each standard peripheral subsystem is an integrated unit, including the device itself, interconnecting cables, I/O controller, and software for its operation. The standard Varian peripherals are supplemented by a list of over 100 other peripheral models and types that may be supplied on special order.

FIXED HEAD DISCS — Low-cost storage, with capacity of 30K, 61K or 123K words; 17 ms average access time; 73.3K word transfer rate; 1 head per track.

MOVING HEAD DISCS — Capacities from 1.17 million words to 58 million words; 12.5 ms and 20 ms on-track access time, average access times to a track of 45 and 60 ms; transfer rates up to 156K words per second.

DRUM MEMORIES—Capacity of 30K, 61K, 123K, 246K, 491K, or 983K words; 8.7 ms average access time; 106K word transfer rate; 1 head per track.

MAGNETIC TAPE — 9-track or 7track, with up to 4 transports per controller, densities of 200, 556, and 800 bpi and speed of 25 ips. TELETYPES—Model ASR 33, ASR 35, or KSR 35 units.

HIGH-SPEED PAPER TAPE — Punch rates up to 75 characters per second and read rates up to 300 characters per second.

CARD READER — Reading speed of 300 cards per minute.

CARD PUNCH — Punching speed of 35 cards per minute.

LINE PRINTER — 245 to 1100 lines per minute, up to 132 characters per line, buffered, ASCII code, 64 alphanumeric characters and symbols.

DIGITAL PLOTTER — 300 steps per second, 0.01-inch step size, other sizes are available.

ELECTROSTATIC PLOTTER—Statos Printer/Plotters; produce graphic displays and alphanumeric information at rates up to 5,000 lines per minute.

ANALOG INPUT — Multiplex/Controllers expandable up to 256 single ended or differential channels. Analogto-digital converters for word lengths to 13 bits, conversion rates to 55K words per second.

ANALOG OUTPUT — Controllers expandable to 64 channels, word lengths to 14 bits per channel.

DIGITAL INPUT — Multiplex/controllers expandable up to 2048 channels of 16 bits. DIGITAL OUTPUT — Controllers expandable up to 64 output channels of 16 bits each.

CRT DISPLAY — 11-inch storage scope.

RELAY INTERFACES — Contact inputs and mercury-wetted contact outputs: 0.5 to 3 A; up to 400 V.

GENERAL PURPOSE INTERFACES— Buffer Interlace Controller; Buffered I/O Controller; Digital I/O Controller; Universal Serial Asynchronous Controller.

DATA SET COUPLERS — Interface with Type 103, 201, 202 and 301 modems, hardware or software sync character detection; transmission rates up to 50,000 baud; controller available for 801 Automatic Call Unit.

COMMUNICATIONS CONTROLLER — Multiplexes, controls and provides data interface for up to 64 data sets; synchronous and asynchronous lines may be intermixed; modular line controllers for RS 232B, CCITT, discrete, and relay communication systems.

THE ALL-NEW VARIAN 73 ... POWERFUL OPERATING SYSTEMS AND SYSTEM SOFTWARE

Operating Systems — Two comprehensive software operating systems are available for use with Varian 73 computers: VORTEX and MOS.

Both systems incorporate a full repertoire of utility programs, as well as DAS MR and FORTRAN IV language processors. MOS also includes RPG IV.

VORTEX (Varian Omnitask Real-Time Executive) is a multi-programming system with special features designed for real-time applications. A number of different tasks may be stored in the main memory or on a rotating memory device. These tasks are scheduled by a resident executive program that gives highest priority to real-time "foreground" programs. Lower priority "background" programs are executed during the idle-time intervals embedded in most real-time operations. The effect is to give the system the utility of two computers for the price of one.

VORTEX also increases the efficiency of any installation in which the computer is required to operate on a number of different programs in sequence. The user simply establishes the priority of the jobs to be executed; the system automatically schedules and runs the programs without further operator intervention.

Example of VORTEX Operation

When Real-Time Executive senses (1) that time is available for the scheduling of a background task (following an initial operator request), the Job Control Processor is read into the background area of the main memory (2 and 3). The JCP responds to a directive from the System Input Device (4) and Joads a background task from either the rotating memory (5 and 6) or the System Input Device (7).

Varian **MOS** (Master Operating System) is an integrated batch-process software system designed to boost performance and simplify operation for the medium-to-large-scale system user.

MOS is available in disc, drum, and magnetic-tape resident versions, and includes a complete I/O Control System and System Executive.

Features offered by MOS are automatic identification of both printed listings and binary object output with the job title and date to provide for program control and job accountability; a system preparation program, system maintenance program, source program editor, object program debug package, and a program library.

MOS conserves main memory space for the user by allowing all software elements, except for a small Resident Monitor, to be stored on the rotating memory or magnetic tape and loaded into the computer only when needed. This applies even to the System Executive which serves as the central control element.

Example of MOS Operation

A directive from the System Input Device [1] instructs the Resident Monitor to load the System Executive, I/O Control Module, and appropriate I/O drivers (2 and 3). The System Executive loads and executes a program from the rotating memory (4 and 5) or any logical input unit (6). Programs can overlay the System Executive, but not the I/O Control and Driver modules.

SYSTEM SOFTWARE

DAS Assemblers

Three versions of the Varian 73 DAS Assembler are available. DAS 4A is designed for a minimum system consisting of a computer with 4K memory and a teletype. DAS 8A provides expanded capabilities for systems with at least 8K of memory, and utilizes additional peripheral devices, such as a rotating memory, magnetic tape transport, card equipment, paper tape system, or line printer.

