Chapter 1
Executive Summary

In this Focus Report, Dataquest has assembled a worldwide team of experts to offer their views on the ongoing Asian financial crisis. There are five viewpoints presented: the Korean regional and Korean DRAM perspectives, a focus on China/Hong Kong, insight into the impact of the crisis on the region's PC market, and discussion of its effect on capital spending.

Analysis of the Korean regional situation suggests that the worldwide DRAM recession is one of the reasons for the Korean financial crisis. DRAM pricing is predicted to fall further if the Korean, Taiwanese, and Japanese currencies continue to slide against the U.S. dollar.

Dataquest believes that China/Hong Kong will not be impaired in the short term by the crisis, but it faces long-term challenges. Although China/Hong Kong's long-term semiconductor forecast has been lowered, it will still account for 26 percent of Asia/Pacific consumption by 2001.

Analysis of the PC market provides insight into the early impacts of currency devaluations in the region on the personal computer industry and suggests that the outlook for recovery has shifted from the near term to the long term for Thailand, Indonesia, and Malaysia, with the Korean economy possibly beginning to turn around earlier.

The Asian financial crisis will affect capital availability and spending in semiconductors. Because of the severe depreciation of the Korean currency, Dataquest now forecasts that Korean companies will cut capital spending in 1998 about 40 to 60 percent, relative to 1997, in dollar terms.

Chapter 2
Introduction

The beginning of summer 1997 saw the devaluation of the Thai baht amid escalating difficulties in the Thai banking and finance community, which forced the Thai government to finally surrender to the currency speculators. At that time, few people, if any, would have predicted this to be the start of a financial storm, sweeping throughout Asia, with far-reaching global implications.

Shortly after the Thai baht devaluation, the governments of Malaysia, Indonesia, and the Philippines succumbed one by one to the speculative currency attacks. The rapid currency devaluation sent shock waves through the regional stock markets of Thailand, Malaysia, Indonesia, and the Philippines. Singapore and Hong Kong, which remained largely unaffected initially, saw their stock markets tumble in October amid growing investor anxiety.

The financial crisis deepened in November as it spread to Korea and Japan, the world's 11th-largest and second-largest economies respectively. The value of the Korean won dropped sharply, along with Korea's stock market, after the Korean government gave up its battle to prop up its currency in November. A $57 billion rescue package led by the International Monetary Fund (IMF) was negotiated for Korea, after $40 billion and $17 billion were negotiated for Indonesia and Thailand, respectively. In the meantime, Japan saw the closure of its fourth-largest securities firm, Yamaichi Securities Co., on November 24, following the closure of Hokkaido Takushoku Bank, its 10th-largest commercial bank, a week earlier. On December 22, the Nikkei average closed below the psychologically important 15,000 mark for the first time since July 1995.

The beginning of 1998 brought fresh hope to Korea as global bankers agreed to roll over Korea's short-term debt and started to work on a massive debt restructuring to keep the country from defaulting on its loans. This occurred after Korea's president-elect, Kim Dae-jung, reaffirmed his country's commitment to the economic reforms. Contrary to that hope, the situation in Southeast Asia took a dramatic turn for the worse as the regional currencies and stock markets recorded successive new lows, triggered by Indonesia's announcement of a fiscal budget perceived not to be in line with IMF-mandated reforms. On January 12, Peregrine Investment Holdings Ltd., Hong Kong's once high-flying financial power house, filed for liquidation after the company incurred substantial losses from its Indonesian bond operations; the news of the collapse sent the Hang Seng Index plunging 8.7 percent in that day.

Table 1-1 displays the extent of the depreciation of Asian currencies against the U.S. dollar between June 1997 and January 9, 1998. The Hong Kong dollar is the only currency in the region that has withstood the speculative attack so far. The hardest hit have been the Indonesian rupiah, the Thai baht, and the Korean won, which have all lost more than half of their values.

Table 1-1
Depreciation of Asian Currencies against the U.S. Dollar between June 1, 1997, and January 9, 1998 (Percent)

Currency	Depreciation (%)
Indonesian Rupiah	69.3
Thai Baht	54.3
Korean Won	50.8
Malaysian Ringgit	45.3
Philippine Peso	40.9
Singapore Dollar	19.6
Taiwan Dollar	18.9
Japanese Yen	13.1
Hong Kong Dollar	0.1

Source: Dataquest (January 1998)

The dramatic decline of the currency values combined with the downfall of the local stock markets will have serious impact on the region's economy and, subsequently, the world economy. To analyze the potential impact of the Asian financial crisis, experts from Dataquest's worldwide research operations offer their views on this issue in this Dataquest Focus Report.

There are five viewpoints presented in this report. The Korean regional and Korean DRAM perspectives, respectively, are presented in Chapter 3, by J.H. Son, and Chapter 4, by C.S. Kim, Jerry Yeh, Jim Handy, George Iwanyc, and Clark Fuhs. Chapter 5, by Dan Heyler, focuses on China/ Hong Kong. Chapter 6, by Bruce McCabe, and Chapter 7, by Clark Fuhs, provide insight into the impact of the crisis on the region's PC market and capital spending, respectively.

Chapter 3
The Korean Regional Perspective

Introduction

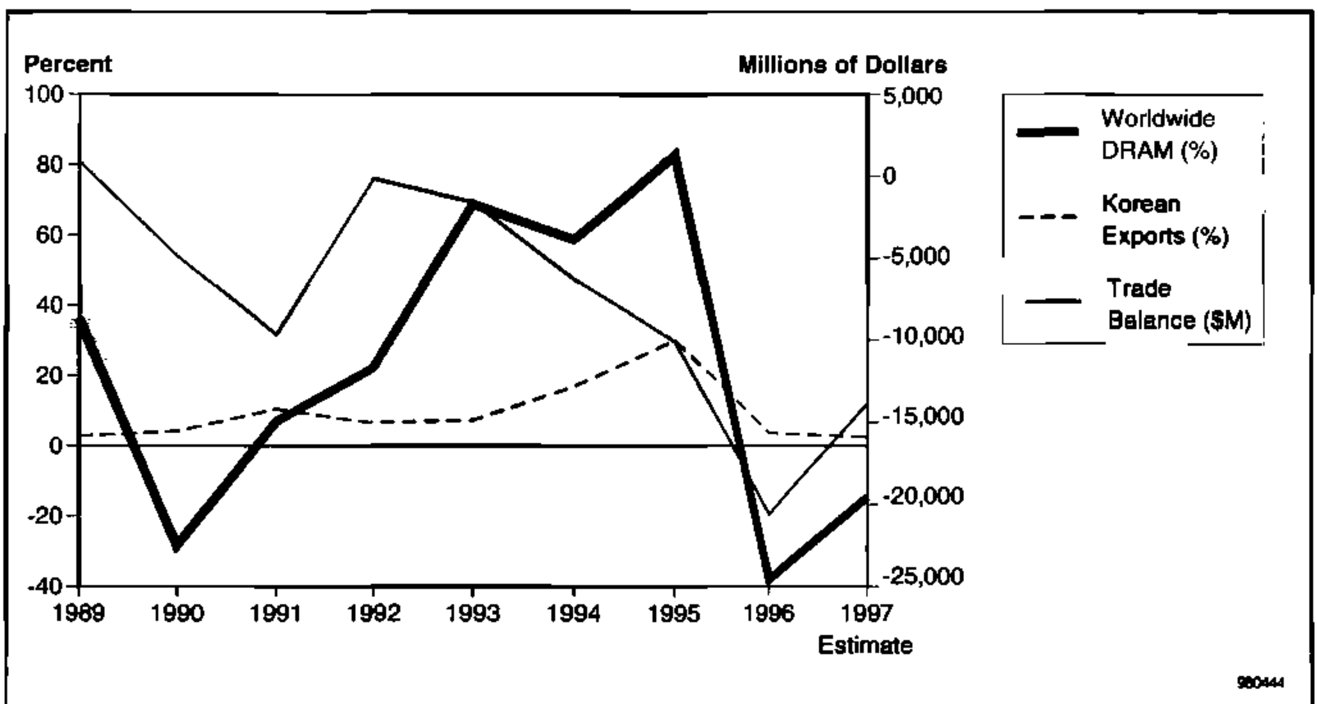
This chapter offers a Korean regional perspective on the reason behind Korea's financial crisis. It argues that the worldwide DRAM recession is one of the reasons for the Korean financial crisis. The impact of the financial crisis on the Korean semiconductor market is also discussed.

Why Did Korea's Financial Crisis Occur?

Figure 3-1 shows the relationship between worldwide DRAM revenue growth and the export growth of Korea. The two elements showed no correlation until the end of the 1980s. After 1990, however, as DRAM became one of Korea's major export items, these two elements started to show a strong correlation.

Korea's exports were solid until 1995. However, Korea's total trade balance was still negative. This means that the semiconductor surplus covered most of the other industries' deficit. In 1996, however, the semiconductor business flagged because of DRAM's drop in prices, so that it could no longer cover the other industries' trade deficit. As a result, a $20.6 billion negative trade balance was recorded in 1996 alone. The drop in DRAM prices continued in 1997—as of the end of September 1997, a $10.6 billion negative trade balance had already been recorded. The cumulative negative balance from 1994 is estimated to be about $50 billion. This amount is very similar to the IMF loan.

Figure 3-1
Relationship between Worldwide DRAM Revenue Growth Rate and Korean Export Growth Rate



Source: Dataquest (January 1998)

© 1998 Dataquest

Korea's financial crisis might stem from the worldwide DRAM recession. Comparing the data for semiconductor statistics with Korea's trade balance of Korea offers some support for this assertion. This cannot be the only reason, but Dataquest believes that it is one of the factors generating Korea's financial crisis.

In 1995, Korea had an $8.8 billion trade surplus in semiconductors by virtue of its good DRAM business. At that time, Korea's total trade deficit was only $10.1 billion. In 1996, however, Korea's semiconductor surplus had shrunk to $0.4 billion, a reduction of $8.4 billion from the surplus in 1995. In the same year, the total trade deficit was $20.6 billion, an increase of $10.5 billion over 1995. The reduced semiconductor surplus of $8.4 billion in 1996 was a major contributing factor in the trade deficit of $10.5 billion, as shown in Table 3-1.

Table 3-1
Total Exports and Imports and Semiconductor Exports and Imports for Korea, 1995 through 1997 (Millions of Dollars)

	1995	1996	Change, 1995-1996	First Nine Months of 1997
Total Exports	125,058	129,715	4,657	99,709
Total Imports	135,119	150,339	15,220	110,094
Balance	-10,061	-20,624	-10,563	-10,385
Semiconductor Exports	17,643	15,293	-2,350	12,746
Semiconductor Imports	8,887	14,855	5,968	9,465
Balance	8,756	438	-8,318	3,281

Source: Dataquest (January 1998)

Actually, the financial crisis in Korea dates from the beginning of this year. The key reason for it is the cumulative trade deficit of many years. Many chaebol (conglomerate) companies started to fail, beginning with Hanbo Iron and Steel, and followed by Sammi Steel, Jinro, Kia Motors, New Core, and Halla, among others. Many small and medium-size companies followed the lead of the chaebols and fell also.

The chaebol companies failed in this financial crisis because of their weak financial structures. Most of the companies have capital ratios of under 20 percent. There are many under 10 percent. Tight money controls in this crisis caused the downfall of many companies.

Impact of the Asian Financial Crisis on Korea's Semiconductor Market

Most of the Korean semiconductor companies will reduce their capital spending plans in 1998 to 40 to 60 percent of their 1997 level. Also, many projects will be delayed, including overseas projects. This reduced capital spending will influence mostly 64Mb and 256Mb DRAM production capacity. Korea's 16Mb and 64Mb DRAM production lines will be less affected because, for most 16Mb and 64Mb DRAM lines, investment had already been completed or is in the final stage of the pipeline. Korea will likely lose some market share, and Taiwan semiconductor companies will likely gain. Korean semiconductor companies will invest less for capacity expansion than to increase yield or reduce chip size. As one more way to reduce capital spending, they may try to upgrade their old fabs using an isolated "minienvironment" automation system.

Samsung Electronics Company Ltd.'s direction under this crisis is to suspend capital spending for capacity expansion. Instead, the company will increase productivity by reducing chip size and increasing yield. Samsung's 1998 capital spending will be about 40 to 60 percent of its 1997 level. Hyundai Electronics Company Ltd. has also decided to reduce its 1998 capital spending plan. LG Semicon Co. Ltd. is trying to minimize its capital spending. Anam Semiconductor has decided to delay its second fab investment. Dongbu Group has proceeded with its license with IBM and has already started plant construction. But the company seems to be in a dilemma now as to how to deal with this financial crisis, because there is no funding for this facility.

All overseas semiconductor projects are facing a crisis, also. Samsung's Austin, Texas, plant and Hyundai's second Eugene, Oregon, plant will be delayed, perhaps by more than a year if this financial crisis continues. Hyundai's Scotland project and LG Semicon's Wales project are likely to be delayed, but as yet no company has announced clearly the future of its overseas plants.

Chapter 4
The Korean DRAM Perspective

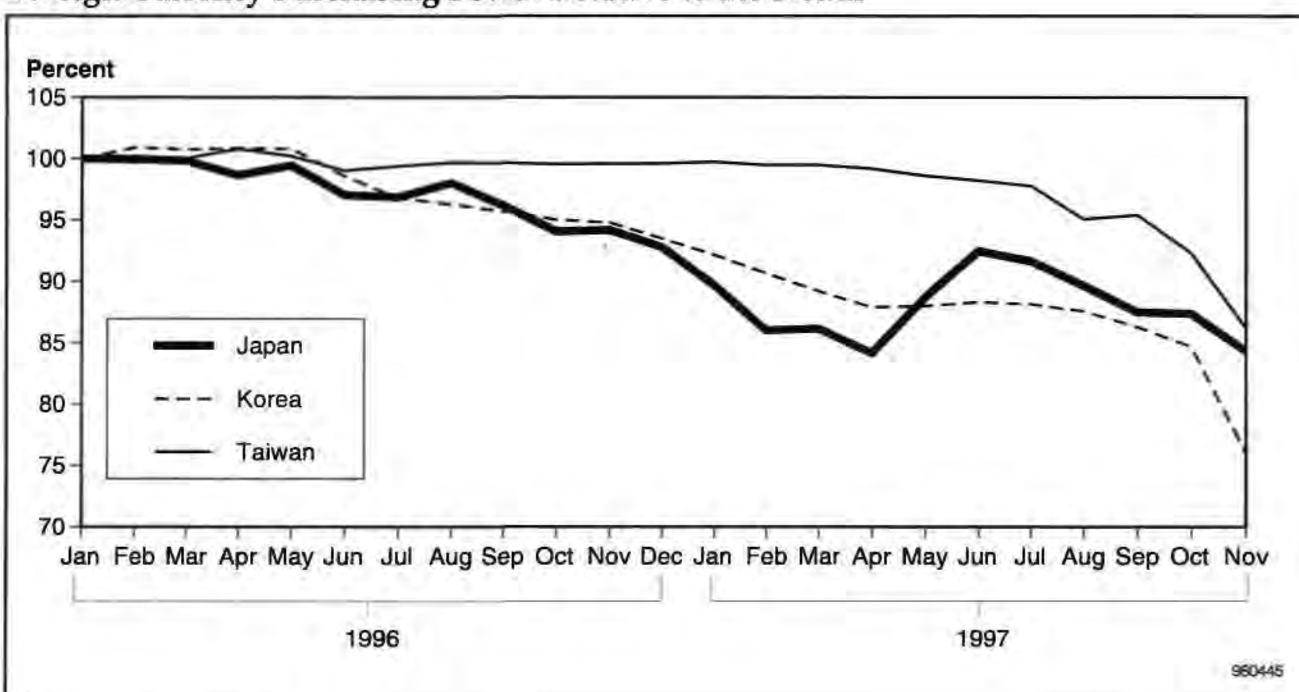
Introduction

This chapter discusses the impact of the Korean financial crisis on the worldwide DRAM market. DRAM pricing is predicted to fall further if the Korean, Taiwanese, and Japanese currencies continue to slide against the U.S. dollar.

The Impact on the DRAM Market of the Korean Financial Crisis

South Korea and the International Monetary Fund have agreed to a rescue package totaling $57 billion. South Korea agreed to implement IMF-recommended measures to revitalize its faltering economy in return for accepting the bailout. Even with the agreement, there are fears that the rescue may not succeed and that Korea's links to other Asia/Pacific countries may endanger those countries, as well. Figure 4-1 shows foreign currency purchasing power relative to the dollar.

Figure 4-1
Foreign Currency Purchasing Power Relative to the Dollar



Source: Dataquest (January 1998)

Given the stringent management and restructuring requirements of the IMF bailout, the Korean semiconductor industry is planning to cut capital investment by 40 to 60 percent over last year. Korean DRAM manufacturers fear that their cutbacks could result in a drastically dwindling share of the world market, with market share lost particularly to Japanese and Taiwanese companies. The threat of shrinking market share is something Korean DRAM manufacturers haven't been accustomed to; they have enjoyed steady market share growth since 1990.

Samsung, currently the world's leading DRAM producer, is expected to implement a 30 percent cut in overall investment and is considering further cuts in coming weeks. Samsung's plans are to earmark W800 billion to W900 billion for semiconductor and LCD investment next year and W400 billion to W500 billion on research and development. LG Semicon and Hyundai are also cutting back investment. LG Semicon plans to lower investment by 30 percent, or W1.05 trillion to W1.10 trillion for next year, and Hyundai is considering a 40 percent cut. As with Samsung, both LG Semicon and Hyundai have yet to make their investment plans final.

What impact will these cutbacks have on projects already under consideration? LG Semicon is expected to delay the construction of its second LCD plant in southern Korea. LG Semicon and Hyundai are re-examining their plans to construct DRAM fabs in the United Kingdom, although both expect to go ahead with plans as scheduled. Most expansion plans for DRAM fabs in the United States by Samsung, LG Semicon, and Hyundai are expected to be suspended. Dongbu, which earlier this year announced plans to enter the semiconductor industry, decided to postpone this indefinitely, citing difficulties in borrowing money.

It will take one to two years for next year's cutbacks in Korean investment to make a significant impact on company market share and DRAM industry capacity. There is more than enough capacity already to support current demand, and as all manufacturers continue to shrink their 16Mb and 64Mb devices, industry overcapacity will continue through most of 1998 and possibly into 1999. To put device die size into perspective, the average die size of 16Mb DRAM at the end of 1998 will be 60 percent of the average die size of 4Mb DRAM at the end of 1995.

Taiwanese DRAM manufacturers will have a significant impact on when the market comes into balance. If Taiwanese companies continue with their aggressive expansion, the equilibrium point may be pushed out three to six months, well into 1999. Before the IMF actions, the Taiwanese companies planned to increase capital spending in local currency (NT dollars) by 10 percent. In U.S. dollar terms, this may actually represent declining capital spending because of currency devaluation (more on this later). The Korean cutback in spending may encourage Taiwanese DRAM vendors to accelerate investment in an effort to take market share away from the Koreans. If Korean companies cut their capital spending as indicated and if Taiwanese companies continue with their capital spending plans for foundry, memory, and joint ventures, Taiwan may surpass Korea in capital spending in 1998. However, not all Taiwanese DRAM vendors are expected to increase capital spending—at this time, Mosel Vitelic Inc. and Powerchip Semiconductor Corporation are expected to decrease their capital spending in 1998, and others may follow.

Dataquest believes there is a good possibility that Taiwanese manufacturers will not implement their aggressive capital spending plans. The Taiwanese companies are newcomers to the DRAM industry and haven't experienced prior industry downturns. As they gain experience in the current downturn, they may decide to stop DRAM spending abruptly. This will come with the realization that, while aggressive expansion will buy market share, it will also lengthen the DRAM industry downturn.

On top of all the changes in Korea's financial situation and the long-term effects of the IMF bailout plan, there is also the short-term phenomenon of a currency devaluation adding to the problem. Korea, Taiwan, and even Japan have seen the value of their currencies slide dramatically in relationship to the U.S. dollar as well as against European currencies.

Normalized to January 1996, an item with a fixed local currency price that could be purchased in the United States for $1 in January 1996 could be purchased in November 1997 for $0.84 if it came from Japan, $0.86 if it came from Taiwan, and $0.76 if it came from Korea. Of course, DRAM per-megabyte prices descend at a relatively steady rate (28 percent per year), but the effects of currency rate changes layer on top of this. If the manufacturing cost, measured in won, of a Korean DRAM drops at 28 percent per year over the course of 1997, and if in that same time the won dropped 20 percent (which it did), then the minimum price that could be charged for that DRAM in the United States without triggering antidumping measures would have dropped 42 percent! This implies that there should continue to be exceptional price slides for DRAMs from Japan, Korea, and Taiwan into the United States and Europe. This has a great impact on the worldwide market because, in 1996, Japan, Korea, and Taiwan had a combined share of 77 percent of the DRAM market, and DRAM consumption in the United States and Europe accounted for 56 percent of the world market.

This, though, is not the end. The November average tells only a part of the story. As of December, the won had dropped to 54 percent of its January 1996 level. The end of the drop is not in sight today. Korean manufacturers accounted for only 34 percent of 1996 DRAM sales, so the impact of the price slide will not perfectly match the exchange rate drop times normal DRAM price declines. The effect will be less than this; however, it will be important!

In short, DRAM prices, which have been falling at a rate based largely on the cost of manufacture, should continue to fall faster than this rate as long as Korean, Taiwanese, and Japanese currencies continue to slide against European and American currencies.

Chapter 5

Semiconductor Market Forecast: The Impact of Asia/Pacific's Currency Crises on China/Hong Kong

Introduction

Shifting the focus from Korea to China/Hong Kong, this chapter looks at the impact of the Asian financial crisis on electronic equipment assumptions and semiconductor consumption in China/Hong Kong. Dataquest has lowered its regional forecast for 1997 from 15 percent to 8 percent growth. Dataquest believes that China/Hong Kong will not be impaired in the short term, but it faces long-term challenges. Although China/Hong Kong's long-term semiconductor forecast has been lowered, it will still account for 26 percent of Asia/Pacific consumption by 2001.

Asia/Pacific and China/Hong Kong Forecasts

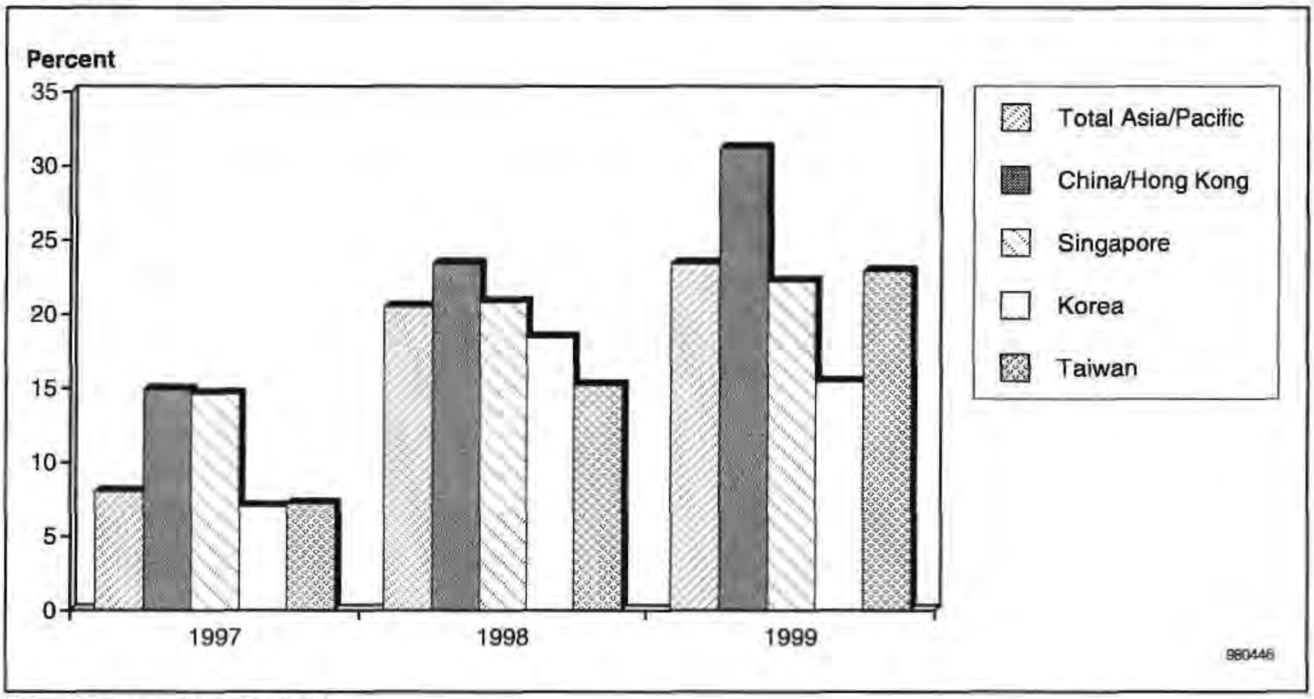
Prior to the financial havoc that has rocked Asia/Pacific's currency markets, Dataquest had lowered its forecast of 1997 electronic equipment production in Asia/Pacific from 17.4 percent to 14.9 percent. Dataquest's October Asia/Pacific semiconductor market forecast was lowered to 8 percent from 14.6 percent. Weaker growth was caused by slower second-half growth exacerbated by the currency crisis during the fourth quarter. Forecasts of electronics production and semiconductor consumption in China/Hong Kong were both lowered insignificantly by about 1 percentage point to 17.8 percent and 14.9 percent, respectively.

Dataquest expects that 1998 will have a higher level of growth than 1997 across the region. Helped by a long-awaited worldwide recovery in the second half of the year, memory prices should have, at long last, bottomed out. Korean and Japanese capital constraints should help to curb fab expansion and alter cutthroat pricing strategies to improve margins.

Figure 5-1 presents Dataquest's regional, country-level forecasts of semiconductor consumption from 1997 to 1999. China/Hong Kong's semiconductor market, helped by the combination of a strong PC industry and memory pricing improvements, will grow by 23 percent in 1998 and 31 percent in 1999. Critical to this high-level growth is also the performance of China's electronics output, which Dataquest assumes will grow by 20 percent in 1998 and 18 percent in 1999. At the top level, industry growth is the result of broad-based equipment investment, active foreign investment in the market, strong and steady local consumption, and competitive electronics exports.

© 1998 Dataquest

Figure 5-1
Forecast of Semiconductor Consumption Growth by Region in Asia/Pacific, 1997 to 1999 (Percent)



Source: Dataquest (January 1998)

Impact of Currency Depreciation

Dataquest understands the importance of stable financial markets to long-term economic prosperity in the region. But financial markets do not necessarily reflect the fundamental characteristics of the electronics industry's health. The impact of currency volatility needs to be viewed in the context of fundamental industry issues. Dataquest views the following electronics industry and semiconductor market fundamentals as key drivers potentially affected by the currency crisis:

- Slower growth experienced in the second half of 1997 is the result of decelerating exports to key export markets, including Europe, Japan, and North America and, to a lesser extent, slower growth within Asia/Pacific's developing domestic markets.
- There is a short-term effect on manufacturers in currency-depreciating countries that are struggling to make payments and order commitments to suppliers of semiconductors and other components.
- Local consumption has slowed in numerous countries, and deflationary forces have become more pressing. Because a small percentage of Asia/Pacific electronics production relies on Asia/Pacific consumption, the slowdown in local consumption of end equipment has a negligible impact on total production. Nevertheless, industry observers are watching the Japanese and Korean end-equipment markets carefully. Dataquest sees a direct impact of these large markets on Asia/Pacific electronics exports, especially Japan's imports of PCs from Taiwan.

 © 1998 Dataquest

The degree of the currency devaluation's impact on electronics companies depends, in part, on the percentage of semiconductor components imported by manufacturers in Asia/Pacific. Southeast Asian countries such as India, Indonesia, Malaysia, the Philippines, and Singapore rely almost entirely on foreign suppliers. However, the bulk of electronics production comes from the multinational companies (MNCs) that have relocated production from Europe, Japan, Korea, North America, or Taiwan. The advantages of the MNCs in Asia/Pacific is their ability to secure long-term global procurement contracts in U.S. dollars that buffer currency fluctuations.

Manufacturers in Asia/Pacific, which are part of conglomerates, also manufacture semiconductors that may use internally transferred semiconductors and therefore are not directly affected by currency fluctuations. Japanese consumer electronics manufacturers rely heavily on internally transferred components. In both cases, a major portion of costs are fixed. Export revenue then increases for the same units of goods shipped because more local currency is received for the same U.S. dollar export price.

Stronger Exports Likely to Make Up for Slower Domestic Consumption

Dataquest's long-term forecast of semiconductor consumption by region is shown in Figure 5-2. It shows Asia/Pacific's high growth relative to other worldwide regions but with significant country variances.

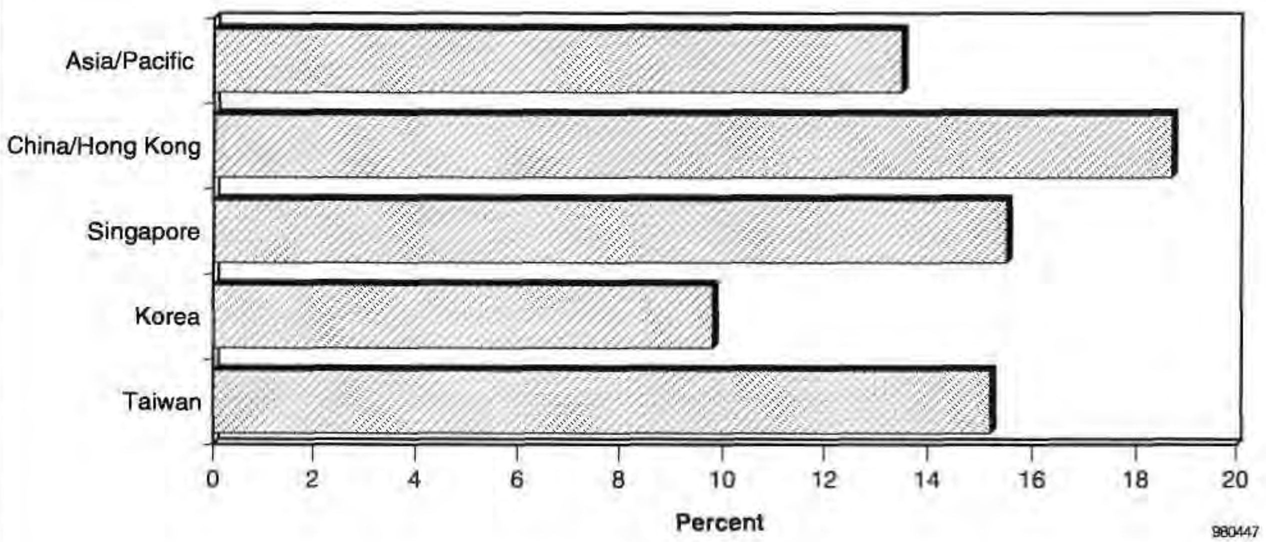
In 1997 and 1998, Asia/Pacific's electronics industry as a whole will become more competitive in exports because of devalued currencies. Export markets will continue to be the key to the region's high semiconductor consumption growth rates because of the immaturity of the region's end-equipment markets that are a percentage of the gross domestic product (GDP). Dataquest's electronic equipment and semiconductor forecasts assume a 3 percent to 4 percent economic growth in the United States in 1998 and 1999 and a modest economic recovery in Japan. Weakened industrial growth in Japan and Korea, as well as Asia/Pacific's lower cost base, will continue to benefit Southeast Asia's electronics industry (as has been the case for 10 years).

Singapore Sustains Growth

The China/Hong Kong and Singapore markets will grow by about 15 percent in 1997. Singapore has not experienced the negative short-term effects of currency depreciation because its production is dominated by MNCs that operate global procurement organizations. Real GDP in the third quarter of 1997 rose 10.1 percent, and this growth was fairly broad-based. As reflected in the forecast, a weaker currency may have a long-term positive effect by lowering export costs, Singapore's lifeblood, assuming import component costs increased less, proportionately.

 © 1998 Dataquest

Figure 5-2
Long-Term Forecast of Semiconductor Consumption by Region in Asia/Pacific, 1996 to 2001 (Compound Annual Growth Rate)



Source: Dataquest (January 1998)

Taiwan's Fundamentals Are Still Strong

Anticipated slower growth in Taiwan in 1996 to 1998 is attributable more to memory price erosion than to currency depreciation because memories represent 46 percent of Taiwan's semiconductor consumption. Dataquest believes that Taiwan's economy and financial institutions are fundamentally strong, and GDP growth is forecast to exceed 6 percent in 1998. Dataquest also expects electronic equipment production to show the second-fastest growth in Asia/Pacific from 1997 to 2001. Dataquest, therefore, forecasts a strong semiconductor market in Taiwan in 1999 because of an anticipated recovery in its memory market.

Tighter capital markets will help control capacity spending primarily in Korea and Japan, but to a lesser extent in Taiwan, which shows a higher level of liquidity than the rest of Asia. Overall, it is likely that the crises in Korea and Japan will have a positive effect on memory pricing in the longer term, after late 1998 and in 1999. In segments where Taiwan competes directly with Korea, such as DRAMs, companies may face severe competition from Korean suppliers that now have an exchange advantage. However, note that most business is conducted in U.S. dollars, and prices are rising because of the lack of cash and capital in Korea's chaebols.

 © 1998 Dataquest

Korean Market Faces Structural, Not Cyclical, Problems

As shown in Dataquest's long-term regional semiconductor market forecast, the weakest market will be Korea from 1998 to 2001. Korea will have trouble increasing exports enough to compensate for the huge increase in its debt-service ratio. When the won drops, the debt-service ratio increases on a one-to-one basis, but exports will not increase on a one-to-one basis. Furthermore, electronic equipment exports will continue to suffer because of a lack of new, higher-margin products and because of falling profits exacerbated by a global consumer electronics slump. On top of these problems, the currency crisis affects these conglomerates insofar as they are dependent on imported semiconductor components. However, the free-falling won makes exports much cheaper—but only if prices are not raised to cover increased component costs. The lack of a diverse component supply base, as seen in Taiwan and Japan, makes the structural nature of Korea's problems more severe. Korean electronics manufacturers have been shifting production offshore in an attempt to develop new markets and increase competitiveness.

China/Hong Kong Is Still the Rising Star, but with Challenges

Dataquest believes that the currency and financial market problems in Asia/Pacific have more to do with speculative "bubbles" in property, construction, and semiconductors than to fundamental economics and manufacturing efficiencies. China and Hong Kong are not immune, but they seem to be dealing with these bubbles more effectively by popping them before they get too big. China's economic czar, Zhu Rongji, successfully burst the stock market bubble, property bubble, and construction bubble in 1996 and 1997. After October's Party Congress, he is now more empowered than ever to pop the next speculative runs, whatever they may be. Next year, he will be promoted to prime minister. Zhu's charter is to fix the state-owned enterprises to avoid overwhelming the financial system with bad loans. If China slacks off, it will face serious problems, potentially worse than those of Korea. Korea's lessons are being learned by others, and China can avoid this kind of crisis (having U.S.$200 billion in combined reserves with Hong Kong will help, too). A strong U.S. and European economy will be critical to China and the rest of the Asia/Pacific region.

As with Russia, a nonconvertible currency does not necessarily insulate China from possible depreciation. Several years ago, China devalued its renminbi and may have to do so again sometime next year because of mounting pressure in the region and competitive pressures on the export front (discussed later in this document). However, because the long-term goal is to merge the renminbi and Hong Kong dollar, it is not likely that the Hong Kong dollar will lose its U.S. dollar peg.

Currency depreciation has lowered production costs in various Southeast Asian countries. So, will China become less competitive in its vital export markets? Dataquest believes that because significant currency depreciation caused lower export costs, there will be increasing competition for foreign investment with China, which could result in more than $20 billion in electronics production revenue by 2001.

 © 1998 Dataquest

China faces the following three formidable challenges that are becoming more acute because of the recent currency crisis:

- Raising the competitiveness of its faltering domestic companies, especially state-owned enterprises, before entering the World Trade Organization (WTO)
- Countering the serious slowdown in foreign investments because of the rising cost of doing business in China
- Maintaining 7 percent to 10 percent GDP growth and raising the rate of domestic consumption to absorb excess capacity and overdependence on exports
  - A slowdown in Japanese imports of consumer electronics and PCs from Asia/Pacific may hurt China the most because its currency has not depreciated and, therefore, its costs are increasing relative to those of other countries.
  - Korea and other affected countries will rely heavily on exports to try to pull themselves out of their economic turmoil.

All three issues affect the electronics industry. In light of these challenges and Dataquest's survey of producers in China and Hong Kong, Dataquest believes that a 20 percent growth in electronics production is achievable in 1998, decelerating to 18 percent in 1999.

The following factors will help China to overcome these three challenges and maintain high growth rates:

- A large proportion of Chinese electronics companies are successfully competing against major MNCs, particularly in the computer and consumer equipment markets. Dataquest believes that the Chinese government will continue to support these companies before and after entry into the WTO because its international competitiveness will be imperative to its future survival. The priority for the government is improving efficiencies and quality; therefore, information technology will continue to be rapidly deployed as an infrastructure necessity.
- Although total investment is down in 1997, the production capacity of the large MNCs and local electronics manufacturers has increased by more than 50 percent. Business costs are rising in China, but the two main reasons for investing remain to develop the long-term potential of the domestic market and to take advantage of an abundant, inexpensive labor force. Note that efficiencies and quality are increasing faster than costs. Investment from Taiwan to China increased by nearly 30 percent in 1997, despite the attempt of the Republic of China government to slow the flow of business to China.
- Inflation was the major concern last year at this time, but now deflation is the top priority of the government. Interest rates are likely to fall to stimulate growth.
- Japanese manufacturers are shipping goods worldwide from China. Exports of electronics to Japan from China represent 10 to 15 percent of China's total electronics exports. Therefore, Japan's slowdown in consumption will have a minor effect on Chinese production.

 © 1998 Dataquest

- Korean companies and other affected Asia/Pacific electronics and semiconductor companies may have an increasing currency advantage for exports relative to China in the short term. However, these companies are seriously hurt by increased debt-service costs. With depreciation, there is a debt-service ratio increase of one to one, and exports cannot possibly expand enough to counter such costs. Major cost-cutting measures may be necessary to service foreign and local debt that impairs the level of export expansion necessary for recovery. Certainly, capacity expansion is not viable at this point.

Lower Long-Term Growth Forecast for China/Hong Kong

Figure 5-3 presents Dataquest's long-term regional electronic equipment production forecast. Although Dataquest expects China to maintain a relatively high level of growth, Dataquest has lowered its 1996-to-2001 forecast for China/Hong Kong electronic equipment production from a compound annual growth rate (CAGR) of 26 to 24 percent in light of recent deflationary industry developments in the region. Dataquest expects the industry to reach $70 billion by 2001, rather than $90 billion as previously forecast. The currency devaluation's impact on semiconductor consumption will be lower between 1996 and 2001; in fact, the original CAGR of 39.7 percent is now expected to become 33.9 percent. Dataquest's 2001 forecast has been lowered from $21 billion to $18 billion.

As shown in Figure 5-4, growth in China/Hong Kong is expected to outpace the rest of Asia/Pacific because of its growth in production efficiencies, export growth, and local demand. China/Hong Kong's electronics industry produced 24 percent of Asia/Pacific's electronics in 1997, which will increase to 29 percent by 2001. Semiconductor consumption will grow from a 20 percent to a 26 percent share of Asia/Pacific's consumption. These growth rates may seem very high, but they are actually relatively low in comparison to overall GDP size and growth because China is still a developing economy. Dataquest's industry surveys and detailed analysis of China/Hong Kong's electronics production and companies are presented in a Focus Report (*China/Hong Kong's Computers, Communications, and Consumer Electronics Industry in 2001*, SEMI-CH-FR-9701, November 1997).

Semiconductor Device Forecast

All these issues affect the electronics industry in China and Hong Kong. From 1996 to 2001, China/Hong Kong growth is expected to exceed Asia/Pacific growth in electronics production by 6.8 percent and to exceed semiconductor market growth by 9.6 percent (see Table 5-1). Consequently, its share of Asia/Pacific semiconductor market revenue will grow from 20 percent in 1997 to 26 percent in 2001.

Cautious business planning is required at this time because the volatile financial markets will take another three to six months to begin to stabilize. The situation requires rapid and extreme government action in Korea and Japan before the downward financial slide in the region reverses course.

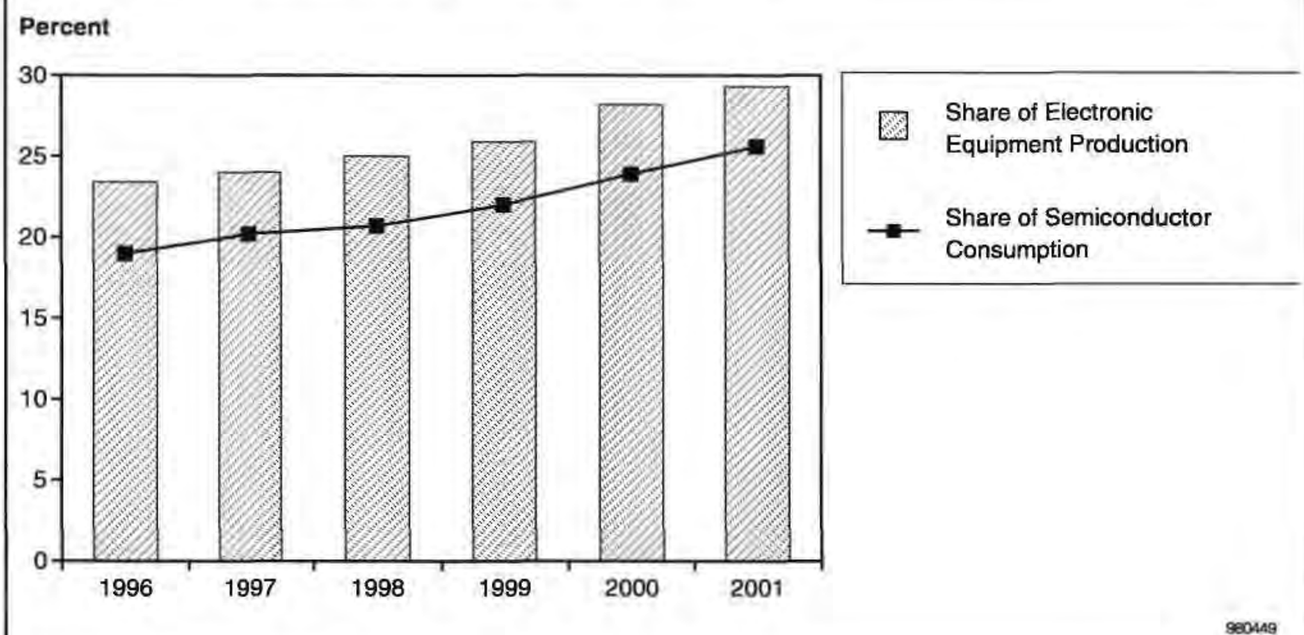
Figure 5-4
China/Hong Kong's Share of Asia/Pacific Electronic Equipment Production and Semiconductor Consumption, 1996 to 2001 (Percent)



Source: Dataquest (January 1998)

© 1998 Dataquest

Figure 5-5 compares total semiconductor consumption with DRAM and non-DRAM markets. Dataquest's semiconductor forecast incorporates both the macroeconomic and electronic equipment assumptions discussed earlier. After a flat market performance of 0.5 percent in 1996, the China/Hong Kong semiconductor market picked up a 15 percent growth in 1997. Assuming higher average selling prices (ASPs) for 64Mb DRAMs, the mainstream product in 1998, as well as other memory devices, Dataquest expects 1998 to outperform 1997. With a DRAM growth of 36 percent in China/Hong Kong, the overall market should reach 23 percent in 1998, with stronger DRAM growth occurring in the second half of the year.

The currency devaluation's impact on the DRAM market becomes more pronounced after 1999 because of the anticipated formidable growth in PC production. Boosting the expected DRAM growth is the incredible surge in China's PC market. China, excluding Hong Kong, will take about 30 percent share of Asia/Pacific's PC consumption in 1998 and maintain an average annual growth rate of about 40 percent until 2001, the fastest growth in Asia/Pacific. Non-DRAM products continue to experience more stable, long-term growth because of China/Hong Kong's broad-based electronic equipment production growth.

Table 5-1
Total Electronics Production and Semiconductor Market Forecast in China/Hong Kong and Asia/Pacific, 1997 to 2001 (Millions of U.S. Dollars)

	1997	1998	1999	2000	2001	CAGR (%) 1996 to 2001
China/Hong Kong						
Electronics Production Revenue	42,387	50,780	59,924	71,763	84,803	23.9
Semiconductor Market Revenue	6,490	8,008	10,504	14,926	18,077	33.7

Dataquest Perspective

The financial crises have adversely affected semiconductor shipments to end-equipment companies that are dependent on sales within the affected countries. Dataquest highlights the economic woes in Japan and Korea because they will weaken Asia/Pacific electronic equipment production overall—again, because of weakened exports mainly in consumer electronics but also in computer-related equipment producer countries. Consumption of electronics in Malaysia, India, Indonesia, Malaysia, Singapore, Thailand, and Taiwan is also damaged by higher import costs and weaker consumer spending in 1997 and 1998. However, the majority of production in the affected countries comes from companies exporting to Europe, Japan, and North America, so a local market slowdown has minimal effect on overall production of Asia/Pacific as a whole. Furthermore, export sales are conducted in U.S. dollars, and semiconductor purchases from multinational vendors are usually conducted in U.S. dollars also—thereby avoiding the ill effects of currency fluctuation.

China/Hong Kong has not been affected by this financial crisis in the short term because of the stable renminbi and Hong Kong dollar, which are backed by about U.S.$200 billion in combined foreign reserves. However, Dataquest has outlined the deflation and investment challenges within China. Dataquest's lower long-term electronic production and semiconductor consumption forecasts for China/Hong Kong assume that Southeast Asia will receive increased investment that would otherwise have gone to China (after four years of very high foreign investment levels in China). However, the power of the Chinese market and its production prowess for international markets will continue to attract investment, enabling it to extend its lead as the largest and fastest-growing semiconductor markets in Asia/Pacific.

Chapter 6
Currency Meltdown: Impact on Asia/Pacific PC Markets

Introduction

After the previous three chapters' regional perspectives on Korea and China/Hong Kong, Dataquest now turns to the PC market. This chapter aims to provide insight into the currency devaluation's early impacts on the personal computer industry, to assist PC suppliers in understanding the factors involved, and to highlight the key areas on which to focus when steering a path through the crisis.

Background

The economic conditions that have spread to nearly every Southeast Asian country started on a much smaller scale. South Korea was already experiencing severe economic difficulties following a series of bankruptcies among its large industrial conglomerates when difficulties in the Thai banking and finance community escalated to a devaluation of the baht during the first half of 1997. A ripple effect quickly followed, sparking similar devaluations in Malaysia, Indonesia, and the Philippines. Initially, Hong Kong and Singapore remained largely unaffected by the difficulties faced by their neighbors, but this situation changed late in September as investor nervousness spread to other Asian markets. Similarly, the Australian dollar became more seriously affected this October. At the end of October, the Thai baht and Indonesian rupiah were both trading at about half the values they held at the beginning of the year. The Malaysian ringgit had fallen more than 35 percent, closely followed by the Philippine peso, down about 32 percent. Most other currencies were trading between 10 percent and 15 percent lower than their values at the beginning of 1997. China, Hong Kong, and Japan were the least affected. In both Thailand and Indonesia, the IMF has stepped in to assist with the crisis.

Economists have a range of opinions on both the causes and the solutions to the economic crises, but it has become clear that there have been several different underlying factors. These include cozy relationships between government and favored business leaders, irrational investment in high-profile projects (such as in real estate) instead of in productive areas of the economy, and the failure to open up large monopolies to competition. The Thai banking and finance sector has been sharply criticized, as has economic policy in Thailand, Malaysia, Indonesia, and the Philippines. Most other affected countries have been victims of a "contagion" effect, as nervous investors apply the same high-risk label to all Asian markets.

A speedy recovery is not part of the outlook. Investors have been deeply critical of policy response in most countries, which they consider to have been grossly inadequate so far. In Thailand, for example, the government recently decided not to implement higher taxes on oil—as recommended by the IMF—thus placing a U.S.$16 billion rescue package at risk and sparking several ministerial resignations. Malaysia's prime minister, Dr. Mahathir Mohamad, has shifted too much blame onto currency speculators and failed to deliver a budget with the teeth desired by investors. In Indonesia, IMF recommendations have also been actively resisted.

© 1998 Dataquest

Instead of easing, investor nervousness has spread to include more countries and has introduced a level of turbulence in stock markets around the world. The relative health of the Asian markets remains highly volatile, and major currency shifts are likely to continue—even as this document goes to print. The general consensus among economists is that the hardest-hit Asian economies will take two years to fully recover, and Dataquest has been revising PC consumption forecasts for the region downward.

Impact on PC Shipments

Figure 6-1 shows the declining growth rates seen so far this year in Korea, Indonesia, Malaysia, and Thailand—the countries most affected by the financial crisis. It reveals the Korean situation to be quite different from that of other countries because PC shipments have been depressed—with no growth—since the fourth quarter of 1996. Conversely, Indonesia, Malaysia, and Thailand suffered a shared impact from the financial crisis much more recently, with the major downturn in PC shipments coming in the third quarter of 1997.

The Malaysian market has been somewhat less affected than the Thai and Indonesian markets (it is the only one in which third quarter 1997 shipments are up over the previous year), although the impact is still clearly visible. This lower impact is in part a reflection of the reduced scale of the currency crisis in that country, which only produced PC price rises late in the third quarter.

Dataquest has observed further price rises in the fourth quarter and expects a larger impact before year's end. PC shipments in most other Asian countries have yet to be affected by the financial crisis, although many have been experiencing lower growth for other reasons, such as market maturity.

In Thailand, Malaysia, and Indonesia, the greatest reduction in PC consumption has consistently been in the corporate sector, especially in the banking and finance industry. As a result, vendors that focus heavily on this segment (such as IBM) have typically suffered the most impact. The next biggest concern for vendors is the potential falloff in government business in Indonesia and Thailand (but not in Malaysia, where the government has reaffirmed its commitment to existing projects). This situation differs in Korea, where the home market has been most affected—probably reflecting the longer period of economic uncertainty and its impact on consumer confidence.

Market Dynamics

Rising Cost of Imports

Fully imported PCs and imported components such as monitors, microprocessors, hard drives, and memory modules are affected equally by exchange rate variation, in theory giving no advantage to vendors buying either one. Locally manufactured components, however, such as Acer Computer International Ltd.'s motherboards in Taiwan, Samsung's memory chips and monitors in South Korea, and batteries and monitors from Delta Electronics Industrial Ltd.'s operation in Thailand, will not be affected by exchange rate variation when sold on the local market, thus handing an advantage to vendors that use these local components over imports. Also, local labor costs have fallen considerably relative to other

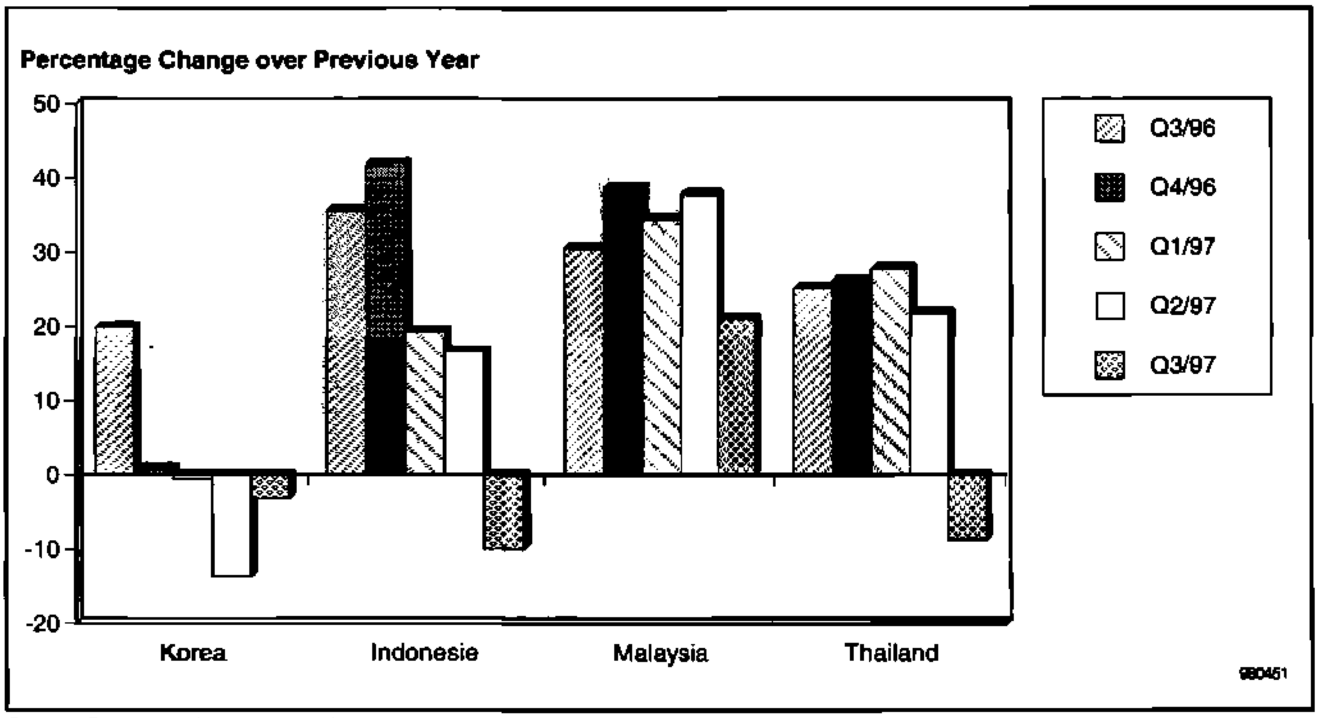
Figure 6-1
Year-on-Year Growth in PC Shipments in Korea, Indonesia, Malaysia, and Thailand: Q3/96 to Q3/97



Source: Dataquest (January 1998)

countries, providing an advantage to any manufacturer (multinational or local) undertaking part or full assembly of PCs in the local market. The same relative advantage applies to most of the facilities and service-related costs for a PC plant.

Rising PC Prices

The most important inhibitor of PC sales within affected economies has been rising prices. At the same time, many suppliers have switched to pricing in U.S. dollars to avoid having to adjust continually for exchange-rate variations. In Thailand and Indonesia, price rises in PC hardware have been offset in part by the regular cycle of worldwide component price cuts, particularly those of Intel Corporation, ensuring that, although currencies might have dropped up to 50 percent in value, PC price rises have generally been limited to under 15 percent. A similar process has taken place in Malaysia, although vendors in that country have managed to delay price increases a little longer.

Canceled and Deferred Purchases

Many buyers are waiting for the local currency to improve to maximize the spending power of their limited budgets, and at the same time many of their budgets are being reduced. Either way, the effect is the same: Premeltdown budgets are inadequate for postmeltdown prices. Within the government and corporate sectors, there is a strong inclination to defer making large purchases. In the case of government, there is considerable pressure to exercise restrained fiscal policy and to set spending priorities toward areas that the investment community sees as most important to stabilizing the economy.

In both Indonesia and Thailand, government information technology (IT) purchases are expected to be especially conservative. The Thai government has already announced that the IT budget for 1998 is to be cut from 7.8 billion to 3.7 billion baht. The Indonesian finance minister announced in August that U.S.$35.6 billion worth of government and state-related projects were to be postponed or reviewed, indicating that mining, energy, public works, and the transportation sector would be hit hardest. This move is expected to have a substantial impact on PC purchases in those sectors.

In the home sector, spending on all high-priced luxury items diminishes during periods of economic uncertainty. Additionally, like business buyers, many families find that what they would have purchased before the currency decline has simply become too expensive. Other factors will indirectly affect PC purchases by reducing spending power. These include an increase in the value-added tax in Thailand from 7 percent to 10 percent (following IMF recommendations), increased import tariffs to 30 percent, and expected increases in fuel and electricity prices in Indonesia—which will ultimately be passed on to all consumer goods.

Late Payments

Maintaining adequate cash flow has been a particularly serious problem for many vendors as companies delay paying for equipment that has been delivered. With their debts owed in U.S. dollars, buyers hold out payments in anticipation of any small rise in local currency value. The risk is, of course, that the local currency value will decline further and that the longer delay will actually increase the debt. Although delayed payments are affecting every stage of the procurement process, the problem is most pronounced when it comes to vendors getting payment from channel partners. This applies particularly to first-tier channel partners, which are most likely to hold stock and have to buy in U.S. dollars (selling to the second tier in local currency).

Technology Lag

Dataquest has found little evidence of "slimming down" of PC configurations to reduce costs, nor of any major switch to upgrade purchases at the expense of new PC purchases. There is, however, strong evidence that microprocessor life cycles, particular for Intel's Pentium 166-MHz chip, have been extended in desktop and deskside machines. This extension is a trade-off for limiting price rises to manageable levels: Under normal circumstances, component price cuts would be accompanied by a strong shift by manufacturers to later-generation processors. Also, fewer buyers are able to afford the latest Pentium II processor, thus contributing to the slow take-up rate across the region. The overall result is a greater technology lag behind the U.S. market. Dataquest expects this lag to lengthen, at least temporarily, in Indonesia, Thailand, and to a lesser extent, Malaysia.

A second, related effect is likely to be the shift by manufacturers and buyers toward cheaper microprocessors from Advanced Micro Devices Inc. and Cyrix Corporation. No data is yet available to confirm if this shift has taken place, but early indications are that Intel was disappointed with its third quarter performance, while AMD reported a strong demand in Asia.

 © 1998 Dataquest

Export Competitiveness

Vendors that manufacture in countries now heavily impacted by currency depreciation are better positioned for export to less-affected markets within Asia or to other world markets. Acer, for example, has already indicated that a depreciation of the Taiwan dollar, although relatively minor compared with other Asian countries, should prove highly beneficial to its 1997 financial results.

Survival Strategies

New Targets

Preliminary third quarter results show that the Chinese, Taiwanese, Hong Kong, and Australian PC markets have not been affected by the Asian economic crisis. Although this situation may change at any time, Dataquest anticipates that these countries will remain the best opportunities for PC sales while the crisis continues for the rest of Asia. China's growth will be unlikely to slow, and the other markets are all underpinned by solid economic fundamentals. Where opportunity allows, vendors operating in multiple markets through the region should look to put most of their current resources behind sales efforts in these countries. Similarly, within the deeply affected markets, Dataquest has observed that not all sectors have been affected to the same extent, with the education and small business sectors having provided better opportunities relative to other sectors in the third quarter.

Zero Inventory

One ironic result of rapid currency devaluation is that those manufacturers that have poorly managed their inventories gain a short-term advantage. Having purchased or manufactured excess stock under favorable exchange rates, these suppliers are able to hold off on announcing price rises the longest. Having passed this stage, however, inventory management becomes far more critical than under normal market conditions. Vendors will need to keep minimal stocks to take advantage of short-term price fluctuations on components. Acer, for example, has taken the opportunity to announce a more streamlined build-to-order (BTO) and delivery strategy in Thailand. Later, when currency values begin to rise, excess inventory will be punished severely, and it is likely that a number of PC suppliers will sustain large losses.

Compress Channels

The advantages of shorter supply lines will be increased under the present economic circumstances for two reasons. The first is lower inventory through the system, for the same reasons as those mentioned above. The second is that a shorter supply line will minimize the exposure to bad debt, which has already shown itself to be a problem in the third quarter. Vendors that sell direct have only to worry about one set of payments. Vendors that use a multitiered channel are exposed—if the buyer, reseller, or distributor defaults—multiplying their risk.

 © 1998 Dataquest

Boost Local Content

There is a substantial competitive advantage from increasing use of local hardware and labor content within markets heavily affected by currency depreciation or from importing components from facilities located in those countries wherever possible. Both these actions will reduce overall production costs. Just as important, however, is the need to maintain flexibility in these arrangements so sources of supply can be quickly altered to take advantage of further currency fluctuations and to avoid being locked into arrangements that become less competitive as currencies appreciate.

A Long-Term Opportunity?

Southeast Asia's lower exchange rates have made these countries more attractive for locating full-scale production facilities. For all the difficulties IBM is facing in selling PCs into the Thai market, it is now reaping the rewards for its decision to establish a U.S.$300 million plant to manufacture hard drive and storage products in Prachinburi, Thailand. Fujitsu Ltd. and Seagate Technology Inc. are also establishing new facilities or expanding existing ones in Thailand. At the same time, traditional production locations such as Singapore have become increasingly expensive during the past year. Shifting production facilities to affected countries has high potential rewards, but, because of the size of the investment involved, it also carries high risks.

Do Current Conditions Favor Local Vendors?

In recent years, the unbranded "whitebox" PC clone industry has been a dominant part of the PC mix in Asia, although it shows signs of stabilizing as markets mature and has been forecast to decline as a proportion of most countries' markets in the next few years (see Dataquest report *Cheap, Fast, and Flexible: Whitebox PCs in Asia/Pacific*, PCIS-AP-MT-9702, October 1997). At the same time, Dataquest sees a strong pressure on large, branded, local assemblers—such as Wearnes Technology, V-Tech Systems Limited, Powell Computer Co. Ltd., and Total Peripherals Group Pty. Ltd.—from multinational giants such as IBM, Compaq Computer Corporation, and Dell Computer Corporation, steadily squeezing the former group out of the market.

Economic uncertainty seems to favor many local vendors, however, with indications that buyers have shifted toward these suppliers in Indonesia and Thailand (Powell and ATEC Computer Co. Ltd. are just two examples of local vendors that did well in the Thai market in the third quarter). There is no doubt that, in these markets, a consequence of reduced buying power and higher PC prices has been a shift toward whitebox purchases to achieve required purchase volumes with limited funds or to continue buying PCs with the same equipment levels without paying the higher prices. It would appear that, in these markets, economic pressure has temporarily reduced the perceived value of the warranty/service/quality package offered by brand-name suppliers. Also, Indonesian government departments are following a directive to favor local vendors when buying desktops while the crisis continues.

 © 1998 Dataquest

The opposite trend has been seen in Malaysia, however. Here, local vendors seem to be having more difficulty capitalizing on component price fluctuations, and buyers are placing greater emphasis on reliability (with a view to extending equipment life) under the present conditions. Nor are local vendors faring better in Korea, although Dataquest has observed an increase in demand for secondhand PC systems.

Dataquest believes that local companies' key advantage lies in their higher proportion of local assembly relative to their multinational competitors (although multinational giants such as Dell and Gateway 2000 Inc. that operate factories in Malaysia or other affected countries are also well positioned). Local assembly gives vendors a critical advantage when it comes to pricing PCs on the local market. On the minus side, local companies are at a disadvantage when it comes to financing their operations. Investment is harder than ever to secure in countries such as Thailand and Indonesia, and many whitebox suppliers—although prosperous in high-growth markets—are ill-equipped to ride out periods of reduced cash flow. In contrast, multinational suppliers can afford a long-term strategy, riding out unprofitable periods in one or two countries to secure a strong market position in the long term.

On balance, although not helping any vendor sell more PCs, the current conditions should temporarily negate many of the advantages held by multinational companies over local vendors. In particular, Asian companies that also manufacture components should be more competitive in their home markets over fully imported products. Overall, Dataquest expects a temporary halt to the market share slide being experienced by local vendors in Southeast Asian markets, with multinationals retaking the upper hand when economic conditions improve.

Dataquest's Market Outlook

Generally speaking, the outlook for recovery has shifted from a near-term to long-term expectation in Thailand, Indonesia, and Malaysia, with Malaysia somewhat better positioned than the other two. PC vendors will thus need to be prepared to survive a sustained period of difficult and depressed trading. Economists are indicating that the Korean economy could begin to turn around earlier—perhaps starting a slow climb early in 1998, but early indications are that the fourth-quarter performance of the PC markets in Indonesia, Malaysia, and Thailand will be even more badly affected than the third quarter. For as long as this situation lasts, Dataquest expects PC shipments to be inhibited, especially as government projects and large corporations play such an important role in driving IT acquisition in Southeast Asian markets.

On the positive side, spending on PCs is unlikely to be as deeply affected as other capital expenditure because improving the communications and technology infrastructure in Southeast Asia is seen as one of the building blocks for recovery. Additionally, the overall growth in the Asian region will continue to be solid in 1998 and 1999, driven by the booming Chinese market. Given the highly contagious nature of currency fluctuations within the region, however, the situation for most of the markets, particularly those in Southeast Asia, remains volatile and unpredictable.

 © 1998 Dataquest

Chapter 7
The Impact on Capital Spending of the Asian Financial Crisis

Introduction

This final chapter represents a recap of Dataquest's views over the past several months of how the Asian financial situation will affect capital availability and spending in semiconductors. Dataquest has just released the spending forecast for 1998, with both a forecast and downside risk scenario. The details of those scenarios are published in a Dataquest Perspective ("Wafer Fab Equipment Market Forecast Update: Question Marks for 1998 as the Second Half of the 'W' Unfolds," SEMM-WW-DP-9801, January 1998), and an overview is presented here.

Will the Southeast Asia Currency Issue Cause a Decline in Capital Spending in the Region? Yes! Here's Why ...

In early August 1997, when the Asian financial systems began experiencing stress, Dataquest went on record as seeing more downside risk than upside potential to our 1998 capital spending forecast, in part because the Southeast Asia currency issues could put a damper on capital availability in the region. That statement was made before the fourth quarter meltdown, based on fundamentals of capital availability.

The real issue? The entire Southeast Asian banking system is in a liquidity crisis, with declining or negative cash flow. This has caused devaluation of currencies throughout the region as a natural, self-correcting economic response, resulting in equity market upheavals as the world "readjusts." The original, higher-order cause of the liquidity issue is complex, involving factors such as current account imbalances and the DRAM price collapse, among other things.

It is important to understand how capital is raised in the United States and Europe, as opposed to Asia. In the United States and Europe, capital is raised by a combination of debt (usually corporate bonds, sometimes convertible to stock) and equity placements (public offerings on the stock market). A company's ability to raise capital successfully in the equity market depends primarily on profitability. Profits are also a major source of capital, and U.S. and European companies are structured and managed for this goal. In Asia, a much larger portion of the capital raised (sometimes exclusively) is from the banking system in the form of loans. The evaluation criterion is fundamentally different there—cash flow. In a highly leveraged company, cash flow can easily be positive while losses are piling up. Asian companies, as a result, are primarily managed for cash flow. This has been the key reason why the capital spending-to-semiconductor production revenue ratio is estimated to be about 23 percent in the United States while near 70 percent for Asia/Pacific, keeping the worldwide ratio at almost 29 percent—a level that is too high, in Dataquest's opinion.

© 1998 Dataquest

The Korean banking system has been in a liquidity crisis for some time, and the Japanese banking system has already been under pressure from the struggling economy of Japan. Debt-to-equity ratios are quite high in Korea, and capital spending from companies in both these countries has been depressed for several quarters now. Both these systems received more pressure from Southeast Asia in late summer. Taiwan's banking system has higher relative reserves than its Southeast Asian neighbors but is feeling the weight as well and is viewing the situation with caution.

Decreasing chip prices have taken a major toll on the cash flow of many semiconductor companies in the region. Less capital is available in the system because cash flow id not available to pay some existing debt.

Assuming demand for chips is not affected by the situation, the natural economic responses to be expected in the region should include:

- Higher interest rates (which will raise the cash flow requirements of companies requesting money)
- Higher cash flow requirements (which will mean the amount for which the companies qualify is less)
- Less capital available (as a result of the previous point and the lower liquidity in the system)
- Significantly lower capital spending plans, complicated by the fact that local currency buys less equipment from U.S. and Japanese companies because of the devaluation

There has been a trend for Asian companies to seek other sources of capital, such as Eurobonds and equity offerings in the United States. Dataquest believes these avenues will be available to some companies but will fall very short of adequately covering the loss of capital from the banking system overall. The recent quakes in equity markets worldwide present a difficult environment in the short term, as well.

What exists today is a situation that will take several quarters to play out, and one that equipment companies must realize will affect them materially. In a sanguine tone, Dataquest must say that, in the long run, capital spending restraint over the next several quarters will ultimately be very healthy for the semiconductor industry, bringing supply and demand into better balance and ultimately stabilizing pricing and profitability.

And Then Korea Falls—What about Taiwan?

In late November 1997, the South Korean government admitted that some outside help was going to be required to address a massive liquidity crisis in the country. The "official" request was initially about $20 billion, but the agreed-upon bailout was $57 billion, and this may be in the process of being increased. Putting this into perspective is key, because we saw a report recently that places the annual capital spending level for *all* Korean companies in *all* industries at about the $50 billion to $55 billion! The three culprits being pointed to in Korea are memory chips, steel, and autos. All industries are in huge states of overcapacity, and the IMF will likely place some restrictions on the use of capital in these industries in the near term.

The Japanese banking system, already under pressure with the struggling economy of Japan, is now feeling added strain. All the banking roads from Asia appear to lead to Japan, and questions are now being raised as to whether this evolving situation will harm the recovery in Japan, perhaps sending the economy into another recession. The closing of the fourth-largest securities firm in Japan because of lack of liquidity has not helped. Trickling repercussions can be expected.

Meanwhile, the currencies have continued to depreciate relative to the U.S. dollar. Since the beginning of the year, the currency of South Korea has depreciated 40 to 50 percent, Taiwan's about 18 to 20 percent, and Japan's about 10 to 11 percent relative to the U.S. dollar. These fell precipitously in the last months of 1997 and may come under further pressure before stabilizing.

What is the likely fallout? Dataquest believes there are three issues to watch in coming months: capital spending cuts, DRAM prices, and the dynamics of the foundry market.

In conversations over the last couple of months, Dataquest described the South Korean situation as the linchpin. If Korea could keep it together, then the crisis could be controlled without turning into something much worse. But if Korea fell, then watch out! Well, Korea fell, and we are officially saying—watch out! The magnitude of the situation is mind-boggling, and we are forecasting that Korean companies will cut capital spending in 1998 about 40 to 60 percent, relative to 1997 in dollar terms. It is safe to say that *all* Korean capital projects are stopped dead in their tracks at present, and we would estimate that it will be late spring before the situation settles to the point at which some of these projects may be cautiously restarted.

Because the Japanese banking system is under strain, there is not much money available, and Dataquest is forecasting that spending plans for Japanese companies in 1998 are likely to be about 7 to 14 percent lower in dollar terms than in 1997.

What about Taiwan? The second and third issues actually are the keys to Taiwan. The currency valuations may actually be of more importance in the intermediate and long term than capital availability. Taiwan is outright defiant at present, and it have some reason to be. Its financial system is based on a stock market system rather than banking, and a major portion of the country's semiconductor business, foundry, is still very profitable and growing.

However, depreciation levels are approaching that will dramatically impact competitiveness and pricing among regional companies. Not quite, but almost, half of the DRAM capacity is in Korea and Taiwan now. These suppliers now have a "cost holiday" relative to competitors in the United States, Europe, and, in part, Japan. Dataquest estimates that perhaps 55 to 60 percent of the cost of making a semiconductor chip is sensitive to local currency.

 © 1998 Dataquest

Will these companies sit on their marginal profits? If history is a guide, the answer would be no. A continuing free fall of DRAM prices will put profitability pressures on Micron Technology Inc., Siemens AG, and perhaps even Texas Instruments Inc., to a lesser degree. Capital spending plans for these companies may come under review in the near term and perhaps be lowered.

So, will the foundry industry be the savior? Maybe in part, but right now it is the *only* bright spot, and every company is now looking toward it. We can expect a flood of announcements (which have already started) from companies coming into the foundry market. Taiwan Semiconductor Mfg. Co. recently released a forecast stating that its gross margins were increasing in a growing market. This is true and understandable, given the currency valuation trends and the fact that the bulk of its customer base is in U.S. dollars. Although TSMC is the technology leader and premier foundry supplier, it has not typically led pricing downward but has been a price follower. LG Semicon has been a price leader in the past, and Dataquest is expecting LG Semicon to retake the pricing lead, maybe joined by others, giving TSMC's margin improvement a relatively short life. LG Semicon has the capacity, needs the cash, and is motivated to take business through pricing because there is beginning to be a separation in the valuation of the Taiwan dollar and the Korean won.

So what about Taiwan capital spending in 1998? Dataquest believes it will be split. Taiwan is fundamentally different from its Asian neighbors because capital-raising techniques used there rely more heavily on equity markets than debt markets or the banking system. The Taiwan banking system is the soundest in Asia, but we think Taiwan is watching and being very cautious at present so as not to follow Korea to the IMF. A company's ability to raise capital in the equity market depends primarily on profitability. And even then, today's environment is not really favorable to raising capital on the equity markets.

Dataquest believes the equity market will be available to foundry companies but is not likely to be favorable to memory producers. For this reason, we think that the memory producers in Taiwan (Powerchip, Nan Ya Technology Corporation, and Mosel Vitelic) may find it more difficult to raise capital, while the foundry producers will be able to raise spending levels slightly in 1998. However, currency depreciation will lower the spending levels on a U.S. dollar basis. We think only a few leading companies, such as TSMC, Chartered Semiconductor Mfg. Pte. Ltd. , and United Microelectronics Corporation, will be in a position to raise spending levels in U.S. dollar terms for 1998. Memory companies will likely be forced to cut spending in 1998. Overall, Taiwanese spending is expected to increase about 13 percent in 1998 to $7 billion.

The Taiwanese foundries are still very profitable, and although the situation may degrade through the year, spending for 1998 seems fairly secure. Dataquest's forecast assumes that Taiwanese foundry spending will increase more than 40 percent to $4.3 billion (excluding foundries outside Taiwan).

 © 1998 Dataquest

Dataquest expects spending in DRAM capacity to remain at a high level. Some companies will cut spending, but companies such as Vanguard International Semiconductor Corporation (owned in part by TSMC) will actually increase spending heavily. Overall, in local currency, spending will be flat in the DRAM area but down about 15 percent in U.S. dollars.

This situation is continuing to play out and will not be settled for several months yet. The picture is increasingly beginning to resemble a sharper decline in sequential spending than originally anticipated in the DRAM area.

Thailand fell, Hong Kong crashed, Korea admitted it needed help, and even Japan is feeling added strain and experiencing the collapse of a securities company—each of these events has been accompanied by someone stating, "It is an isolated incident," "We are only minimally affected," or, "It should be possible for this to be controlled within that country." Does anyone still doubt that we are in the midst of a worldwide earthquake? The tremors will be relatively minor in the United States—but they will be, and are starting to be, felt.

Chapter 1

Market Share Survey Overview

Each year, Dataquest surveys semiconductor vendors to estimate their annual sales. The survey currently covers more than 150 semiconductor vendors worldwide (this varies according to mergers, acquisitions, liquidations, start-ups, and so on) by 61 individual semiconductor product categories (excluding subtotals), six application segments, and four world regions (Europe is split into further subregions). This exercise helps Dataquest maintain its dynamic database of semiconductor supply by company and semiconductor vendor revenue by world region and product. The information gained is supplemented by, and cross-checked with, Dataquest's various other information sources.

The semiconductor market share survey process starts during the fourth quarter of each calendar year. The first-phase, top-level estimates for large companies are completed by the end of the calendar year under review, and the results are summarized in several Dataquest reports.

The final detailed survey of all companies starts just after the end of the calendar year under review. These estimates are published in the second quarter of the year following the calendar year under review.

The categories for which semiconductor revenue is reported are defined comprehensively for the purpose of clarity and guidance to survey participants. These definitions may occasionally be revised, altered, or expanded to reflect changes in the industry. To support these definitions, Dataquest will issue an annual survey guide to all participants in its semiconductor market share survey program. This document is the 1997 survey guide.

Chapter 2
Semiconductor Companies Surveyed Worldwide

For 1997, Dataquest will survey semiconductor companies throughout the world.

Americas Companies Surveyed

The following Americas companies were surveyed during 1996:

- ACC Microelectronics
- Actel
- Adaptec
- Advanced Micro Devices
- Allegro MicroSystems
- Altera
- Analog Devices
- Applied Micro Circuits
- AT&T
- Atmel
- Brooktree
- Burr-Brown
- C-Cube Microsystems
- California Micro Devices
- Catalyst
- Cherry Semiconductor
- Chips & Technologies
- Cirrus Logic
- Cypress Semiconductor
- Cyrix
- Dallas Semiconductor
- DSP Semiconductor
- Elantec
- Electronic Designs
- ETEQ Microsystems
- Exar
- General Instrument
- Gennum
- Gould AMI

- International Microelectronic Products
- International Rectifier
- Kulite
- Lattice
- Linear Technology
- Linfinity
- Logic Devices
- LSI Logic
- Maxim
- Micrel
- Micro Linear
- Micro Power Systems
- Microchip Technology
- Micron Technology
- Microsemi
- Mitel
- Motorola
- National Semiconductor
- NCR
- Optek
- OPTi
- Paradigm
- Performance Semiconductor
- Powerex

- Q Logic
- Quality Semiconductor
- Quality Technologies
- QuickLogic
- Ramtron
- Raytheon
- Rockwell
- S3
- Seeq Technology
- Semtech
- Sierra Semiconductor
- Silicon General
- Silicon Systems
- Sipex
- Solitron
- Standard Microsystems
- Supertex
- Symphony Laboratories
- Tektronix
- Telcom
- Texas Instruments
- Trident Microsystems
- TriQuint Semiconductor
- Tseng Labs
- Unitrode
- Universal
- Vitesse
- VLSI Technology
- VTC
- WaferScale Integration
- Weitek
- Western Digital
- Xicor
- Xilinx
- Zilog

Japanese Companies Surveyed

The following Japanese companies were surveyed in 1996:

- Fuji Electric
- Fujitsu
- Hitachi
- Matsushita Electronics
- Mitsubishi Electric
- NEC
- New Japan Radio
- Nippon Steel
- Oki Electric Industry
- Ricoh
- Rohm
- Sanken Electric
- SANYO Electric
- Seiko Epson
- Sharp
- Shindengen Electric Manufacturing
- Sony
- Toko
- Toshiba
- Yamaha

European Companies Surveyed

The following European companies were surveyed in 1996:

- ABB-Hafo
- ABB-Ixys
- Austria Mikro Systeme
- Elex
- Elmos
- EM Microelectronic
- Ericsson
- Eupec
- European Silicon Structures
- Fagor
- GEC Plessey Semiconductors

- ITT
- Micronas
- Mietec
- Philips Semiconductors
- Semikron
- SGS-Thomson
- Siemens
- TCS (Thomson Composants Spatiaux)
- TEMIC
- Thesys
- Westcode Semiconductors
- Zetex

Asia/Pacific Companies Surveyed

The following Asia/Pacific companies were surveyed in 1996:

- Acer
- Daewoo
- LG Semicon
- Hualon Microelectronics
- Hyundai
- Korean Electronics
- Macronix
- Mosel Vitelic
- Samsung
- Silicon Integrated Systems
- United Microelectronics
- Vanguard
- Winbond Electronics

Summary

The following summarizes the semiconductor companies surveyed in 1996:

- 100 Americas companies
- 20 Japanese companies
- 23 European companies
- 13 Asia/Pacific companies
- 156 companies worldwide

Chapter 3
General Sales Definitions

Dataquest tracks semiconductor vendors' revenue as defined in the following paragraphs.

Revenue

Revenue is the gross sales generated by a vendor or manufacturer, measured in unit currency.

Semiconductor Vendor

A vendor is the last entity in the chain that brands a product and sells it either directly to end users or through a channel. A semiconductor vendor may design and manufacture its own products, in which case it is also an original component manufacturer, or the vendor may procure semiconductors from a component contract manufacturer.

Vendor Revenue

Vendor revenue is defined as the average selling price of a semiconductor product multiplied by the vendor's unit shipments of that product.

Revenue Based on Customer Location

All revenue from sales is reported according to customer location, that is, the shipping destination. The four regions that Dataquest uses for the purpose of this survey are the Americas; Japan; Europe, Africa, and Middle East; and Asia/Pacific.

Manufacturer

A manufacturer is a producer of branded or unbranded finished products. A semiconductor manufacturer could be a contract manufacturer, an original manufacturer, or both.

Original Component Manufacturer

This is a manufacturer that designs and produces components such as semiconductors and design tools either for sale under its brand name or for use internally. An original component manufacturer is also a vendor.

Contract Component Manufacturer

This is a manufacturer that produces components such as semiconductors under an original manufacturer's brand name or that produces components for a semiconductor vendor that brands them. In the semiconductor industry, a contract component manufacturer is sometimes referred to as a "foundry."

Any business done by a semiconductor manufacturer on a contract manufacturing basis is *excluded* as vendor revenue regarding that manufacturer.

©1998 Dataquest

Companies that produce exclusively on a contract manufacturing basis are excluded from the list of semiconductor vendors.

Finished Semiconductor Products

Finished products are assembled and tested semiconductor products. Count only sales of finished semiconductor products to equipment manufacturers and through channels (that is, distributors). Do not include sales of finished semiconductors to other semiconductor vendors for value-added resale. Resale revenue is counted as revenue of the semiconductor vendor to which it is sold. Also, count only sales made by an overseas subsidiary to a equipment manufacturer or distributor, as opposed to counting sales from headquarters to an overseas subsidiary.

Unfinished Semiconductor Products

These are wafer and die foundry products. Count only sales of unfinished semiconductor products to equipment manufacturers or channels (that is, distributors). Do not include sales of unfinished semiconductors to other semiconductor vendors for resale. Resale revenue will be estimated separately for these companies. Also, count only sales made by an overseas subsidiary to equipment manufacturers or distributors, as opposed to counting sales from headquarters to an overseas subsidiary.

Internal Semiconductor Sales

This is defined as revenue from finished or unfinished semiconductor products from intracompany (internal) transfers to divisions of that company or subsidiaries of the parent company that manufactures end equipment. Internal semiconductor sales are classified as in-house sales or captive sales, depending on whether the company sells semiconductors on the merchant market.

In-House Semiconductor Sales

This is defined as internal semiconductor sales if the company also sells semiconductors on the merchant market. Count all in-house semiconductor sales at market prices. Market price is defined as the price at which the same or equivalent product is sold to equipment manufacturers.

Captive Semiconductor Sales

This is defined as internal semiconductor sales if your company does not sell semiconductors on the merchant market. We do not include any captive semiconductor sales.

Multichip Modules

Multichip modules (MCMs) are semiconductor-based functions that include more than one semiconductor device. The multiple dies are arranged either on a thin-film deposited (MCM-D) substrate, a ceramic (MCM-C) substrate, or a polyimide or laminate (MCM-L) substrate. Count only sales of MCM products and board-level products that conform with the definitions for "finished semiconductor products" or "unfinished semiconductor products." MCMs are not considered hybrids or monolithic ICs. MCMs are an advanced form of package interconnect.

 ©1998 Dataquest

System-Level Products

These are products that comprise a number of module or board-level products amounting to a single system or subsystem. Examples include development systems, hardware platforms, and box-level products. Do not include any sales from such system-level products. By contrast, do include application-specific ICs (ASICs) that provide system-level integration into silicon.

Nonrecurring Engineering Charges

Nonrecurring engineering (NRE) charges are charges made to customers as the result of costs incurred during the design or customizing of a semiconductor device for that customer. Count NRE charges only when they occur in the following product areas:

- Design charges for ASICs, including gate arrays, cell-based ICs, and full-custom ICs
- Mask charges that result from the customizing of a programmable array logic (PAL), when the customer's fuse pattern is masked into it to produce a hard-wired array logic (HAL)
- Mask charges that result from the customizing of ROMs
- Mask charges that result from the storage of the customer's program in a microcontroller

Count revenue from NRE charges only on active semiconductor products that conform with the definitions for "finished semiconductor products" or "unfinished semiconductor products." Include these NRE charges as part of the revenue received from associated semiconductor product. Do not include revenue from NRE charges incurred during research, feasibility studies, or facility rental to third parties.

Electronic Design Automation Software

Electronic design automation (EDA) software is used to automate the design of semiconductors. Dataquest includes revenue from ASIC semiconductor vendors that also sell their own EDA software. Include any revenue derived from EDA software in the appropriate ASIC product category. The applicable categories are programmable logic device (PLD), gate array, and cell-based IC.

Intellectual Property Rights Income

This includes intellectual property rights (IPR) income from royalties, licensing agreements, technology transfers, and dispute settlements. Do not include any IPR income.

 ©1998 Dataquest

Chapter 4
Exchange Rate Definitions

When converting a company's local currency sales into U.S. dollars, or vice versa, it is important to use the 1997 exchange rates provided by Dataquest. This will prevent inconsistencies in the conversion of offshore sales between each company.

Dataquest will provide an exchange rate table with the survey in January 1998.

©1998 Dataquest

Chapter 5
Semiconductor Product Category Hierarchy

The semiconductor product category hierarchy in Table 5-1 begins with total semiconductor, and indents each subcategory in the left-hand column according to its position in the hierarchy. At each level in the hierarchy, all subcategories that contribute to this level are shown as a subcategory summation in the right-hand column. Any level in the hierarchy that does not depend on any subcategory is marked as a "Data Point."

Table 5-1

Chapter 6

Semiconductor Product Category Definitions

The semiconductor product category definitions in Table 6-1 begin with total semiconductor and continue through each subcategory in the same order as shown in the preceding semiconductor product category hierarchy. At each level in the hierarchy, all subcategories that contribute to this level are shown as a subcategory summation in the right-hand column. Comprehensive definitions are given at every level. Table 6-2 shows microcomponent word widths.

Table 6-1
Semiconductor Product Category Definitions

Category	Definition
Total Semiconductor	(Total Monolithic Integrated Circuit + Total Discrete + Total Optical Semiconductor)
	Defined as an active semiconductor product that contains semiconducting material (such as silicon, germanium, or gallium arsenide but excluding ceramics) and reacts dynamically to an input signal, either by modifying its shape or adding energy to it. This definition excludes standalone passive components, such as capacitors, resistors, inductors, oscillators, crystals, transformers, and relays.
Total Monolithic Integrated Circuit	(Digital Monolithic Bipolar IC + Digital Monolithic MOS IC + Analog IC)
	A monolithic IC is one that is formed on a single chip of semiconducting material. This designation has been applied more broadly to mean any device, even multiple-chip packaged devices, that does not contain other, nonsemiconductor, components. This differentiates monolithic ICs from hybrid ICs that may also be multiple chip, but represent a "hybrid" in the sense of mixing other technologies within the IC package, such as film resistors or chip capacitors.
Digital Bipolar IC	(Bipolar Digital Memory IC + Bipolar Digital Logic IC)
	A bipolar digital IC is defined as a monolithic semiconductor product in which 100 percent of the die area performs digital functions, and, concurrently, 100 percent of the die area is manufactured using bipolar semiconductor technology. A digital function is one in which data is carried as numerical values, usually in a binary code.
Bipolar Digital Memory IC	A bipolar digital semiconductor product in which binary data is stored and electronically retrieved. Includes emitter-coupled logic (ECL) random-access memory (RAM), read-only memory (ROM), programmable ROM (PROM), last-in/first-out (LIFO) memory, and first-in/first-out (FIFO) memory. Not included are products made with mixed bipolar CMOS (that is, BiCMOS) with transistor-transistor logic (TTL) or ECL outputs, which are classified as Other Bipolar Digital Logic.

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Bipolar Digital Logic IC	(Bipolar Digital Logic Application-Specific IC + Bipolar Digital Standard Logic IC + Other Bipolar Digital Logic IC) A bipolar semiconductor product that serves a general-purpose function using bit-processing technology. This bit processing is defined by hardwiring, mask programming, or field programming. Logic ICs also include customer-specific logic ICs.
Bipolar Digital Logic ASIC	(Bipolar Digital Gate Array + Bipolar Digital Programmable Logic Device + Bipolar Digital Cell-Based IC/Bipolar Digital Full-Custom IC) A single-user bipolar digital logic IC that is manufactured using vendor-supplied tools or libraries. Does not include bipolar digital ASICs incorporating microprocessor cells or microcontroller cells; these should be reported in the Other Bipolar Digital Logic IC category.
Bipolar Digital Gate Array	A bipolar digital gate array is defined as an ASIC device that is customized by the vendor to end-user specification using layers of interconnect. Included in this category are generic or base wafers with embedded functions, such as static RAM (SRAM) and electrically erasable PROM (EEPROM).
Bipolar Digital Programmable Logic Device	An ASIC device that is customized by the end user after assembly. Included in this category are bipolar field-programmable logic (bipolar FPL), bipolar field-programmable gate array (bipolar FPGA), bipolar programmable array logic (bipolar PAL), bipolar programmable logic array (bipolar PLA), bipolar electrically programmable logic devices (bipolar EPLDs), and bipolar complex PLDs.
Bipolar Digital Cell-Based IC/ Full-Custom IC	A bipolar digital cell-based IC is an ASIC device that is produced from a library of standard circuits/cells to a single-user specification. This process involves automatic routing and placement of cells using a full mask set. Included in this definition are bipolar standard cell ICs. Excluded from this definition are cell-based ICs with processor cores. These should be reported under Other Bipolar Digital Logic IC. A full-custom IC is an ASIC device that is produced for a single user using a full set of masks. This manufacturing process involves manual routing and placement of cells.
Bipolar Digital Standard Logic IC	A commodity bipolar family logic with fewer than 150 gates. Sometimes referred to as glue logic. Examples include TTL, ECL, and the following other family logic: TTL-compatible SSI, MSI, and LSI; standard, AS, FAST, LS, and ALS lines; and ECL-compatible SSI, MSI, and LSI. Also included are RTL and DTL.
Other Bipolar Digital Logic IC	All other bipolar digital logic ICs not accounted for in the preceding categories. Includes bipolar commodity family logic with 150 or more gates, bipolar digital general-purpose logic not belonging to any families, and bipolar digital microcomponent ICs.