The third and most comprehensive assembler is DAS MR, an integral part of the VORTEX and MOS operating systems. DAS MR is a macro assembler which produces relocatable object modules that may be loaded into any sector of the computer memory.

FORTRAN IV

Varian FORTRAN IV is an integrated software package that consists of a single-pass compiler for interpreting FORTRAN statements, converting them to machine-language instructions, a relocating loader for assembling object modules, and a run-time package that includes I/O drivers and a full set of arithmetic and data-conversion subroutines.

The package is available either as a stand-alone version requiring only 8K of memory, or as an integral part of the VORTEX and MOS operating systems.

BASIC

BASIC is an advanced version of the self-teaching system developed at Dartmouth College. It is applicable to a variety of business and scientific applications.

The programming language is simple and easy to use. Source statements are typed directly on a system console; if any errors are entered, the computer immediately responds and a correction can be made.

Extended BASIC

Extended BASIC expands the BASIC language to make it a more powerful tool for researchers. Special statements have been developed to facilitate the interaction between the computer and an external data-acquisition or processcontrol system. Other statements are designed to establish and control data files stored on a rotating memory device, and to facilitate changing of program overlay segments. Extended BASIC has been developed to operate with the ADAPTS hardware/software system.

RPG IV

Varian RPG IV (Report Program Generator) is a business-oriented language for preparing statistical data and tabular reports such as inventory records, sales analyses, and personnel summaries.

The Varian RPG IV compiler is an advanced version of RPG systems now widely used throughout industry for commercial applications. It is available

either as a free-standing software package, or under control of the MOS batch operating system.

BEST

BEST (Basic Executive Scheduler and Timekeeper) is a real-time monitor that automatically schedules core-resident programs according to the time of day, at fixed time intervals, or at the earliest opportunity.

BEST can operate with any Varian 73 computer equipped with 4K of memory, making it a valuable addition to dedicated real-time computer systems.

Utility Programs

Varian 73 utility programs are standard software elements supplied (along with an Assembler) with every Varian computer.

BLD II is used to load object programs from a paper tape or TTY reader.

AID II is an on-line debugging program for correcting programming errors.

EDIT is used to add, delete, and correct any portion of a symbolic program.

MAINTAIN II checks that all hardware elements in the system are operating correctly.

MATH LIBRARY is a comprehensive set of mathematical function subroutines.

The Varian 73 incorporates a number of innovative packaging concepts, all aimed at increasing reliability and performance, as well as simplifying the task of system expansion or change.

For the first time, a truly universal mainframe backplane has been provided. All computer circuitry is mounted on large single-board modules, 15.6 inches by 19 inches, inserted through the front of the computer. The modules plug into a multilayer printedcircuit backplane which contains the dual memory buses and control signals. Any module can be placed in any slot position.

Connected to the front of the modules are flexible cables with controlled impedance for the I/O interconnections (Programmed I/O, DMA, High-Speed DMA, and PMA).

A valuable side benefit of this packaging technique is that no extender boards or other devices that might alter the computer performance are required for servicing the individual modules. The module is simply moved to the uppermost slot and with the computer chassis drawn out on slides, serviced from the top.

The combination of large board packaging and extensive use of MSI and LSI circuits has reduced both the component count and the path lengths between components. With a minimum number of interconnections and boardto-board cabling, the Varian 73 represents an optimum design for reliable service.

Two Mainframe Chassis — The systems designer has the choice of two Varian 73 mainframe chassis. The 7-inch chassis provides 7 slot positions, plus space for two I/O controllers. The 14-inch chassis increases the slot positions to 17. A 32K MOS-memory system can be contained in the smaller chassis; a 120K system in the larger. Additional memory can be housed in a second 7-inch or 14-inch chassis. If space is required for additional I/O controllers, a 10½-inch I/O Expansion Chassis is used.

Two Mainframe Consoles — Two types of mainframe consoles are available. The Programmer's Console has all the controls and indicators needed to load and debug programs. The Operator's Console has only those controls needed to start and stop the computer. A key switch provides security for the program being run.

Power Supply — A separate 5¹/₄-inch power supply can drive a full 32K system, core or MOS. A Power Failure/ Restart mainframe option provides protection against momentary loss or reduction of ac power. A Data Save option can be added to provide standby battery power for MOS memory modules.

THE ALL-NEW VARIAN 73... PACKAGED FOR RELIABILITY AND EASE OF EXPANSION

Processor Module carries all centralprocessor circuits, including the 16 general-purpose registers, arithmetic and logical control unit, microprogram ROM, memory interface, and the data portion of the I/O interface.

Core-Memory Module carries 4K or 8K of dual-port memory, including all drive and control circuits. The first board occupies one slot in the mainframe or expansion chassis; succeeding boards occupy two slots.

I/O Module carries the control portion of the I/O interface, plus the Real Time Clock, Power Failure/Restart, Teletype Controller and such options as Memory Protect, Memory Parity, and Priority Memory Access.

MOS-Memory Module is available with 1K, 2K, 4K, or 8K words. It occupies one slot in the mainframe or excircuit controller, or three slots with a wire-wrapped controller. Additional I/O controllers can be individually housed in a separate 101/2-inch Expan-