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
MOS Digital IC	(MOS Digital Memory IC + MOS Digital Microcomponent IC + MOS Digital Logic IC) A monolithic semiconductor product in which 100 percent of the die area performs digital functions, and, concurrently, any portion of the die area that is manufactured using metal-oxide semiconductor (MOS) technology. A digital function is one in which data is carried as numerical values, usually in a binary code. Includes mixed-technology manufacturing, such as BiMOS and BiCMOS, where there is some MOS technology employed.
MOS Digital Memory IC	(DRAM + SRAM + EPROM + EEPROM + Flash Memory + Mask ROM + Other MOS Digital Memory IC) A MOS digital IC in which binary data is stored and electronically retrieved.
DRAM	Dynamic RAM, multiport-DRAM (M-DRAM), video RAM (V RAM), synchronous DRAM (SDRAM), cached DRAM (CDRAM), and self-refreshed DRAM. DRAMs have memory cells consisting of a single transistor and require regular memory cell refreshes. These are volatile memories, and addressing is multiplexed.
SRAM	Static RAM, multiport-SRAM (M-SRAM), battery backed-up SRAM (BB-SRAM), and pseudo SRAM (PSRAM). SRAMs have memory cells consisting of a minimum of four transistors, except PSRAM, which has a memory cell consisting of a single transistor and is similar to a DRAM with nonmultiplexed addresses. SRAMs do not require memory cell refreshes (except in the case of PSRAM). These are volatile memories and addressing is not multiplexed. Note that color palette digital-to-analog converters (DACs) are included in the Data Converter/Switch/Multiplexer IC category of analog ICs.
EPROM	Erasable programmable read-only memory. This product classification includes ultraviolet EPROM (UV EPROM) and one-time programmable read-only memory (OTP ROM). EPROMs have nonvolatile memory cells consisting of a single transistor and do not require any memory cell refreshes. These devices are considered nonvolatile memories.
EEPROM	Electrically erasable programmable read-only memory. Includes serial EEPROM (S-EEPROM), parallel EEPROM (P-EEPROM), and electrically alterable read-only memory (EAROM). EEPROMs have memory cells consisting of a minimum of two transistors and do not require memory cell refreshes. Also includes nonvolatile RAM (NV-RAM), also known as shadow RAM. These semiconductor products are a combination of SRAM and EEPROM technologies in each memory cell. The EEPROM functions as a shadow backup for the SRAM when power is lost. These devices are considered nonvolatile memories.

 ©1998 Dataquest

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Flash Memory	Nonvolatile products designed as flash EPROM/EEPROM that incorporate either 5V or 12V programming supplies and one-transistor (1T) or two-transistor (2T) memory cells with electrical programming and fast bulk/block erase. Flash memory can erase data only by bulk/block, not by byte.
Mask ROM	Mask-programmable read-only memory. Mask ROM is a form of memory that is programmed by the manufacturer to a user specification using a mask step. Mask ROM is programmed in hardware rather than software. These devices are considered nonvolatile memories.
Other MOS Digital Memory IC	All other MOS digital memory not already accounted for in the preceding categories. Includes MOS digital content addressable memory (CAM), MOS digital cache-tag RAM, MOS digital first-in/first-out memory (FIFO), MOS digital last-in/first-out (LIFO) memory, and ferroelectric memory.
Microcomponent IC	(Microprocessor + Microcontroller + Digital Signal Processor + Microperipheral)
	Microcomponents are a category of metal oxide semiconductor (MOS) integrated circuits (ICs), which are mostly digital, made up of the microprocessor (MPU), microcontroller (MCU), programmable digital signal processor (DSP), and microperipheral (MPR) product subcategories.
Microprocessor	(8-Bit MPU +16-Bit MPU + 32-Bit and Greater Computational MPU + 32-Bit and Greater Embedded MPU)
	Microprocessor (MPU): An MPU is a MOS digital integrated circuit that includes an instruction decoder, arithmetic logic unit (ALU), registers, and additional logic. It may contain instruction, data, or unified caches, memory management systems, and auxiliary ALUs for floating-point and other special data types. An MPU's functions are determined by fetching and executing instructions and manipulating data held in registers, internal cache, or external memory. MPUs operate out of external memory systems typically ranging from 1MB to 64MB of RAM and often backed by secondary memory systems (such as disks). More highly integrated versions of MPUs may contain on-chip peripherals, interface, and support circuits. The MPU category includes MPUs incorporating or originating from an ASIC design. MPUs are subdivided into 8-bit, 16-bit, or 32-bit and up word width. Beginning in 1997, 32-bit and larger MPUs are further divided into computational and embedded according to the applications into which they are designed. MPUs can be complex-instruction-set-computer (CISC) or reduced-instruction-set computer (RISC) implementations, although Dataquest no longer divides RISC and CISC in favor of architectural family distinctions (68000, x86, MIPS, and SPARC, among others). Similar terms are processor, central processor unit (CPU), and integrated processor.

 ©1998 Dataquest

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Microcontroller	(4-Bit MCU + 8-Bit MCU + 16-Bit MCU + 32-Bit and greater MCU) An MCU is a MOS digital integrated circuit designed for standalone operation that includes a programmable processing unit, program memory, read/write data memory, and some input/output capability. The processing unit contains an instruction decoder, arithmetic logic unit, registers, and additional logic. The MCU's functions are determined by fetching and executing instructions and manipulating data held in on-chip program and data memory (not including cache memories). MCU devices must be available with on-chip program store (ROM, EPROM, and flash, among others), typically ranging from 1KB to 64KB. As an option, some MCU devices can be purchased without on-chip memory for use during the debug and development phase of the system. Peripheral circuits are typically included on chip to assist in sophisticated input, output, and control functions. The MCU category includes MCUs incorporating, or originating from, an ASIC design. Standalone digital signal processors are not included with MCUs. MCUs are subdivided into 4-bit, 8-bit, 16-bit, or 32-bit word width. In 1996, Dataquest began separating 32-bit MCUs from 16-bit MCUs. All MCUs are designed into embedded applications. A similar term is microcomputer.
Digital Signal Processor	A digital signal processor (DSP) is a programmable MOS digital integrated circuit (IC) designed for standalone operation, constituting a high-speed arithmetic unit (typically a multiplier-accumulator unit) designed to perform complex mathematical operations such as Fourier transforms in real time to generate, manipulate, or interpret digital representations of analog signals. Modern DSPs typically access multiple pieces of data in different locations of on-chip memory over separate data paths using specialized addressing modes. Most DSP functions, such as the multiply-and-accumulate function, complete in a single instruction clock. DSPs usually include peripherals, which may include analog circuits like analog-to-digital converters. DSPs typically operate on 16 or 24 bits of fixed-point data or 32 bits of floating-point data, although Dataquest does not currently subdivide DSPs into these categories. DSPs that have no version that can be reprogrammed by the user in assembly or a higher-level language are not included but are classified as fixed-function application-specific standard products (ASSPs) or microperipherals. DSPs integrated on-chip with an independent microprocessor or microcontroller are classified as either an MPU or an MCU, respectively. All DSPs are designed into embedded applications. A similar term is programmable DSP (pDSP).
Microperipheral	(System Core Logic Chipsets +Graphics and Imaging Controllers + Communications Controllers + Mass Storage Controllers + Audio/Other Controllers)

©1998 Dataquest

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
	A microperipheral is a MOS digital integrated circuit that serves as a dedicated logical support function to a microprocessor or microcontroller in a system, performing sophisticated input, output, and control functions. Microperipherals are not programmable from assembly language, although they are often highly configurable by software or electrical signals. This definition includes MPRs comprising more than one device, such as PC or core logic chipsets. The MPR category includes MPRs incorporating, or originating from, an ASIC design. MPRs might be implemented using microprocessor, microcontroller, or digital signal processing elements, although this is generally not evident to the user. A similar term is peripheral. Note that this definition may change radically for 1998.
System Core Logic Chipset	Devices dedicated to a particular microprocessor interface that perform some of the basic interface functions such as memory management, DRAM control, cache control, bus interface control, DMA control, and interrupt control
Graphics and Imaging Controller	Devices that typically interface to some form of systems bus to interpret, control, and display the visual output systems (computer-generated graphics, live video, and other images).
Communications Controller	Devices that control, format, and perform handshaking for the serial transmission and reception of information between systems or intelligent devices, including network controllers, integrated fax/modem chips, serial UARTs, and other communications interfaces
Mass Storage Controller	Devices that are used to control data storage into and retrieval from all forms of mass storage media (magnetic, optical, and others), which include controllers used within host computers (host-side) and within mass storage drives (device-side)
Audio/Other Controller	Devices used to input or output information through other forms, including audio input/output controllers, keyboard controllers, pen input controllers, parallel port controllers, and various other devices
Word Width	A programmable device's word width is the width, in bits, of one of the inputs to the primary on-chip integer arithmetic and logic unit. This measurement is independent of the data bus width or any other bus associated with the device. Wider and narrower data types might be operated on by the processor, with multiple passes through the ALU or special hardware. The word width classification is not influenced by the existence of additional integer units or of floating point and other special data type processors. A similar term is bit size.
Logic IC	(Total ASIC + MOS Digital Standard Logic IC + Other MOS Digital Logic IC)

©1998 Dataquest

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
	A MOS semiconductor product that serves a general-purpose function using bit-processing technology. This bit processing is defined by hardwiring, mask programming, or field programming. MOS microcomponents and MOS memory ICs are MOS logic ICs, but are either dedicated to a function (such as MOS microperipherals or MOS memory ICs) or are software programmable (such as MOS microprocessors and MOS microcontrollers). MOS logic ICs also include customer-specific MOS logic ICs.
Total ASIC	(Traditional Digital Gate Array + Embedded Gate Array + Digital Programmable Logic Device + Digital Cell-Based IC + Digital Full-Custom IC + Mixed ASIC + Linear Array)
	Defined as a single-user digital logic IC that is manufactured using vendor-supplied tools or libraries. Does not include digital ASICs incorporating microprocessor cells or microcontroller cells; these should be reported in the microprocessor IC or microcontroller IC category, respectively.
Traditional Digital Gate Array	Traditional gate arrays are ASICs that contain a configuration of uncommitted elements in a prefabricated base wafer. They are customized by interconnecting these elements with one or more metal routing layers. Included in this category are channeled and sea-of-gates architectures.
Embedded Gate Array	Embedded gate arrays are ASICs with a portion of the chip having traditional gate array architecture (channeled or sea-of-gates) and with megacells such as SRAM diffused into the gate array base wafer
Digital Programmable Logic Device	An ASIC device that is customized by the end user after assembly. Included in this category are MOS field-programmable logic (MOS FPL), MOS field-programmable gate array (MOS FPGA), MOS programmable array logic (MOS PAL), MOS programmable logic array (MOS PLA), MOS electrically programmable logic device (MOS EPLD), and MOS complex PLDs.
Digital Cell-Based IC	An ASIC device that is produced from a library of standard circuits or cells to a single-user specification. This process involves automatic routing and placement of cells utilizing a full mask set. Included in this definition is MOS standard cell IC.
Digital Full-Custom IC	An ASIC device that is produced for a single user using a full set of masks. This process involves manual routing and placement of cells.
Linear Array ASIC	A single-user linear IC that is manufactured using vendor-supplied tools or libraries. Linear arrays fall into one of three types, as follows: 1. Arrays of discrete-level cells such as transistors and diodes 2. Arrays of discrete device combinations, referred to as tiles 3. Arrays of higher-level functional macro cells such as operational amplifiers, comparators, voltage-controlled oscillators (VCOs), references, and other analog functions. These arrays are interconnected with a metal mask or by means of some user-programmable interconnect scheme. Unlike cell-based designs, they do not have a unique set of masks for all layers.

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Mixed-Signal ASIC	A mixed-signal ASIC that is manufactured for a single user, using vendor-supplied tools or libraries and containing analog in more than 50 percent of the die area. ASICs with analog making up less than 50 percent of the die area should be counted in the appropriate category under digital ASIC.
MOS Digital Standard Logic IC	Commodity MOS family logic with fewer than 150 gates. Sometimes referred to as glue logic. Examples include: HC/HCT, AC/ACT, FACT, and 74BC/BCT BiCMOS family logic.
LCD Driver	Display driver IC designed to control and drive liquid crystal display (LCD) panels. LCD drivers convert digital inputs into the multi-level signals needed to drive liquid crystal displays. Excluded from this category are microperipheral controller/driver ICs that include the LCD drive function and TV LCD drivers that accept analog video inputs. These devices are counted as part of the microcomponent category or analog IC category, respectively.
Other MOS Digital Logic IC	All other MOS digital logic ICs not accounted for in the preceding categories. Includes MOS commodity family logic with 150 or more gates and MOS digital general-purpose logic not belonging to any families.
Total Analog IC	(Amplifier/Comparator IC + Voltage Regulator/Reference IC + Data Converter/Switch/Multiplexer IC + Interface IC + Telecom IC + Disk Drive IC + Other Special-Function IC + Linear Array/ASIC + Mixed-Signal ASIC + Total Special Consumer IC + Special Automotive IC + Smart Power IC) An analog IC is a semiconductor product that deals in the realm of electrical signal processing, power control, or electrical drive capability. It is one in which some of the inputs or outputs can be defined in terms of continuously or linearly variable voltages, currents, or frequencies. Includes only monolithic analog ICs manufactured using bipolar, MOS, or BiCMOS technologies. Includes monolithic linear IC and monolithic mixed-signal IC. A monolithic linear IC is characterized by having 100 percent analog input/output, while a mixed-signal IC carries information in both digital (numeric) and signal/power forms.
Amplifier/Comparator IC	An amplifier is a general-purpose linear IC that provides a voltage or current gain to an input signal. Includes operational amplifiers (mono, dual, and quad, among others), instrumentation amplifiers, buffer amplifiers, and power amplifiers. Consumer-dedicated amplifier ICs are counted in special consumer IC. Amplifier ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.

 ©1998 Dataquest

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
	A comparator IC is defined as a general-purpose linear IC that compares two analog signal inputs and provides a single logic bit output. Although the output could be considered digital, these products are classed as linear ICs because they are specialty high-gain amplifiers, used in an open-loop mode, for which the output is constrained to only two states. By using a comparator, an unknown voltage can be compared with a known reference voltage. Comparator ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
Voltage Regulator/ Reference IC	A voltage regulator IC is defined as a general-purpose linear IC that outputs a variable current at a regulated DC voltage to other circuits from a variable current and voltage input. Regulator ICs are either linear regulators, in which the device provides an input-to-output voltage drop, or switching regulators, in which the device provides switched quantities of power to a smoothing circuit to gain higher efficiency and reduce power dissipation. Voltage regulator ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
	A voltage reference IC is defined as a general-purpose linear IC that outputs a precise reference voltage to other circuits from a variable voltage input. A reference IC differs from a regulator IC in that it is not expected to power other circuits. In fact, voltage regulator ICs incorporate a voltage reference circuit. Voltage reference ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
Data Converter/Switch/ Multiplexer IC	A data converter IC is defined as a general-purpose mixed-signal IC that converts an analog signal into a digital signal or vice versa. Includes analog-to-digital converters (ADCs), digital-to-analog converters (DACs), sample-and-hold circuits (SHCs), voltage-to-frequency circuits (VFCs), frequency-to-voltage circuits (FVCs), synchro-to-digital circuits (SDCs), and digital-to-synchro circuits (DSCs). All these are general-purpose data ICs. Also included in this category are color-palette DACs. Consumer-dedicated data converter ICs are counted in special consumer IC, under monolithic linear ICs. Data converter ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.

 ©1998 Dataquest

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
	A switch/multiplexer IC is defined as a mixed-signal IC that digitally controls analog transmission gates. These products connect or disconnect the analog signal path in analog circuits. Analog switches operate in a mode where each switch is operated independently by a single logic bit. Multiplexers are multiple analog switches that are connected in a dependent manner, where only one signal path is connected through to the output, depending on the state of a digital address word (greater than one bit). Thus, analog multiplexers are really addressable signal selector switches that select one of many signals for further analog processing. Because these addressable analog switches were the key element in time-division multiplexing, the term "multiplexer" has remained. They are an important part of the data conversion product family in that they are used to provide time-division multiplexing of signal inputs to a fast analog-to-digital converter. Switch/multiplexer ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Interface IC	A general-purpose mixed-signal IC that serves as an interface between a digital system and other external nonsemiconductor systems. Includes line drivers, peripherals drivers, receivers, transmitters, and transceivers. Interface ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Telecom IC	A general-purpose mixed-signal IC that is used for voice band communication or data communication over voice band media. This category includes codecs, combos and SLACs, subscriber line interface circuits (SLICs), modem and fax/modem ICs, dialer and ringer ICs, repeaters, cellular communications ICs, ISDN ICs, telecom filter ICs, and other telecom-specific circuits. Telecom ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Disk Drive IC	A mixed-signal IC that is designed specifically for the rotating mass storage market. Applications include the read/write path from preamplifier up to the ENDEC, head-positioning controller, and spindle motor control. Disk drive ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Other Special-Function IC	An IC that is either a general-purpose IC that does not fit into the other categories or market or application specific ICs for which a category does not yet exist. The main products that fall into this category include timers, phase-locked loops (PLLs), voltage-controlled oscillators, signal- or function-generator ICs, and analog multipliers. Other special-function ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in the linear array/ASIC IC category.

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Total Special Consumer IC	(Video Special Consumer IC + Audio Special Consumer IC + Other Special Consumer IC) A general-purpose IC that is dedicated to general consumer applications but is not application-specific. Consumer ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
Video Special Consumer IC	An IC implemented for video applications
Audio Special Consumer IC	An IC implemented for audio applications, including radio and speech synthesis and recognition
Other Special Consumer IC	An IC implemented in other consumer applications such as electronic games, personal and home appliances, and electronic cameras
Special Automotive IC	An IC that is used in the following automotive applications: entertainment, engine control, safety, traction, or in-car electrical and suspension systems. Special automotive ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
Total Discrete	(Transistor + Diode + Thyristor + Other Discrete) A discrete semiconductor is defined as a single semiconductor component such as a transistor, diode or thyristor. Although multiple devices may be present in a package, they are still considered discretes if they have no internal functional interconnection and are applied in the same manner as other discrete devices.
Transistor	(Small-Signal Transistor + Power Transistor)
Small-Signal Transistor	Signal transistors, RF microwave transistors, dual transistors, MOS field-effect transistors (MOSFETs), conductivity modulated field-effect transistors (COMFETs), insulated gate bipolar transistors (IGBTs), and MOS-bipolar transistors (MBTs). All rated below 1W power dissipation.
Power Transistor	(Bipolar Power Transistor + MOS Power Transistor + Power IGBT) All are rated at 1W power dissipation and above.
Bipolar Power Transistor	Bipolar Darlington transistor, bipolar microwave transistor, and bipolar radio frequency (RF) transistor.
MOS Power Transistor	MOS field-effect transistor (MOSFET), MOS microwave transistor, and MOS radio frequency (RF) transistor.
IGBT Power Transistor	Insulated gate bipolar transistor (IGBT). Also includes conductivity modulated field-effect transistor (COMFET), MOS-bipolar transistor (MBT), and GEMFET.
Diode	(Small-Signal/Reference Diode + Power Diode/Rectifier)
Small-Signal/Reference Diode	Signal diodes, Schottky diodes, zener diodes, switching diodes, voltage reference diodes, voltage regulator diodes, and rectifier diodes. All are rated below 0.5A.
Power Diode/Rectifier	Zener diodes and rectifier diodes. All are rated 0.5A and above.
Thyristor	Thyristors, silicon-controlled rectifiers (SCRs), diacs, and triacs. Also includes solid-state relays (SSRs) incorporating triacs, thyristors, resistors, and capacitors

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Other Discrete	All other discrete semiconductor products not accounted for in the preceding categories. Includes microwave diodes, varactors, tuning diodes, tunnel effect diodes, and selenium rectifiers. Does not include thermistors and varistors
Total Optical Semiconductor	(Total LED Lamp/Display + Optocoupler + CCD + Laser Diode + Photosensor + Other Optical Semiconductor)
	A semiconductor product in which photons induce the flow of electrons or vice versa. Other functions may also be integrated onto the product. This category does not include LCDs, incandescent displays, fluorescent displays, cathode ray tubes (CRTs), or plasma displays.
Total LED Lamp/Display	(Infrared LED Lamp/Display + Other LED Lamp/Display)
Infrared LED Lamp/ Display	Infrared LED lamps/displays are single light-emitting diodes (LEDs) or an array of LEDs consisting of more than one die (in the case of displays) functioning in the invisible infrared range.
Other LED Lamp/Display	Includes visible LEDs and other LED products not included elsewhere. A visible LED lamp is defined as a light-emitting diode for which the light is visible: a semiconductor product consisting of a single die in which photons are emitted at frequencies dependent upon the semiconductor material employed. An LED display is defined as an array of LEDs: a semiconductor product consisting of more than one die in which photons are emitted at frequencies dependent upon the semiconductor material employed and where the light transmission is visible.
Optocoupler	An optocoupler or optoisolator. A semiconductor product consisting of an LED separated from a photosensor by a transparent, insulating, dielectric layer. These are mounted inside an opaque package. Includes optointerrupters, in which the separation between LED and photosensor is large enough to allow external physical systems to influence the device.
Charge-Coupled Device	A charge-coupled device (CCD) is a semiconductor product consisting of an array of photodiodes, an analog CCD shift register, and an output circuit. Includes linear array CCDs with serial shift registers and area array CCDs with parallel shift registers. Includes charge injection device (CID), charge-coupled photodiode (CCP), charge-priming device (CPD), and self-scanning photodiode (SSP).
Laser Diode	A diode that produces coherent light. A semiconductor product in which the heterojunction structure stimulates light amplification by stimulated emission of radiation (laser), resulting in coherent light. Includes Fabrey-Perot laser diodes, pulsed laser diodes, and phase-shifted laser diodes
Photosensor	(Photodiode + Phototransistor)
	A diode or transistor in which photons are used to affect current flow or electric potential.
Other Optical Semiconductor	All other optical semiconductor devices not accounted for in the preceding categories. Includes solar cells and optical thermal piles.

Chapter 7

Worldwide Geographic Region Definitions and Regional Roll-Ups

Americas

Includes countries of North America, Central America, and South America.

Dataquest officially treats the countries of South America, Central America, Mexico, and Puerto Rico as the Latin America region.

Japan

Japan is the only single-country region.

Europe, Africa, and Middle East

Europe

Western Europe

Includes Austria, Belgium, Denmark, Finland, France, Germany (including the former East Germany), Greece, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom, and Rest of Western Europe

Rest of Western Europe. Includes Andorra, Cyprus, Faroe Islands, Gibraltar, Greenland, Guernsey, Iceland, Isle of Man, Jersey, Liechtenstein, Luxembourg, Malta, Monaco, San Marino, and Svalbard

Eastern Europe

Includes Belarus, Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Russia, Slovakia, Ukraine, and Rest of Eastern Europe

Rest of Eastern Europe. Includes Albania, Armenia, Azerbaijan, Bosnia and Herzegovina, Croatia, Georgia, Kazakstan, Kyrgyzstan, Macedonia, Moldova, Romania, Slovenia, Tajikistan, Turkmenistan, Uzbekistan, and Yugoslavia (Serbia and Montenegro)

Africa

Middle East

Asia/Pacific

Includes Australia, China, Hong Kong, India, Indonesia, South Korea, Malaysia, Singapore, Taiwan, Thailand, and Rest of Asia/Pacific

©1998 Dataquest

Rest of Asia/Pacific. American Samoa, Ashmore and Cartier Islands, Baker Island, Bangladesh, Bhutan, Bouvet Island, Brunei, Cambodia, Christmas Island, Cocos (Keeling) Islands, Cook Islands, Coral Sea Islands, Federated States of Micronesia, Fiji, French Polynesia, Guam, Howland Island, Jarvis Island, Johnston Atoll, Kingman Reef, Kiribati, Laos, Macau, Maldives, Marshall Islands, Midway Islands, Mongolia, Myanmar (Burma), Nauru, Nepal, New Caledonia, New Zealand, Niue, Norfolk Island, Northern Mariana Islands, North Korea, Pakistan, Palau, Palmyra Atoll, Papua New Guinea, Paracel Islands, Philippines, Pitcairn Islands, Solomon Islands, Spratly Islands, Sri Lanka, Tokelau, Tonga, Tuvalu, Vanuatu, Vietnam, Wake Island, Wallis and Futuna, and Western Samoa.

Chapter 8
Semiconductor Application Segment Definitions

Data Processing

Defined as computer systems, data storage, input/output devices, dedicated systems, and other data processing equipment:

- Computer systems: The computer estimate does not include the value of the following systems: rigid disk drive, flexible disk drive, keyboards, and displays. The computer estimate does include the value of aftermarket sales of the following: graphics boards, motherboards, memory cards or single in-line memory modules (SIMMs), storage host adapters, and serial and parallel I/O boards. Worldwide computer systems production has been re-estimated and revalued to equal the value of worldwide (factory) revenue and shipments of computer systems as estimated by the Dataquest Computer Systems and Peripherals Worldwide group and to eliminate double-counting of system sales of storage devices, keyboards, and displays. Computer systems include supercomputers, mainframe computers, midrange computers (also known as superminicomputers and minicomputers), workstations, and personal computers (including portable computers). This includes the value of central processing units (that is, boxes) only.
- Data storage includes rigid disk drives, flexible disk drives, optical disk drives, and tape drives.
- Input/output devices include alphanumeric terminals and graphics terminals (for example, X terminals), monitors, and funds-transfer terminals; and printers, media-to-media data conversion, magnetic ink character recognition, optical scanning equipment, plotters, mice, keyboards, and digitizers.
- Dedicated systems include electronic copiers, electronic calculators and personal organizers, smart cards (IC cards), dictation and transcribing equipment, electronic typewriters and dedicated word processors, point-of sale terminals and electronic cash registers, and mailing, letter-handling, and addressing equipment.
- Other data processing includes sound and audio boards, digital video boards, accelerator boards, and embedded CPU boards.

Communications

Defined as premise telecom equipment, public telecom equipment, mobile communications equipment, broadcast and studio equipment, and other telecom equipment:

- Premise telecom equipment includes image and text communication, such as facsimile and facsimile cards, and video teleconferencing; data communications equipment such as modems and modem cards, statistical multiplexers, T1 multiplexers, front-end processors, data service unit/channel service unit (DSU/CSU), protocol converters, (local area) network interface cards, LAN hubs and internetworking equipment, packet data switching systems; premise switching equipment, such as PBX telephone equipment, and key telephone systems; call-processing equipment, such as voice messaging, interactive voice response systems, and automatic call distributors; and desktop terminal equipment, such as telephone sets/pay telephones and cordless telephones, and teleprinters.

- Public telecom equipment includes transmission equipment, such as multiplexers, carrier systems, microwave radio, laser and infrared transmission equipment, and satellite communications equipment; and central office switching equipment.
- Mobile communications equipment includes mobile radio systems such as cellular telephones, microcellular telephones, mobile radios, mobile radio base station equipment and pagers; portable radio receivers and transmitters; and radio checkout equipment.
- Broadcast and studio equipment includes audio equipment, video equipment, transmitters and RF power amplifiers, studio transmitter links, cable TV (head-end) equipment, closed-circuit TV equipment, and other equipment, such as studio and theater equipment.
- Other telecom equipment includes intercom equipment and electrical amplifiers; and communications equipment not elsewhere classified.

Industrial

Defined as security/energy management systems, manufacturing systems/instruments, medical equipment, and other industrial equipment:

- Security/energy management includes alarm systems, such as intrusion-detection and fire-detection systems, and energy management systems.
- Manufacturing systems/instruments include semiconductor production equipment, controls, process controls, control and processing displays and robots and test and measuring equipment such as semiconductor-dedicated automatic test equipment (ATE), other test and measurement equipment, and nuclear electronics.
- Medical equipment includes diagnostic equipment, therapeutic equipment, patient monitoring equipment, surgical support systems, and irradiation equipment.
- Other industrial equipment includes vending machines, power supplies, traffic-control equipment, and industrial equipment not elsewhere classified.

Consumer

Defined as audio equipment, video equipment, personal electronics, appliances, and other consumer equipment:

- Audio equipment includes compact disc players, radios, stereo components, musical instruments, and tape recorders.
- Video equipment includes VCRs and VTRs, video cameras and camcorders, videodisc players, color and monochrome TVs, and cable/satellite set-top decoders.

 ©1998 Dataquest

- Personal electronics includes electronic games and toys (systems and cartridges), cameras, watches, and clocks.
- Appliances includes air conditioners, microwave ovens, washers and dryers, refrigerators, dishwashers, and ranges and ovens.
- Other consumer equipment includes automatic garage door openers and consumer equipment not elsewhere classified.

Military and Civil Aerospace

Defined as military electronic equipment and civil aerospace.

- Military/civil aerospace: North American military/civil aerospace production has been re-estimated and revalued to reflect U.S. Department of Commerce estimates of U.S. defense and civil (aerospace) electronics. Military/civil aerospace includes radar/sonar/reconnaissance systems, missile/space-related electronics, navigation equipment, electronic warfare, aircraft flight systems, and command and control systems.

Transportation

Defined as in-car entertainment, body control electronics, power train systems, and safety and convenience systems.

- In-car entertainment includes systems such as AM/FM radios, cassette and compact disc players, and radio/cassette combination systems.
- Body control electronics includes four-wheel steering control, two-wheel drive/four-wheel drive (2WD/4WD) control; multiplex systems such as driver's door console, door locks, windshield wipers, heated rear windows, memory seats, memory steering wheel, remote security systems, and suspension control and traction control systems; lighting controls including automatic headlight systems, timers, reminders, and sequential signal controls; and other body control electronics including aerodynamic aid control and power roof/window controls; driver information systems including electronic dashboard/instrument clusters, analog or digital clusters, electronic analog/digital clocks and compasses, electronic thermometers, head-up displays, navigation and location systems, signal and warning lights, and trip computers.
- Power train systems include engine management systems, power train sensors, ignition control, fuel injection systems, fuel flow, engine temperature, air temperature, coolant level, wheel speed sensors, and transmission control.
- Safety and convenience systems include climate control systems (air conditioning/heating), air purifier systems, air bag control systems, antilock braking systems, collision warning systems, and cruise control.

Chapter 1
Final 1997 Worldwide Semiconductor Market Share

Introduction

This document contains detailed information on Dataquest's view of the semiconductor market. Included in this document are the following:

- 1995-1997 market share estimates
- 1996-1997 market share rankings

Worldwide market share estimates combine data from many countries, each of which has a different and fluctuating exchange rate. Estimates of non-U.S. market consumption or revenue are based on the average exchange rate for the given year. Refer to the section titled "Exchange Rates" for more information regarding these average rates. As a rule, Dataquest's estimates are calculated in local currencies and then converted to U.S. dollars.

More detailed data on this market may be requested through Dataquest's client inquiry service. Qualitative analysis of this data is provided in Dataquest Perspectives.

Segmentation and Definitions

A detailed explanation of device segmentation and related definitions is contained in the Semiconductor Market Definitions Guide (SCND-WW-GU-9801).

Market Share Methodology

Dataquest uses both primary and secondary sources to produce market statistics data. In the fourth quarter of each year, Dataquest surveys all major participants within each industry. Selected companies are resurveyed during the first quarter of the following year to verify final annual results. This primary research is supplemented with additional primary research and secondary research to verify market size, shipment totals, and pricing information. Sources of data used by Dataquest include the following:

- Information published by major industry participants
- Estimates made by knowledgeable and reliable industry spokespersons
- Government data or trade association data (such as WSTS, MITI, and U.S. DOC)
- Published product literature and price lists
- Interviews with knowledgeable manufacturers, distributors, and users
- Relevant economic data
- Information and data from online and CD-ROM data banks
- Articles in both the general and trade press

- Reports from financial analysts
- End-user surveys

Dataquest believes that the estimates presented in this document are the most accurate and meaningful statistics available.

Despite the care taken in gathering, analyzing, and categorizing the data in a meaningful way, careful attention must be paid to the definitions and assumptions used herein when interpreting the estimates presented in this document. Various companies, government agencies, and trade associations may use slightly different definitions of product categories and regional groupings, or they may include different companies in their summaries. These differences should be kept in mind when making comparisons between data and numbers provided by Dataquest and those provided by other sources.

Notes on Market Share

In the process of conducting data collection and preparing market statistics information, Dataquest will sometimes consolidate or revise a particular company, model, series, or industry's numbers. In this section, we explain any such changes contained within this document for your reference.

Notes to Market Share Tables

1. Cyrix was acquired by National Semiconductor in 1997.

2. National Semiconductor divested itself of Fairchild in 1997.

3. National Semiconductor's 1997 revenue includes all of Cyrix's 1997 revenue and part of Fairchild's calendar first quarter revenue.

4. Power Innovations was formed through the acquisition of the Power Semiconductor interests of Texas Instruments.

5. Melexis was formerly known as Elex.

6. Micronas acquired ITT in 1997.

7. The following companies were added to the market share database in 1997:

- Fairchild
- Vitesse
- TriQuint
- Power Innovations
- Robert Bosch
- Stanley

8. Toko is now tracked in other Japanese companies.

9. IBM's 1996 revenue was restated in 1997.

Exchange Rates

Dataquest uses an average annual exchange rate in converting revenue to U.S. dollar amounts. Table 1-1 outlines these rates for 1995 through 1997.

Table 1-1
Exchange Rates

	1995	1996	1997
Japan (Yen/U.S.$)	93.90	108.81	121.10
France (Franc/U.S.$)	4.97	5.12	5.84
Germany (Deutsche Mark/U.S.$)	1.43	1.50	1.73
United Kingdom (U.S.$/Pound Sterling)	1.59	1.56	1.64

Chapter 1
Americas Fab Database

Background and Methodology

This report contains the Americas portion of Dataquest's wafer fab database. The records in these tables are fabs located in the Americas region. The Semiconductor Equipment, Materials, and Manufacturing Worldwide (SEMM) program conducts extensive annual surveys, complemented with quarterly secondary research to maintain this database. Published once a year, this document represents Dataquest's best insights and estimates into the end-market of semiconductor equipment.

The tables in this report cover planned and existing merchant, captive, and foundry fab lines. A fab line is a series of equipment to do front-end (from initial oxide through wafer probe) semiconductor manufacturing. Occasionally, two or more separate product-specific fab lines or wafer sizes operate in a single clean room or physical plant. In this situation, Dataquest divides the clean room as separate fab lines if the company dedicates equipment to each wafer size or product line. If a company installs substantially different equipment during an expansion (for example, equipment to increase its maximum wafer diameter), again Dataquest divides the clean room and creates two entries into the database. Therefore, a company may operate many fab lines at one location.

Worldwide Geographic Region Definitions and Regional Roll-Ups

Americas
Includes Central America (all nations), Canada, Mexico, United States, Puerto Rico, and South America (all nations).

Japan
Japan is the only single-country region.

Europe, Africa, and Middle East
Includes Africa (all nations), Albania, Andorra, Armenia, Azerbaijan, Belarus, Belgium, Bulgaria, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Georgia, Germany, Gibraltar, Hungary, Iceland, Israel, Italy, Kazakhstan, Kyrgyzstan, Latvia, Liechtenstein, Lithuania, Luxembourg, Malta, Middle East (all nations), Moldova, Monaco, Netherlands, Norway, Poland, Romania, Russia, San Marino, Scandinavia, Slovakia, Spain, Sweden, Sweden, Switzerland, Tajikistan, Turkey, Turkmenistan, Ukraine, United Kingdom, Uzbekistan, Vatican City, and all nations within the former Yugoslavia.

Asia/Pacific
Includes Australia, Bangladesh, Cambodia, China, Hong Kong, India, Indonesia, Laos, Malaysia, Maldives, Myanmar, Nepal, New Zealand, Pakistan, Philippines, Singapore, South Korea, Sri Lanka, Taiwan, Thailand, and Vietnam.

Field Definitions

The Company field indicates the operator of the fab line. For contract manufacturers that trade capacity for capital investment in the fab, Dataquest lists the contract manufacturer. For incorporated joint ventures, Dataquest lists either the incorporated entity or the major investors, separated with slashes.

The City field displays the most detailed location information. This reference is usually a city or town, but could be an often-used district name (for example, Science Park in the city of Hsinchu, Taiwan). If this field lists a district, Dataquest will list the city in the State or Province field. In some cases, a reference to a state or province will be included in the City or District field to create a unique identifier for this location.

The Prefecture field denotes the second most detailed location. This reference is usually a state (for the United States), province (for Canada and many European and Asian countries), or a prefecture (for Japan). For countries within the United Kingdom, Dataquest lists the country name (for example, "Scotland") in this field so Dataquest can list the descriptor "U.K." in the Country field.

The Country field indicates the broadest location identifier in this report. This reference is usually a country, except in the case of the United Kingdom (see "State or Province" above). Because Japan is a single-country region, there is no regional qualifier for fabs in Japan.

The Fab Name field provides a reference to a particular fab or fab line to distinguish it from other fabs or lines owned by that company. Although Dataquest makes every attempt to match the nomenclature used by the company, occasionally some additional qualifiers (for example, "Phase 1") will appear to provide insight to the facility's history or organization.

The Products field lists the products manufactured at this site. The listings generally fall into five product groups, with the following nomenclature and definitions (when warranted):

- MOS memory
  - DRAM: Dynamic RAM
  - EEPROM: Electrically erasable PROM
  - EPROM: Ultraviolet erasable PROM
  - FERRAM: Ferroelectric RAM
  - FIFO: First-in/first-out memory
  - Flash: Flash memory
  - Mem: Memory
  - NV Mem: Nonvolatile memory (ROM, PROM, EPROM, EEPROM, and FERRAM)
  - PROM: Programmable ROM
  - RAM: Random-access memory

- ROM: Read-only memory
- SGRAM: Synchronous graphics RAM
- Sp Mem: Other specialty memory (such as dual-port, shift-register, or color lookup)
- SRAM: Static RAM
- VRAM: Video RAM

- MOS microcomponent/digital logic
  - Array: Gate array
  - ASIC: Application-specific IC
  - ASSP: Application-specific standard product
  - Bit: Bit slice (subset of MPU functions)
  - CBIC: Cell-based IC
  - Custom: Full-custom IC (single user)
  - DSP: Digital signal processor
  - FPGA: Field-programmable gate array
  - LISP: 32-bit list instruction set processor for AI
  - Logic: Standard logic
  - LSI: Large-scale integration
  - MCU: Microcontroller unit
  - MixSig ASIC: Mixed-signal ASIC
  - MPR: Microperipheral
  - MPRCom: MPR digital communication (ISDN, LAN, UART, or modem)
  - MPU: Microprocessor unit
  - PLD: Programmable logic device
  - RISC: Reduced-instruction-set computation 32-bit MPU
  - Telecom: Telecommunications chip
- Power/discrete/analog (including bipolar power)
  - A/D D/A: Analog-to-digital, digital-to-analog converter
  - Automotive: Dedicated to automobile applications
  - CODEC: Coder/decoder
  - Diode
  - Discrete
  - FET: Field-effect transistor
  - GTO: Gate turn-off thyristor
  - HEMT: High-electron-mobility transistor
  - IGBT: Insulated-gate bipolar transistor

©1999 Dataquest

- Interface: Interface IC
- Linear: Linear/analog device
- MDiode: Microwave diode
- MESFET: Metal semiconductor field-effect transistor
- MFET: Microwave field-effect transistor
- Modem: Modulator/demodulator
- MMIC: Monolithic Microwave IC
- MOSFET: MOS-based field-effect transistor
- Op Amp: Operational amplifier
- Pwr IC: Power IC
- Pwr Tran: Power transistor
- Rectifier
- Reg: Voltage regulator
- RF: Radio frequency
- SCR: Schottky rectifier
- Sensor
- Smart Pwr: Smart power
- SST: Small-signal transistor
- Switches: Switching device
- Thyristor
- Tran: Transistor
- Zener Diode

- Optoelectronic
  - CCD: Charge-coupled device (imaging)
  - Coupler: Photocoupler
  - IED: Infrared-emitting diode
  - Image Sensor
  - Laser: Semiconductor laser or laser IC
  - LED: Light-emitting diode
  - Opto: Optoelectronic
  - PDiode: Photo diode
  - PTran: Photo transistor
  - SAW: Surface acoustic wave device
  - SIT Image Sensor: Static induction transistor image sensor

- Bipolar Digital and Other Devices (includes all digital ICs using a bipolar process)
    - Darlington
    - Micromachining sensors
    - MilStd: Military Standard Logic
    - RadHard: Radiation hardened

The Process Technology field indicates each fab's use of five major types of processes. The process grouping is as follows:

- P/CMOS: P-channel metal-oxide semiconductor (PMOS) or complementary metal-oxide semiconductor (CMOS)
- NMOS: N-channel metal-oxide semiconductor (NMOS)
- BiCMOS: Bipolar and CMOS combined on a chip
- Bipolar
- III-V: Gallium arsenide and other compound semiconductor processes

The Estimated Minimum Geometry is the smallest linewidth feature size, measured in microns, attainable in production volume.

The Wafer Diameter represents the maximum wafer size that the fab or fab line can process. Wafer diameters, although expressed colloquially in inches, conform to metric specifications. For wafers greater than 3 inches in diameter, expression in inches becomes inaccurate. When calculating square inches, Dataquest uses the following approximations:

- Stated diameter of 4 inches (100mm) = Approximate diameter of 3.938 inches
- Stated diameter of 5 inches (125mm) = Approximate diameter of 4.922 inches
- Stated diameter of 6 inches (150mm) = Approximate diameter of 5.906 inches
- Stated diameter of 8 inches (200mm) = Approximate diameter of 7.87 inches
- Stated diameter of 12 inches (300mm) = Approximate diameter of 11.84 inches.

The Year and Quarter of Initial Production displays the year (and quarter, if available) in which this line, having completed all qualifications, began manufacturing in production volumes. The format for this reference is "year.quarter" (for example, 1994.3 translates to the third calendar quarter of 1994).

The Initial Monthly Wafer Starts field indicates the initial monthly volume of production wafer throughput.

The Estimated Maximum Monthly Wafer Starts field contains the equipment-limited wafer start capacity per four-week period. Only the throughput of the installed equipment and the process complexity limits the maximum starts. Dataquest does not consider current staffing or the number of shifts operating in determining this metric.

©1999 Dataquest

The Fab Type field shows the types of semiconductor manufacturing performed at this location. The fab types include the following:

- "F" indicates that this is a production-based fab.
- "R" indicates a semiconductor R&D and/or trial production facility.
- "P" means that this location produces a pilot line.
- "T" means that this location performs assembly or testing.
- "N" indicates that this is location performs foundry production, or contract manufacturing.
- "VD" means that this location performs VHDL design.
- "PD" means that this location performs IC place and route design.

Chapter 1

Final 1997 Americas Semiconductor Market Share

Introduction

This document contains detailed information on Dataquest's view of the semiconductor market. Included in this document are the following:

- 1995-1997 market share estimates
- 1996-1997 market share rankings

Americas market share estimates combine data from various countries, each of which has a different and fluctuating exchange rate. Estimates of non-U.S. market consumption or revenue are based on the average exchange rate for the given year. Refer to the section titled "Exchange Rates" for more information regarding these average rates. As a rule, Dataquest's estimates are calculated in local currencies and then converted to U.S. dollars.

More detailed data on this market may be requested through Dataquest's client inquiry service. Qualitative analysis of this data is provided in Dataquest Perspectives.

Segmentation and Definitions

A detailed explanation of device segmentation and related definitions is contained in the Semiconductor Market Definitions Guide (SCND-WW-GU-9801).

Market Share Methodology

Dataquest uses both primary and secondary sources to produce market statistics data. In the fourth quarter of each year, Dataquest surveys all major participants within each industry. Selected companies are resurveyed during the first quarter of the following year to verify final annual results. This primary research is supplemented with additional primary research and secondary research to verify market size, shipment totals, and pricing information. Sources of data used by Dataquest include the following:

- Information published by major industry participants
- Estimates made by knowledgeable and reliable industry spokespersons
- Government data or trade association data (such as WSTS, MITI, and U.S. DOC)
- Published product literature and price lists
- Interviews with knowledgeable manufacturers, distributors, and users
- Relevant economic data
- Information and data from online and CD-ROM data banks
- Articles in both the general and trade press

©1998 Dataquest

- Reports from financial analysts
- End-user surveys

Dataquest believes that the estimates presented in this document are the most accurate and meaningful statistics available.

Despite the care taken in gathering, analyzing, and categorizing the data in a meaningful way, careful attention must be paid to the definitions and assumptions used herein when interpreting the estimates presented in this document. Various companies, government agencies, and trade associations may use slightly different definitions of product categories and regional groupings, or they may include different companies in their summaries. These differences should be kept in mind when making comparisons between data and numbers provided by Dataquest and those provided by other sources.

Notes on Market Share

In the process of conducting data collection and preparing market statistics information, Dataquest will sometimes consolidate or revise a particular company, model, series, or industry's numbers. In this section, we explain any such changes contained within this document for your reference.

Notes to Market Share Tables

1. Cyrix was acquired by National Semiconductor in 1997.

2. National Semiconductor divested itself of Fairchild in 1997.

3. National Semiconductor's 1997 revenue includes all of Cyrix's 1997 revenue and part of Fairchild's calendar first quarter revenue.

4. Power Innovations was formed through the acquisition of the Power Semiconductor interests of Texas Instruments.

5. Melexis was formerly known as Elex.

6. Micronas acquired ITT in 1997.

7. The following companies were added to the market share database in 1997:

- Fairchild
- Vitesse
- TriQuint
- Power Innovations
- Robert Bosch
- Stanley

8. Toko is now tracked in other Japanese companies.

9. IBM's 1996 revenue was restated in 1997.

Exchange Rates

Dataquest uses an average annual exchange rate in converting revenue to U.S. dollar amounts. Table 1-1 outlines these rates for 1995 through 1997.

Table 1-1
Exchange Rates

	1995	1996	1997
Japan (Yen/U.S.$)	93.90	108.81	121.10
France (Franc/U.S.$)	4.97	5.12	5.84
Germany (Deutsche Mark/U.S.$)	1.43	1.50	1.73
United Kingdom (U.S.$/Pound Sterling)	1.59	1.56	1.64

Chapter 2
Market Share Tables

Table 2-1 gives vendor revenue from shipments to North and Latin America. Tables 2-2 through 2-11 show each company's factory revenue by technology category. Tables 2-12 through 2-21 show the top companies' factory revenue by technology category.

Table 2-1
Individual Company Vendor Revenue from Shipments of Total Semiconductors to North and Latin America, 1997 (Millions of U.S. Dollars)

	*North America	*Latin America	Americas
Total Market	**43,548**	**4,538**	**48,086**
Intel	8,713	908	9,621
Motorola	3,513	366	3,879
IBM	2,426	253	2,679
Texas Instruments	1,994	208	2,202
NEC	1,930	201	2,131

Chapter 1
Executive Summary

Dataquest's worldwide semiconductor forecast for year-end 1998 through 2002, as shown in Table 1-1, projects a market in severe decline in 1998. Worldwide semiconductor revenue is expected to decline 5.9 percent to $138 billion in 1998. If the market experiences price stability and a strengthening in demand in 1999, a market rebound could see worldwide revenue return to stronger double-digit growth in 2000. Within the scope of the current forecast for 1999, the non-DRAM sector could grow 9.7 percent, while DRAM revenue could grow 30 percent.

As shown in Figure 1-1, the comparison of DRAM versus non-DRAM product revenue illustrates the disastrous effects of DRAM downturns on the market. The non-DRAM products usually represent revenue stability in the semiconductor market.

Table 1-1
Worldwide Semiconductor Forecast, 1997-2002 (Millions of Dollars)

	1997	1998	1999	2000	2001	2002	CAGR (%) 1998-2002

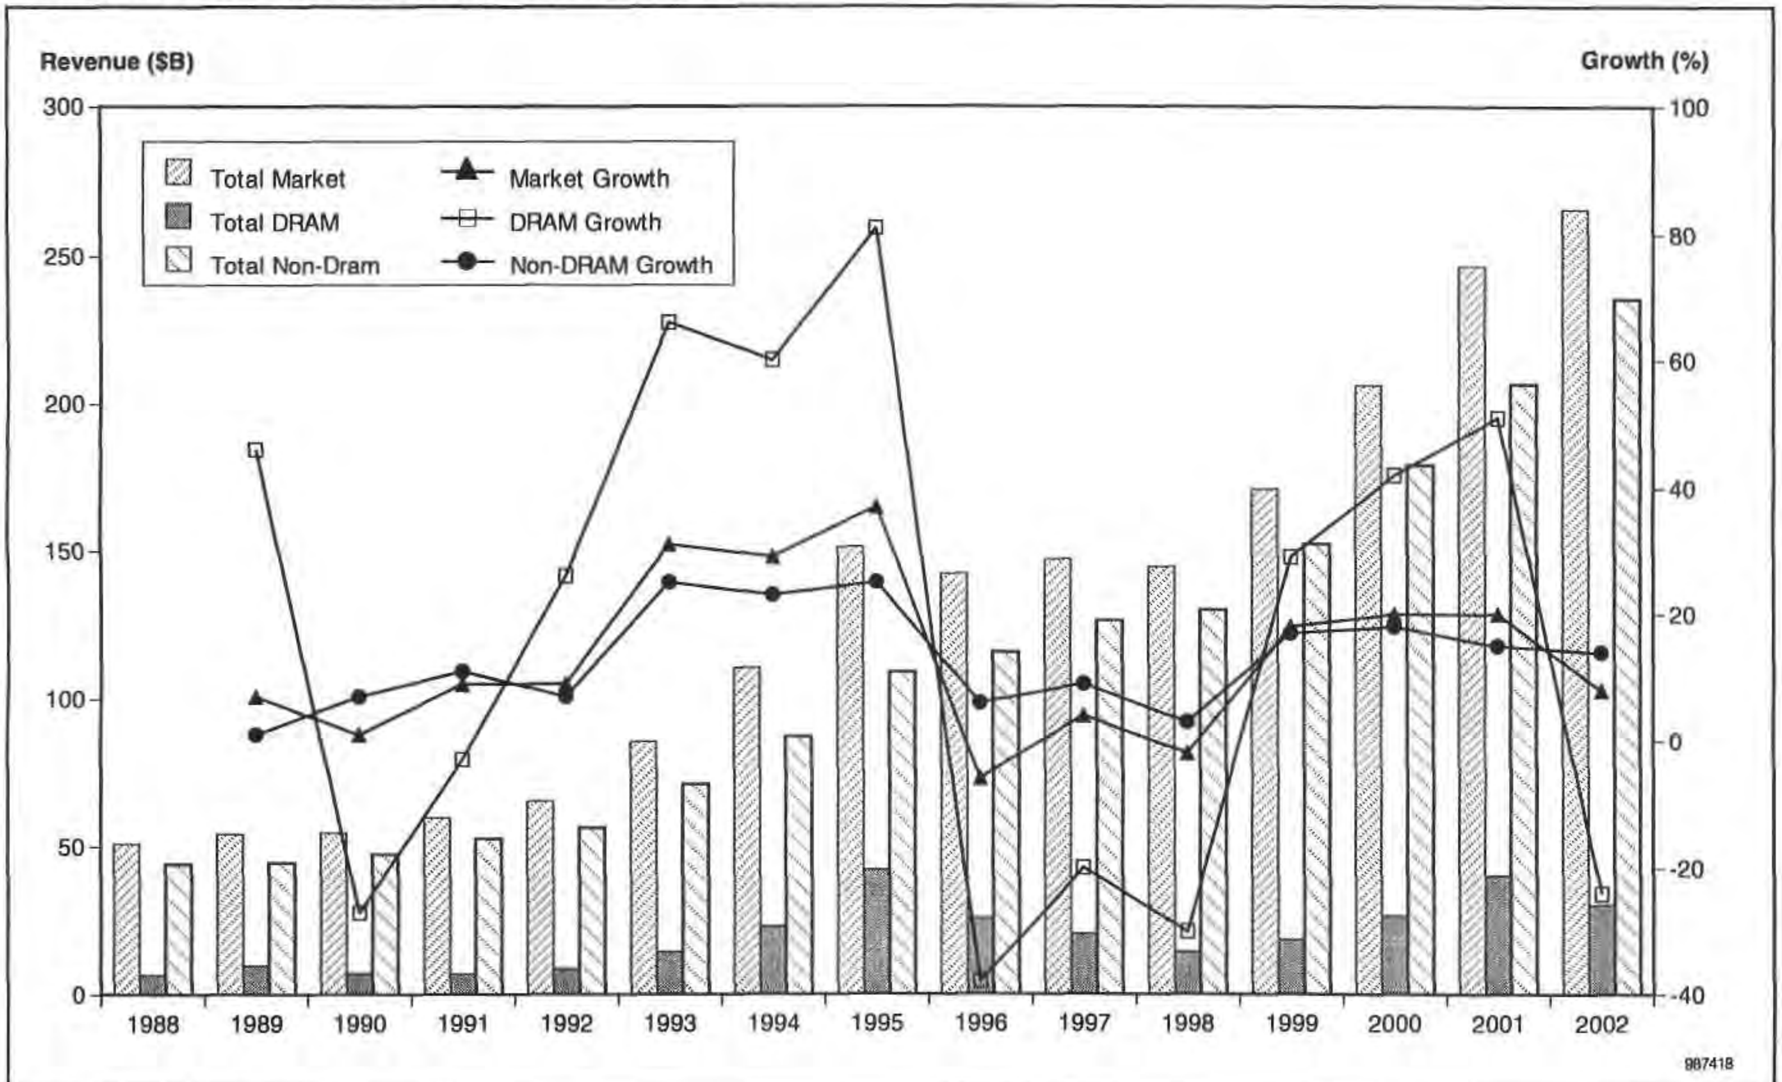
Worldwide Semiconductor Market Growth, 1988-2002



Source: Dataquest (October 1998)

©1998 Dataquest

DRAMs have always been the key driver for growth and the culprit for decline in the semiconductor industry. In the major DRAM and overall semiconductor market downturns, excess capacity or strategic inventory is the real culprit. A series of worldwide events from 1995 to 1998 resembles previous market downturns, especially those that occurred in 1985 through 1987. These are listed in Table 1-2.

The DRAM market declined 52 percent, from $3.5 billion in 1984 to $1.7 billion in 1985. In 1984, suppliers hoarded product and buyers double-ordered on contracts to guarantee shipments. In 1985, as suppliers began dumping products and lowering prices, buyers canceled long-range contracts to reap the benefits of lower prices. Pricing wars raged until trading wars and dumping issues resulted in government intervention, and foreign market value (FMV) duties were imposed. The suppliers to this market suffered worse losses and faced worse price erosion than in any other device market. Several companies made well-publicized withdrawals from the DRAM market during that year. Manufacturers that fared best were those that were well positioned in the 256Kb DRAM market, which enabled them to shift their revenue base over as the 64Kb market declined.

Table 1-2
Market Comparisons: 1985-1987 versus 1995-1998

1985-1987 Market	1995-1998 Market
Product hoarding/double-ordering led to supply excess, which precipitated price erosion.	Excessive capital spending added to an overcapacity situation precipitated price erosion.
Capital spending was depressed in the U.S. because of uncertainty about proposed tax reforms.	Capital spending depressed in the U.S., Japan, Europe, and Korea because of capital spending binge.
International trade issues over product prices reaching below fair market values led to antidumping duties on DRAMs and EPROMs.	Uncertainty of antidumping duties on DRAMs as rumors abound over dumping product below cost to gain market share.
Damaged by price erosion, a depressed market, and aggressive competitors, Mostek, Intel, and Inmos disappeared from key market sectors.	Damaged by excessive spending, price erosion, and aggressive competitors, some DRAM suppliers are evaluating departure from the market.
A crossover point in price was reached between the 64Kb DRAM and 256Kb DRAM. The 1Mb DRAMs reached price per bit parity with 256Kb year-end 1987.	In a dance of death, 64Mb DRAM chases the 16Mb DRAM. Price per bit parity could be reached by year-end 1998. A 4Mb to 16Mb crossover occurred during this time.
The yen exchange rate changed dramatically, from 254 in 1985 to 128.4 at year-end 1987.	The yen exchange rate changed dramatically, assumed at 129.73 for the spring forecast period and 143 for 1999. The Korean won devalued to 50 percent of its dollar exchange rate this time, as the yen did in the 1985-1987 time frame.
Prices for all memory products eroded.	Prices for the majority of ICs eroded.

 ©1998 Dataquest

The stability of the top 20 semiconductor suppliers in retaining vendor positions during a downturn reflects their ability to grow the non-DRAM portion of their product sector and to reposition their products into applications beyond the PC, where non-DRAM products are of greater importance.

A brief look at historical market share provides interesting insight into the fluctuations of DRAM versus non-DRAM focus and its effect on vendor rankings. The DRAM versus non-DRAM competitive highlights are listed in Table 1-3. Typically, the top 10 suppliers to the world garnered their largest revenue share via DRAM products. During the last two years, almost all of the top 20 suppliers suffered revenue losses. There appeared to be very few safe havens in the semiconductor market in 1997 and 1998. Only a few companies in Table 1-4 experienced positive growth as they moved into 1998, a second year of downturn. The top 20 suppliers listed in this table will be profiled in this report.

Table 1-3

Chapter 2
Competitive Analysis by Product

The total number of semiconductor suppliers to the world varies with estimates now ranging above 300. Table 2-1 is an alphabetical listing of semiconductor suppliers of products surveyed by Dataquest.

Of the top 20 suppliers for 1997, Intel ranked No. 1 because of its strength in microprocessor products. Suppliers No. 2 through No. 9, listed in Table 2-2, were broad-line suppliers—suppliers to every major product segment.

Figure 2-1 illustrates the strength of the top 20 suppliers by product revenue and the dependency of some companies on single products for revenue. Figures 2-2 and 2-3 illustrates memory versus nonmemory product revenue for the top 20. Figure 2-3 strongly illustrates how a company's revenue (for example, Intel's) is highly leveraged by high-growth products. Intel has used its core technology as a profit center by expanding into applications beyond or in conjunction with the PC. The figure also illustrates the relative positions of companies that have maintained market strength and growth potential through product diversification.

Chapter 3
Competitive Positions by Region

Two decades of incremental changes in process technology, monumental capital investment in fab equipment and facilities, and a serious market downturn resulted in a major reshuffling of the top 20 in 1997. Table 3-1 offers a quick review of regional consumption. The market has seen significant fluctuations in regional shares. Price instability, moderate growth of PCs, currency devaluations, and regional recessions changed regional shares for vendors in Japan and Asia/Pacific. Table 3-2 provides the production by region. A vendor's region is defined as its home base of origin, not the region where the vendor's devices are fabricated.

Table 3-3 is a summary of product share for the suppliers headquartered in the four regions. The regions with the largest share of product revenue have been highlighted. Americas vendors' strength is in the bipolar digital, microcomponent, logic, and analog product areas. Japan is the second-largest vendor region and is dominant in the memory, discrete, and optical product arenas. Table 3-4 is a review of the top 20 semiconductor suppliers by their regional market revenue and share of the worldwide market. Intel is the only semiconductor supplier that maintains strong revenue share in all four regions. More specific company details for the top 20 are outlined in Chapter 4.

Table 3-1
Semiconductor Consumption by Region, 1987-1997 (Millions of Dollars)

Region	1987	1988	1989	1990	1991	1992	1993	1994	1995	1996	1997

Chapter 4
Top 20 Supplier Profiles

No. 1: Intel

Intel posted a 20 percent increase in corporate revenue in 1997 over 1996. One of the company's major announcements concerned the purchase of Digital Equipment Corporation's semiconductor operations for $700 million. This acquisition brought several facilities under the expanding Intel umbrella. The facilities include the Hudson, Massachusetts, group and development operations in Jerusalem, Israel, and Austin, Texas.

Intel's net sales from all business sectors were more than $25 billion. The company grew its semiconductor share of revenue by 22.3 percent in 1997. Intel surpassed the No. 2 supplier, NEC, by more than $11.5 billion and the No. 3 supplier, Motorola, by $13.6 billion. As of 1997, Intel had introduced its latest 0.25-micron manufacturing process technology for its next generation of microprocessor products. Intel's R&D spending for 1997 was $2.4 billion. Intel's strategy is to introduce higher-performance microprocessors for the worldwide computer market that includes servers, workstations, higher-end PCs, basic PCs, and other product lines. Intel's geographic distribution for total revenue was as follows: North America, 44 percent; Europe, 27 percent; Asia/Pacific, 19 percent; and Japan, 10 percent. Table 4-1 illustrates the distribution of Intel's semiconductor revenue in 1997 by product and by region.

Intel's strength lies in the microprocessor market. It now lays claim to more than 42 percent of the world's microprocessor market. Intel is not a broad-line semiconductor supplier. Table 4-2 is a 10-year history of Intel's revenue for each of the major semiconductor product categories.

Figure 4-1 illustrates the difference between Intel's growth rate and that of the total semiconductor industry since 1987. Intel's level of spending for microprocessor technology has ranked as high as that of the largest memory capital spenders in the industry. Intel introduced its 0.25-micron technology in 1997. Figure 4-2 illustrates Intel's capital spending versus the Americas region's spending history. The majority of Intel's spending is targeted at development of high-performance microprocessor technology and related manufacturing technology. Table 4-3 lists the contribution of each of Intel's product types to Intel's total semiconductor revenue.

Table 4-4 lists the market shares of Intel's products in the worldwide market.

No. 2: NEC

NEC maintained the No. 2 position, but lost market share worldwide. The company's market share declined from 7.3 percent in 1996 to 6.9 percent in 1997. Like many DRAM manufacturers, NEC saw its semiconductor revenue decline as memory prices dropped below cost and relative price pressures affected all semiconductor products. Table 4-5 shows the source of NEC's revenue in 1997 by product and region.

NEC was established in 1899; its 1997 business sectors encompassed computers and industrial electronic systems (42 percent), communication systems and equipment (34 percent), electronic devices (20 percent), and other products (4 percent). A 10-year history of NEC's revenue for each of the major semiconductor product categories is given in Table 4-6. NEC's overall revenue ranking suffered because of a decline in memory revenue. NEC's ASIC and microcomputer sectors reported higher sales because of brisk demand for notebook PCs in Japan and other regions in 1997.

Figure 4-3 illustrates the difference between NEC's growth rate and that of the total semiconductor industry since 1987. Figure 4-4 illustrates NEC's capital spending history and how it compares to the region's total spending during the same time frame.

The contribution of each of the product categories to NEC's total semiconductor sales is shown in Table 4-7. Over 10 years, NEC's product mix has shown a decline in the importance of analog and discrete devices as microcomponents, memory, and logic ICs have gained in importance.

NEC's market shares for the worldwide market by product are shown in Table 4-8. The company's share of worldwide memory at 10.4 percent is stronger than before 1989. NEC continues to prove that it can survive severe DRAM downturns.

Table 4-5
NEC's Product Distribution by Region, 1997 (Millions of Dollars)

Products	Americas	Europe	Japan	Asia/Pacific	Total

No. 3: Motorola

Motorola kept its No. 3 position in 1997. The company has been one of the leading providers of wireless communication, semiconductor, and advanced electronic systems components and servers. Motorola's equipment sector includes cellular telephones, two-way radio paging, and data communications, as well as personal communications, automotive, defense and space electronics, and computers. Motorola continues to shift a major portion of its semiconductor-related operations to outsourcing. Motorola's total R&D spending for 1997 was $2.8 billion. Table 4-9 shows the source of Motorola's semiconductor revenue in 1997 by product and region.

Motorola's company sales reached $29.8 billion in 1997. This was a marginal climb from $28 billion in 1996 and $27 billion in 1995. A 10-year history of Motorola's revenue by product is listed in Table 4-10.

Figure 4-5 illustrates the difference between Motorola's growth rate and that of the total semiconductor industry since 1987. Figure 4-6 illustrates Motorola's capital spending history and how it compares to the region's total spending during the same time frame.

The contribution of each of the product categories to Motorola's total semiconductor revenue is shown in Table 4-11. The company's share of the worldwide market is listed in Table 4-12.

Table 4-9
Motorola's Product Distribution by Region, 1997 (Millions of Dollars)

No. 4: Texas Instruments

Texas Instruments jumped into the No. 4 position, displacing Hitachi in 1997. Table 4-13 lists the distribution of TI's 1997 semiconductor revenue by product and region.

TI sold off its DRAM business to Micron Technology in 1997. A 10-year history of TI's revenue for each of the major semiconductor product categories is given in Table 4-14.

Figure 4-7 illustrates the difference between TI's growth rate and that of the total semiconductor industry since 1987. Figure 4-8 illustrates TI's capital spending history and how it compares to the region's spending during the same time frame.

The contribution of each of the product categories to TI's total semiconductor sales is shown in Table 4-15. Up through 1993, logic ICs have been the dominant piece of TI's product line. TI has shifted its focus to microcomponents and analog. Table 4-16 lists TI's worldwide shares by product.

Table 4-13
Texas Instruments' Product Distribution by Region, 1997 (Millions of Dollars)

Products	Americas	Europe	Japan	Asia/Pacific	Total
Total Semiconductor	**2,202**	**1,748**	**1,549**	**1,853**	**7,352**

No. 5: Toshiba

Toshiba maintained its No. 5 position in 1997. The company's corporate sales totaled $43,979 million. Toshiba expects significant growth in DVD-video players as well as system LSIs, including microprocessors, digital signal processors, and memory-embedded logic, to boost revenue in the semiconductor area. A drop in sales prices severely impacted the performance of the company's semiconductor memory operations. Therefore, the company plans to accelerate efforts to reduce reliance on memory devices. Table 4-17 shows the source of Toshiba's revenue in 1997 by product and region.

Toshiba's share of net sales by business segments includes information/communications equipment and electronics (56.8 percent), heavy electrical apparatus (20.5 percent), and consumer products and others (22.7 percent). A 10-year history of Toshiba's revenue for each of the major semiconductor product categories is given in Table 4-18.

Figure 4-9 illustrates the difference between Toshiba's growth rate and that of the total semiconductor industry since 1987. Toshiba's capital spending history and its comparison to the region's spending are illustrated in Figure 4-10.

The contribution of each of the product categories to Toshiba's total semiconductor sales is shown in Table 4-19. Toshiba, like NEC, Motorola, and Hitachi, continues to be a well-balanced broad-line supplier of semiconductors. Except during periodic downturns, memory ICs have historically boosted all of these suppliers' revenue growth and strength in the overall market. Toshiba's worldwide market share by product over the past 10 years is presented in Table 4-20.

Table 4-17
Toshiba's Product Distribution by Region, 1997 (Millions of Dollars)

Products	Americas	Europe	Japan	Asia/Pacific	Total

No. 6: Hitachi

Hitachi's ranking position declined from No. 4. Of the top 20, Hitachi suffered the largest year-to-year change in revenue, experiencing a decline of 22 percent in 1997. Table 4-21 shows the source of Hitachi's revenue in 1997 by product and region.

Founded in 1910, Hitachi's business segments are divided into systems and electronics, power and industrial systems, consumer, materials, and services. The 10-year history of Hitachi's revenue for each of the major semiconductor product categories is given in Table 4-22.

Figure 4-11 illustrates the difference in growth rate between Hitachi and the total semiconductor industry since 1987. Figure 4-12 illustrates Hitachi's capital spending history and how it compares to the region's total spending during the same time frame.

The contribution of each of the product categories to Hitachi's total semiconductor sales is shown in Table 4-23. Hitachi's share of the worldwide market by product is shown in Table 4-24.

Table 4-21
Hitachi's Product Distribution by Region, 1997 (Millions of Dollars)

No. 7: Samsung

Samsung was the second company of the top 20 to report a large year-to-year decline in total semiconductor revenue. Its revenue declined 9.4 percent; most of this decline stemmed from significant losses taken in memory revenue. Table 4-25 shows the source of Samsung's revenue in 1997 by product and region.

Samsung was established in 1969. Its revenue is drawn from semiconductors, home appliances, computers, and communications. Samsung continues to invest heavily in the memory area with developments of the 1Gb DRAM in 1998. Table 4-26 shows 10 years of Samsung's revenue by product family.

Figure 4-13 illustrates the difference in growth rate between Samsung and the total semiconductor industry since 1987. Because of the enormous growth rate seen in 1987, the scale of this chart is quite different from that of the others in this chapter. Samsung has consistently grown faster than the market, even when DRAMs were growing more slowly than the market, because of consistent growth in market share, even in down markets. Figure 4-14 illustrates Samsung's capital spending history in comparison to the region's spending.

The contribution of each of the product categories to Samsung's total semiconductor sales is shown in Table 4-27. Memory ICs dominate Samsung's product line, but the other product categories are showing signs of growth. Table 4-28 lists Samsung's share of worldwide product revenue. Samsung continues to gain share of memory revenue even in a market downturn.

Table 4-25
Samsung's Product Distribution by Region, 1997 (Millions of Dollars)

Products	Americas	Europe	Japan	Asia/Pacific	Total
Total Semiconductor	**2,105**	**1,240**	**589**	**1,922**	**5,856**

No. 8: Fujitsu

Fujitsu retained the No. 8 position. Table 4-29 shows the sources of Fujitsu's 1997 semiconductor revenue by product and region.

Fujitsu was established in 1935. Its business revenue is drawn from computer and data processing systems, communications systems, and electronic devices including ICs, relays, and connectors, as well as from other product operations. A 10-year history of Fujitsu's revenue for each of the major semiconductor product categories is given in Table 4-30.

Figure 4-15 illustrates the difference between Fujitsu's growth rate and that of the total semiconductor industry since 1987. Figure 4-16 shows Fujitsu's capital spending history and how it compares with regional spending.

The contribution of each of the product categories to Fujitsu's total semiconductor sales is shown in Table 4-31. Table 4-32 lists Fujitsu's share of the worldwide market by product.

No. 9: Philips

Philips was one of 11 of the top 20 semiconductor suppliers to show positive growth in most areas. Table 4-33 shows the distribution of Philips' 1997 semiconductor revenue by product and region.

Philips' business revenue is drawn from six major divisions: consumer products, professional products and systems, lighting, components, semiconductors, and other miscellaneous products. Philips' revenue for each of the major semiconductor product categories in 1997 is given in Table 4-34.

Figure 4-17 illustrates the difference between Philips' growth rate and that of the total semiconductor industry since 1987. Figure 4-18 illustrates Philips' capital spending history and how it compares to the region's total spending during the same time frame.

The contribution of each of the product categories to Philips' total semiconductor sales is shown in Table 4-35. Philips' share of the worldwide market by product is listed in Table 4-36.

Table 4-33
Philips' Product Distribution by Region, 1997 (Millions of Dollars)

Products	Americas	Europe	Japan	Asia/Pacific	Total
Total Semiconductor	**831**	**1,847**	**182**	**1,580**	**4,440**

No. 10: STMicroelectronics

STMicroelectronics, formerly named SGS-Thomson, maintained its No. 10 position but saw a 2.3 percent decline in revenue from 1996 to 1997. Table 4-37 lists the distribution of the company's 1997 semiconductor revenue by product and region.

STMicroelectronics' revenue in 1997 for each of the major semiconductor product categories is given in Table 4-38.

Figure 4-19 illustrates the difference between STMicroelectronics' growth rate and that of the total semiconductor industry since 1987. Figure 4-20 illustrates STMicroelectronics' capital spending history and how it compares to regional spending.

The contribution of each of the product categories to STMicroelectronics' total semiconductor sales is shown in Table 4-39, and its product share of the worldwide market is shown in Table 4-40.

Table 4-37
STMicroelectronics' Product Distribution by Region, 1997 (Millions of Dollars)

No. 11: Mitsubishi

Mitsubishi maintained its No. 11 position, and and its revenue declined by only 4.3 percent in 1997. Table 4-41 shows the sources of Mitsubishi's 1997 semiconductor revenue by product and region.

A 10-year history of Mitsubishi's revenue for each of the major semiconductor product categories is given in Table 4-42.

Figure 4-21 illustrates the difference between Mitsubishi's growth rate and that of the total semiconductor industry since 1987. Figure 4-22 illustrates Mitsubishi's capital spending history and how it compares with regional spending.

The contribution of each of the product categories to Mitsubishi's total semiconductor revenue is shown in Table 4-43. Its share of the worldwide market by product is shown in Table 4-44.

Table 4-41

No. 12: Siemens

Siemens strengthened its ranking and was one of six of the top 20 companies that showed double-digit growth in revenue in 1997. Table 4-45 lists Siemens' 1997 semiconductor revenue by product and region.

Siemens AG was founded in 1847 by Werner von Siemens. After 151 years in business, its revenue is drawn from five sectors: communications systems, industrial technology, power generation, information technology, and other technology. Siemens' semiconductor revenue in 1997 for each of the major semiconductor product categories is given in Table 4-46.

Figure 4-23 illustrates the difference between Siemens' growth rate and that of the total semiconductor industry since 1987. Figure 4-24 illustrates Siemens' capital spending history and how it compares to the region's total spending.

The contribution of each of the product categories to Siemens' total semiconductor revenue is shown in Table 4-47. Table 4-48 lists Siemens' share of the worldwide market by product.

Table 4-45
Siemens' Product Distribution by Region, 1997 (Millions of Dollars)

No. 13: IBM

IBM's overall semiconductor revenue stabilized at 6 percent in 1997. Table 4-49 shows the sources of IBM's 1997 semiconductor revenue by product and region. IBM's business revenue is drawn from five sectors: hardware, which includes the company's high-end and midrange processors, PCs, and RISC workstations; services; software; maintenance; and financing and other operations. Table 4-50 lists IBM's product profile for 1993 to 1997.

Without a full set of historical data to look at, the comparison of IBM revenue growth with that of the semiconductor industry is of limited value but is nonetheless presented in Figure 4-25. The company's capital spending history for the same time frame is illustrated in Figure 4-26.

IBM's product contribution and focus is digital. Each of its major product families is shown in Table 4-51. IBM's share of the worldwide market by product is shown in Table 4-52.

No. 14: Matsushita

Matsushita's ranking did not change much from 1996, but its revenue declined 5.2 percent in 1997. Matsushita is a very strong vertically integrated company; its merchant market presence is small, but its Panasonic, National, Technics, and Quasar name brands are well-known product consumers. Table 4-53 shows the sources of Matsushita's 1997 semiconductor revenue by product and region.

Matsushita was established in 1918. Its semiconductor revenue is but a small portion of a very large corporation whose business revenue is drawn from four major segments: communications/industrial equipment, audio-visual equipment, home appliances, and other appliances. Matsushita's 1997 revenue for each of the major semiconductor product categories is given in Table 4-54.

Figure 4-27 illustrates the difference between Matsushita's growth rate and that of the total semiconductor industry since 1987. Matsushita's presence in memories is small. Therefore, the company's growth or decline will not be as rapid as that of the total market. Figure 4-28 illustrates Matsushita's capital spending history and how it compares to its region's spending history.

The contribution of each of the product categories to Matsushita's total semiconductor revenue is shown in Table 4-55. Its share of the worldwide market by product is shown in Table 4-56. Matsushita is a very stable broad-line semiconductor supplier as would be expected of a vertically integrated consumer electronics vendor. The product lines support the end-equipment needs, but the end-equipment market for non-PC-related products has been slowing.

Table 4-53
Matsushita's Product Distribution by Region, 1997 (Millions of Dollars)

Products	Americas	Europe	Japan	Asia/Pacific	Total

No. 15: Lucent Technologies

The microelectronics division of Lucent Technologies grew by more than 30 percent in 1996 and 30.9 percent in 1997. The company moved from the No. 25 spot in 1995 to the No. 20 rank in 1996 and up to the No. 15 position in 1997. Lucent's strength in product acceptance and improvement in product marketing is well worth mentioning, because the company did not even rank in the top 40 in 1994. Lucent's semiconductor revenue from the merchant market has been available only since 1994. Spun off from AT&T in 1994, Lucent's revenue is drawn from the following segments: network systems, business communications systems, microelectronics, consumer products, and other products. Table 4-57 illustrates Lucent's semiconductor revenue in 1997 by product and region. At 30.9 percent, Lucent had the largest year-to-year growth of the top 20 in 1997. The company's product profile is listed in Table 4-58.

Figure 4-30 illustrates the difference between Lucent's growth rate and that of the total industry. Figure 4-31 shows Lucent's capital spending history and how it compares to the region's total spending during that time frame. Table 4-59 lists the contribution of each of Lucent's products to its total semiconductor revenue. Table 4-60 lists the market shares of Lucent's products in the worldwide market.

No. 16: National Semiconductor

National Semiconductor maintained its No. 16 ranking but grew its year-to-year revenue by 15.9 percent. Table 4-61 shows the sources of National's 1997 semiconductor revenue by product and region. National's revenue in 1997 for each of the major semiconductor product categories is listed in Table 4-62.

Figure 4-31 illustrates the difference between National's growth rate and that of the total semiconductor industry since 1987. Figure 4-32 shows National's capital spending history and how it compares to the region's total spending during the same time frame.

The contribution of each of the product categories to National's total semiconductor revenue is shown in Table 4-63. National's shares of the worldwide market by product are shown in Table 4-64.

No. 17: SANYO

SANYO's ranking dropped from No. 15 to No. 17 in 1997. Its revenue declined 0.8 percent from 1996 to 1997. SANYO's product and revenue strength has traditionally been in the analog and discrete areas. The sources of SANYO's revenue, by product and regional market, are shown in Table 4-65.

SANYO was established in 1947. Its corporate revenue is drawn from seven business segments: information systems and electronic devices, home appliances, industrial and commercial equipment, video equipment, audio equipment, batteries and other products, and other products. SANYO's 1997 revenue for each of the major product categories is given in Table 4-66.

Figure 4-33 illustrates the difference between SANYO's growth rate and that of the total semiconductor industry since 1987. Figure 4-34 illustrates the company's capital spending history and how it compares to the region's total spending.

The contribution of each of the product categories to SANYO's total semiconductor sales is shown in Table 4-67. SANYO's revenue contribution by product has remained quite stable over the past 10 years. SANYO's shares of the worldwide market by product are shown in Table 4-68.

No. 18: Advanced Micro Devices

Advanced Micro Devices was founded in 1969. AMD's share of market and ranking has changed radically since the company's beginning. AMD shifted its ranking position from No. 22 to No. 18 in 1997 through the growth of its memory, logic, and microprocessor product groups. Net sales in 1997 for each of AMD's business segments were as follows: the Memory Group ($724 million); the Communications Group ($702 million); the Computation Products Group ($682 million); and Vantis, its programmable logic subsidiary ($243 million). Table 4-69 lists AMD's products for 1997 by region. Table 4-70 presents a 10-year history of AMD's products.

Figure 4-35 illustrates the difference between AMD's growth rate and that of the total semiconductor industry since 1987. Figure 4-36 illustrates AMD's capital spending history and how it compares to the region's total spending. Table 4-71 lists AMD's total product revenue as a share of the company's revenue. Table 4-72 lists AMD's share of the worldwide market by product.

No. 19: Sharp

Sharp Corporation was founded in 1912 by Tokuji Hayakawa. From snap-buckles and "Ever-Sharp" pencils, the company, as of March 1998, emerged into a ¥1,790,542 million electronics company with four major business segments. For fiscal 1997 the company's segments' shares of sales revenue were as follows: audiovisual equipment (24.3 percent), home appliances (15.8 percent), communications and information equipment (33.2 percent), and electronic components (26.8 percent). In semiconductors, Sharp achieved a 1 percent revenue increase in 1997, after an 18 percent decline in 1996. Table 4-73 lists Sharp's semiconductor revenue by product and region. The product segments of this company cater to the electronics world. Sharp's semiconductor revenue by product categories in 1997 is listed in Table 4-74.

Figure 4-37 illustrates the difference between Sharp's growth rate and that of the total semiconductor industry since 1987. Sharp is still the No. 1 supplier in optical semiconductors. Figure 4-38 illustrates Sharp's capital spending history and how it compares to the region's total spending. Table 4-75 lists the contribution of each of the product categories to Sharp's total semiconductor revenue. Sharp's share of the worldwide market by product is shown in Table 4-76.

No. 20: Rohm

Rohm was established in Kyoto, Japan, in 1958. The company's semiconductor products include hybrid ICs, transistors, diodes, LEDs, laser diodes as well as resistors, capacitors, LCDs, thermal heads, image sensor heads, and LED displays. As of March 1998, sales were distributed among product categories as follows: ICs (40.1 percent), discrete devices (39.1 percent), passives (12.0 percent), and displays (8.8 percent). Sales by region during that same time were distributed as follows: North America/South America (9.7 percent), Europe (8.8 percent), Japan (46.2 percent), and Asia (35.3 percent). Table 4-77 illustrates the source of Rohm's semiconductor revenue in 1997 by product and region. The company's product profile for 10 years is listed in Table 4-78.

Figure 4-39 illustrates the difference between Rohm's growth rate and the total industry for 10 years. Figure 4-40 shows Rohm's capital spending history and how it compares to the region's total spending during that time frame. Table 4-79 lists the share of each of Rohm's product revenue to its total semiconductor revenue. Table 4-80 lists the market shares of Rohm's products in the worldwide market.

Chapter 1
Executive Summary

Despite continued economic troubles in Japan and elsewhere in Asia, Japanese vendors still engaged in a relatively high number of semiconductor-related alliances in 1997. For the second year in a row, the number of Japanese semiconductor-related alliances rose. Figure 1-1 illustrates the Japanese semiconductor alliance rate from 1980 through 1997.

There are growing indications from alliance activity in 1997 that Japanese vendors are banking on the market success of merged logic-DRAM technology as the future mainstay of their semiconductor businesses. The timing of a transition from a DRAM-centric to an embedded DRAM-centric strategy is significant, because a miscalculation by Japanese vendors could cause them to lose ground in the development of next-generation commodity DRAMs while they divert resources toward the development of embedded DRAM products. The possible gains, however, are significant because the technology has the potential to increase market share in the application-specific IC (ASIC) and logic businesses, a goal that most Japanese vendors have targeted for several years. Alliances not only will allow Japanese vendors to redistribute their resources from a DRAM to an embedded DRAM production orientation, which would effectively merge their now separate memory and logic businesses into a single unit, but they might also provide a fast-response safety net in case the companies' projected time line is off and they need to retreat to a more conservative strategy. If the embedded DRAM technology, for whatever reason, fails to mature before commodity DRAMs return to a supply-limited market, alliances will almost certainly be used as a mechanism for Japanese companies to get back into the commodity DRAM business.

Chapter 2

Diversification and Resource Allocation with Alliances

Many parts of the electronics industry were showing signs of weakness as 1997 came to a close. DRAM production lines were either being shut down or had their expansion plans delayed. Semiconductor fabrication equipment manufacturers experienced order cancellations that eventually led to layoffs of substantial portions of their workforces. Even application vendors, such as disk drive producers, were experiencing market pressures that have resulted in corporate restructuring. While the economic crisis in many parts of Asia, particularly Korea, has forced a change in the semiconductor business practices at companies in these countries and will undoubtedly have a ripple effect on electronics companies worldwide, Japan's economy has, for several years, remained in a state bordering on recession. Despite the weak economic condition of Japan, its domestic PC markets were expected to continue the growth trend that had been established during the previous year. During 1996, PC prices had fallen to world market levels, which caused a growth spurt in PC sales. However, by mid-1997, sales had flattened even though DRAM prices continued to fall, lower-priced machines had been introduced into the Japanese market, and PCs had far less penetration in the Japanese home market than in the United States.

The economic crisis that was beginning to affect many Asian countries in the last quarter of 1997 does not seem to have had much impact on the overall number of alliances that Japanese companies signed in specific countries or regions in the past two years. Nearly 60 percent of the Japan's semiconductor alliances formed in 1997 were with U.S.-based partners. This level is more or less unchanged from 1996 and reflects the continued importance that Japanese vendors place on partnerships with American companies. Figure 2-1 shows the percentage of the alliances that pair a Japanese company with a U.S.-based company over the last 13 years.

DRAMs and 300mm Equipment

In 1997, Japanese vendors continued their quest to diversify away from their traditional overdependence on DRAM revenue. However, in implementing diversification plans, there are often conflicting goals that require a delicate balance of priorities in business strategy, particularly with regard to alliances. A transition to 300mm wafer production is clearly a long-term technology change that all major Japanese vendors will seek to make to remain cost competitive, but it will be difficult to justify the necessary investment in the face of a money-losing DRAM business. Furthermore, most vendors will need to secure permanent sources of commodity DRAMs for both internal consumption and to maintain their semiconductor sales organizations. The difficulty of achieving these goals increased during the year as DRAM prices continued to fall in an oversupplied market. The mass transition to 300mm production technology will occur eventually, but the weak DRAM market will likely delay or slow the adoption rate, because the large-scale equipment consumption of the commodity DRAM manufacturers will be a prerequisite to reducing the cost of 300mm equipment and make it affordable to the majority of logic and ASIC producers. For this reason, commodity DRAM alliances will likely continue with specific emphasis on 300mm equipment development. On the other hand, if DRAMs do not return to profitability before deployment of embedded DRAM products that can generate self-sustaining revenue, then a company could justify minimizing its DRAM-specific investments, farm out commodity DRAM production, and focus resources on building and accelerating its embedded DRAM capabilities. Alliances seem to provide a lot of flexibility for companies to distribute their resources to match their particular array of priorities.

 ©1998 Dataquest

Alliances Send DRAM Production to Partners

Four alliances explicitly involving commodity DRAM occurred in 1997, but almost all can be interpreted within the context of a strategy that diversifies away from an emphasis on the commodity DRAM business (see Table 2-1). This has generally meant developing 300mm technology in joint ventures or licensing DRAM production technology to foreign-based companies, of which the Japanese company may hold a minority stake, in order to secure production output. As an example of transferring DRAM production to foreign companies, Toshiba Corporation agreed in February 1997 to purchase 20 percent of the Austin, Texas-based 64Mb DRAM facility of Samsung Electronics Company Ltd., allowing OEM procurement for Toshiba of 20 percent of the production output. In September 1997, Toshiba also provided Taiwan-based Winbond Electronics Corporation with DRAM production technology, which will secure a supply of both 64Mb and 256Mb from the Taiwan-based facility. Finally, in October 1997, Mitsubishi Electric Corporation agreed to provide Seiko Epson Corporation with 64Mb production technology. Mitsubishi will initially purchase all the production output of Seiko Epson's Sakata plant. Earlier, in May 1997, Mitsubishi had licensed Seiko Epson to produce video memory, also to be built at the Sakata plant, that would integrate 10Mb of DRAM with 2Kb of SRAM and graphics interface logic. All these alliances are consistent with a strategy of diversifying resources away from commodity DRAMs.

The only major joint venture of 1997 involving DRAMs was signed in February by Hitachi Ltd., Mitsubishi, and Texas Instruments Inc. and specified that the partners would jointly develop 1Gb DRAMs. However, this project was put on hold in February 1998. Although the partners have specified that they will resume joint development of 1Gb DRAM in one year, the future of this project will probably depend on the market outlook in 1999.

When Will 300mm Standardization Arrive?

Several other alliances made in 1997 address 300mm technology development.

Toshiba and IBM will cooperate in commercializing 300mm production, and will possibly set up a 300mm line at their joint production plant. Similarly, NEC Corporation and Samsung have agreed to share development of 300mm wafer fabrication equipment and technology across their memory plants. Both alliances are expected to have operational 300mm wafer production lines up and running by 1999. The oversupply of DRAMs, along with weak Asian currencies and economies, are contributing to very tentative ramp-ups of Japanese, Korean, and Taiwanese next-generation DRAM and 300mm wafer facilities. However, although no company has voiced concern, it seems that, if Japanese companies intend to focus their semiconductor businesses on embedded DRAM products, then they would not want any delay in the arrival of next-generation DRAM capabilities that would impede the transition to the next level of embedded DRAM products. This, of course, assumes there exists a next-level single-chip device or application that can use the higher amounts of DRAM, and presumably faster logic, provided by the next-generation merged processes. The applications that will drive the adoption of next-generation embedded DRAM products are not clear, but there are a few candidates, as described in the following sections. This uncertainty is a looming factor in the decision process that will dictate how Japanese vendors structure their alliance activities.

From DRAMs to Embedded DRAMs: How Fast Can We Get There?

There are skeptics, including individuals representing companies such as Intel Corporation, who have voiced their conviction that embedded DRAM technology will never become a mainstream technology. The basis of their argument is that the logic and memory processes of the future are incompatible. Nevertheless, if the critics are proven wrong, this would be somewhat ironic because Intel itself has essentially used its own processing expertise, including the use of BiCMOS, to counter the assault of RISC, with its inherent performance advantages, over the last few years. There have been many processing transitions over the years, such as NMOS to CMOS and bipolar to BiCMOS, and with each transition, there were always a few who either did not believe the new technology would ever become competitive or who miscalculated the timing of the transition. Today, there are enough companies that seem convinced that combining DRAM with fast logic is both feasible and an inevitable mainstream technology that one must consider the implications if these companies are correct. History has frequently proven that processing and circuit innovation has consistently surmounted the barriers they have encountered. The accuracy of Moore's law is a testament to the steady progress being made in integration capabilities. Table 2-2 lists the alliances occurring in 1997 that explicitly covered embedded DRAM technology. However, many of the other alliances of 1997, particularly those relating to RISC MPUs—described in a subsequent section—have also been extended to cover embedded DRAM technology. This is a logical extension of these alliances, since many RISC alliances involve the use of cores in ASIC libraries, which have recently been expanded to include embedded DRAM in addition to the usual RISC cores.

Notebook Graphics Accelerators Still the Only Application for Embedded DRAM in 1997

In contrast to the splash that embedded DRAM alliances made in 1996, the alliance activity involving embedded DRAM technology in 1997 was very subdued. Part of the reason for this is that the graphic accelerator market, the initial market to capitalize on the benefits of embedded DRAM technology, had become overcrowded in 1997. Too many players meant steep drops in accelerator prices and shrinking market windows that resulted in some once high-flying start-ups dropping off the radar screen. With these conditions, it wasn't surprising that the shifts in the market diverted attention away from the progress being made on the merged logic-DRAM processing front. Moreover, falling graphics controller and accompanying memory prices may have also confined the embedded DRAM graphics controllers to the notebook segment only, where power efficiency is the primary selling point, and prevented migration to the desktop world, where the ratio of processing power to cost is usually the only criterion that determines market success.

Although only three or four alliances explicitly involving embedded DRAM technology were signed by Japanese companies in 1997, two of the 1997 alliances were inked by Toshiba. In June, Toshiba licensed its 0.35-micron DRAM-mixed logic technology, later to be migrated to 0.25-micron, to Chartered Semiconductor Mfg. Pte. Ltd. of Singapore. Chartered is expected to launch production with this technology in 1998. As an update to a Toshiba-Chromatic Research Inc. alliance formed in 1995, Toshiba has disclosed plans to use the second generation of Chromatic's Mpact 2 core in an embedded DRAM chip targeting notebook computers. The Mpact DSP uses a very long instruction word architecture, and the Toshiba part will be built sometime in 1998 with 4MB of DRAM and a 128-bit internal bus using Toshiba's 0.25-micron merged logic-DRAM process. The Mpact 1 and 2 were originally designed to use the Rambus DRAM and interface, and the move to an embedded DRAM part is expected to reduce power consumption by several watts, an important savings for notebook applications.

 ©1998 Dataquest

Interestingly, Toshiba also signed an alliance agreement in May 1997 to act as foundry for NeoMagic Corporation notebook graphics controllers. Strong demand for NeoMagic controllers has evidently required the company to supplement its supply of controllers being produced by Mitsubishi. Mitsubishi, an original investor in NeoMagic, will continue to make embedded DRAM controllers for NeoMagic; however, both Mitsubishi and Toshiba are, or shortly will become, competitors to NeoMagic because both have plans to build graphic controllers for notebook applications using their own designs and embedded DRAM technology. As seen below, the Mpact digital signal processor (DSP) is not the only device intended to make a transition from an external Rambus memory interface to an embedded DRAM solution.

Teams Research Multiple-MPU Parallel Processing with Embedded DRAM

Although no Japanese vendor has yet announced a formal alliance with the start-up PixelFusion Limited, based in Bristol, England, its work is particularly interesting in that it is specifically addressing the needs of the very high end of 3-D graphics accelerators by using massively parallel designs, developed at the University of North Carolina at Chapel Hill, in conjunction with an implementation in a merged logic-DRAM process. Silicon prototypes have been built by Chartered Semiconductor Manufacturing of Singapore, but the demands of building numerous processing units with large amounts of memory on a single chip may call for cutting-edge processes. It would therefore not be surprising if PixelFusion sought Japanese vendors as alliance partners to build its production designs. Indeed, the work at PixelFusion parallels the three-year research project being conducted at a Japanese consortium formed at the end of 1996. Based on the work of Professor Murakami from Kyushu University, the consortium initially anticipated that media processors using parallel processing architecture would reach the market by 1998. Similarly, a European research consortium, based at a university in Belgium, announced in December 1997 its intention to develop MPEG-4 chips that will be implemented with mixed logic-DRAM technology. Japanese partners have been included in the consortium, and project is also scheduled to run for three years, beginning in January 1998.

Because Japanese vendors arguably have been working on the development of embedded DRAM technology the longest, they have entered into several noteworthy alliances covering embedded DRAMs. This alliance activity is expected to continue; however, it should also be noted that there are conflicts within the industry that seem to be having a distinctly antialliance effect. Japanese vendors are currently suing several of their major Korean DRAM competitors for royalty payments, and, in some cases, seeking injunctions designed to prevent Korean vendors from selling their parts in the United States. With the Koreans expected to follow the Japanese vendors into the merged DRAM-logic markets, it may be that recent legal actions against the Korean companies are designed to force these competitors to pay for some of the cost of developing an embedded DRAM technology that is likely to benefit all manufacturers eventually, including Korean vendors.

 ©1998 Dataquest

As strange as it might sound, the legal action may actually have the effect of promoting alliances involving embedded DRAM development between Japanese and Korean vendors. Considering the lack of profit from the sales of commodity DRAMs, the cost of developing embedded DRAM technology will be difficult to sustain—predicting when a profitable return-on-investment will occur is not trivial, because it is dependent on finding the right uses for the technology at the right time. Furthermore, once an effective embedded DRAM process is achieved, the learning curve for nondevelopers will be simplified by information passing by way of both direct and indirect alliances. The Korean memory vendors will benefit from the pioneering work and probably cannot afford to pioneer the technology independently. The recent legal action by Japanese vendors is expected to force some Korean vendors to at least discuss either royalty payments, which would help defray the cost of developing technology, or more alliances in which vendors share the development cost of next-generation technologies.

ASICs Combine RISC Cores with Embedded DRAM to Open New Application Areas

Embedded DRAM may need to become the primary driver of the transition to 300mm technology if DRAMs continue to provide inadequate return on investment. Intel is sufficiently afraid of a mass vendor exit from the commodity DRAM business and the potential for a subsequent DRAM shortage that might affect its own microprocessor sales that the company is considering boosting its investments in major DRAM vendors by $1 billion. Meanwhile, most Japanese vendors are pushing ahead with research and development of merged logic and DRAM processes that seeks to minimize performance compromises. Besides graphics controllers for portable computing platforms, embedded DRAM products were expected to make their next appearance in hard disk drives. Because the disk drive industry seems to be in turmoil, there is less discussion of this happening soon. However, many other applications are being discussed as possible system-on-a-chip implementations that would include on-chip DRAM. A number of alliances that originally covered collaboration or licensing of RISC technology have been expanded to include RISC microcontroller (MCU) cores combined with embedded DRAM.

Alliances in Video Games, Windows CE Machines, ...

NEC is working with Nintendo Company Ltd. to eventually migrate its MIPS RISC-based video game controllers away from use of a Rambus memory interface architecture to a more efficient embedded DRAM solution. As with most custom ASICs, this can result in a lower cost-to-performance ratio in very high-volume applications only, such as video game consoles. This application is interesting because it represents a mass market product that, unlike the notebook graphics controller, is probably not using the superior power consumption efficiency of the embedded DRAM technology as its primary selling point. NEC expects to have available to ASIC customers by spring 1998 the capability of merging 200-MHz logic with 32Mb of 100-MHz DRAM connected over a 128-bit bus.

 ©1998 Dataquest

The electrical and market performance of both the Nintendo embedded DRAM video controller and Toshiba's embedded DRAM Mpact 2 chip, both having potentially abandoned the Rambus interface and memory combination, may provide an interesting comparison benchmark for ASIC customers thus far unconvinced of the advantages of using embedded DRAM technology.

In early February 1998, Sega Inc. confirmed a long-rumored alliance with Microsoft Corporation to cooperate on the construction of a game machine. The confirmation by Sega included the revelation that the new platform will use the Windows CE operating system. Just as with the Nintendo-NEC alliance, the Sega-Microsoft game console is an application that can benefit from the use of an integrated game controller that merges embedded DRAM with logic. Dataquest would therefore expect to see in the not too distant future an alliance with a semiconductor producer, such as a manufacturer already building RISC cores for Windows CE platforms and probably at least planning on an embedded DRAM version of the Windows CE device. A large and growing number of vendors would qualify for such a project.

In the first quarter of 1997, Mitsubishi began working with ACCESS Corporation to customize a Mitsubishi chipset for use in portable Internet terminals, which include the M32R/D, a 32-bit RISC processor currently embedded with 2MB of DRAM. This processor family is scheduled to reach a clock speed of 400 MHz with 16MB of embedded DRAM, built with a 0.2-micron geometry, by the year 2000. Mitsubishi will also codevelop, as well as cross license, microcomponent cores embedded with DRAM with Motorola Incorporated, as a continuation of an alliance formed in October 1996. This alliance involves an embedded DRAM version of Mitsubishi's M32R and Motorola's 68EC000 and Coldfire processors.

In the second quarter of 1997, Toshiba partnered with Sun Microsystems Inc. to develop a Java processor for use in network computers. The microJava chip will incorporate a picoJava core, a memory controller, and embedded DRAM. Toshiba also announced in July 1997 the development of its MIPS based, Virtual Socket Interface (VSI)-compliant, TX19. This is a low-power, low-cost, embedded RISC processor that Toshiba intends to combine with embedded DRAM in the company's 0.25-micron DRAM-ASIC process.

In the third quarter of 1997, Hitachi announced that its SH-3 and SH-4 RISC MPU cores would be available in an embedded DRAM-enabled 0.35-micron process that ASIC clients can use to add DRAM in 256Kb increments, called "micromodules" by Hitachi. By 1999, Hitachi expects to field an SH-4 core with flash and micromodules based on 256Mb 0.25-micron DRAM technology. The number of RISC core license agreements, combined with embedded DRAM agreements, would suggest that mobile computing devices, particularly Windows CE machines, are expected to become a significant product segment making heavy use of system-on-a-chip designs that include embedded DRAM.

In the fourth quarter of 1997, NEC and Lucent Technologies formalized an alliance that has Lucent licensing NEC's V800 series of RISC MCUs. As part of this alliance and possibly two previous alliances formed between the partners in June and October 1996, the two companies are said to be working together on an embedded DRAM process that Lucent expects to incorporate into its own 0.25-micron ASIC process by mid-1999.

Table 2-3 shows the alliances that covered RISC technology in 1997.

Table 2-3
RISC-Related Alliances

Chapter 3

Displays, Micromachines, and Sensors Also Head toward Merged Processes

The synergy between traditional semiconductor circuits and integrated displays, sensors, and micromachines continues to grow and, in some cases, is already showing signs of merging with mainstream IC manufacturing. Moreover, VSI will facilitate the connection of not only standard IC cores, but also a growing array of new, CMOS-compatible devices that include sensors, micromachines, and even displays. Although start-up companies have always been expected to gamble on some of these esoteric technologies, many traditional IC companies, never having strayed too far from standard analog or digital IC fabrication technologies (at least in production), are also aggressively building exotic production-worthy process portfolios. For example, National Semiconductor Corporation is attempting to build active-matrix LCDs on standard wafers, Toshiba and Atmel Corporation are building CMOS image sensors, and Texas Instruments has made a heavy, highly publicized investment in its micromachined mirrors, also on standard wafers. The integration of such technologies with a memory-logic process should allow for the creation of such things as a true system-on-a-chip digital camera.

Although traditional IC manufacturing processes are incorporating more nonstandard components, from the opposite end of the processing spectrum, flat panel display manufacturers are starting to build circuits on their thin semiconductor films on glass or quartz substrates. There has been a recent surge in active-matrix LCDs research as this segment of the flat panel display industry continues to give upstart flat panel technologies a moving target. Nine new alliances involving LCDs occurred in 1997, which outpaced the LCD alliance activity of 1996. These alliances are listed in Table 3-1. The breadth of the technologies that are being combined with liquid polarizing crystals is beginning to overwhelm the work in other nascent technologies, such as field emission devices (FEDs), to the degree that some may already have missed their window of opportunity for commercialization because of the rapidly falling cost and improving performance of active-matrix LCDs. Active-matrix LCD reflective displays are being touted for their extreme power efficiency in mobile computing and communications applications, as well as for use in head-mounted displays or viewfinders in digital cameras and camcorders. Windows CE machines and personal digital assistants (PDAs) are expected to be among the first application markets to benefit from efficient reflective devices, some equipped with part-time backlighting capabilities. Sharp Electronics Corporation announced in September 1997 a reflective display for Windows CE machines that features a 30 percent reflection and 10:1 contrast ratio.

On the materials research front, the films used to make active-matrix LCD panels are continuing to reach higher quality levels—meaning fewer defects. Although low-temperature polysilicon films are just beginning to reach commercialization, the films still in development are even closer in characteristics to bulk crystalline silicon. The fundamental materials and thin-film transistor research is yielding advances that suggest that active-matrix LCD and system ICs may well merge into another hybrid class of devices based on yet another merged process. Along these lines, Sharp's continuous grain silicon has continued the trend of improving thin films from amorphous films toward the ultimate goal of crystalline silicon-like electrical characteristics. Achieving this goal would improve the performance of active-matrix LCDs, as well allow the construction of all peripheral circuits right on the same substrate, with improved yield. If this trend continues, the 300mm technology of the silicon wafer industry may begin to have even more in common with the flat panel TFT processing technology than it already has.

Chapter 4
Dataquest Perspective

There is a prevailing notion that for some Japanese vendors, DRAMs and embedded DRAMs have become one and the same industry. During the current DRAM oversupply, it appears that many Japanese chip vendors will continue to use alliances either to shift their commodity DRAM production to offshore joint ventures or to completely transfer their commodity production to licensed Asian partners. At the same time, the major Japanese vendors will attempt to accelerate the transition to embedded DRAM technology for a widening array of multichip products that currently use separate memory parts, particularly those that either require better power-consumption performance, such as notebook computer components, or that rely on high-speed logic-to-memory buses, such as the Rambus interface. There is certainly risk in this strategy, because the Japanese vendors may be forcing themselves to exit the commodity DRAM prematurely, at a time when embedded DRAM revenue may be insufficient to support the upgrades to 300mm equipment. However, the DRAM business for many Japanese vendors is a losing proposition with a cloudy outlook, and the successful deployment of a competitive embedded DRAM technology has the potential to boost the competitiveness of Japanese ASIC and logic businesses substantially. Moreover, alliances may also provide a fast recovery mechanism if the transition to systems-on-a-chip, using embedded DRAM technology, is delayed or the commodity DRAM business again becomes too lucrative to ignore. Regardless of how individual Japanese companies will implement their particular memory and ASIC strategies, the common denominator is certain to be their use of alliances to adapt quickly to market conditions and technology shifts. There are just too many advantages to alliances that outweigh the potential drawbacks.

The last U.S.-Japan Semiconductor Trade Agreement was allowed to expire over a year ago. The robust rate at which Japanese and U.S. companies have entered into new alliances since the expiration, as well as the continuing high market share of foreign companies in Japan, often exceeding 30 percent in the past year, provides some support for those that argue that the decision not to renew the trade agreement at the end of July 1996 was correct.

Appendix A
1997 Japanese Semiconductor Strategic Alliances

Table A-1 lists the companies involved in publicly announced strategic alliances occurring in 1997. The individual alliance agreements are summarized in Appendix.

Dataquest classifies strategic alliances into the following 12 major categories.

- LA—Licensing agreement: A Japanese company receives or issues a license to a partner for an up-front fee or royalties.
- SS—Second-source agreement: Both companies agree to develop consistent specifications to ensure a second source.
- SA—Sales agency agreement: A Japanese company sells its partner's products, either as a sales representative or value-added reseller (VAR).
- FA—Fab agreement: A Japanese company offers fab capacity for a partner's product technology.
- AT—Assembly and testing agreement: A Japanese company sends or receives devices for assembly or testing.
- TE—Technology exchange: Both companies exchange technology, which may or may not include a transfer of money.
- JV—Joint venture: The two companies form a new joint-venture company to develop, manufacture, and market new products.
- JD—Joint development: Both companies agree to develop new products jointly, which may or may not be marketed separately.
- IV—Investment: A Japanese company invests in a partner company to secure new technology or access to new markets.
- CO—Coordination of standards: A Japanese company and a partner agree to device standards to ensure compatibility.
- PC—Procurement agreement: A Japanese company agrees to buy more foreign semiconductors as part of market access program.
- OT—Other: Joint symposia and programs

Appendix B
1997 Alliance Agreements

Access

1. National Semiconductor (United States), September 1997

National Semiconductor Japan has teamed up with Tokyo-based software developer Access in the systems development for Internet-capable home electronics. The Japanese subsidiary of National Semiconductor intends to supply home electronics makers in Japan with a system-on-a-chip LSI that supports Access' Internet connection and search program, Netfront. The system-on-a-chip LSI centers around National's NS486 processor core, complying with Intel's x86 architecture, and integrates PCMCIA controller, IrDA, and other peripherals, providing all the functionality necessary to give a TV or satellite receiver Internet connectivity.

Asahi Glass

2. ASPEC Technology (United States), January 1997

Asahi Glass will market ASIC libraries developed by ASPEC Technology of the United States in Japan. ASPEC already handles ASIC libraries supporting the production processes of 15 chipmakers. The price is ¥300 million per kit. Asahi Glass has also started taking orders from customers in Japan for the ASIC Division of Hyundai Electronics, which uses ASPEC's libraries.

3. Advanced Micro Devices (United States), March 1997

Asahi Glass will step up sales of Advanced Micro Devices microprocessors this fiscal year. The company deals with AMD's Windows PC MPUs and in-built processors. For Windows PC MPUs, Asahi Glass hopes to tap demand for the K6 chip from domestic PC makers. In a move to market built-in processors for numerical control and point-of-sale systems, Asahi Glass has signed a distribution agreement with Microsoft to obtain an MS-DOS license. Plans also call for commercializing AMD MPU boards that incorporate Asahi Glass hybrid ICs.

Canon

4. Scientech (Taiwan), January 1997

Canon set up a stepper sales and support joint venture in Taiwan in early February. The company's third service center in Asia, Canon Semiconductor Equipment Taiwan will be headquartered in Taipei and will be capitalized at about ¥300 million, 80 percent by Canon and 20 percent by a local distributor, Scientech. The new company will initially be staffed by 22 employees. Canon, which has already won an order for more than 20 steppers from ProMos Technologies, a joint venture between Siemens and Mosel Vitelic of Taiwan, is aiming to nearly double its share to about 50 percent of the Taiwanese stepper market by 1999.

Dainippon Screen

5. Kyoto Technica (Japan), March 1997

Dainippon Screen Manufacturing and Kyoto Technica will jointly set up a semiconductor/LCD equipment maintenance service company. Based in Kyoto, DS Tec Kansai is capitalized at ¥50 million, with Dainippon Screen investing 82 percent and Kyoto Technica 15 percent; it will start operations with more than 100 employees. Dainippon Screen, which has entrusted maintenance service to a subsidiary and Kyoto Technica, will commission delivery and maintenance of equipment for its customers in the Kinki, Chugoku, and Shikoku regions to the new company. DS Tec Kansai is expected to achieve annual revenue of ¥1.1 billion in its first year.

DSI

6. Korean company (Korea), October 1997

DSI, a Japan-based semiconductor equipment production venture, will establish a joint venture in Korea in October to manufacture vertical electric furnaces for use in next-generation semiconductor production. To be capitalized at ¥40 million, DSI Korea will be owned 70 percent by a local company and 30 percent by DSI. With an initial staff of three salespeople and two engineers, the joint venture will have a clean room at its main office. DSI, which has been assembling vertical high-vacuum annealing systems at its Shizuoka plant, intends to scale down its domestic operations and shift manufacturing technologies and equipment to the Korean company.

Emplas

7. Hicad (China), June 1997

Emplas will set up an IC test socket sales joint venture in Shanghai with its Singapore distributor, Hicad. To be capitalized at $600,000, Emplas Hicad National Trading will import IC test sockets from Japan and launch sales in late July. The joint venture will target chipmakers, including NEC and Motorola, with IC manufacturing operations in China and will aim for annual sales of ¥2 billion in three years.

Fuji Film Microdevices

8. Kopin (United States), November 1997

Kopin and Fuji Film Microdevices, Japan, announced a strategic business agreement under which the companies will incorporate Kopin's CyberDisplay active-matrix LCD into Fuji's digital camera chipsets. Fuji and Kopin will work together to integrate Fuji charge-coupled device analog and logic circuits with Kopin's CyberDisplay. The goal of the strategic alliance is to make the chipsets available to Fuji internal and external customers by the second quarter of 1998. Based on Kopin's patented Smart Slide technology, the CyberDisplay is a 0.24-inch diagonal transmissive active-matrix LCD imaging device that displays information at 320 x 240 full-color-pixel resolution. It enables portable communications devices and personal information products to display photographic images and other data or video sources.

 ©1998 Dataquest

Fujitsu

9. Advantest (Japan), February 1997

Fujitsu and Advantest will concentrate their joint electron beam (EB) exposure system business at Advantest. The two companies jointly developed the F5120 EB exposure system for use in 256Mb or larger DRAM production, and Advantest has started marketing it. From April 1997, about 50 Fujitsu employees engaged in EB systems development will be on loan at Advantest's R&D center now under construction. Advantest expects to sell five of the ¥1 billion systems the first year.

10. LG Semicon (Korea), March 1997

Fujitsu and LG Semicon in Korea will unify the design guides of their proprietary chip-scale packages under the name "USON," for ultrathin small-outline nonleaded package. The companies plan to ask the Joint Electronic Device Engineering Council (JEDEC) to designate USON as a new standard package for memory devices. Fujitsu developed a chip-scale SON package, which has been used for its flash memory since September 1996. Compared with the conventional thin small-outline package (TSOP), the company claims, the SON package takes up about half the space in mounting, is two-thirds of the thickness, and is half the weight for 16Mb flash memory. LG Semicon developed the bottom-leaded plastic (BLP) package and has been using it for DRAM packaging. BLP is almost the same size as SON.

11. Sand Microelectronics (United States), March 1997

Fujitsu will license Virtual Socket Interface (VSI)-compliant Universal Serial Bus (USB) microcomponents from Sand Microelectronics and will commercialize a microcontroller with integrated USB microcomponents for use in monitors. The USB interface allows peripheral equipment to be connected with the PC with ease. By supporting the USB macro, Fujitsu will be able to offer LSIs that support various standard interfaces, including IEEE 1394, SCSI, and IrDA.

12. Nantong Huada Microelectronics (China), May 1997

Fujitsu has reached agreement with leading Chinese chipmaker Nantong Huada Microelectronics to establish a semiconductor assembly joint venture in China in late June. To be capitalized at $10 million, Nantong Fujitsu Microelectronics will be owned 40 percent and 60 percent by the Japanese and the Chinese companies, respectively. The joint venture will initially employ 400 people to assemble 10 million microcontrollers and linear ICs per month and will construct a new facility starting in fiscal 1998 to raise output to 40 million units.

13. Rambus (United States), July 1997

Fujitsu will team up with Rambus of California in 64Mb high-speed DRAM technology. Fujitsu will receive high-bandwidth Direct Rambus DRAM technology to develop memory systems with gigabyte-per-second-class data transfer speeds. A major reason for the alliance seems to be Intel's plan to use DRAMs with the Rambus interface as the main memory for PCs that will ship starting from 1999. Rambus' high-speed DRAM technology has been transferred to most of DRAM makers including NEC, Toshiba, Hitachi, Samsung, LG Semicon, and Hyundai.

©1998 Dataquest

14. Orckit (Israel), August 1997

Fujitsu Microelectronics and Orckit Communications are teaming up to produce a single-chip, discrete multitone-standard-based Asymmetric Digital Subscriber Line (ADSL) modem. The companies will recast Orckit's two-chip digital solution and its analog front-end, currently based on discrete components, into a 0.35-micron mixed-signal CMOS chip. They will also add Asynchronous Transfer Mode (ATM) and rate-adaptation features in line with a new definition of ADSL known as Issue II. Fujitsu will market the device commercially and to Orckit. The chip is expected to be available in mid-1998.

15. Advanced Micro Devices (United States), October 1997

Advanced Micro Devices and Fujitsu will codevelop a serial NAND-type flash memory architecture, and they expect to begin production with a 64Mb device by October 1999. The two companies currently manufacture NOR-type flash at a joint-venture fab in Aizuwakamatsu, Japan, and have not sold serial flash, which offers a smaller cell size at the expense of random access speeds. A team with staff from both companies is being formed to develop the NAND-type architecture.

16. Sun Microsystems (United States), November 1997

Fujitsu has reached agreement with Sun Microsystems to license Sun's picoJava I, a Java microprocessor core. The company will develop 32-bit RISC microcontroller core specialized in Java software using 0.35-micron technology in 1998 and begin marketing the core for use in PDAs and cellular phones in 1999. The Java processor based on picoJava I is reported to outperform conventional RISC processors such as the SPARClite by a factor of five, and Fujitsu plans to use 0.25-micron technology to expand the core's applications to Network Computers. The company is aiming for Java MPU core sales of ¥10 billion in 2001, and ¥50 billion, or 30 percent of the dedicated Java MPU market, in 2003.

Furukawa Electric

17. Lucent Technologies (United States), February 1997

Furukawa Electric and Lucent Technologies have established an optical semiconductor assembly joint venture in the United States. Fitel Technologies will assemble laser diodes, photo detectors, and other optical semiconductors starting in April and will market the products through the partners' sales channels in Japan and the United States. Furukawa and Lucent, already joined in an optical fiber cable manufacturing venture, Fitel Lucent Technologies, plan to invest a total of about $10 million in the new joint venture by fiscal year 2000.

 ©1998 Dataquest

Gunze Sangyo

18. Plasmaquest (United States), February 1997

Gunze Sangyo has acquired a capital stake in Texas-based semiconductor equipment maker Plasmaquest. Gunze, which has been distributing plasma etching and plasma chemical vapor deposition systems made by Plasmaquest in Japan since 1993, has bought with its U.S. subsidiary, Gunsan America, 14.81 percent of the U.S. company for $1 million. Plasmaquest needed financial support to expand production capacity to keep up with brisk demand for etching equipment in the North American market. Gunze wants to expand Japanese sales of Plasmaquest products to ¥1 billion in two years.

Hitachi

19. Mentor Graphics (United States), April 1997

Hitachi will work with Mentor Graphics to strengthen its 32-bit RISC processor development environment. Plans call for jointly developing SeamlessCVE, a hardware/software coverification tool for the Hitachi SH series microcontrollers. The tool, which will support MCUs in the SH-1, SH-2, and SH-3 series, will allow system designers to verify hardware and software and debug the software in the early stage of SH MCU-based equipment development, slashing development time by over one month. The tool is priced at ¥12 million.

20. Seiko Epson (Japan), November 1997

Hitachi and Seiko Epson announced an agreement concerning the licensing of Hitachi's 32-bit RISC microprocessor core technology to Seiko Epson. Seiko Epson intends to combine its low-power semiconductor technology with Hitachi's SH-3 core to build new ASICs and application-specific standard products (ASSPs) that better meet system requirements. Hitachi has been actively forming partnerships as part of establishing its 32-bit SH RISC engine family as an industry standard. The present agreement makes Seiko Epson the first Japanese partner and, for customers, will mean that more PC peripheral devices and portable information products built around SH MPUs will be available. Seiko Epson has developed 4-, 8-, and 32-bit CPUs. With the SH-3, Seiko Epson will address the need for products with a standard embedded CPU capable of running a standard operating system with its associated development environment.

21. NTT Electronics (Japan), November 1997

Hitachi and NTT Electronics will work together to develop a low-power SH-3 RISC microprocessor using a 0.25-micron process technology. Hitachi will provide its SH-3, designed for a 0.35-micron process, while NTT Electronics, which develops and manufactures ICs for its parent company, Nippon Telegraph & Telephone, will provide its 0.25-micron technology. Hitachi expects the collaboration will help it lower the power consumption of the SH-3 nearly 3 percent and shorten the 0.25-micron SH-3's time to market. The CPU is expected by spring of 1999.

©1998 Dataquest

22. SGS-Thomson (France), December 1997

Hitachi and SGS-Thomson Microelectronics formally unveiled plans to undertake joint development of 64-bit microprocessor cores for the Super-H family. The processor architecture will be backward compatible with Hitachi's SH-4 and is being targeted as a general-purpose engine for a wide range of products. The architecture of the first core that the companies will work on together, called SH-5 by Hitachi and ST50 by SGS-Thomson, is due to be disclosed in 1998, with first implementations sampled in the second half of 2000 and volume production in 2001.

Hitachi/Mitsubishi

23. Texas Instruments (United States), February 1997

Hitachi, Mitsubishi Electric, and Texas Instruments have signed an agreement to jointly develop 1Gb DRAM. The agreement, part of a trend toward huge investments to develop complex and expensive technologies, will allow the three chipmakers to share resources and leading-edge technologies. The three companies are aiming for sample shipments of the next-generation chips by early 2000, sharing the estimated development cost of more than ¥100 billion. Since 1988, TI and Hitachi have been teaming up to research and develop 16Mb, 64Mb, and 256Mb DRAMs, while Hitachi and Mitsubishi have jointly developed 8Mb, 16Mb, and 64Mb flash memory chips. In 1995, Hitachi and TI formed a joint venture, Twinstar, a $0.5 billion wafer fab located in Richardson, Texas.

Hitachi Chemical

24. DuPont (United States), September 1997

Hitachi Chemical and DuPont of the United States will jointly set up ventures in both countries to produce and market liquid polyimide materials for semiconductors and other electronic devices. The two companies have established Hitachi Chemical DuPont Microsystems LLC in the United States, slated to open in April 1999. An initial capital contribution of $14 million for the venture will be shouldered equally by DuPont and Hitachi Chemical's sales subsidiary, Hitachi Chemical America. The new joint venture will then establish Hitachi Kasei DuPont Microsystems K.K., as a wholly owned subsidiary in Japan, with capital of ¥400 million and a targeted operation date in 2002.

Hitachi Construction Machinery

25. Hitachi Medico (Japan), December 1997

Hitachi Construction Machinery has formed a partnership with Hitachi Medico in the semiconductor inspection equipment business. The company will procure as an OEM two types of x-ray-based semiconductor inspection systems from Hitachi Medico. Its goal is to nearly double its factory automation system sales to ¥3.6 billion by 2001 by broadening its x-ray inspection system product line. The MF130M and the MF80M feature focuses of 10 micron, and 8 micron, respectively.

 ©1998 Dataquest

Hitachi Maxell

26. Singlechip Systems (United States), December 1997

Hitachi Maxell has teamed up with Singlechip Systems of California to enter the IC tag business. The partners will combine Hitachi Maxell's non-contact IC card production technology with SCS' single-chip technology to manufacture and market an IC tag that will measure 10 x 60 x 0.25mm and have a memory capacity of 1,024 bits. A reader/writer will use 2.45-GHz signals to simultaneously read data on more than 30 write-once tags that can be 35cm apart. A set of the reader/writer and 100 tags will be priced at ¥600,000 to ¥1,000,000.

Innotech

27. Credence Systems (United States), November 1997

Innotech has established in Yokohama a semiconductor tester production joint venture with Credence Systems of California. Capitalized at ¥100 million, Innotech Credence is 49.9 percent owned by the Japanese semiconductor equipment distributor and 50.1 percent by the U.S. tester maker. The joint venture will manufacture logic and memory testers and put them on the market by spring 1998, aiming to ship a total of 50 units the first year. The first-year sales target is set at ¥4 billion.

Itochu

28. Grand Pacific Petrochemical (Taiwan), April 1997

Itochu, in cooperation with Fukushima-based technical consulting company Sumcon and Taiwanese chemical company Grand Pacific Petrochemical, will set up a joint LCD production company in Taiwan. The new company, Grand Pacific Optoelectronics, will be capitalized at about (4 billion, in which Itochu, Sumcon, and Grand Pacific Petrochemical invest 25 percent, 5 percent, and 70 percent, respectively. The joint venture expected to start constructing a plant in the Hsinchu industrial park in April 1997 and to produce sub-10-inch STN color LCDs for portable information devices and notebook computers from June 1998, aiming for first-year sales of about ¥10 billion.

29. Comdisco Inc. (United States), September 1997

Itochu and U.S. semiconductor equipment leasing company Comdisco have established a joint semiconductor equipment leasing company, Commit Equipment Management Service. Capitalized at ¥490 million, the joint venture is owned 60 percent by the U.S. company and 40 percent by the Japanese trading house. The joint venture is aiming for 20 billion in leasing contracts by 2000. Predicting that demand for used equipment may expand in Asia, the partners plan to sell used equipment to Taiwanese and Korean chipmakers. The used semiconductor equipment market in Japan is estimated at ¥5 billion, about 1/10th of the size of the U.S. used equipment market.

©1998 Dataquest

Kaijo

30. Robotic Vision Systems Inc. (United States), November 1997

Kaijo has teamed up with Robotic Vision Systems Inc. of New York to expand its inspection system business. Kaijo will start marketing and providing support for RVSI's ball grid array (BGA) inspection and bump attachment systems in December. Through an alliance with Kaijo, RVSI wants to boost its Japanese market share, currently about 20 percent of the market.

31. Quad Systems (United States), December 1997

Kaijo has begun marketing a flip-chip bonder made by Quad Systems of Pennsylvania, signing an exclusive domestic sales contract with the U.S. company. The Advanced Packaging System APS-1 supports various types of packaging, including chip-scale package (CSP) and chip on board (COB) and uses an optical noncontact alignment system to achieve a high level of alignment. The price is ¥40 million.

Kanematsu Semiconductor

32. Intergraphics Systems (United States), September 1997

Intergraphics Systems of California will team up with semiconductor distributor Kanematsu Semiconductor and software house Access to market in Japan the CyberPro2010, a system-on-a-chip LSI enabling users to browse Internet home pages on TV. The chip integrates monitor output circuit and image control functions and a flicker-prevention function and features a built-in interface called Flexibus that makes the chip usable with all existing CPUs, including x86 and PowerPC microprocessors and Hitachi SH series microcontrollers. Intergraphics Systems claims that the chip helps Internet TV makers slash development time and design costs by nearly 60 percent, enabling them to lower retail prices from the current ¥300,000 to ¥100,000.

Kyocera Electronics Inc.

33. Johnson Matthey (United Kingdom), October 1997

Kyocera has signed a cross-license agreement with Johnson Matthey of London in the semiconductor plastic package business. The company will introduce plastic package technology from Johnson Matthey and start mass production of plastic land grid arrays (PLGAs) for microprocessors at its Sendai plant in Kagoshima Prefecture in January 1998. In return, Kyocera will provide the U.K. company with build-up substrate technology. Plans call for launching production at 500,000 units per month (45 x 45mm, 540 pins) and boosting output to 1.5 million units by July 1998, when the company will complete a new 10 billion production facility at the plant. Kyocera is aiming for PLGA sales of ¥5 billion to ¥6 billion in fiscal 1998.

 ©1998 Dataquest

Lapmaster SFT

34. Super Silicon Crystal Research Institute (Japan), August 1997

Lapmaster SFT of Tokyo will collaborate with Super Silicon Crystal Research Institute of Gunma Prefecture to develop a fully automated chemical mechanical polishing machine for processing 400mm wafers. Super Silicon will provide wafer samples, while Lapmaster will be in charge of hardware design and software development. Development costs are estimated at (100 million. Scheduled to be developed by May 1998, the machine will achieve a wafer-processing flatness of less than 0.13 micron, a surface particle diameter size of 0.04 micron, and a surface metal impurity level of 10 x 8 stoms/cm^2. The 400mm wafer-processing machine is likely to be priced at about ¥200 million.

Matsushita

35. Texas Instruments (United States), January 1997

Texas Instruments Japan and Matsushita Electric have jointly developed a digital video camera DV terminal IC that conforms to IEEE 1394, a high-speed serial bus standard for next-generation PCs and consumer electronics. The TSB13LV01 integrates on a single chip the functions of conventional LINK and PHY chips and is available in a 144-pin CSP. TI Japan will initially mass-produce the new IC exclusively for use in the latest NV-DE digital video camera from Matsushita Electric.

36. CBL (United States), July 1997

Matsushita Electronics signed an agreement with a California-based venture CBL under which the companies will jointly develop a blue-light laser. Matsushita is aiming by 1999 to commercialize a blue-light laser, necessary for next-generation DVD drives with a storage capacity of 15GB, three times the current level. Set up by Stanford University researchers, CBL has developed large-diameter gallium nitride substrates. Use of this type of substrates increases the life of a blue-light laser from the conventional 30 hours to 5,000.

Mitsubishi

37. Compaq (United States), January 1997

Compaq Computer Corporation has teamed up with Mitsubishi Electric and with Advanced Display, Mitsubishi's LCD production subsidiary, in PC LCD monitor development. The alliance brings together Compaq's understanding of customer needs, Mitsubishi's flat panel technology, and Advanced Display's motherboard and glass processing technologies. The companies developed an LCD monitor and put it on the market in the second half of 1997. Compaq will be in charge of sales and will initially target the financial and health care sectors.

38. Access (Japan), February 1997

Mitsubishi Electric has teamed up with Access, an Internet appliance operating system developer, in the development of a portable Internet terminal chipset. The two companies will jointly develop a three-chip set including Mitsubishi's M32R/D DRAM-embedded microcontroller and a mask ROM and market the chipset at $30 to $40. Mitsubishi plans to develop a two-chip set in 1998 by integrating an ASIC and the M32R/D on a single chip. Mitsubishi, which started shipping samples of the DRAM-embedded MCU in October 1996, will launch production in April and produce 1 million units a month in late 1997. Access' Internet OS has been adopted by Sharp in its Internet TVs and word processor.

39. Wind River Systems (United States), March 1997

Wind River Systems, Japan, will develop the Tornado embedded system development environment for Mitsubishi Electric's 32-bit M32R/D RISC processor, based on an agreement the two companies have signed. The agreement will allow domestic M32R/D users to collectively purchase from Mitsubishi the license to use the VxWorks real-time operating system that is integrated into the Tornado development environment, helping them reduce system development time. Mitsubishi, which teamed up with Integrated Systems Inc. of the United States regarding its pSOS real-time OS in 1996, will support the real-time operating systems that account for some 70 percent of the world market.

40. Rambus (United States), April 1997

Mitsubishi Electric has licensed the Rambus interface technology needed to make 1.6GB/sec Direct Rambus DRAMs. The company has previously been a vocal proponent of other next-generation DRAM technologies. Nine DRAM makers have taken Rambus licenses, and some of the holdouts are believed to be negotiating with Rambus. IBM has a license for the Rambus logic interface but has yet to take a license for the memory-interface technology.

41. Seiko Epson (Japan), May 1997

Mitsubishi Electric will license 3-D video memory technology to Seiko Epson. Mitsubishi's 3D-RAM integrates 10Mb DRAM, 2Kb SRAM, and logic functions on a chip. Seiko Epson is expected to ship samples of the SDM 10092, a 3D-RAM-compatible chip, this fall and launch volume production at 20,000 units per month at its Sakata plant next spring. The sample price is likely to be set at about ¥5,000.

42. Chunghwa Picture Tube (China), May 1997

Mitsubishi Electric and Advanced Display have agreed to license their advanced thin-film transistor (TFT) LCD technologies to Chunghwa Picture Tube, a cathode-ray tube (CRT) manufacturer in Taiwan. Under the agreement, Chunghwa Picture will receive key technologies for the manufacture of TFT LCDs from Advanced Display. The displays to be manufactured by Chunghwa include 12.1-inch SVGA and XGA and 15.1-inch XGA and SXGA models. Volume production is expected to begin in January 1999. Chunghwa, an affiliate of Tatung, develops CRTs for the television and display market as well as super-twisted nematic (STN) LCD flat-panel displays.

43. Stone Group (China), June 1997

Mitsubishi Electric has teamed up with Chinese electric equipment maker Stone Group in semiconductor sales. Mitsubishi, Stone, and Mitsui & Co. established a joint venture in Beijing in 1996, and the joint venture is building a semiconductor plant expected to be ready for operations in April 1998. Mitsubishi plans to market semiconductors to be made by the plant for use in electric appliances. First-year China semiconductor sales are expected to be ¥10 billion, including sales to be generated through distribution via Hong Kong.

44. Mentor Graphics (United States), June 1997

Mitsubishi Electric will develop system-on-a-chip LSI development software with Mentor Graphics. Hardware-Software Cosimulation Environment, the software the two companies will develop, will combine Mentor's Seamless CVE and Mitsubishi's 32-bit M32R RISC microcontroller core instruction set simulator. The new software will allow system-chip LSI design engineers to test software as hardware is being designed, helping reduce design and development time from the current eight months to five months. Sample shipment is slated for late this year.

45. Powerchip Semiconductor (Taiwan), November 1997

Mitsubishi Electric expects to provide Powerchip Semiconductor of Taiwan with DRAM-embedded microcontroller production technology in early 1998. A joint venture established by Mitsubishi, a trading company, Kanematsu, and a Taiwanese electronics maker, the UMAX Group, Powerchip will begin to produce eRAM, a system-on-a-chip LSI that integrates Mitsubishi's proprietary 32-bit RISC MCU and DRAM on a single chip. Slated to begin in mid-1998, production will reach 4,000 eight-inch wafers per month by September 1998.

Mitsubishi Materials

46. Symmetrix (United States), December 1997

Mitsubishi Materials has licensed technology to produce and market ferroelectric materials from Symmetrix of Colorado. Plans call for producing Y-1, a ferroelectric material developed by the U.S. company for forming thin-film capacitors through enhanced metallorganic deposition (EMOD) at a mass production facility under construction in the company's Mita plant. Construction will be completed by year's end, and operations have been slated to start in March 1998. The company is aiming for sales of ¥200 million in 2000.

 ©1998 Dataquest

Mitsui & Co.

47. Micron Communications/ID Micro Systems (United States), April 1997

Mitsui & Co. will work with Micron Communications and ID Micro Systems, both of the United States, to develop a low-cost noncontact tag. The new tag will have a storage capacity of 256 bits and use the spread spectrum format to read and write data. The companies aim to price the product at about (100, enabling it to be used as a disposable tag in production and distribution management and IC card applications. Mitsui and Micron Communications will share the development cost, while ID Micro will provide noncontact tag technology. Mitsui will sell the tag in Japan and overseas, except for the United States. The tag was expected to reach the market in late 1997, with a first-year sales goal set at 10 million units.

Mitsui High-Tec

48. Ball Semiconductor (United States), August 1997

Mitsui High-Tec has invested in Ball Semiconductor of Texas, acquiring nearly 50 percent of the U.S. company for $26 million. Ball Semiconductor was established by former Texas Instruments vice president Akira Ishikawa in October 1996. Ball has developed technology to create semiconductor circuits on the surface of a silicon ball in order to increase the level of integration. The U.S. company claims that the silicon balls are easier to manufacture than silicon wafers and that a silicon ball semiconductor plant can be constructed at lower cost than conventional chip plants. Semiconductor equipment maker Disco is also reported to have chipped in more than ¥100 million to the U.S. venture.

NEC

49. Wind River Systems (United States), January 1997

NEC will procure an embedded RISC microprocessor operating system from Wind River Systems. NEC and the Japanese arm of Wind River have signed an agreement, under which the U.S. software company will develop a version of the Tornado operating systems supporting NEC's V830 series of 32-bit RISC MPUs. The B830 family is popular among office business machines and car navigation system applications, and the combination of the RISC MPU and Tornado will allow designers to develop such application systems easily. Japanese customers have been able to purchase the Tornado runtime version license together with the MPU from April 1997.

50. Datapath Systems (United States), February 1997

NEC has teamed up with U.S. venture Datapath Systems to develop an extended partial response maximum likelihood (EPRML) LSI for use in large-capacity hard disk drives (HDDs). NEC will continue its process technology with the U.S. company's circuit design technology to develop as early as this year the LSI that will enable 30 percent HDD capacity expansion over the conventional PREL system. NEC, which has to date manufactured HDD write and read LSIs, intends to expand its semiconductor business by moving into the HDD LSI market, a promising segment with huge growth potential.

51. Synopsys (United States), April 1997

NEC and Synopsys of California have reached an agreement to jointly develop microcontroller-embedded ASIC design verification technology. The move is aimed at providing a tool to enable single-chip embedded system designers to simultaneously verify both hardware and software functions and at reducing development lead time. For the development of embedded systems, hardware functions are typically verified using EDA capability and software functions using an in-circuit emulator. NEC expects the new tool will help expand sales of its V850 family of ASICs.

52. Shanghai Hua Hong Microelectronics (China), May 1997

NEC announced that it will set up a joint venture with Chinese chipmaker Shanghai Hua Hong Microelectronics to supply technology to a Chinese national project to boost domestic semiconductor output. Shanghai Hua Hong is affiliated with the Chinese government. The Chinese government will own about a 70 percent stake in the venture, to be capitalized at $700 million, and NEC will own the rest. The project, which is part of China's five-year economic plan, is called Project 909. Running through 2000, the venture will produce 20,000 chips a month. NEC will provide technology for processing memory chips.

53. Cadence Design Systems (United States), July 1997

Cadence Design Systems has signed an IC design tool contract with NEC. The three-year, $18 million contract will allow NEC to use Silicon Ensemble-DSM, an IC design tool, for deep-submicron design at its design centers worldwide. The tool boosts circuit design speed more than 20 times that of conventional tools.

54. Samsung (Korea), July 1997

NEC and Samsung have decided to cooperatively design a plant for 300mm wafers and help each other in equipment development. The alliance is aiming to get its 300mm wafer line up and running around 1999.

55. Tseng Labs (United States), September 1997

NEC Electronics announced the availability of an OEM reference design that combines the PowerVR PCX2 3-D graphics accelerator with Tseng Labs' 128-bit ET6100 2-D graphics and multimedia engine. NEC has formed a strategic alliance with Tseng Labs to develop PCI-compliant single-card reference designs based on the PowerVR architecture. This design offers PC OEM and graphics board manufacturers an all-in-one graphics solution that delivers arcade-quality 3-D rendering and high-performance 2-D acceleration for Windows applications. The single-slot PCI card supports game and entertainment titles written for Direct3D, PowerSGL, and DirectDraw, including more than 100 game titles that have been developed for or ported to the PowerVR architecture. VideoLogic's Apocalypse 5-D graphics board is the first product using the technology from NEC and Tseng Labs.

©1998 Dataquest

56. Philips Semiconductor (Netherlands), November 1997

NEC and Philips Semiconductor have reached agreement to jointly develop system-on-a-chip LSIs for use in digital consumer electronic products. They will use the 64-bit VR4300 RISC microprocessor based on MIPS Technologies architecture as a core for the system-chip LSIs and share peripheral circuit libraries. Consumer sales account for 15 percent of NEC's semiconductor sales and 45 percent of Philips', respectively. The two companies plan to begin to commercialize system-chip LSIs in the second half of 1998, cooperating in production as well as marketing.

57. Lucent Technologies (United States), December 1997

Lucent Technologies' Microelectronics Group and NEC announced that Lucent has licensed NEC's 32-bit V850 MCU family core. Lucent will integrate the core into its 0.25- and 0.35-micron Silicon Suite system-level IC offering, enabling customers to design system-level integrated circuits based on NEC's 32-bit RISC MCU architecture. The agreement means the V850 core will now be available from the two companies. The core will be available to Lucent customers for integration in April 1998.

Nichimen Electronic Components

58. Luxsonor (United States), May 1997

Nichimen Electronic Components has teamed up with Luxsonor of California in DVD chip sales. The U.S. fabless company focuses on MPEG-2 decoder part development, and Nichimen planned to release as early as June the LS220, a DVD decoder chip built into a PC motherboard. To be made in Taiwan, the chip will be sold for less than 4,000. The Japanese distributor is aiming for first-year sales of ¥500 million. Luxsonor is working on the LS240, a power-saving chip, and Nichimen intends to market it, targeting notebook computer makers, within the year.

NKK Corporation

59. Toshiba (Japan), September 1997

NKK will reorganize its semiconductor business by introducing state-of-the-art semiconductor technology from Toshiba. Plans call for starting 32-bit RISC microcontroller production within the year. The steel company will pay Toshiba a one-time fee of an estimated ¥1 billion as well as license fees and will manufacture RISC chips at its Ayase Research Laboratory. NKK, which entered the semiconductor business in 1992, hopes to put its semiconductor operations into the black by fiscal year 2000, reducing its dependence on the memory business significantly.

 ©1998 Dataquest

Nomura Microsciences

60. Ionics (United States), July 1997

Nomura Microsciences has teamed up with Ionics Inc. of Massachusetts to market pure water-processing electrical deionization (EDI) equipment targeting semiconductor, pharmaceutical, and food processing companies in Japan, Korea, and Taiwan. The EDI system uses no chemicals and requires no waste water processing and therefore can remove 99 percent of silica, a task considered difficult. The U.S. company has supplied its EDI equipment to more than 50 plants worldwide, and Nomura is aiming to sell ¥20 billion to ¥30 billion worth of ultrapure water-processing systems over the next five years.

Nozaki Industry

61. High Yield Technology (United States), May 1997

Nozaki Industry will import a particle monitor system from High Yield Technology of California. The In Situ Particle Monitor (ISPM) is attached to vacuum process semiconductor equipment and eliminates use of a dummy safer. The standard system is priced at about ¥4 million. Nozaki is aiming first-year shipment of 100 ISPM systems.

Oki

62. Synopsys (United States), January 1997

Silicon Architects of Synopsys has announced that Oki Electric of Japan has licensed Synopsys' cell-based array (CBA) architecture for its 0.35-micron ASIC products. Oki will use the CBA architecture to develop 0.35-micron ASICs for both internal and commercial use. Other products will include microcontrollers, MPU and peripheral ICs, speech ICs, and telecom ICs. Oki will develop designs using CBA design tools, which integrate CBA libraries, CBA compilers, the CBA Design Systems, and commercial EDA tools. Over the past year, Synopsys has also announced CBA licensing agreements with Fujitsu, Matsushita, Mitsubishi, NEC, Toshiba, and TriTech.

63. Artisan (United States), April 1997

Artisan Components, formerly VLSI Libraries, a supplier of embedded memories and other physical component intellectual property (IP), has received a multimillion dollar worldwide purchase agreement from Oki Electric. Oki has selected Artisan as its sole external supplier of memory generators and has agreed to incorporate Artisan's family of physical IP components into all of its new 0.35- and 0.45-micron internal standard products and ASSPs. Under the agreement, Oki will purchase a complete family of Artisan's memory generator, including standard single-port and dual-port SRAMs. Also, Oki's R&D centers in both Japan and the U.S. are adopting Artisan's technology.

Rohm

64. DSP Group (United States), March 1997

Rohm will license DSP core technology from DSP Group of California. Rohm will use DSP Group-developed 16-bit fixed-point PineDSPCore and OakDSPCore to develop system-on-a-chip LSIs for mobile communications and multimedia equipment. Specifically, Rohm expected to commercialize controllers for cellular phones, high-speed modems, and CD-ROM/DVD drives by the end of 1997. DSP Group licenses its audio-compression technology to a dozen companies, including AT&T, Intel, and Microsoft, and its DSP core technology to more than 20 companies, including Asahi Chemical, Kenwood, and NEC.

Ryosho Electronics

65. NeoParadigm Labs (United States), April 1997

Ryosho Electronics signed an exclusive agreement to sell in Japan LCD signal processing ICs developed by NeoParadigm Lab (NPL) of California, a start-up developer of multimedia LSIs. Designed for large STN LCD panels, the new LCD signal-processing IC directly processes analog RGB signals from the PC, reducing the signal-processing circuit cost to less than ¥10,000. Sample shipment was expected to begin in September, and Ryosho aims to sell 50,000 units the first year. Ryosho was established to sell DRAMs produced by Powerchip Semiconductor, a Taiwan-based joint venture, and by Mitsubishi Electric, Kanematsu and the UMAX Group of Taiwan, and aimed for fiscal 1997 sales of ¥6 billion.

Sankyo Engineering

66. Sugai (Japan), April 1997

Japan-based Sankyo Engineering and Sugai revealed that the companies will form a partnership for developing new auto wet stations, which can be used for 256Mb DRAM cleaning processes and new processes for 12-inch wafers. The companies will also begin developing common part specifications for their equipment in order to reduce parts inventory, and hence cost, while maintaining availability. According to the announcement, Sankyo Engineering and Sugai will consider exchanging stock or further investment in future partnerships if they find enough benefits.

Santoku Chemical

67. Mitsui & Co./Merck (Germany), October 1997

Santoku Chemical, Mitsui & Co., and Merck of Germany have established a joint venture in Singapore to produce ultrapure hydrogen peroxide water for cleaning semiconductor chips. Capitalized at about ¥700 million, Santoku Merck is owned 49 percent by Merck, 31 percent by Santoku, and 20 percent by Mitsui. The partners will invest ¥2 billion to construct a plant with an annual processing capacity of 10,000 tons, which will start operations in November 1998. Plans call for producing hydrogen peroxide water with particle per trillion-level purity. Santoku Merck is aiming for sales of ¥2.5 billion in 2005.

Seiko Epson

68. Lattice Semiconductor (United States), March 1997

Lattice Semiconductor has signed an agreement to advance Seiko Epson up to $150 million to assist in the funding of a new 8-inch wafer fab, currently under construction in Sakata, Japan. The agreement calls for Lattice to make a $90 million advance payment to Seiko Epson to set up the new fab over the next two years, with an option for an additional $60 million advance. In return, Lattice will receive guaranteed 8-inch, submicron wafer capacity. The advance payments will be repaid by Seiko Epson with wafers over a multiyear period. Lattice planned to manufacture next-generation, high-density, in-system programmable logic devices (PLDs) at the new facility beginning in 1998, initially using 0.35-micron CMOS process technology and later migrating to 0.25-micron process technology.

69. Exemplar (United States), June 1997

California-based logic synthesis tool supplier Exemplar Logic announced an agreement to jointly develop libraries for Seiko Epson/SMOS ASIC libraries for Exemplar's Leonardo design environment. As a result of this agreement, Seiko Epson/SMOS ASIC libraries are being distributed by both Seiko Epson and Exemplar Logic, and Exemplar's Leonardo becomes part of Seiko Epson/SMOS ASIC design flow worldwide. The high-precision delay models jointly developed by both companies interface to the Seiko Epson ASIC development system, Auklet. They are available to Seiko Epson/SMOS customers.

70. Mitsubishi (Japan), October 1997

Seiko Epson has tied up with Mitsubishi Electric in the DRAM business. The companies have agreed that Mitsubishi will provide Seiko Epson with 64Mb DRAM design and production technology and that the latter will launch production at 1 million units per month at its Sakata plant from the second quarter of 1998. Mitsubishi will initially purchase all units to be produced at the plant, but Seiko Epson is considering marketing the memory chips under its own brand name. Seiko Epson, which recently completed a ¥100 billion semiconductor production facility at the plant, had been looking for memory products, which will help with stability of operation.

Seiko Seiki

71. Jenoptik Infab (Germany), December 1997

Seiko Seiki, a Seiko Instruments Group company, will team up with German automated semiconductor production system maker Jenoptik Infab. The companies are signing an agreement concerning the standard mechanical interface SMIF() system, a localized clean environment system for wafer transport. Under the agreement, Seiko will provide installation, maintenance, and servicing in Japan for Jenoptik's SMIF systems, which are widely used in Europe, the United States, and Taiwan.

 ©1998 Dataquest

Sharp

72. SanDisk (United States), January 1997

SanDisk and Sharp signed a cross-licensing agreement that gives the companies worldwide rights to each other's patents for flash memory products. Terms of the agreement were not disclosed.

Shin-Etsu Handotai

73. Soitec (France), May 1997

Shin-Etsu Handotai will form a partnership with France-based Silicon on Insulator Technologies to mass-produce next-generation SOI wafers. Soitec has a cutting-edge SOI wafer technology known as Smart Cut, which combines a hydrogen ion implantation process with a conventional wafer-bonding method. This process seems to have an advantage in fabricating so-called ultrathin-film SOI wafers. Soitec has shipped the wafers under the Unibond name since the middle of 1996, and the company plans to expand its production facility in Grenoble, France. SEH and Soitec will develop mass-production technology for this process, and SEH also will construct a factory for SOI wafer production in Japan. Both companies plan to provide 1 million 8-inch wafers per year by 2000.

Sony

74. Toyoda Automatic Loom (Japan), June 1997

Sony and Toyoda Automatic Loom, the funding company of the Toyota Motor Group, are negotiating joint manufacturing of low-temperature, polysilicon active-matrix LCDs. The arrangement would give Sony the production capability to take advantage of emerging high-volume display opportunities, including the enormous automotive market, and it would provide Toyota with captive access to leading-edge display components.

75. Advanced RISC Machines (United Kingdom), July 1997

Sony has forged an alliance with Advanced RISC Machines of the United Kingdom in the 32-bit RISC processor business. Sony will develop and supply system-on-a-chip LSIs based on the ARM7TDMI RISC processor core targeting digital AV equipment, cellular phone, and PDA applications. Sony positions the ARM7 core as an MPU core for its 0.4-micron ASCS ASIC products. ARM's MPU core has been licensed to about 20 chipmakers and used for a range of applications.

76. Sharp/Philips (Netherlands), July 1997

Sony, Sharp, and Philips are jointly developing a next-generation large LCD for such applications as a wall TV. Not to be outdone by its competitors, including Fujitsu, that are leading in the large-screen display competition by concentrating on plasma display panels, the three partners will develop a plasma address LCD that they believe can be as large as 40 inches. Plans call for installing a pilot line at Sony Mizunami, where the partners will send their engineers to develop mass production technology. The companies are aiming for commercialization in 1998.

77. Oki (Japan), August 1997

Sony and Oki Electric will team up in the system-on-a-chip LSI business. They are discussing mutually commissioning production of a chip that integrates a microprocessor and DRAM on a single chip using a 0.25-micron process technology. The two companies, which reached agreement to jointly develop 0.25-micron system-chip LSIs in May 1995, are independently marketing system-chip LSI made using a 0.35-micron process. Sony and Oki, which are about to see the result of their joint development effort, seek to effectively use their management resources by commissioning production to each other.

Sumitomo Chemical

78. Olin (United States), September 1997

Sumitomo Chemical announced that it will cooperate with Olin, a U.S. chemical company, in the area of i-line photoresists used in production of 16Mb to 64Mb memories. Olin will have exclusive manufacturing rights to Sumitomo Chemical's advanced i-line photoresists in the United States and Europe. Olin, a supplier of i-line photoresists in the U.S. and European markets, will also have nonexclusive rights to sell such materials in those regions. Use of Olin's production facilities will enable Sumitomo Chemical to secure a foothold in these markets. Sumitomo Chemical is planning to increase annual sales of i-line photoresists from the current ¥12 billion to ¥30 billion in five years.

Sumitomo Corporation

79. Tokyo Kaseihin and others (Japan), January 1997

Tokyo Kaseihin will establish a lead frame production venture in Singapore with two Japanese manufacturers through its local subsidiary. To be capitalized at $50,000, the new venture will be owned by Tokyo Kaseihin subsidiary TOK Singapore, Osaka-based parts maker Iijima Metal Seisakujo, and Osaka-based packaging materials maker Shinko at a ratio of 1:2:2.

80. R. Howard Strasbaugh (United States), June 1997

Sumitomo Corporation set up in July a joint venture with R. Howard Strasbaugh of California to sell next-generation wafer-polishing machines developed by Strasbaugh. SC Semicon Technology is capitalized at 300 million, in which Sumitomo and Strasbaugh invested 85 percent and 10 percent, respectively. The CMP machine developed by Strasbaugh features a wafer surface roughness of 250 angstroms, 10 times the precision of conventional machines, and can process about 60 wafers per hour, three times the usual throughput. It is priced at ¥200 million. SC Semicon is aiming for first-year sales of ¥3.5 billion, targeting manufacturers of 64Mb DRAM chips.

81. Pixtec (United States), November 1997

Sumitomo Corporation has bought exclusive domestic sales rights to field-emission display (FED) panels from California-based Pixtec. The company, which is also authorized to market the products in Asia, will invest $10 million in the U.S. company in return. Pixtec plans to commission 5.2-to 8.0-inch FED panel production to leading Taiwanese LCD maker Unipac and ship 10,000 units per month starting in April 1998. Sumitomo, which handles ¥50 billion worth of CRT and LCD materials and products annually, is aiming to expand FED sales to ¥3 billion and ¥10 billion in the first and third years, respectively.

Tokyo Seimitsu

82. Super Silicon Institutes (Japan), March 1997

Tokyo Seimitsu will develop a 400mm-wafer wire saw jointly with the Super Silicon Institutes (SSI). The company will deliver a wire saw to the SSI by November, and the parties will jointly make enhancements with the goal of completing a practical unit by 2001. The SSI is a Gunma-based institute specialized in 400mm wafer technologies, established in March 1996.

83. Seiko Seiki (Japan), December 1997

Tokyo Seimitsu will form an alliance with Seiko Seiki in the semiconductor equipment business. The partners will combine Tokyo's alignment-measuring technology with Seiko's high-precision processing technology to develop wafer dicing and other technologies. In the meantime, Seiko Seiki, which has been marketing dicing saws since 1995, will stop production and procure products from Tokyo Seimitsu.

Toshiba

84. Unigen (United States), February 1997

Unigen announced that it will work with Toshiba America Electronic Components as a manufacturer of Toshiba-certified memory modules for sale under the Toshiba brand name. Toshiba expected to audit and qualify Unigen's production facility in the first quarter of 1997, and the Unigen/Toshiba team could begin shipping Toshiba product in the second quarter. Unigen is a Fremont, California-based third-party memory module manufacturer that focuses on the OEM channel.

85. Samsung (Korea), February 1997

Toshiba will acquire 20 percent of Samsung Austin Semiconductor of Texas, a Samsung Electronics subsidiary, and procure the 20 percent of 64Mb DRAMs the Texas company will manufacture for sales under its own brand name. Slated for completion in June 1997, the first facility of the Korean subsidiary, in which Intel also has a capital stake, expected to launch 64Mb DRAM production by year's end and have a monthly output capacity of 2.3 million units by the end of 1998, when it expects to be fully operational. Samsung Austin Semiconductor plans to invest $1.3 billion to construct three facilities by 2003.

86. Motorola/Fairchild (United States), March 1997

Toshiba, Motorola, and Fairchild Semiconductor will jointly develop next-generation high-speed CMOS standard logic ICs. The three companies will work together to develop 2.5- and 3.3V CMOS standard logic ICs with a propagation delay time of 2ns. The new devices will be suited for ATM and ISDN network and engineering workstation memory address control use. They will introduce compatible products simultaneously to develop an untapped market. Plans called for commercializing the fast standard logic ICs by the end of 1997. The high-speed standard logic IC market is forecast to grow to ¥35 billion in 2000.

87. Sun Microsystems (United States), April 1997

Toshiba and Sun Microsystems have agreed to develop a Java processor chip for use in network computer terminals. The chip will consist of picoJava, microJava, and ultraJava. PicoJava will be the microprocessor's core, and microJava will integrate DRAM and a controller into picoJava. UltraJava will be an advanced model. Toshiba will be involved in developing a low-power microJava chip, with commercialization by Sun in 1998.

88. MIPS Technologies (United States), April 1997

Toshiba has licensed RISC microcontroller technology from the MIPS Group. The MIPS 16ASE is a 32-bit MCU core that helps to reduce the size and power consumption of printers and portable information devices. It allows for significant reduction of overall code size by compressing some instruction sets to 16-bit. The company plans to commercialize TX19 series MCUs based on the licensed core. The RISC type accounts for less than 10 percent of the company's total MCU sales in volume terms.

89. Technology Modeling Associates (United States), April 1997

Toshiba and Technology Modeling Associates have entered into a multi-year agreement in which the two companies will work jointly on development of software for 3-D simulation of semiconductor processes. The software tool will perform advanced modeling for diffusion, oxidation, ion implantation, rapid thermal annealing, silicidation, and point defects modeling. Toshiba is expected to use the simulator for the development of future generations of memory, microprocessor, and ASIC devices. Under the term of the agreement, Toshiba will provide funding, deep-submicron process technology development requirements, and test data. The TMA product, part of TMA's suite of semiconductor simulation tools, is expected to be released in late 1998.

90. NeoMagic (United States), May 1997

Toshiba announced in May that the company was about two months away from first silicon on a notebook graphics controller, with embedded DRAM, that will be manufactured for NeoMagic. To date, NeoMagic has worked with Mitsubishi Electric as the foundry for its graphics controllers. Toshiba will employ a 0.25-micron process optimized for embedded memory and a 128-bit on-chip memory bus.

91. Chartered Semiconductor (Singapore), June 1997

Toshiba will license DRAM-mixed logic IC technology to Chartered Semiconductor of Singapore, to which it licensed CMOS logic technology in November 1994. The Singapore company will use Toshiba's 0.25- to 0.35-micron process technology to launch production in 1998. The DRAM-mixed system-chip LSI market is expected to reach about ¥400 billion in 2000.

92. iReady (United States), June 1997

Toshiba will license Internet access LSI technology from iReady of California. The company has signed a five-year contract to use the U.S. company's Internet tuner technology for providing Internet access using an LSI, which eliminates control by a CPU and cuts power to 1/700th the level of software-driven Internet access. Toshiba planned to develop by the fall a functional block that will be embedded on a system-on-a-chip LSI to be built into cellular phones and TVs.

93. ViewLogic (United States), July 1997

Toshiba has teamed up with ViewLogic of the United States in the ASIC business. The companies will support Motive, a static timing tool that helps significantly reduce the time needed to design system ASICs with 1 million gates, and Testgen, a tool to automatically generate test patterns to test path delay trouble. Toshiba explained that, with the tools, logic testing time can be slashed to 1/40th the time it takes now. They were expected to become available starting in October.

94. IBM (United States), July 1997

Toshiba and IBM will form an alliance in new memory plant construction. The two companies will cooperate in commercializing a 300mm wafer by exchanging equipment technology information and are considering installing a joint production line at their joint production plant.

95. Winbond (Taiwan), September 1997

Toshiba has expanded its relationship with Winbond Electronics of Taiwan to include 256Mb DRAM production. Toshiba will provide Winbond with 256Mb DRAM production technologies and procure chips as an OEM starting around 2000, when demand is expected to pick up. As part of its move to establish a global DRAM production system, Toshiba expected to begin procuring 64Mb DRAMs from the Taiwanese chipmaker in January 1998.

96. Worldwide Semiconductor Manufacturing Co. (Taiwan), October 1997

Toshiba has teamed up with WSMC of Taiwan in semiconductor production. Toshiba will provide 0.25-micron logic PC process technology to the Taiwanese chipmaker and commission some of its logic IC production. A dedicated foundry set up in May 1996, WSMC is expected to start foundry production in July 1998 and launch a new line in 1999.

 ©1998 Dataquest

Tosoku

97. Samsung (Korea), October 1997

Automotive part and precision machinery maker Tosoku has teamed up with Samsung Aerospace of Korea in the semiconductor wire bonder business. The partners planned to begin in December marketing a IC wire bonder they developed cooperatively by combining the Japanese company's semiconductor equipment and the Korean maker's linear motor technologies. The wire bonder achieves a leadframe transfer speed of 0.5 seconds/26.42mm and can process 400 42SOJ packages per hour. The companies are inclined to set the price below ¥9 million and intend to sell 100 units the first year.

Ulvac

98. Ramtron International (United States), March 1997

Semiconductor equipment maker Ulvac teamed up with Ramtron International of Colorado in ferroelectric RAM (FRAM) technology development. The companies will jointly develop ferroelectric materials such as lead zirconium titanate, ferroelectric thin-film process technology, and sputtering, etching, and ashing equipment over the next four years. Ulvac will start in 1999 to supply the new equipment it is developing in the joint project to chipmakers such as Hitachi, Rohm, Samsung, and SGS-Thomson, which uses Ramtron's FRAM technology.

99. Idemitsu Kosan (Japan), June 1997

Ulvac and Idemitsu Kosan will jointly develop a TFT panel transparent conductive film for larger substrates. They will combine Idemitsu-developed indium lead-based IDIXO film and Ulvac's sputtering equipment and process techniques to develop a transparent conductive film for use with LCD substrates of 13 and 14 inches to 17 and 20 inches. At present, polycrystal indium thin oxide film is typically used for TFT transparent conductive film. Ulvac and Idemitsu expect that LCD panel makers will start using the new film on production lines as early as 1998.

Yamaha

100. Xicor (United States), February 1997

Yamaha has teamed up with Xicor of California in the EEPROM business. Initially, the U.S. company will commission the Japanese company to manufacture EEPROMs, and both companies will cooperate in process technology development. Yamaha Kagoshima Semiconductor will start production in May 1998 at 2,000 six-inch wafers per month and will supply EEPROMs to cellular phone makers under Xicor's brand name. The world's No. 3 EEPROM maker, Xicor is reported to control the largest share, 30 percent, of the Japanese market for EEPROM used in cellular phones. Yamaha projects that Xicor-brand sales will reach ¥2 billion in the first year.

Chapter 1
Executive Summary

In this Focus Report, Dataquest has assembled a worldwide team of experts to offer their views on the ongoing Asian financial crisis. There are five viewpoints presented: the Korean regional and Korean DRAM perspectives, a focus on China/Hong Kong, insight into the impact of the crisis on the region's PC market, and discussion of its effect on capital spending.

Analysis of the Korean regional situation suggests that the worldwide DRAM recession is one of the reasons for the Korean financial crisis. DRAM pricing is predicted to fall further if the Korean, Taiwanese, and Japanese currencies continue to slide against the U.S. dollar.

Dataquest believes that China/Hong Kong will not be impaired in the short term by the crisis, but it faces long-term challenges. Although China/Hong Kong's long-term semiconductor forecast has been lowered, it will still account for 26 percent of Asia/Pacific consumption by 2001.

Analysis of the PC market provides insight into the early impacts of currency devaluations in the region on the personal computer industry and suggests that the outlook for recovery has shifted from the near term to the long term for Thailand, Indonesia, and Malaysia, with the Korean economy possibly beginning to turn around earlier.

The Asian financial crisis will affect capital availability and spending in semiconductors. Because of the severe depreciation of the Korean currency, Dataquest now forecasts that Korean companies will cut capital spending in 1998 about 40 to 60 percent, relative to 1997, in dollar terms.

Project Analyst: Jim Liang (Semiconductors Worldwide)

Chapter 2
Introduction

The beginning of summer 1997 saw the devaluation of the Thai baht amid escalating difficulties in the Thai banking and finance community, which forced the Thai government to finally surrender to the currency speculators. At that time, few people, if any, would have predicted this to be the start of a financial storm, sweeping throughout Asia, with far-reaching global implications.

Shortly after the Thai baht devaluation, the governments of Malaysia, Indonesia, and the Philippines succumbed one by one to the speculative currency attacks. The rapid currency devaluation sent shock waves through the regional stock markets of Thailand, Malaysia, Indonesia, and the Philippines. Singapore and Hong Kong, which remained largely unaffected initially, saw their stock markets tumble in October amid growing investor anxiety.

The financial crisis deepened in November as it spread to Korea and Japan, the world's 11th-largest and second-largest economies respectively. The value of the Korean won dropped sharply, along with Korea's stock market, after the Korean government gave up its battle to prop up its currency in November. A $57 billion rescue package led by the International Monetary Fund (IMF) was negotiated for Korea, after $40 billion and $17 billion were negotiated for Indonesia and Thailand, respectively. In the meantime, Japan saw the closure of its fourth-largest securities firm, Yamaichi Securities Co., on November 24, following the closure of Hokkaido Takushoku Bank, its 10th-largest commercial bank, a week earlier. On December 22, the Nikkei average closed below the psychologically important 15,000 mark for the first time since July 1995.

The beginning of 1998 brought fresh hope to Korea as global bankers agreed to roll over Korea's short-term debt and started to work on a massive debt restructuring to keep the country from defaulting on its loans. This occurred after Korea's president-elect, Kim Dae-jung, reaffirmed his country's commitment to the economic reforms. Contrary to that hope, the situation in Southeast Asia took a dramatic turn for the worse as the regional currencies and stock markets recorded successive new lows, triggered by Indonesia's announcement of a fiscal budget perceived not to be in line with IMF-mandated reforms. On January 12, Peregrine Investment Holdings Ltd., Hong Kong's once high-flying financial power house, filed for liquidation after the company incurred substantial losses from its Indonesian bond operations; the news of the collapse sent the Hang Seng Index plunging 8.7 percent in that day.

Table 1-1 displays the extent of the depreciation of Asian currencies against the U.S. dollar between June 1997 and January 9, 1998. The Hong Kong dollar is the only currency in the region that has withstood the speculative attack so far. The hardest hit have been the Indonesian rupiah, the Thai baht, and the Korean won, which have all lost more than half of their values.

Table 1-1
Depreciation of Asian Currencies against the U.S. Dollar between June 1, 1997, and January 9, 1998 (Percent)

Currency	Depreciation (%)
Indonesian Rupiah	69.3
Thai Baht	54.3
Korean Won	50.8
Malaysian Ringgit	45.3
Philippine Peso	40.9
Singapore Dollar	19.6
Taiwan Dollar	18.9
Japanese Yen	13.1
Hong Kong Dollar	0.1

Source: Dataquest (January 1998)

The dramatic decline of the currency values combined with the downfall of the local stock markets will have serious impact on the region's economy and, subsequently, the world economy. To analyze the potential impact of the Asian financial crisis, experts from Dataquest's worldwide research operations offer their views on this issue in this Dataquest Focus Report.

There are five viewpoints presented in this report. The Korean regional and Korean DRAM perspectives, respectively, are presented in Chapter 3, by J.H. Son, and Chapter 4, by C.S. Kim, Jerry Yeh, Jim Handy, George Iwanyc, and Clark Fuhs. Chapter 5, by Dan Heyler, focuses on China/ Hong Kong. Chapter 6, by Bruce McCabe, and Chapter 7, by Clark Fuhs, provide insight into the impact of the crisis on the region's PC market and capital spending, respectively.

Chapter 3
The Korean Regional Perspective

Introduction

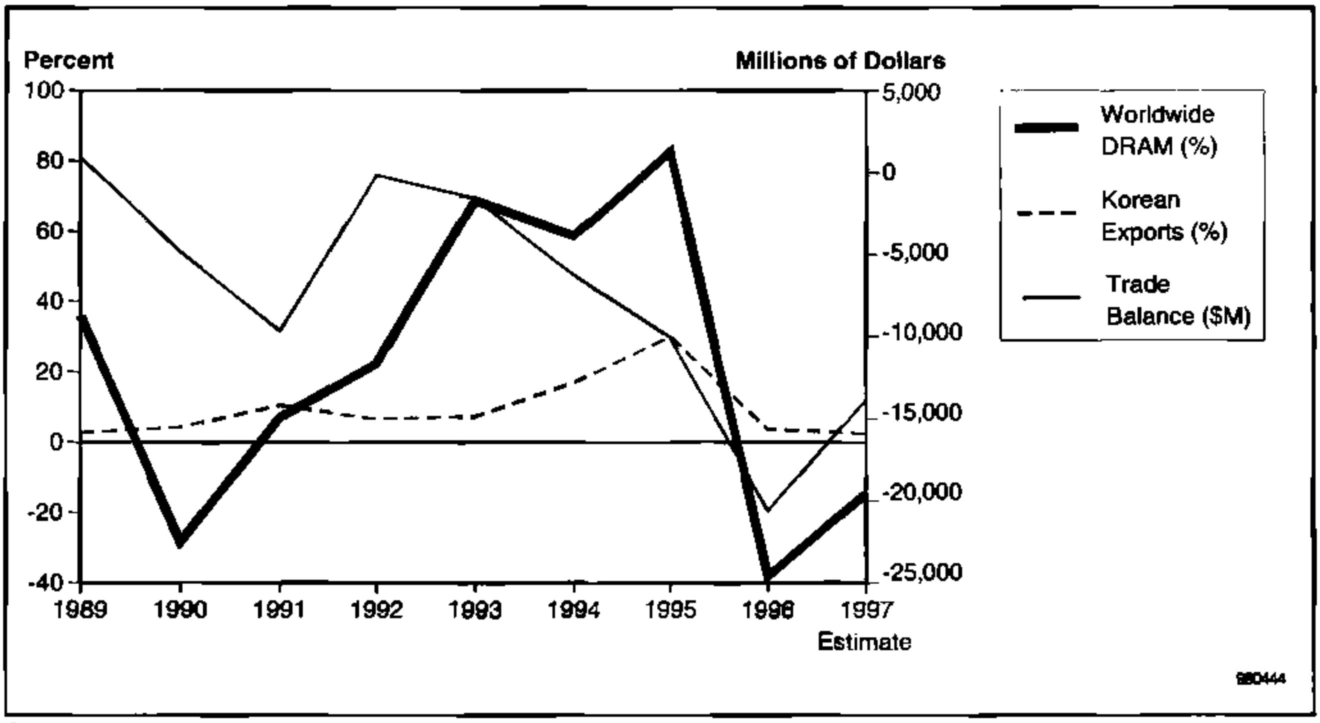
This chapter offers a Korean regional perspective on the reason behind Korea's financial crisis. It argues that the worldwide DRAM recession is one of the reasons for the Korean financial crisis. The impact of the financial crisis on the Korean semiconductor market is also discussed.

Why Did Korea's Financial Crisis Occur?

Figure 3-1 shows the relationship between worldwide DRAM revenue growth and the export growth of Korea. The two elements showed no correlation until the end of the 1980s. After 1990, however, as DRAM became one of Korea's major export items, these two elements started to show a strong correlation.

Korea's exports were solid until 1995. However, Korea's total trade balance was still negative. This means that the semiconductor surplus covered most of the other industries' deficit. In 1996, however, the semiconductor business flagged because of DRAM's drop in prices, so that it could no longer cover the other industries' trade deficit. As a result, a $20.6 billion negative trade balance was recorded in 1996 alone. The drop in DRAM prices continued in 1997—as of the end of September 1997, a $10.6 billion negative trade balance had already been recorded. The cumulative negative balance from 1994 is estimated to be about $50 billion. This amount is very similar to the IMF loan.

Figure 3-1
Relationship between Worldwide DRAM Revenue Growth Rate and Korean Export Growth Rate



Source: Dataquest (January 1998)

Korea's financial crisis might stem from the worldwide DRAM recession. Comparing the data for semiconductor statistics with Korea's trade balance of Korea offers some support for this assertion. This cannot be the only reason, but Dataquest believes that it is one of the factors generating Korea's financial crisis.

In 1995, Korea had an $8.8 billion trade surplus in semiconductors by virtue of its good DRAM business. At that time, Korea's total trade deficit was only $10.1 billion. In 1996, however, Korea's semiconductor surplus had shrunk to $0.4 billion, a reduction of $8.4 billion from the surplus in 1995. In the same year, the total trade deficit was $20.6 billion, an increase of $10.5 billion over 1995. The reduced semiconductor surplus of $8.4 billion in 1996 was a major contributing factor in the trade deficit of $10.5 billion, as shown in Table 3-1.

Table 3-1
Total Exports and Imports and Semiconductor Exports and Imports for Korea, 1995 through 1997 (Millions of Dollars)

	1995	1996	Change, 1995-1996	First Nine Months of 1997
Total Exports	125,058	129,715	4,657	99,709
Total Imports	135,119	150,339	15,220	110,094
Balance	-10,061	-20,624	-10,563	-10,385
Semiconductor Exports	17,643	15,293	-2,350	12,746
Semiconductor Imports	8,887	14,855	5,968	9,465
Balance	8,756	438	-8,318	3,281

Source: Dataquest (January 1998)

Actually, the financial crisis in Korea dates from the beginning of this year. The key reason for it is the cumulative trade deficit of many years. Many chaebol (conglomerate) companies started to fail, beginning with Hanbo Iron and Steel, and followed by Sammi Steel, Jinro, Kia Motors, New Core, and Halla, among others. Many small and medium-size companies followed the lead of the chaebols and fell also.

The chaebol companies failed in this financial crisis because of their weak financial structures. Most of the companies have capital ratios of under 20 percent. There are many under 10 percent. Tight money controls in this crisis caused the downfall of many companies.

Impact of the Asian Financial Crisis on Korea's Semiconductor Market

Most of the Korean semiconductor companies will reduce their capital spending plans in 1998 to 40 to 60 percent of their 1997 level. Also, many projects will be delayed, including overseas projects. This reduced capital spending will influence mostly 64Mb and 256Mb DRAM production capacity. Korea's 16Mb and 64Mb DRAM production lines will be less affected because, for most 16Mb and 64Mb DRAM lines, investment had already been completed or is in the final stage of the pipeline. Korea will likely lose some market share, and Taiwan semiconductor companies will likely gain. Korean semiconductor companies will invest less for capacity expansion than to increase yield or reduce chip size. As one more way to reduce capital spending, they may try to upgrade their old fabs using an isolated "minienvironment" automation system.

Samsung Electronics Company Ltd.'s direction under this crisis is to suspend capital spending for capacity expansion. Instead, the company will increase productivity by reducing chip size and increasing yield. Samsung's 1998 capital spending will be about 40 to 60 percent of its 1997 level. Hyundai Electronics Company Ltd. has also decided to reduce its 1998 capital spending plan. LG Semicon Co. Ltd. is trying to minimize its capital spending. Anam Semiconductor has decided to delay its second fab investment. Dongbu Group has proceeded with its license with IBM and has already started plant construction. But the company seems to be in a dilemma now as to how to deal with this financial crisis, because there is no funding for this facility.

All overseas semiconductor projects are facing a crisis, also. Samsung's Austin, Texas, plant and Hyundai's second Eugene, Oregon, plant will be delayed, perhaps by more than a year if this financial crisis continues. Hyundai's Scotland project and LG Semicon's Wales project are likely to be delayed, but as yet no company has announced clearly the future of its overseas plants.

Chapter 4
The Korean DRAM Perspective

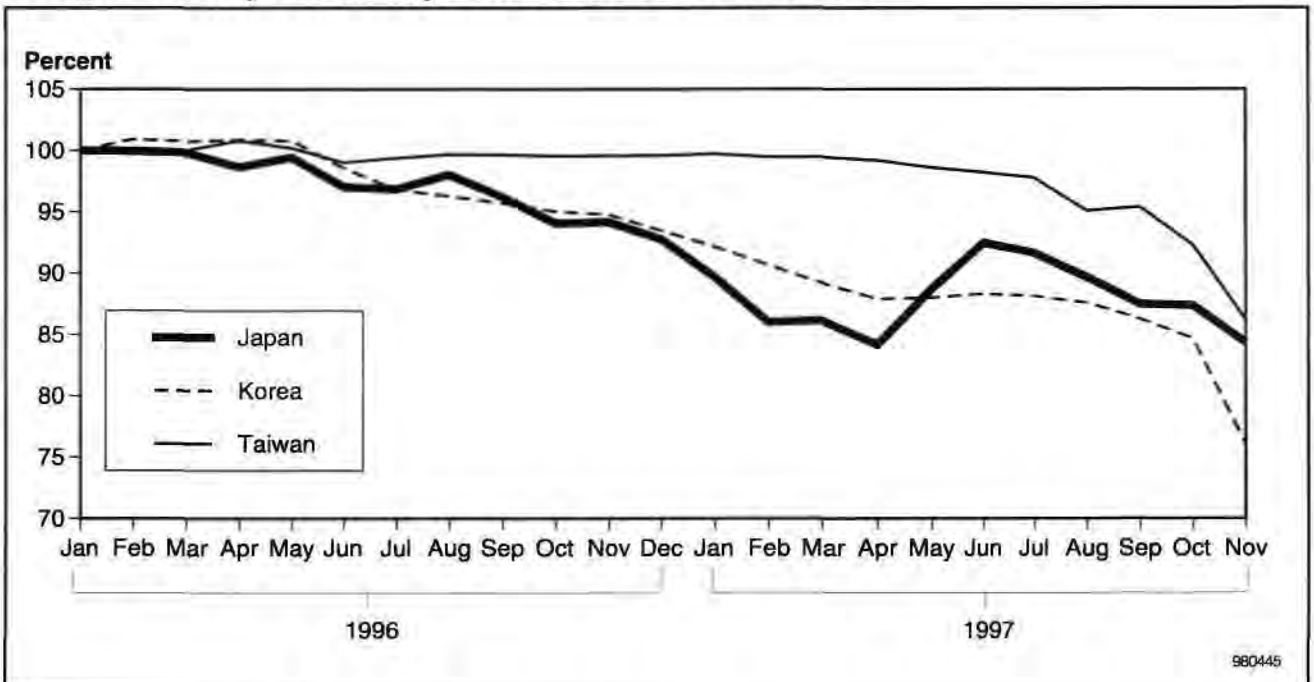
Introduction

This chapter discusses the impact of the Korean financial crisis on the worldwide DRAM market. DRAM pricing is predicted to fall further if the Korean, Taiwanese, and Japanese currencies continue to slide against the U.S. dollar.

The Impact on the DRAM Market of the Korean Financial Crisis

South Korea and the International Monetary Fund have agreed to a rescue package totaling $57 billion. South Korea agreed to implement IMF-recommended measures to revitalize its faltering economy in return for accepting the bailout. Even with the agreement, there are fears that the rescue may not succeed and that Korea's links to other Asia/Pacific countries may endanger those countries, as well. Figure 4-1 shows foreign currency purchasing power relative to the dollar.

Figure 4-1
Foreign Currency Purchasing Power Relative to the Dollar



Source: Dataquest (January 1998)

© 1998 Dataquest

Given the stringent management and restructuring requirements of the IMF bailout, the Korean semiconductor industry is planning to cut capital investment by 40 to 60 percent over last year. Korean DRAM manufacturers fear that their cutbacks could result in a drastically dwindling share of the world market, with market share lost particularly to Japanese and Taiwanese companies. The threat of shrinking market share is something Korean DRAM manufacturers haven't been accustomed to; they have enjoyed steady market share growth since 1990.

Samsung, currently the world's leading DRAM producer, is expected to implement a 30 percent cut in overall investment and is considering further cuts in coming weeks. Samsung's plans are to earmark W800 billion to W900 billion for semiconductor and LCD investment next year and W400 billion to W500 billion on research and development. LG Semicon and Hyundai are also cutting back investment. LG Semicon plans to lower investment by 30 percent, or W1.05 trillion to W1.10 trillion for next year, and Hyundai is considering a 40 percent cut. As with Samsung, both LG Semicon and Hyundai have yet to make their investment plans final.

What impact will these cutbacks have on projects already under consideration? LG Semicon is expected to delay the construction of its second LCD plant in southern Korea. LG Semicon and Hyundai are re-examining their plans to construct DRAM fabs in the United Kingdom, although both expect to go ahead with plans as scheduled. Most expansion plans for DRAM fabs in the United States by Samsung, LG Semicon, and Hyundai are expected to be suspended. Dongbu, which earlier this year announced plans to enter the semiconductor industry, decided to postpone this indefinitely, citing difficulties in borrowing money.

It will take one to two years for next year's cutbacks in Korean investment to make a significant impact on company market share and DRAM industry capacity. There is more than enough capacity already to support current demand, and as all manufacturers continue to shrink their 16Mb and 64Mb devices, industry overcapacity will continue through most of 1998 and possibly into 1999. To put device die size into perspective, the average die size of 16Mb DRAM at the end of 1998 will be 60 percent of the average die size of 4Mb DRAM at the end of 1995.

Taiwanese DRAM manufacturers will have a significant impact on when the market comes into balance. If Taiwanese companies continue with their aggressive expansion, the equilibrium point may be pushed out three to six months, well into 1999. Before the IMF actions, the Taiwanese companies planned to increase capital spending in local currency (NT dollars) by 10 percent. In U.S. dollar terms, this may actually represent declining capital spending because of currency devaluation (more on this later). The Korean cutback in spending may encourage Taiwanese DRAM vendors to accelerate investment in an effort to take market share away from the Koreans. If Korean companies cut their capital spending as indicated and if Taiwanese companies continue with their capital spending plans for foundry, memory, and joint ventures, Taiwan may surpass Korea in capital spending in 1998. However, not all Taiwanese DRAM vendors are expected to increase capital spending—at this time, Mosel Vitelic Inc. and Powerchip Semiconductor Corporation are expected to decrease their capital spending in 1998, and others may follow.

 © 1998 Dataquest

Dataquest believes there is a good possibility that Taiwanese manufacturers will not implement their aggressive capital spending plans. The Taiwanese companies are newcomers to the DRAM industry and haven't experienced prior industry downturns. As they gain experience in the current downturn, they may decide to stop DRAM spending abruptly. This will come with the realization that, while aggressive expansion will buy market share, it will also lengthen the DRAM industry downturn.

On top of all the changes in Korea's financial situation and the long-term effects of the IMF bailout plan, there is also the short-term phenomenon of a currency devaluation adding to the problem. Korea, Taiwan, and even Japan have seen the value of their currencies slide dramatically in relationship to the U.S. dollar as well as against European currencies.

Normalized to January 1996, an item with a fixed local currency price that could be purchased in the United States for $1 in January 1996 could be purchased in November 1997 for $0.84 if it came from Japan, $0.86 if it came from Taiwan, and $0.76 if it came from Korea. Of course, DRAM per-megabyte prices descend at a relatively steady rate (28 percent per year), but the effects of currency rate changes layer on top of this. If the manufacturing cost, measured in won, of a Korean DRAM drops at 28 percent per year over the course of 1997, and if in that same time the won dropped 20 percent (which it did), then the minimum price that could be charged for that DRAM in the United States without triggering antidumping measures would have dropped 42 percent! This implies that there should continue to be exceptional price slides for DRAMs from Japan, Korea, and Taiwan into the United States and Europe. This has a great impact on the worldwide market because, in 1996, Japan, Korea, and Taiwan had a combined share of 77 percent of the DRAM market, and DRAM consumption in the United States and Europe accounted for 56 percent of the world market.

This, though, is not the end. The November average tells only a part of the story. As of December, the won had dropped to 54 percent of its January 1996 level. The end of the drop is not in sight today. Korean manufacturers accounted for only 34 percent of 1996 DRAM sales, so the impact of the price slide will not perfectly match the exchange rate drop times normal DRAM price declines. The effect will be less than this; however, it will be important!

In short, DRAM prices, which have been falling at a rate based largely on the cost of manufacture, should continue to fall faster than this rate as long as Korean, Taiwanese, and Japanese currencies continue to slide against European and American currencies.

Chapter 5
Semiconductor Market Forecast: The Impact of Asia/Pacific's Currency Crises on China/Hong Kong

Introduction

Shifting the focus from Korea to China/Hong Kong, this chapter looks at the impact of the Asian financial crisis on electronic equipment assumptions and semiconductor consumption in China/Hong Kong. Dataquest has lowered its regional forecast for 1997 from 15 percent to 8 percent growth. Dataquest believes that China/Hong Kong will not be impaired in the short term, but it faces long-term challenges. Although China/Hong Kong's long-term semiconductor forecast has been lowered, it will still account for 26 percent of Asia/Pacific consumption by 2001.

Asia/Pacific and China/Hong Kong Forecasts

Prior to the financial havoc that has rocked Asia/Pacific's currency markets, Dataquest had lowered its forecast of 1997 electronic equipment production in Asia/Pacific from 17.4 percent to 14.9 percent. Dataquest's October Asia/Pacific semiconductor market forecast was lowered to 8 percent from 14.6 percent. Weaker growth was caused by slower second-half growth exacerbated by the currency crisis during the fourth quarter. Forecasts of electronics production and semiconductor consumption in China/Hong Kong were both lowered insignificantly by about 1 percentage point to 17.8 percent and 14.9 percent, respectively.

Dataquest expects that 1998 will have a higher level of growth than 1997 across the region. Helped by a long-awaited worldwide recovery in the second half of the year, memory prices should have, at long last, bottomed out. Korean and Japanese capital constraints should help to curb fab expansion and alter cutthroat pricing strategies to improve margins.

Figure 5-1 presents Dataquest's regional, country-level forecasts of semiconductor consumption from 1997 to 1999. China/Hong Kong's semiconductor market, helped by the combination of a strong PC industry and memory pricing improvements, will grow by 23 percent in 1998 and 31 percent in 1999. Critical to this high-level growth is also the performance of China's electronics output, which Dataquest assumes will grow by 20 percent in 1998 and 18 percent in 1999. At the top level, industry growth is the result of broad-based equipment investment, active foreign investment in the market, strong and steady local consumption, and competitive electronics exports.

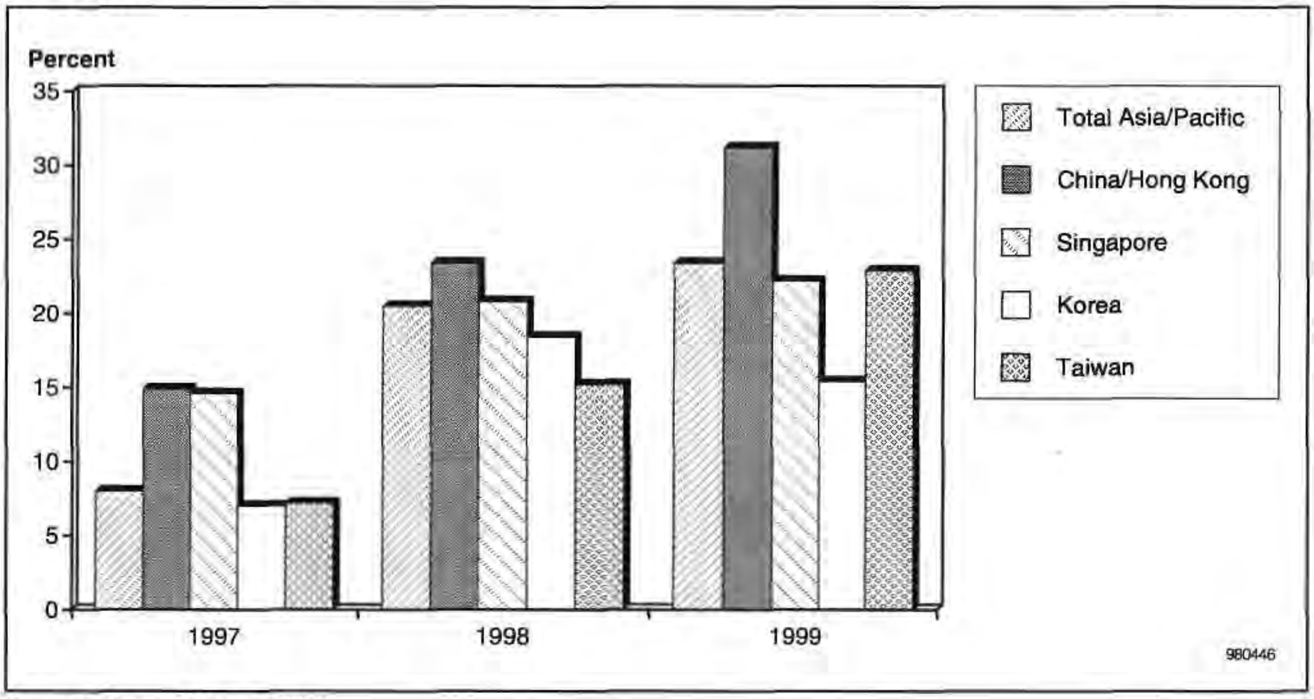
Figure 5-1
Forecast of Semiconductor Consumption Growth by Region in Asia/Pacific, 1997 to 1999 (Percent)



Source: Dataquest (January 1998)

Impact of Currency Depreciation

Dataquest understands the importance of stable financial markets to long-term economic prosperity in the region. But financial markets do not necessarily reflect the fundamental characteristics of the electronics industry's health. The impact of currency volatility needs to be viewed in the context of fundamental industry issues. Dataquest views the following electronics industry and semiconductor market fundamentals as key drivers potentially affected by the currency crisis:

- Slower growth experienced in the second half of 1997 is the result of decelerating exports to key export markets, including Europe, Japan, and North America and, to a lesser extent, slower growth within Asia/Pacific's developing domestic markets.
- There is a short-term effect on manufacturers in currency-depreciating countries that are struggling to make payments and order commitments to suppliers of semiconductors and other components.
- Local consumption has slowed in numerous countries, and deflationary forces have become more pressing. Because a small percentage of Asia/Pacific electronics production relies on Asia/Pacific consumption, the slowdown in local consumption of end equipment has a negligible impact on total production. Nevertheless, industry observers are watching the Japanese and Korean end-equipment markets carefully. Dataquest sees a direct impact of these large markets on Asia/Pacific electronics exports, especially Japan's imports of PCs from Taiwan.

 © 1998 Dataquest

The degree of the currency devaluation's impact on electronics companies depends, in part, on the percentage of semiconductor components imported by manufacturers in Asia/Pacific. Southeast Asian countries such as India, Indonesia, Malaysia, the Philippines, and Singapore rely almost entirely on foreign suppliers. However, the bulk of electronics production comes from the multinational companies (MNCs) that have relocated production from Europe, Japan, Korea, North America, or Taiwan. The advantages of the MNCs in Asia/Pacific is their ability to secure long-term global procurement contracts in U.S. dollars that buffer currency fluctuations.

Manufacturers in Asia/Pacific, which are part of conglomerates, also manufacture semiconductors that may use internally transferred semiconductors and therefore are not directly affected by currency fluctuations. Japanese consumer electronics manufacturers rely heavily on internally transferred components. In both cases, a major portion of costs are fixed. Export revenue then increases for the same units of goods shipped because more local currency is received for the same U.S. dollar export price.

Stronger Exports Likely to Make Up for Slower Domestic Consumption

Dataquest's long-term forecast of semiconductor consumption by region is shown in Figure 5-2. It shows Asia/Pacific's high growth relative to other worldwide regions but with significant country variances.

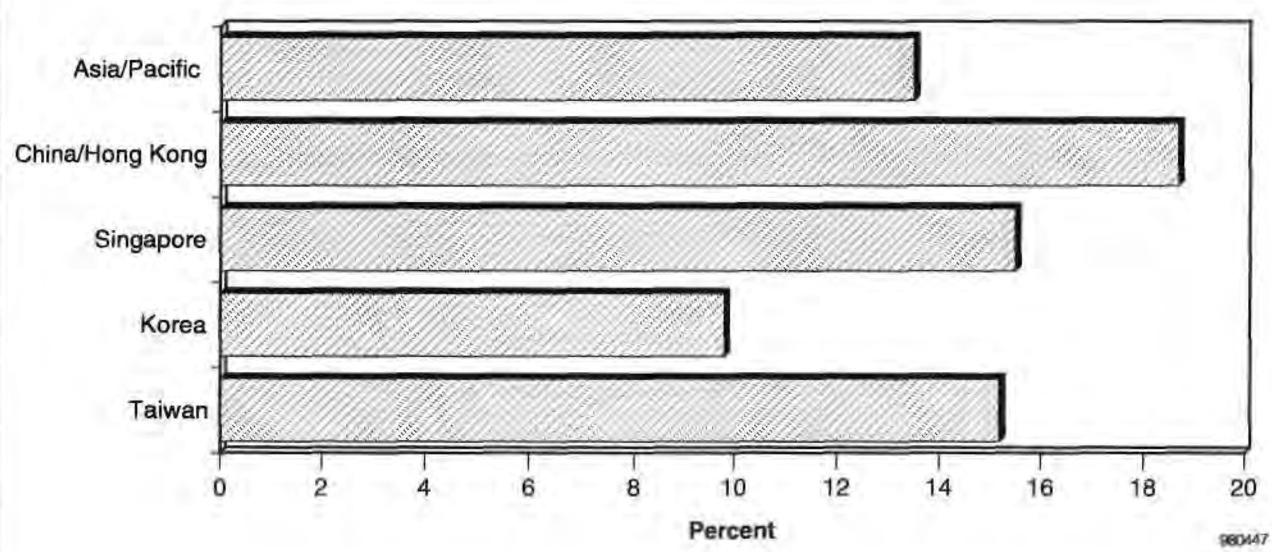
In 1997 and 1998, Asia/Pacific's electronics industry as a whole will become more competitive in exports because of devalued currencies. Export markets will continue to be the key to the region's high semiconductor consumption growth rates because of the immaturity of the region's end-equipment markets that are a percentage of the gross domestic product (GDP). Dataquest's electronic equipment and semiconductor forecasts assume a 3 percent to 4 percent economic growth in the United States in 1998 and 1999 and a modest economic recovery in Japan. Weakened industrial growth in Japan and Korea, as well as Asia/Pacific's lower cost base, will continue to benefit Southeast Asia's electronics industry (as has been the case for 10 years).

Singapore Sustains Growth

The China/Hong Kong and Singapore markets will grow by about 15 percent in 1997. Singapore has not experienced the negative short-term effects of currency depreciation because its production is dominated by MNCs that operate global procurement organizations. Real GDP in the third quarter of 1997 rose 10.1 percent, and this growth was fairly broad-based. As reflected in the forecast, a weaker currency may have a long-term positive effect by lowering export costs, Singapore's lifeblood, assuming import component costs increased less, proportionately.

 © 1998 Dataquest

Figure 5-2
Long-Term Forecast of Semiconductor Consumption by Region in Asia/Pacific, 1996 to 2001 (Compound Annual Growth Rate)



Source: Dataquest (January 1998)

Taiwan's Fundamentals Are Still Strong

Anticipated slower growth in Taiwan in 1996 to 1998 is attributable more to memory price erosion than to currency depreciation because memories represent 46 percent of Taiwan's semiconductor consumption. Dataquest believes that Taiwan's economy and financial institutions are fundamentally strong, and GDP growth is forecast to exceed 6 percent in 1998. Dataquest also expects electronic equipment production to show the second-fastest growth in Asia/Pacific from 1997 to 2001. Dataquest, therefore, forecasts a strong semiconductor market in Taiwan in 1999 because of an anticipated recovery in its memory market.

Tighter capital markets will help control capacity spending primarily in Korea and Japan, but to a lesser extent in Taiwan, which shows a higher level of liquidity than the rest of Asia. Overall, it is likely that the crises in Korea and Japan will have a positive effect on memory pricing in the longer term, after late 1998 and in 1999. In segments where Taiwan competes directly with Korea, such as DRAMs, companies may face severe competition from Korean suppliers that now have an exchange advantage. However, note that most business is conducted in U.S. dollars, and prices are rising because of the lack of cash and capital in Korea's chaebols.

 © 1998 Dataquest

Korean Market Faces Structural, Not Cyclical, Problems

As shown in Dataquest's long-term regional semiconductor market forecast, the weakest market will be Korea from 1998 to 2001. Korea will have trouble increasing exports enough to compensate for the huge increase in its debt-service ratio. When the won drops, the debt-service ratio increases on a one-to-one basis, but exports will not increase on a one-to-one basis. Furthermore, electronic equipment exports will continue to suffer because of a lack of new, higher-margin products and because of falling profits exacerbated by a global consumer electronics slump. On top of these problems, the currency crisis affects these conglomerates insofar as they are dependent on imported semiconductor components. However, the free-falling won makes exports much cheaper—but only if prices are not raised to cover increased component costs. The lack of a diverse component supply base, as seen in Taiwan and Japan, makes the structural nature of Korea's problems more severe. Korean electronics manufacturers have been shifting production offshore in an attempt to develop new markets and increase competitiveness.

China/Hong Kong Is Still the Rising Star, but with Challenges

Dataquest believes that the currency and financial market problems in Asia/Pacific have more to do with speculative "bubbles" in property, construction, and semiconductors than to fundamental economics and manufacturing efficiencies. China and Hong Kong are not immune, but they seem to be dealing with these bubbles more effectively by popping them before they get too big. China's economic czar, Zhu Rongji, successfully burst the stock market bubble, property bubble, and construction bubble in 1996 and 1997. After October's Party Congress, he is now more empowered than ever to pop the next speculative runs, whatever they may be. Next year, he will be promoted to prime minister. Zhu's charter is to fix the state-owned enterprises to avoid overwhelming the financial system with bad loans. If China slacks off, it will face serious problems, potentially worse than those of Korea. Korea's lessons are being learned by others, and China can avoid this kind of crisis (having U.S.$200 billion in combined reserves with Hong Kong will help, too). A strong U.S. and European economy will be critical to China and the rest of the Asia/Pacific region.

As with Russia, a nonconvertible currency does not necessarily insulate China from possible depreciation. Several years ago, China devalued its renminbi and may have to do so again sometime next year because of mounting pressure in the region and competitive pressures on the export front (discussed later in this document). However, because the long-term goal is to merge the renminbi and Hong Kong dollar, it is not likely that the Hong Kong dollar will lose its U.S. dollar peg.

Currency depreciation has lowered production costs in various Southeast Asian countries. So, will China become less competitive in its vital export markets? Dataquest believes that because significant currency depreciation caused lower export costs, there will be increasing competition for foreign investment with China, which could result in more than $20 billion in electronics production revenue by 2001.

 © 1998 Dataquest

China faces the following three formidable challenges that are becoming more acute because of the recent currency crisis:

- Raising the competitiveness of its faltering domestic companies, especially state-owned enterprises, before entering the World Trade Organization (WTO)
- Countering the serious slowdown in foreign investments because of the rising cost of doing business in China
- Maintaining 7 percent to 10 percent GDP growth and raising the rate of domestic consumption to absorb excess capacity and overdependence on exports
  - A slowdown in Japanese imports of consumer electronics and PCs from Asia/Pacific may hurt China the most because its currency has not depreciated and, therefore, its costs are increasing relative to those of other countries.
  - Korea and other affected countries will rely heavily on exports to try to pull themselves out of their economic turmoil.

All three issues affect the electronics industry. In light of these challenges and Dataquest's survey of producers in China and Hong Kong, Dataquest believes that a 20 percent growth in electronics production is achievable in 1998, decelerating to 18 percent in 1999.

The following factors will help China to overcome these three challenges and maintain high growth rates:

- A large proportion of Chinese electronics companies are successfully competing against major MNCs, particularly in the computer and consumer equipment markets. Dataquest believes that the Chinese government will continue to support these companies before and after entry into the WTO because its international competitiveness will be imperative to its future survival. The priority for the government is improving efficiencies and quality; therefore, information technology will continue to be rapidly deployed as an infrastructure necessity.
- Although total investment is down in 1997, the production capacity of the large MNCs and local electronics manufacturers has increased by more than 50 percent. Business costs are rising in China, but the two main reasons for investing remain to develop the long-term potential of the domestic market and to take advantage of an abundant, inexpensive labor force. Note that efficiencies and quality are increasing faster than costs. Investment from Taiwan to China increased by nearly 30 percent in 1997, despite the attempt of the Republic of China government to slow the flow of business to China.
- Inflation was the major concern last year at this time, but now deflation is the top priority of the government. Interest rates are likely to fall to stimulate growth.
- Japanese manufacturers are shipping goods worldwide from China. Exports of electronics to Japan from China represent 10 to 15 percent of China's total electronics exports. Therefore, Japan's slowdown in consumption will have a minor effect on Chinese production.

 © 1998 Dataquest

- Korean companies and other affected Asia/Pacific electronics and semiconductor companies may have an increasing currency advantage for exports relative to China in the short term. However, these companies are seriously hurt by increased debt-service costs. With depreciation, there is a debt-service ratio increase of one to one, and exports cannot possibly expand enough to counter such costs. Major cost-cutting measures may be necessary to service foreign and local debt that impairs the level of export expansion necessary for recovery. Certainly, capacity expansion is not viable at this point.

Lower Long-Term Growth Forecast for China/Hong Kong

Figure 5-3 presents Dataquest's long-term regional electronic equipment production forecast. Although Dataquest expects China to maintain a relatively high level of growth, Dataquest has lowered its 1996-to-2001 forecast for China/Hong Kong electronic equipment production from a compound annual growth rate (CAGR) of 26 to 24 percent in light of recent deflationary industry developments in the region. Dataquest expects the industry to reach $70 billion by 2001, rather than $90 billion as previously forecast. The currency devaluation's impact on semiconductor consumption will be lower between 1996 and 2001; in fact, the original CAGR of 39.7 percent is now expected to become 33.9 percent. Dataquest's 2001 forecast has been lowered from $21 billion to $18 billion.

As shown in Figure 5-4, growth in China/Hong Kong is expected to outpace the rest of Asia/Pacific because of its growth in production efficiencies, export growth, and local demand. China/Hong Kong's electronics industry produced 24 percent of Asia/Pacific's electronics in 1997, which will increase to 29 percent by 2001. Semiconductor consumption will grow from a 20 percent to a 26 percent share of Asia/Pacific's consumption. These growth rates may seem very high, but they are actually relatively low in comparison to overall GDP size and growth because China is still a developing economy. Dataquest's industry surveys and detailed analysis of China/Hong Kong's electronics production and companies are presented in a Focus Report (*China/Hong Kong's Computers, Communications, and Consumer Electronics Industry in 2001*, SEMI-CH-FR-9701, November 1997).

Semiconductor Device Forecast

All these issues affect the electronics industry in China and Hong Kong. From 1996 to 2001, China/Hong Kong growth is expected to exceed Asia/Pacific growth in electronics production by 6.8 percent and to exceed semiconductor market growth by 9.6 percent (see Table 5-1). Consequently, its share of Asia/Pacific semiconductor market revenue will grow from 20 percent in 1997 to 26 percent in 2001.

Cautious business planning is required at this time because the volatile financial markets will take another three to six months to begin to stabilize. The situation requires rapid and extreme government action in Korea and Japan before the downward financial slide in the region reverses course.

 © 1998 Dataquest

Figure 5-5 compares total semiconductor consumption with DRAM and non-DRAM markets. Dataquest's semiconductor forecast incorporates both the macroeconomic and electronic equipment assumptions discussed earlier. After a flat market performance of 0.5 percent in 1996, the China/Hong Kong semiconductor market picked up a 15 percent growth in 1997. Assuming higher average selling prices (ASPs) for 64Mb DRAMs, the mainstream product in 1998, as well as other memory devices, Dataquest expects 1998 to outperform 1997. With a DRAM growth of 36 percent in China/Hong Kong, the overall market should reach 23 percent in 1998, with stronger DRAM growth occurring in the second half of the year.

The currency devaluation's impact on the DRAM market becomes more pronounced after 1999 because of the anticipated formidable growth in PC production. Boosting the expected DRAM growth is the incredible surge in China's PC market. China, excluding Hong Kong, will take about 30 percent share of Asia/Pacific's PC consumption in 1998 and maintain an average annual growth rate of about 40 percent until 2001, the fastest growth in Asia/Pacific. Non-DRAM products continue to experience more stable, long-term growth because of China/Hong Kong's broad-based electronic equipment production growth.

Table 5-1
Total Electronics Production and Semiconductor Market Forecast in China/Hong Kong and Asia/Pacific, 1997 to 2001 (Millions of U.S. Dollars)

	1997	1998	1999	2000	2001	CAGR (%) 1996 to 2001
China/Hong Kong						
Electronics Production Revenue	42,387	50,780	59,924	71,763	84,803	23.9
Semiconductor Market Revenue	6,490	8,008	10,504	14,926	18,077	33.7
Electronics Production Growth (%)	17.8	19.8	18.0	19.8	18.2	-

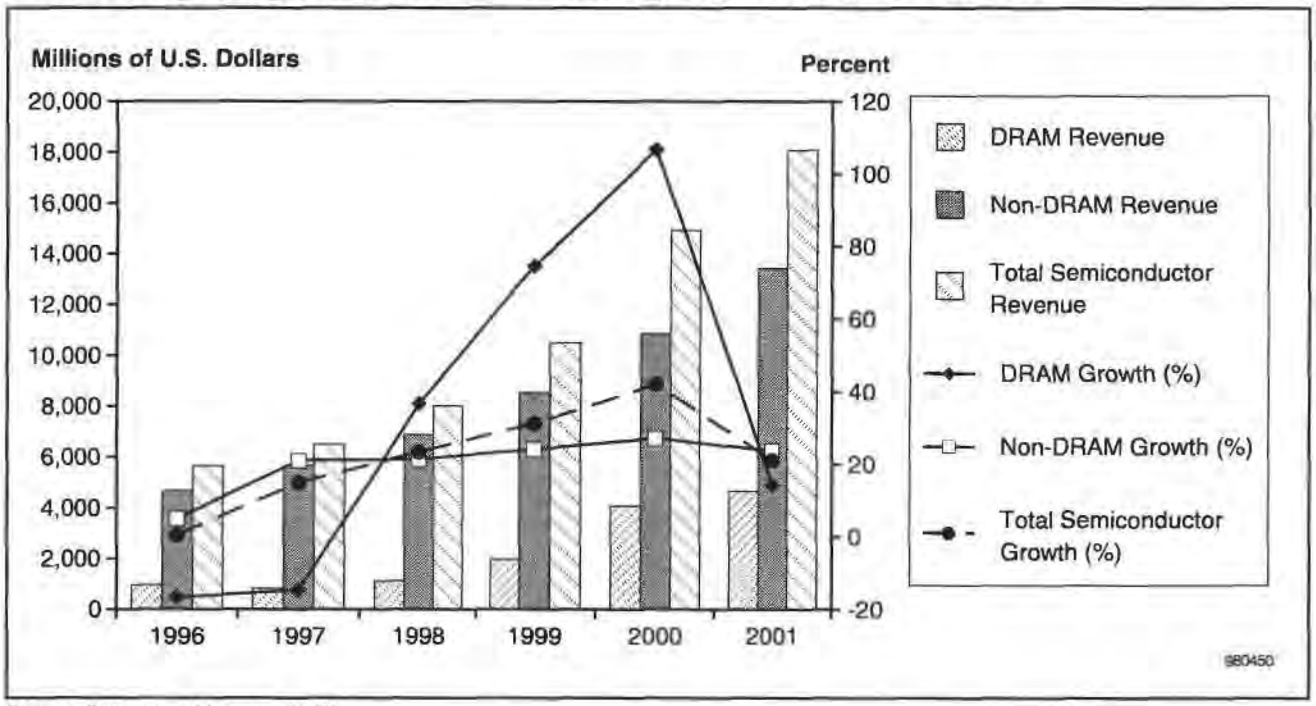
Figure 5-5
China/Hong Kong Semiconductor Consumption Forecast, 1996 to 2001



Source: Dataquest (January 1998)

Dataquest Perspective

The financial crises have adversely affected semiconductor shipments to end-equipment companies that are dependent on sales within the affected countries. Dataquest highlights the economic woes in Japan and Korea because they will weaken Asia/Pacific electronic equipment production overall—again, because of weakened exports mainly in consumer electronics but also in computer-related equipment producer countries. Consumption of electronics in Malaysia, India, Indonesia, Malaysia, Singapore, Thailand, and Taiwan is also damaged by higher import costs and weaker consumer spending in 1997 and 1998. However, the majority of production in the affected countries comes from companies exporting to Europe, Japan, and North America, so a local market slowdown has minimal effect on overall production of Asia/Pacific as a whole. Furthermore, export sales are conducted in U.S. dollars, and semiconductor purchases from multinational vendors are usually conducted in U.S. dollars also—thereby avoiding the ill effects of currency fluctuation.

China/Hong Kong has not been affected by this financial crisis in the short term because of the stable renminbi and Hong Kong dollar, which are backed by about U.S.$200 billion in combined foreign reserves. However, Dataquest has outlined the deflation and investment challenges within China. Dataquest's lower long-term electronic production and semiconductor consumption forecasts for China/Hong Kong assume that Southeast Asia will receive increased investment that would otherwise have gone to China (after four years of very high foreign investment levels in China). However, the power of the Chinese market and its production prowess for international markets will continue to attract investment, enabling it to extend its lead as the largest and fastest-growing semiconductor markets in Asia/Pacific.

Chapter 6
Currency Meltdown: Impact on Asia/Pacific PC Markets

Introduction

After the previous three chapters' regional perspectives on Korea and China/Hong Kong, Dataquest now turns to the PC market. This chapter aims to provide insight into the currency devaluation's early impacts on the personal computer industry, to assist PC suppliers in understanding the factors involved, and to highlight the key areas on which to focus when steering a path through the crisis.

Background

The economic conditions that have spread to nearly every Southeast Asian country started on a much smaller scale. South Korea was already experiencing severe economic difficulties following a series of bankruptcies among its large industrial conglomerates when difficulties in the Thai banking and finance community escalated to a devaluation of the baht during the first half of 1997. A ripple effect quickly followed, sparking similar devaluations in Malaysia, Indonesia, and the Philippines. Initially, Hong Kong and Singapore remained largely unaffected by the difficulties faced by their neighbors, but this situation changed late in September as investor nervousness spread to other Asian markets. Similarly, the Australian dollar became more seriously affected this October. At the end of October, the Thai baht and Indonesian rupiah were both trading at about half the values they held at the beginning of the year. The Malaysian ringgit had fallen more than 35 percent, closely followed by the Philippine peso, down about 32 percent. Most other currencies were trading between 10 percent and 15 percent lower than their values at the beginning of 1997. China, Hong Kong, and Japan were the least affected. In both Thailand and Indonesia, the IMF has stepped in to assist with the crisis.

Economists have a range of opinions on both the causes and the solutions to the economic crises, but it has become clear that there have been several different underlying factors. These include cozy relationships between government and favored business leaders, irrational investment in high-profile projects (such as in real estate) instead of in productive areas of the economy, and the failure to open up large monopolies to competition. The Thai banking and finance sector has been sharply criticized, as has economic policy in Thailand, Malaysia, Indonesia, and the Philippines. Most other affected countries have been victims of a "contagion" effect, as nervous investors apply the same high-risk label to all Asian markets.

A speedy recovery is not part of the outlook. Investors have been deeply critical of policy response in most countries, which they consider to have been grossly inadequate so far. In Thailand, for example, the government recently decided not to implement higher taxes on oil—as recommended by the IMF—thus placing a U.S.$16 billion rescue package at risk and sparking several ministerial resignations. Malaysia's prime minister, Dr. Mahathir Mohamad, has shifted too much blame onto currency speculators and failed to deliver a budget with the teeth desired by investors. In Indonesia, IMF recommendations have also been actively resisted.

 © 1998 Dataquest

Instead of easing, investor nervousness has spread to include more countries and has introduced a level of turbulence in stock markets around the world. The relative health of the Asian markets remains highly volatile, and major currency shifts are likely to continue—even as this document goes to print. The general consensus among economists is that the hardest-hit Asian economies will take two years to fully recover, and Dataquest has been revising PC consumption forecasts for the region downward.

Impact on PC Shipments

Figure 6-1 shows the declining growth rates seen so far this year in Korea, Indonesia, Malaysia, and Thailand—the countries most affected by the financial crisis. It reveals the Korean situation to be quite different from that of other countries because PC shipments have been depressed—with no growth—since the fourth quarter of 1996. Conversely, Indonesia, Malaysia, and Thailand suffered a shared impact from the financial crisis much more recently, with the major downturn in PC shipments coming in the third quarter of 1997.

The Malaysian market has been somewhat less affected than the Thai and Indonesian markets (it is the only one in which third quarter 1997 shipments are up over the previous year), although the impact is still clearly visible. This lower impact is in part a reflection of the reduced scale of the currency crisis in that country, which only produced PC price rises late in the third quarter.

Dataquest has observed further price rises in the fourth quarter and expects a larger impact before year's end. PC shipments in most other Asian countries have yet to be affected by the financial crisis, although many have been experiencing lower growth for other reasons, such as market maturity.

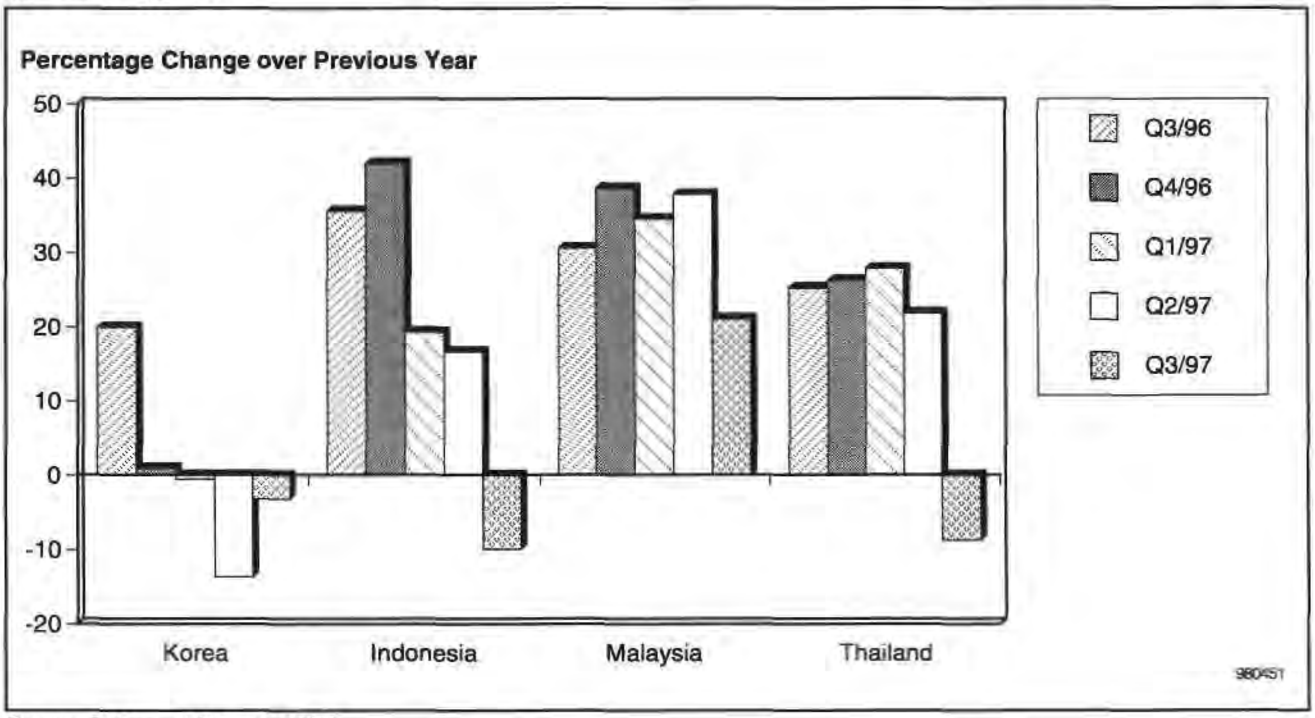
In Thailand, Malaysia, and Indonesia, the greatest reduction in PC consumption has consistently been in the corporate sector, especially in the banking and finance industry. As a result, vendors that focus heavily on this segment (such as IBM) have typically suffered the most impact. The next biggest concern for vendors is the potential falloff in government business in Indonesia and Thailand (but not in Malaysia, where the government has reaffirmed its commitment to existing projects). This situation differs in Korea, where the home market has been most affected—probably reflecting the longer period of economic uncertainty and its impact on consumer confidence.

Market Dynamics

Rising Cost of Imports

Fully imported PCs and imported components such as monitors, microprocessors, hard drives, and memory modules are affected equally by exchange rate variation, in theory giving no advantage to vendors buying either one. Locally manufactured components, however, such as Acer Computer International Ltd.'s motherboards in Taiwan, Samsung's memory chips and monitors in South Korea, and batteries and monitors from Delta Electronics Industrial Ltd.'s operation in Thailand, will not be affected by exchange rate variation when sold on the local market, thus handing an advantage to vendors that use these local components over imports. Also, local labor costs have fallen considerably relative to other

Figure 6-1
Year-on-Year Growth in PC Shipments in Korea, Indonesia, Malaysia, and Thailand: Q3/96 to Q3/97



Source: Dataquest (January 1998)

countries, providing an advantage to any manufacturer (multinational or local) undertaking part or full assembly of PCs in the local market. The same relative advantage applies to most of the facilities and service-related costs for a PC plant.

Rising PC Prices

The most important inhibitor of PC sales within affected economies has been rising prices. At the same time, many suppliers have switched to pricing in U.S. dollars to avoid having to adjust continually for exchange-rate variations. In Thailand and Indonesia, price rises in PC hardware have been offset in part by the regular cycle of worldwide component price cuts, particularly those of Intel Corporation, ensuring that, although currencies might have dropped up to 50 percent in value, PC price rises have generally been limited to under 15 percent. A similar process has taken place in Malaysia, although vendors in that country have managed to delay price increases a little longer.

Canceled and Deferred Purchases

Many buyers are waiting for the local currency to improve to maximize the spending power of their limited budgets, and at the same time many of their budgets are being reduced. Either way, the effect is the same: Premeltdown budgets are inadequate for postmeltdown prices. Within the government and corporate sectors, there is a strong inclination to defer making large purchases. In the case of government, there is considerable pressure to exercise restrained fiscal policy and to set spending priorities toward areas that the investment community sees as most important to stabilizing the economy.

 © 1998 Dataquest

In both Indonesia and Thailand, government information technology (IT) purchases are expected to be especially conservative. The Thai government has already announced that the IT budget for 1998 is to be cut from 7.8 billion to 3.7 billion baht. The Indonesian finance minister announced in August that U.S.$35.6 billion worth of government and state-related projects were to be postponed or reviewed, indicating that mining, energy, public works, and the transportation sector would be hit hardest. This move is expected to have a substantial impact on PC purchases in those sectors.

In the home sector, spending on all high-priced luxury items diminishes during periods of economic uncertainty. Additionally, like business buyers, many families find that what they would have purchased before the currency decline has simply become too expensive. Other factors will indirectly affect PC purchases by reducing spending power. These include an increase in the value-added tax in Thailand from 7 percent to 10 percent (following IMF recommendations), increased import tariffs to 30 percent, and expected increases in fuel and electricity prices in Indonesia—which will ultimately be passed on to all consumer goods.

Late Payments

Maintaining adequate cash flow has been a particularly serious problem for many vendors as companies delay paying for equipment that has been delivered. With their debts owed in U.S. dollars, buyers hold out payments in anticipation of any small rise in local currency value. The risk is, of course, that the local currency value will decline further and that the longer delay will actually increase the debt. Although delayed payments are affecting every stage of the procurement process, the problem is most pronounced when it comes to vendors getting payment from channel partners. This applies particularly to first-tier channel partners, which are most likely to hold stock and have to buy in U.S. dollars (selling to the second tier in local currency).

Technology Lag

Dataquest has found little evidence of "slimming down" of PC configurations to reduce costs, nor of any major switch to upgrade purchases at the expense of new PC purchases. There is, however, strong evidence that microprocessor life cycles, particular for Intel's Pentium 166-MHz chip, have been extended in desktop and deskside machines. This extension is a trade-off for limiting price rises to manageable levels: Under normal circumstances, component price cuts would be accompanied by a strong shift by manufacturers to later-generation processors. Also, fewer buyers are able to afford the latest Pentium II processor, thus contributing to the slow take-up rate across the region. The overall result is a greater technology lag behind the U.S. market. Dataquest expects this lag to lengthen, at least temporarily, in Indonesia, Thailand, and to a lesser extent, Malaysia.

A second, related effect is likely to be the shift by manufacturers and buyers toward cheaper microprocessors from Advanced Micro Devices Inc. and Cyrix Corporation. No data is yet available to confirm if this shift has taken place, but early indications are that Intel was disappointed with its third quarter performance, while AMD reported a strong demand in Asia.

Export Competitiveness

Vendors that manufacture in countries now heavily impacted by currency depreciation are better positioned for export to less-affected markets within Asia or to other world markets. Acer, for example, has already indicated that a depreciation of the Taiwan dollar, although relatively minor compared with other Asian countries, should prove highly beneficial to its 1997 financial results.

Survival Strategies

New Targets

Preliminary third quarter results show that the Chinese, Taiwanese, Hong Kong, and Australian PC markets have not been affected by the Asian economic crisis. Although this situation may change at any time, Dataquest anticipates that these countries will remain the best opportunities for PC sales while the crisis continues for the rest of Asia. China's growth will be unlikely to slow, and the other markets are all underpinned by solid economic fundamentals. Where opportunity allows, vendors operating in multiple markets through the region should look to put most of their current resources behind sales efforts in these countries. Similarly, within the deeply affected markets, Dataquest has observed that not all sectors have been affected to the same extent, with the education and small business sectors having provided better opportunities relative to other sectors in the third quarter.

Zero Inventory

One ironic result of rapid currency devaluation is that those manufacturers that have poorly managed their inventories gain a short-term advantage. Having purchased or manufactured excess stock under favorable exchange rates, these suppliers are able to hold off on announcing price rises the longest. Having passed this stage, however, inventory management becomes far more critical than under normal market conditions. Vendors will need to keep minimal stocks to take advantage of short-term price fluctuations on components. Acer, for example, has taken the opportunity to announce a more streamlined build-to-order (BTO) and delivery strategy in Thailand. Later, when currency values begin to rise, excess inventory will be punished severely, and it is likely that a number of PC suppliers will sustain large losses.

Compress Channels

The advantages of shorter supply lines will be increased under the present economic circumstances for two reasons. The first is lower inventory through the system, for the same reasons as those mentioned above. The second is that a shorter supply line will minimize the exposure to bad debt, which has already shown itself to be a problem in the third quarter. Vendors that sell direct have only to worry about one set of payments. Vendors that use a multitiered channel are exposed—if the buyer, reseller, or distributor defaults—multiplying their risk.

 © 1998 Dataquest

Boost Local Content

There is a substantial competitive advantage from increasing use of local hardware and labor content within markets heavily affected by currency depreciation or from importing components from facilities located in those countries wherever possible. Both these actions will reduce overall production costs. Just as important, however, is the need to maintain flexibility in these arrangements so sources of supply can be quickly altered to take advantage of further currency fluctuations and to avoid being locked into arrangements that become less competitive as currencies appreciate.

A Long-Term Opportunity?

Southeast Asia's lower exchange rates have made these countries more attractive for locating full-scale production facilities. For all the difficulties IBM is facing in selling PCs into the Thai market, it is now reaping the rewards for its decision to establish a U.S.$300 million plant to manufacture hard drive and storage products in Prachinburi, Thailand. Fujitsu Ltd. and Seagate Technology Inc. are also establishing new facilities or expanding existing ones in Thailand. At the same time, traditional production locations such as Singapore have become increasingly expensive during the past year. Shifting production facilities to affected countries has high potential rewards, but, because of the size of the investment involved, it also carries high risks.

Do Current Conditions Favor Local Vendors?

In recent years, the unbranded "whitebox" PC clone industry has been a dominant part of the PC mix in Asia, although it shows signs of stabilizing as markets mature and has been forecast to decline as a proportion of most countries' markets in the next few years (see Dataquest report *Cheap, Fast, and Flexible: Whitebox PCs in Asia/Pacific,* PCIS-AP-MT-9702, October 1997). At the same time, Dataquest sees a strong pressure on large, branded, local assemblers—such as Wearnes Technology, V-Tech Systems Limited, Powell Computer Co. Ltd., and Total Peripherals Group Pty. Ltd.—from multinational giants such as IBM, Compaq Computer Corporation, and Dell Computer Corporation, steadily squeezing the former group out of the market.

Economic uncertainty seems to favor many local vendors, however, with indications that buyers have shifted toward these suppliers in Indonesia and Thailand (Powell and ATEC Computer Co. Ltd. are just two examples of local vendors that did well in the Thai market in the third quarter). There is no doubt that, in these markets, a consequence of reduced buying power and higher PC prices has been a shift toward whitebox purchases to achieve required purchase volumes with limited funds or to continue buying PCs with the same equipment levels without paying the higher prices. It would appear that, in these markets, economic pressure has temporarily reduced the perceived value of the warranty/service/quality package offered by brand-name suppliers. Also, Indonesian government departments are following a directive to favor local vendors when buying desktops while the crisis continues.

 © 1998 Dataquest

The opposite trend has been seen in Malaysia, however. Here, local vendors seem to be having more difficulty capitalizing on component price fluctuations, and buyers are placing greater emphasis on reliability (with a view to extending equipment life) under the present conditions. Nor are local vendors faring better in Korea, although Dataquest has observed an increase in demand for secondhand PC systems.

Dataquest believes that local companies' key advantage lies in their higher proportion of local assembly relative to their multinational competitors (although multinational giants such as Dell and Gateway 2000 Inc. that operate factories in Malaysia or other affected countries are also well positioned). Local assembly gives vendors a critical advantage when it comes to pricing PCs on the local market. On the minus side, local companies are at a disadvantage when it comes to financing their operations. Investment is harder than ever to secure in countries such as Thailand and Indonesia, and many whitebox suppliers—although prosperous in high-growth markets—are ill-equipped to ride out periods of reduced cash flow. In contrast, multinational suppliers can afford a long-term strategy, riding out unprofitable periods in one or two countries to secure a strong market position in the long term.

On balance, although not helping any vendor sell more PCs, the current conditions should temporarily negate many of the advantages held by multinational companies over local vendors. In particular, Asian companies that also manufacture components should be more competitive in their home markets over fully imported products. Overall, Dataquest expects a temporary halt to the market share slide being experienced by local vendors in Southeast Asian markets, with multinationals retaking the upper hand when economic conditions improve.

Dataquest's Market Outlook

Generally speaking, the outlook for recovery has shifted from a near-term to long-term expectation in Thailand, Indonesia, and Malaysia, with Malaysia somewhat better positioned than the other two. PC vendors will thus need to be prepared to survive a sustained period of difficult and depressed trading. Economists are indicating that the Korean economy could begin to turn around earlier—perhaps starting a slow climb early in 1998, but early indications are that the fourth-quarter performance of the PC markets in Indonesia, Malaysia, and Thailand will be even more badly affected than the third quarter. For as long as this situation lasts, Dataquest expects PC shipments to be inhibited, especially as government projects and large corporations play such an important role in driving IT acquisition in Southeast Asian markets.

On the positive side, spending on PCs is unlikely to be as deeply affected as other capital expenditure because improving the communications and technology infrastructure in Southeast Asia is seen as one of the building blocks for recovery. Additionally, the overall growth in the Asian region will continue to be solid in 1998 and 1999, driven by the booming Chinese market. Given the highly contagious nature of currency fluctuations within the region, however, the situation for most of the markets, particularly those in Southeast Asia, remains volatile and unpredictable.

Chapter 7
The Impact on Capital Spending of the Asian Financial Crisis

Introduction

This final chapter represents a recap of Dataquest's views over the past several months of how the Asian financial situation will affect capital availability and spending in semiconductors. Dataquest has just released the spending forecast for 1998, with both a forecast and downside risk scenario. The details of those scenarios are published in a Dataquest Perspective ("Wafer Fab Equipment Market Forecast Update: Question Marks for 1998 as the Second Half of the 'W' Unfolds," SEMM-WW-DP-9801, January 1998), and an overview is presented here.

Will the Southeast Asia Currency Issue Cause a Decline in Capital Spending in the Region? Yes! Here's Why ...

In early August 1997, when the Asian financial systems began experiencing stress, Dataquest went on record as seeing more downside risk than upside potential to our 1998 capital spending forecast, in part because the Southeast Asia currency issues could put a damper on capital availability in the region. That statement was made before the fourth quarter meltdown, based on fundamentals of capital availability.

The real issue? The entire Southeast Asian banking system is in a liquidity crisis, with declining or negative cash flow. This has caused devaluation of currencies throughout the region as a natural, self-correcting economic response, resulting in equity market upheavals as the world "readjusts." The original, higher-order cause of the liquidity issue is complex, involving factors such as current account imbalances and the DRAM price collapse, among other things.

It is important to understand how capital is raised in the United States and Europe, as opposed to Asia. In the United States and Europe, capital is raised by a combination of debt (usually corporate bonds, sometimes convertible to stock) and equity placements (public offerings on the stock market). A company's ability to raise capital successfully in the equity market depends primarily on profitability. Profits are also a major source of capital, and U.S. and European companies are structured and managed for this goal. In Asia, a much larger portion of the capital raised (sometimes exclusively) is from the banking system in the form of loans. The evaluation criterion is fundamentally different there—cash flow. In a highly leveraged company, cash flow can easily be positive while losses are piling up. Asian companies, as a result, are primarily managed for cash flow. This has been the key reason why the capital spending-to-semiconductor production revenue ratio is estimated to be about 23 percent in the United States while near 70 percent for Asia/Pacific, keeping the worldwide ratio at almost 29 percent—a level that is too high, in Dataquest's opinion.

 © 1998 Dataquest

The Korean banking system has been in a liquidity crisis for some time, and the Japanese banking system has already been under pressure from the struggling economy of Japan. Debt-to-equity ratios are quite high in Korea, and capital spending from companies in both these countries has been depressed for several quarters now. Both these systems received more pressure from Southeast Asia in late summer. Taiwan's banking system has higher relative reserves than its Southeast Asian neighbors but is feeling the weight as well and is viewing the situation with caution.

Decreasing chip prices have taken a major toll on the cash flow of many semiconductor companies in the region. Less capital is available in the system because cash flow id not available to pay some existing debt.

Assuming demand for chips is not affected by the situation, the natural economic responses to be expected in the region should include:

- Higher interest rates (which will raise the cash flow requirements of companies requesting money)
- Higher cash flow requirements (which will mean the amount for which the companies qualify is less)
- Less capital available (as a result of the previous point and the lower liquidity in the system)
- Significantly lower capital spending plans, complicated by the fact that local currency buys less equipment from U.S. and Japanese companies because of the devaluation

There has been a trend for Asian companies to seek other sources of capital, such as Eurobonds and equity offerings in the United States. Dataquest believes these avenues will be available to some companies but will fall very short of adequately covering the loss of capital from the banking system overall. The recent quakes in equity markets worldwide present a difficult environment in the short term, as well.

What exists today is a situation that will take several quarters to play out, and one that equipment companies must realize will affect them materially. In a sanguine tone, Dataquest must say that, in the long run, capital spending restraint over the next several quarters will ultimately be very healthy for the semiconductor industry, bringing supply and demand into better balance and ultimately stabilizing pricing and profitability.

And Then Korea Falls—What about Taiwan?

In late November 1997, the South Korean government admitted that some outside help was going to be required to address a massive liquidity crisis in the country. The "official" request was initially about $20 billion, but the agreed-upon bailout was $57 billion, and this may be in the process of being increased. Putting this into perspective is key, because we saw a report recently that places the annual capital spending level for *all* Korean companies in *all* industries at about the $50 billion to $55 billion! The three culprits being pointed to in Korea are memory chips, steel, and autos. All industries are in huge states of overcapacity, and the IMF will likely place some restrictions on the use of capital in these industries in the near term.

 © 1998 Dataquest

The Japanese banking system, already under pressure with the struggling economy of Japan, is now feeling added strain. All the banking roads from Asia appear to lead to Japan, and questions are now being raised as to whether this evolving situation will harm the recovery in Japan, perhaps sending the economy into another recession. The closing of the fourth-largest securities firm in Japan because of lack of liquidity has not helped. Trickling repercussions can be expected.

Meanwhile, the currencies have continued to depreciate relative to the U.S. dollar. Since the beginning of the year, the currency of South Korea has depreciated 40 to 50 percent, Taiwan's about 18 to 20 percent, and Japan's about 10 to 11 percent relative to the U.S. dollar. These fell precipitously in the last months of 1997 and may come under further pressure before stabilizing.

What is the likely fallout? Dataquest believes there are three issues to watch in coming months: capital spending cuts, DRAM prices, and the dynamics of the foundry market.

In conversations over the last couple of months, Dataquest described the South Korean situation as the linchpin. If Korea could keep it together, then the crisis could be controlled without turning into something much worse. But if Korea fell, then watch out! Well, Korea fell, and we are officially saying—watch out! The magnitude of the situation is mind-boggling, and we are forecasting that Korean companies will cut capital spending in 1998 about 40 to 60 percent, relative to 1997 in dollar terms. It is safe to say that *all* Korean capital projects are stopped dead in their tracks at present, and we would estimate that it will be late spring before the situation settles to the point at which some of these projects may be cautiously restarted.

Because the Japanese banking system is under strain, there is not much money available, and Dataquest is forecasting that spending plans for Japanese companies in 1998 are likely to be about 7 to 14 percent lower in dollar terms than in 1997.

What about Taiwan? The second and third issues actually are the keys to Taiwan. The currency valuations may actually be of more importance in the intermediate and long term than capital availability. Taiwan is outright defiant at present, and it have some reason to be. Its financial system is based on a stock market system rather than banking, and a major portion of the country's semiconductor business, foundry, is still very profitable and growing.

However, depreciation levels are approaching that will dramatically impact competitiveness and pricing among regional companies. Not quite, but almost, half of the DRAM capacity is in Korea and Taiwan now. These suppliers now have a "cost holiday" relative to competitors in the United States, Europe, and, in part, Japan. Dataquest estimates that perhaps 55 to 60 percent of the cost of making a semiconductor chip is sensitive to local currency.

 © 1998 Dataquest

Will these companies sit on their marginal profits? If history is a guide, the answer would be no. A continuing free fall of DRAM prices will put profitability pressures on Micron Technology Inc., Siemens AG, and perhaps even Texas Instruments Inc., to a lesser degree. Capital spending plans for these companies may come under review in the near term and perhaps be lowered.

So, will the foundry industry be the savior? Maybe in part, but right now it is the *only* bright spot, and every company is now looking toward it. We can expect a flood of announcements (which have already started) from companies coming into the foundry market. Taiwan Semiconductor Mfg. Co. recently released a forecast stating that its gross margins were increasing in a growing market. This is true and understandable, given the currency valuation trends and the fact that the bulk of its customer base is in U.S. dollars. Although TSMC is the technology leader and premier foundry supplier, it has not typically led pricing downward but has been a price follower. LG Semicon has been a price leader in the past, and Dataquest is expecting LG Semicon to retake the pricing lead, maybe joined by others, giving TSMC's margin improvement a relatively short life. LG Semicon has the capacity, needs the cash, and is motivated to take business through pricing because there is beginning to be a separation in the valuation of the Taiwan dollar and the Korean won.

So what about Taiwan capital spending in 1998? Dataquest believes it will be split. Taiwan is fundamentally different from its Asian neighbors because capital-raising techniques used there rely more heavily on equity markets than debt markets or the banking system. The Taiwan banking system is the soundest in Asia, but we think Taiwan is watching and being very cautious at present so as not to follow Korea to the IMF. A company's ability to raise capital in the equity market depends primarily on profitability. And even then, today's environment is not really favorable to raising capital on the equity markets.

Dataquest believes the equity market will be available to foundry companies but is not likely to be favorable to memory producers. For this reason, we think that the memory producers in Taiwan (Powerchip, Nan Ya Technology Corporation, and Mosel Vitelic) may find it more difficult to raise capital, while the foundry producers will be able to raise spending levels slightly in 1998. However, currency depreciation will lower the spending levels on a U.S. dollar basis. We think only a few leading companies, such as TSMC, Chartered Semiconductor Mfg. Pte. Ltd. , and United Microelectronics Corporation, will be in a position to raise spending levels in U.S. dollar terms for 1998. Memory companies will likely be forced to cut spending in 1998. Overall, Taiwanese spending is expected to increase about 13 percent in 1998 to $7 billion.

The Taiwanese foundries are still very profitable, and although the situation may degrade through the year, spending for 1998 seems fairly secure. Dataquest's forecast assumes that Taiwanese foundry spending will increase more than 40 percent to $4.3 billion (excluding foundries outside Taiwan).

 © 1998 Dataquest

Dataquest expects spending in DRAM capacity to remain at a high level. Some companies will cut spending, but companies such as Vanguard International Semiconductor Corporation (owned in part by TSMC) will actually increase spending heavily. Overall, in local currency, spending will be flat in the DRAM area but down about 15 percent in U.S. dollars.

This situation is continuing to play out and will not be settled for several months yet. The picture is increasingly beginning to resemble a sharper decline in sequential spending than originally anticipated in the DRAM area.

Thailand fell, Hong Kong crashed, Korea admitted it needed help, and even Japan is feeling added strain and experiencing the collapse of a securities company—each of these events has been accompanied by someone stating, "It is an isolated incident," "We are only minimally affected," or, "It should be possible for this to be controlled within that country." Does anyone still doubt that we are in the midst of a worldwide earthquake? The tremors will be relatively minor in the United States—but they will be, and are starting to be, felt.

The Impact of the Asian Financial Crisis on Worldwide Electronics Production and the Semiconductor Market

Abstract: *The Asian financial crisis will dampen the growth in 1998 of worldwide electronic equipment production and the semiconductor market to lower than previously forecast by Dataquest. This document examines the negative impact the Asian crisis will have on these forecasts.*
By Semiconductor Industry Analysts

Section I: Introduction

The financial crisis in Asia is a daily topic of discussion and in publications as the world tries to assess the impact of the crisis on worldwide financial markets, stock markets, banking systems, and national economies. At Dataquest, clients are continually asking us to assess the impact of the Asian crisis on the electronics, PC, and semiconductor industries, and much has been written by Dataquest about this.

In particular, our semiconductor clients are asking us how Asia's financial woes will affect Dataquest's 1998 semiconductor industry and electronic equipment production forecasts. These forecasts were released in October 1997, and much has happened since then. To date, we have refrained from issuing new formal forecasts mainly because the situation is still very, very fluid, and we felt we were unable to publish accurate 1998 forecasts until more information was at hand. Nevertheless, our clients want to know what our thinking is.

This document is a summary of Dataquest's current thinking about the impact of the Asian financial crisis on electronics production, the semiconductor market, including DRAMs, and semiconductor capital

Dataquest
Program: Semiconductors Top Views
Product Code: SCND-WW-DP-9801
Publication Date: February 2, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductors Regional Markets and Manufacturing binder)

spending. The analysis presented in this document represents a qualitative point of view of the potential impact. Dataquest will issue new formal 1998 forecasts at the end of April. In the interim, we will keep our clients up to date as the Asian crisis evolves and more information becomes available.

This analysis represents the collective thinking of Dataquest's semiconductor analysts in all regions of the world. Further information on any of the topics is available from the analysts listed at the end of each section or by referring to the other documents, noted in the text, that Dataquest has already published on Asia's financial crisis.

The Bottom Line

The following are the major conclusions of this analysis:

- In 1998, worldwide electronic equipment production will likely decline from Dataquest's previously forecast $1,009 billion to $953 billion. This means that 1998 electronic equipment production will grow only about 3 percent instead of the 9 percent previously forecast.
- Solely because of the decrease in electronic equipment production, the worldwide semiconductor market is likely to decline from our previously forecast $175 billion to $165 billion.
- Also, because of the potentially lower cost of DRAM manufacturing, the 1998 DRAM market could decline by $3 billion to $5 billion from our previous forecast.
- Combining the effects of decreased electronic equipment production and the lower DRAM market, the overall 1998 worldwide semiconductor market could be as low as $160 billion. Our previous 1998 forecast (released in October 1997) was $175 billion, for a growth of 17 percent over 1997. The new forecast of $160 billion represents a growth of about 7 percent over 1997.
- Capital spending is forecast to be down 4 percent in 1998 to $43 billion and does reflect the conditions in Asia through December. Dataquest has also published a detailed downside capital spending scenario with a set of changed assumptions that places the downside risk at $39 billion, about a 12 percent decline from 1997 levels.

It is important to note that the numbers presented in this document are not "official forecasts" but are meant to provide guidance to clients until we do publish firmer forecasts. This forecast represents our current thinking about the impact of the Asian financial crisis and is subject to change as the situation continues to unfold.

Section II: Background on the Asian Financial Crisis

The beginning of summer 1997 saw the devaluation of the Thai baht amid escalating difficulties in the Thai banking and finance community, which forced the Thai government to finally surrender to the currency speculators.

At that time, few people, if any, would have predicted this to be the start of a financial storm sweeping throughout Asia, with far-reaching global implications.

Shortly after the Thai baht devaluation, the governments of Malaysia, Indonesia, and the Philippines succumbed one by one to the speculative currency attacks. The rapid currency devaluation sent shock waves through the regional stock markets of Thailand, Malaysia, Indonesia, and the Philippines. Singapore and Hong Kong, which remained largely unaffected initially, saw their stock markets tumble in October amid growing investor anxiety.

The financial crisis deepened in November as it spread to Korea and Japan, the world's 11th-largest and second-largest economies, respectively. The value of the Korean won dropped sharply, along with Korea's stock market, after the Korean government gave up its battle to prop up its currency in November. A $57 billion rescue package led by the International Monetary Fund (IMF) was negotiated for Korea, after $40 billion and $17 billion were negotiated for Indonesia and Thailand, respectively. In the meantime, Japan saw the closure of its fourth-largest securities company, Yamaichi Securities Company, on November 24, following the closure of Hokkaido Takushoku Bank, its 10th-largest commercial bank, a week earlier.

Behind these events lies a tale of massive regional expansion based largely on politically manipulated debt directed over the past 40 years to conglomerates that are now unable to pay the money back.

Simply stated, the current Asian financial crisis stems from the inability of South Korean and other regional companies to repay their short-term debts. The expansion that has given South Korea an average annual gross domestic product (GDP) growth rate of 8.6 percent during the past 30 years has been achieved largely on the back of massive, politically backed short-term borrowing, which was rolled over regularly and renewed by the country's top companies—family-run conglomerates, commonly known as chaebols. Problems have occurred with this short-term borrowing strategy because many of the investments made were long term and not suited to short-term returns. More important, the primarily South Korean banks, which in turn borrowed mainly U.S. dollars from Japanese banks, are now unable to continue rolling over the debts and granting extensions. Inevitably, huge debts are now due for repayment. There are several factors that have caused this.

Until mid-1997, the Southeast Asian currencies and the Korean won were pegged to the U.S. dollar. With the growth in the strength of the dollar since mid-1995, caused by the improving performance of the U.S. economy, the won and the Southeast Asian currencies also strengthened, in conjunction with the U.S. dollar. The strong local currencies resulted in the slowdown of Southeast Asian and Korean exports because they became more expensive and less competitive in a worldwide market that was already showing signs of slowing and overcapacity. The slowdown in exports contributed to the large current account deficit in Southeast Asian countries and Korea, which ultimately left the currencies in those countries susceptible to devaluation.

The dramatic currency devaluation that occurred in Southeast Asian countries and Korea will now make exports more cost-competitive. However, these devaluations increased the local value of debts borrowed in foreign currencies, massively increasing the amount of home currencies required by banks and conglomerates to repay their debts.

The second catalyst for the crisis concerns the primarily Japanese banks that, by lending to the region's banks, including South Korean banks, financed the growth of South Korea and other countries. Japanese banks were unable to renegotiate their South Korean debts because of their own liquidity problems. Much of the security on which Japanese banks based their value was property and stock market-based investments; however, in the early 1990s, the Japanese property and stock markets collapsed, taking with them much of the equity on which Japanese banks relied. The loss of equity and the effectively defaulted loans of Japanese companies caught in the collapse impaired their ability to borrow money on the international money markets; thus, less new money was available to renegotiate South Korean debts. South Korean loans therefore came due for repayment.

The problem is so severe that the South Korean ministry of finance and economy estimates that about $21.5 billion of external debt will be due for repayment in the first three months of 1998. In the first six months of 1998, about $70 billion of external liabilities will be payable—this represents about 70 percent of the nation's total external debt.

These debt levels, devaluing currencies, and slowing revenue mean that mass restructuring will be needed in the South Korean and other Southeast Asian economies to restore the market confidence necessary to allow the region to recover. This restructuring will involve mass layoffs as loss-making companies and insolvent banks are closed down and the giant chaebols are restructured to focus on core competencies.

Contributing Analysts: Edmund Gemmell (United Kingdom), Jim Liang (United States), and J.H. Son (Korea)

Section III: The Macroeconomic Effects of Asia's Financial Crisis and the Impact on Electronics Production and Semiconductor Consumption

Asia's Macroeconomic Outlook for 1998 Has Changed Dramatically

Asia's currency and financial crisis has dramatically changed the macroeconomic outlook for most Asian economies. Changes in outlook have been the greatest for the economies most affected by the crisis: Indonesia, South Korea, and Thailand. Economic forecasters have uniformly downgraded their estimates of GDP for Asia's troubled Pacific Basin region in 1998. Based on a survey of prominent forecasters, Dataquest estimates that 1998 GDP for the region will be reduced about $690 billion from the levels expected at the time of Dataquest's fall forecasts. GDP estimates for

Indonesia, South Korea, and Thailand have been reduced especially sharply. These significant changes in the outlook for GDP have been accompanied by equally significant changes in the outlook for inflation. Inflation is expected to increase markedly throughout the region, especially for Indonesia, South Korea, and Thailand, as lower currency values push up the prices of imports.

Macroeconomic Outlook Elsewhere Remains Mixed but Could Sour If Asia's Troubles Worsen

The macroeconomic outlook for the rest of the world remains mixed in the face of Asia's troubles. Forecasters have generally downgraded their outlook for Japan in 1998. They have done this not so much because of Asia's crisis but because of continuing economic difficulties in Japan. Japan remains deeply mired in an ongoing economic recession. Continued troubles in Asia pose a significant threat to Japan's recovery. Because most Asian currencies have depreciated far more against the dollar than the yen has since summer, Japan has lost much of the competitive advantage it had regained from its Asian rivals during the past few years. More important, Japan holds significant amounts of the dollar-denominated debt floated by Asian economies before the onset of the crisis. Outright default on this debt would likely paralyze Japan's already crippled financial system. As things currently stand, Dataquest estimates that Japanese 1998 GDP will prove $650 billion lower than expected.

Forecasters' outlooks for the United States remain surprisingly bright. The prospects for economic growth in the United States remain strong in spite of Asia's troubles. Asia's difficulties are expected to exert some drag on the U.S. economy, but America's domestic economy is currently so strong it appears capable of overcoming adverse effects from Asia. The outlook for Western Europe is somewhat more enigmatic. For the moment, most forecasters appear to believe that economic growth will not be adversely impacted by Asia's troubles. But this outlook is qualified with the recognition that Western Europe could suffer serious impacts if Asia's difficulties were to worsen significantly. Western Europe has extensive economic and financial ties with many of Asia's crisis-afflicted economies. What is more, ongoing economic growth in Western Europe is still heavily dependent on exports. A tidal wave of Asian debt default combined with a collapse of Asian imports would hobble Western European economic performance. All in all, Dataquest estimates that 1998 GDP for the United States and Western Europe combined will be about $80 billion lower than previously expected because of the U.S. dollar's continuing strength against Western European currencies.

Macroeconomic Impacts on 1998 Electronics Production and Semiconductor Consumption

We can use this information about changing macroeconomics in combination with Dataquest's fall forecasts of electronics production and semiconductor consumption to infer the potential impact of changing macroeconomics on worldwide electronics production and semiconductor consumption. We want to warn readers up front that the following discussion is an inexact first-order analysis based on some very simplifying assumptions about the

 ©1998 Dataquest

links between macroeconomics and the markets for electronics and semiconductors. It is important to note that a comprehensive and conclusive analysis would require extensive study of interrelated demand and supply impacts in both the electronics and semiconductor markets.

Worldwide Electronics Production to Decline about $56 Billion

The analysis begins by linking macroeconomic changes to electronics demand. For this simplified analysis, we believe it is reasonable to assume that electronics demand is related to GDP and will vary with changes in GDP. Research by the Technology Foresight Programme, a British government-sponsored organization, estimates that Asia's Pacific Basin economies expend about 5 percent of their GDP on electronics consumption. For Japan, it estimates that about 3 percent of GDP is expended on electronics consumption. For the United States and Western Europe, the estimate is 3.5 percent. These numbers compare favorably with Dataquest's own estimates of worldwide expenditure on electronics relative to GDP. Based on figures from our fall forecasts and IMF estimates of world GDP, we estimate worldwide electronics spending amounted to about 3 percent of world GDP in 1997.

Unfortunately, these various figures reflect average rates of expenditure on electronics from GDP. They do not tell us how electronics spending will change as a result of changes in GDP. For that, we would need to know the marginal rates of expenditure on electronics from GDP. There is good reason to believe the marginal rates of expenditure on electronics from GDP in all these regions are actually higher than the average rates cited earlier. Because of this, impacts based on these average rates could be understated.

Nonetheless, the result of applying these average rates to the changes in 1998 GDP noted earlier is that electronics demand is likely to be reduced $34.5 billion in Asia's Pacific Basin, $19.5 billion in Japan, and $2.8 billion in the United States and Western Europe combined. For the sake of simplified analysis, the decline in worldwide demand reflected in the sum of these figures is assumed to generate an equal decline in worldwide electronics production. Please note that Dataquest is not assuming that the declines in demand for each region generate equal declines in production for each region. As discussed later, this certainly will not be the case. Given this assumption, Dataquest expects 1998 electronics production to decline $56 billion relative to the fall forecast, which was $1,009 billion. This represents a decrease of 5.6 percent from the fall forecast.

Semiconductor Consumption to Decline about $10 Billion

Naturally, the forecast decline in electronics production has implications for semiconductor consumption. Here again, Dataquest makes a simplifying assumption. In the fall semiconductor consumption forecast, we estimated that worldwide semiconductor consumption would average 17.3 percent of worldwide electronics production value in 1998. Assuming that semiconductor content remains unaffected by the changing macroeconomics stemming from Asia's financial crisis, Dataquest estimates that worldwide semiconductor consumption will fall about $9.8 billion from the previous

 ©1998 Dataquest

forecast for 1998. This would (again) represent a 5.6 percent decline from the fall semiconductor forecast, which was $175 billion, resulting in an estimated $165 billion semiconductor forecast for 1998.

More Detailed Demand and Supply Analysis Needed

Once again, it is important to emphasize that these results are based on several simplifying assumptions in lieu of more detailed demand and supply analysis. These assumptions are open to serious question. The potential bias to these results that stems from using average rates of expenditure on electronics from GDP in the analysis instead of marginal rates of expenditure has already been discussed. Also, these results may be biased by the assumption that a forecast decline in worldwide electronics demand will generate an equal decline in worldwide electronics production.

In the final analysis, the dollar-valued volume of electronics produced worldwide is determined by the interaction of demand and supply in the market for electronics. Dataquest's assumption that declining electronics demand will generate an equal decline in electronics production is tantamount to assuming that electronics supply is perfectly price elastic and will remain unaffected by the changing macroeconomics of Asia's crisis. The former seems highly unlikely, and the latter is almost certainly not true. Although we cannot be absolutely certain, we suspect that electronics production may ultimately decline less than electronics demand. As demand subsides, it is likely that electronics prices will fall, especially for Asian goods whose producers are both willing and able to press the production cost advantage that currency devaluations have given them. Backed by aggressive marketing, declining electronics prices could stimulate sufficient new demand to counter much of the decline being forecast.

Dataquest's results are also likely to be biased by the assumption that the semiconductor content of electronics will remain unaffected by changing macroeconomics. Like the dollar-valued volume of electronics produced and semiconductors consumed from which it is derived, semiconductor content emerges from the outcome of market interactions among electronics and semiconductor producers. Precisely because semiconductor content is ultimately determined by the mechanics of the electronics and semiconductor markets, it is unreasonable to assume values for it. Changes in semiconductor content must be deduced from detailed analysis of forecast changes in market demand and supply for both the electronics and semiconductor markets. On the whole, we are inclined to believe that semiconductor content will decline in 1998. Dataquest believes that the interaction of declining semiconductor demand induced by lower electronics production and of increased semiconductor supply induced by lower production costs in Asia will cause dollar-valued semiconductor consumption to decline more than electronics production. This would de facto lower semiconductor content.

 ©1998 Dataquest

Currency and Financial Impacts on Electronics and Semiconductor Supply—Asian Producers Face Potential Double Bind

The dramatic declines in Asian currency values, the most visible aspect of the crisis, have at least temporarily altered the relative economics of both electronics and semiconductor production across regions. Despite the very real pain these devaluations have caused, they have imparted a potentially large production cost advantage to Asia, especially to countries such as South Korea that have experienced the sharpest devaluations. Of course, this cost advantage is somewhat tempered by devaluation-induced increases in the cost of components and subsystems that must be imported from Japan and outside Asia. Still, there is an advantage to exploit if Asian electronics producers can maintain the working capital needed to finance their day-to-day operations.

In this regard, South Korean producers could paradoxically emerge as the crisis' biggest winner, at least over the short term. Assuming that Korean electronics producers can retain sufficient working capital, they appear well-positioned to increase significantly their share of electronics and semiconductors sold outside Asia. Unfortunately, they could have trouble defending their increased share over the long term if they are unable to generate the investment capital necessary to expand capacity. By the same token, producers outside Asia now have increased incentive to locate production in the region. Although this is unlikely to happen so long as economic and political uncertainty remained heightened, it is likely to occur once stability is re-established and the crisis appears to be moving toward resolution, especially if Asian currency values remain at or near their current levels.

Non-Asian Producers Also Face Risks

The currency upheavals and financial upset of Asia's crisis threaten consequences not only to the fortunes of Asian companies but also to the operations of non-Asian companies. In 1996, Asia/Pacific-based electronics equipment manufacturers accounted for $29.7 billion, or about 21 percent, of worldwide semiconductor sales. About 18 percent of American semiconductor sales, 18 percent of Japanese sales, and nearly 25 percent of European sales were derived from sales to Asia/Pacific. This, in turn, fed electronics manufacturing worth $153.7 billion, about 18 percent of the worldwide total. Clearly, a significant decline in semiconductor demand among Asian electronics producers could harm non-Asian semiconductor companies dependent on the region.

The perils to continuing business in Asia for both Asian and non-Asian companies is probably best illustrated with circumstances in South Korea. Most manufacturing locations within South Korean are locally owned. This means liquidity problems arising from Korea's financial difficulties are a real issue for these manufacturers. With IMF restrictions in place, South Korean companies will now find it very difficult to obtain letters of guarantee, which are essential if they are to make purchases on credit. Without these letters, their only option is to pay cash for purchases of semiconductors. Currency devaluation has made this cash now twice as expensive to obtain, and obtaining it may prove very difficult.

The availability of credit is potentially one of the major issues of the crisis. Should credit in the form of letters of guarantee and the like become available again through IMF intervention, the liquidity issues that indigenous manufacturers face will be significantly reduced, and they will be able to continue purchasing the raw materials needed for manufacturing. Only then will they be able to press home the cost advantage that currency devaluations have given them. If, however, these letters do not become available, manufacturing in South Korea, as well as in other crisis-impacted countries, could be seriously curtailed as manufacturers run out of raw materials, with only a diminished ability to purchase operational stocks. Indeed, the issue of credit availability has already been raised in a recent announcement from Atmel Corporation.

Just recently, this American supplier of nonvolatile memory and application-specific ICs (ASICs) announced a fourth quarter charge of $160 million, citing "credit problems with specific Asian customers." Although this statement may be open to further scrutiny, it does raise the important point that non-Asian companies may be exposed to the risk of potential bad debts and future loss of market because of the inability of Asian OEMs and contract equipment manufacturers (CEMs) to obtain letters of guarantee. Should similar problems be encountered by other semiconductor manufacturers with their "Asian customers," then potentially significant semiconductor market share could be put at risk.

Summing Up

Dataquest believes that both worldwide electronics production and semiconductor consumption will be affected in 1998 as a result of Asia's financial crisis. Our simplified analysis suggests that electronics production will be reduced about $56 billion and semiconductor consumption about $10 billion. These changes represent about a 5.6 percent decline from Dataquest's fall forecast for 1998. We remain uncertain about the prospects for individual regions and consumers. Although it is clear that Asian-based electronics and semiconductor producers have gained some production cost advantages owing to currency devaluations, it is not clear that they will be able to press home those advantages because of potential problems with liquidity and credit arising from the financial upsets of the crisis. Moreover, many non-Asian companies are clearly at risk owing to their strong dependence on Asia and their close financial relationships with Asian producers. Although we do not believe that Asia's financial crisis will break worldwide electronics and semiconductor markets, we do believe it will test them as never before.

Section IV: Impact of the Crisis on DRAM Costs and the Forecast

The effect of the Asian financial crisis on Dataquest's DRAM forecast will be caused mainly by the fall of the Korean won against other world currencies and by some of the restructuring of financing the IMF has required of the Korean chaebols. These two causes will result in two key effects, one short term and the other long term. Taiwanese DRAM manufacturers are disregarded in this analysis because, in 1996, Korean companies provided 33.6 percent of the world DRAM market, while Taiwanese companies shipped only 2.4 percent (*Worldwide Memory Market Share 1994 to 1996*, MMRY-WW-MS-9701, May 1997).

Short-Term Effects

Throughout 1997, DRAMs have been priced at a level near their manufacturing cost, a minimum that must be followed if antidumping measures are to be avoided. Going into 1998, Dataquest sees a continuing overcapacity, forcing manufacturers to continue their efforts to keep prices low to win the fight for their share of their customers' business, a fight they encounter at buyers' desks.

In a competitive market, semiconductor manufacturers use manufacturing cost reductions to reduce the selling price of their products. A knowledge of semiconductor manufacturing cost trends is useful for projecting long-term costs/selling price relationships, which vary from product to product and company to company, as well as by market and business conditions.

What happens with a devaluation of the Korean won against other currencies? It only stands to reason that a devaluation of the won would lower manufacturing costs (as measured in any other currency). How much impact will the devaluation have? Dataquest has analyzed the situation, and it appears that at least 55 percent of the cost to manufacture a DRAM is in won-based transactions rather than foreign currency-based transactions ("Dataquest's Tactical Memories Newsletter, Volume II, No. 26," MMRY-WW-DP-9733, December 1997).

The Dataquest semiconductor cost model uses 16 variables of semiconductor manufacturing. These variables cover the main areas where costs accrue and processes can improve. The variables that have the most influence over cost are wafer processing, wafer size, die size, sort yield, package type, and final test yield. The financial crisis in Asia has caused major changes in Asian cost structures based on devalued local currencies, compared with the U.S. dollar. The costs affected are those whose basis is predominantly local Asian currencies. This category includes all the major costs associated with wafer processing and test ("Dataquest's Tactical Memories Newsletter, Volume II, No. 26," MMRY-WW-DP-9733, December 1997). For the purposes of this conservative model, we have assumed that 50 percent of all wafer processing and test costs are won-based.

Table 1 shows the DRAM cost model and compares the DRAM costs before won devaluation and after devaluation. Differences in this cost model are based mainly on exchange rate variations, but Dataquest has also included a

 ©1998 Dataquest

comparison of costs for different die sizes (Micron Technology Inc. alone has a 42mm^2 16Mb DRAM, whereas die sizes for Korean and Japanese manufacturers range from 58mm^2 to over 90mm^2.)

*Costs directly affected by local currency devaluation:-50 percent wafer/test costs
Source: Dataquest (January 1998)

For the past year, DRAM price levels have hovered at or near cost levels to the extent that few suppliers were or are profitable in this business. The cost model highlights how changes in local currency costs dramatically alter the cost structure as reported in dollars. Using Micron as an efficient 16Mb

DRAM cost benchmark, this model shows that, even with die shrinks and lower wafer processing costs, Micron still cannot produce at a lower cost than the Korean companies, because the revalued won has substantially reduced wafer processing and test costs, even with a larger Korean die.

The upshot of this analysis is that Asian companies now have a significantly less expensive DRAM cost of manufacture in dollar terms than either their Japanese or American competitors. This also means that the Korean companies could sell DRAM at a lower price than the other regional manufacturers without running the risk of dumping charges. In other words, the Korean suppliers could reduce the selling price of a DRAM to a point at which the Japanese or American companies will not be able to compete without being accused of dumping. How will the Korean companies behave?

If they are interested in simply increasing market share, then they can drop DRAM prices, outprice their competitors, and sell a larger DRAM volume. Using this approach, these companies could run their facilities at full capacity while forcing their competitors to close their fabs. Although it is unlikely that such a severe change will occur, Dataquest believes that in 1998 Korean manufacturers' share of the DRAM market will increase.

Alternatively, they could maintain current DRAM market prices and reap the windfall of much greater profits per device sold. Both scenarios are win/win situations for the Korean DRAM manufacturers. In both, their foreign currency cash flow increases significantly, as do their profit margins.

Buyers outside Asia/Pacific, always eager to get the best deal, will be pushing hard for price reductions, playing the trump card of continued market oversupply to force the Korean companies' hand. In the current oversupplied market, it remains to be seen which way Asia/Pacific suppliers will go in pricing their newly profitable product lines.

This discussion has examined Asia/Pacific only as a DRAM supplier. What about the demand side? Most of the DRAM consumed in Asia/Pacific is used to produce computing equipment sold in the Americas, Europe, and Japan. The cost of DRAM to the end users in these three regions is unaffected by the exchange rate in the Asia/Pacific country where the system is assembled. Dataquest believes that the devaluation will not affect the price or quantity of DRAM purchased in Asia/Pacific as much as it affects Asia/Pacific wages compared with the wages in other regions. More competitive wages should shift more manufacturing away from other regions and into Asia/Pacific.

Dataquest expects to lower the DRAM forecast by $3 billion to $5 billion to compensate for the combined effects of the Asian financial crisis and the additional DRAM capacity that was put into place in 1997. The net effect will be a decrease of the 1998 DRAM market to between $22 billion and $25 billion, representing a growth range of 0 to 7 percent over 1997's estimated $22 billion.

 ©1998 Dataquest

Long-Term Effects

One condition of the IMF bailout is that loans must be granted based on standard good business practice, rather than on less tangible reasons. For this reason, Korean DRAM manufacturers find it harder to get loans for new equipment. Previously, a company's mission to become a market leader was a sufficient reason for a loan to be granted, but now the prospects for repayment are more important. Under this restriction, Korean DRAM manufacturers have cut their spending plans to the bare essentials.

The full ramifications of reduced capital spending in 1998 will take about two years to appear. In 2000, Dataquest expects to see a relatively severe deficiency of competitive manufacturing capacity in Korea as Korean fabs start to lag the technology available in other countries. As a result of this, the Korean market share gains that Dataquest expects to see in 1998 will be lost to other countries in 2000. The winners will be those that have invested continuously during the time that Korean companies have cut back.

This coincides with the period in which Dataquest expects to see a mild worldwide DRAM capacity shortage, and prices will firm for about half a year to a full year.

There will be a Dataquest Telebriefing on February 13, 1998, at 8:30 PST, discussing the impact of the Asian financial crisis on the spring memory forecast. To confirm attendance, please call Carole Phillips at (408) 468-8376 or Jenny Williams at (408) 468-8263 or fax them at (408) 468-8044.

Section V: How Will the Asian Financial Crisis Impact Capital Spending?

Even without the Asian financial crisis, the fundamentals have not changed much and indeed may have gotten worse as a result of the aggressive spending patterns in 1997. Overcapacity never went away, and acceleration of shrinks has actually exacerbated the situation.

In DRAM, with the shrink factor and the addition of net capacity of the last 18 months, the situation has not improved. Given these facts, Dataquest is no longer convinced that the market will be balanced by the end of 1998 unless capacity is actively removed from the market.

Dataquest's analysis of supply and demand in the foundry industry at 0.35-micron technology continues to show that, although demand is strong, supply base plans are about three months ahead of demand for the leading-edge 0.35-micron technology through 1999. Evidence supporting this can be found in the continued pricing pressure, with greater than normal declines. Given the evidence that more suppliers are entering the foundry business, this situation is likely to deteriorate somewhat during the next year.

©1998 Dataquest

Dataquest is therefore continuing to call 1998 an essentially flat spending year overall. The stronger-than-expected 1997 actually pushes the sustained recovery in spending, driven by a balance in capacity, into mid-1999. Companies will continue to concentrate on technology, with emphasis on 0.25-micron and 300mm technology, along with investments in new interconnect materials and processes.

What Are the Assumptions and Downside Risks for 1998 Capital Spending?

Dataquest's forecast and assumptions are more explicitly detailed in a Perspective ("Wafer Fab Equipment Market Forecast Update: Question Marks for 1998 as the Second Half of the 'W' Unfolds," SEMM-WW-DP-9801, January 1998) and a Market Trends Report to be published shortly (*Year-End 1997 Forecast: Capital Spending, Wafer Fab Equipment, and Silicon Markets,* SEMM-WW-MT-9801). The base forecast calls for an essentially flat year, with capital spending down 3 percent and wafer fab equipment experiencing 2 percent growth.

Dataquest has developed a detailed second scenario for the 1998 wafer fab equipment market to give clients a "window" of outcomes possible if several of the key assumptions are changed based on the Asian financial crisis. For the most part, these changes simply reflect the timing differences of spending plans. For the "downside risk" scenario, the following assumptions are made:

- Korean companies will cut back spending almost 60 percent in U.S. dollar terms, with at least one project in Europe falling out of 1998 (quite likely Hyundai's, because LG Semicon. has significantly lower debt-to-equity ratios). Dataquest's forecast assumes a 40 percent cut.
- Taiwanese companies' DRAM spending will be cut by 45 percent overall in U.S. dollar terms as funding from Japan is lost and profitability concerns govern loan approvals. The forecast assumes a 15 percent cut.
- Taiwanese foundry spending growth is assumed to remain at 40 percent, because the primary source of funds is the profitable players.
- Taiwanese company spending overall would therefore be down only 2 percent, to $6 billion. The forecast assumes growth of 13 percent to $6.9 billion.
- Japanese companies will cut spending overall by 8 to 10 percent in yen terms, or 14 percent in U.S. dollar terms, compared to 1997. Dataquest's forecast assumes an overall spending cut of only 5 percent in U.S. dollar terms.
- Spending on 300mm equipment will be reduced to $700 million, based on the timing of shipments into Japan and the United States. Siemens' project appears safe in 1998 because the German government is funding a portion. Dataquest's forecast assumes that $1.1 billion will be spent on 300mm equipment.

 ©1998 Dataquest

- The U.S. and European major companies that are increasing spending in 1998 will cut these levels back 5 to 10 percent. This places the group at a 4 percent growth instead of the forecast scenario of 10 percent and makes Intel Corporation's spending flat (excluding the Digital Equipment Corporation plant acquisition), compared to 1997. Philips Electronics NV, SGS-Thomson Microelectronics B.V., and Advanced Micro Devices Inc. will continue to increase spending in this scenario for 1998.

Putting this all together, capital spending levels would be cut by about $3.7 billion compared to the 1998 forecast scenario, with these cuts reflected primarily in discretionary equipment spending and with all regions being affected. The wafer fab equipment market would be reduced by about $2.4 billion, with about 70 percent of the difference being related to lower DRAM spending. These reductions have about a 9 to 10 percentage point negative impact on growth of spending in 1998.

The U.S. market would be the least affected, because the reduction in Korean company spending is already accounted for in the forecast scenario; the European and Asia/Pacific markets are likely to see the largest negative impacts. The equipment technologies focused on enabling logic and 0.25-micron processing, such as chemical mechanical polishing (CMP) and deep-UV steppers, would not be affected much by these changed assumptions. However, the equipment segments dependent on capacity or DRAM-sensitive investment, such as diffusion tubes and implant, would be more heavily affected.

Should the downside scenario come to pass, there should be a silver lining—the DRAM market will likely come into balance sooner, leading to stronger profitability in the chip sector and renewed higher growth in spending on equipment.

Section VI: Worldwide PC Market Overview

Despite the volatility experienced in some Asia/Pacific countries during the second half of 1997, preliminary Dataquest estimates indicate that the worldwide PC industry's unit growth rate was just under 16 percent, off slightly from Dataquest's original forecast of 17 percent. Dataquest estimates that more than 82 million PCs were shipped by manufacturers in 1997.

Although both Japanese and Asia/Pacific demand for PCs did not meet our expectations in 1997, flourishing markets in the United States and Western Europe aided greatly in keeping the global PC industry healthy. At the beginning of last year, Dataquest had predicted that the Japanese market would grow by 9.6 million PCs and that Asia/Pacific would experience growth resulting in 11.4 million additional units.

Dataquest now estimates that actual PC shipments into Japan were 7.9 million units and that Asia/Pacific absorbed 9.7 million units. We expect that

Japan's unit growth rate will be less than 10 percent in 1998 and that the Asia/Pacific region will grow at a respectable 15 percent.

Dataquest believes now that the strong growth in the United States and Western Europe will continue to offset in part the setbacks in Japan and Asia/Pacific. We still expect worldwide PC unit growth to be in the mid-teens. Total PC production will exceed 94 million units.

For many years, total worldwide demand for personal computers has sustained sensational growth, and Dataquest expects this trend to continue through the foreseeable future. Regardless of fluctuating economies, the demand fundamentals are compelling for both the commercial PC market and the consumer market. The most significant of these demand fundamentals is the concept of "critical mass." In effect, this Dataquest theory asserts that when the majority of participants in a specific PC market segment require a personal computer, then all participants in that segment must acquire and use a PC.

"Critical mass" has already been reached in the United States and other regional commercial PC market segments, and the requirement for personal computers in U.S. homes is growing each year. Dataquest estimates that more than 42 percent of all U.S. households have at least one PC. We are near "critical mass" in the U.S. home market, and this phenomenon will spread throughout the world well into the next century.

Solid unit growth will continue for years to come. However, solid revenue growth may elude many PC manufacturers and component suppliers in the coming years. Dataquest believes that the pricing trends followed in the U.S. consumer market last year will spill over into the commercial PC market as early as the second quarter of 1998. The sub-$1,000 PC is a harsh reality, and this price point is as appealing to the business segment as to the home segment; its allure will reach all regions by year's end.

The sub-$1,000 PC is possible for two major reasons. First, component suppliers have been drained of their customary "rightful share of profits." There simply is not enough money in a $700 PC for everyone. Second, successful PC manufacturers have adjusted to a business model of return on investment rather than gross margin. "Velocity manufacturing" is a requisite in this industry, and it manifests itself as build to order, channel assembly, and contract manufacturing.

Finally, Dataquest expects that the "elite few" PC manufacturers that captured nearly 70 percent of growth in the worldwide PC market in 1997 will continue to dominate the industry, forcing continued consolidation and straining the deep pockets of some megaparents.

Section VII: What about China?

Dataquest has recently published a detailed analysis of China/Hong Kong's electronics production in a Focus Report (*China/Hong Kong's Computers, Communications, and Consumer Electronics Industry in 2001*, SEMI-CH-FR-9701, November 1997). The highlights are presented in this section.

Dataquest believes that the Asian financial crisis has a lot to do with speculative investment "bubbles" in property, construction, semiconductors, and other industries. It is clear what happens when rapid economic growth occurs in the absence of a transparent financial system and clean government regulations: overcapacity and irrational loans. The effects of these bubbles can become so serious as to bring down entire financial systems and impair international confidence and, hence, economic growth.

China and Hong Kong are not immune to these problems, although they seemed to be dealing with these bubbles more effectively by popping them before they get too big. China's economic czar, Zhu Rongji, burst the stock market bubble, property bubble, and construction bubble in 1996 and 1997. After 1997's October party congress, he is now more empowered than ever to pop the next speculative runs, whatever they may be. In 1998, he will be promoted to prime minister. Zhu's charter is to fix the state-owned enterprises to avoid overwhelming the financial system with bad loans. If China slacks off, its financial system will face serious problems, potentially worse than those of Korea. China is learning to avoid Korea's expensive lesson—although having $200 billion in combined reserves with Hong Kong will help, too. Strong economic growth in North America and Europe will be critical to China and the region because Japanese consumption is weakening with its own economic malaise.

That China's currency is not convertible may help in the short run, although this does not necessarily insulate China from the possibility of a major depreciation. In 1994, the Chinese government significantly devalued its renminbi. It may have to do so again in the near future because of mounting pressure in the region and because of competition from Asian neighbors on the export front. However, because the government's stated long-term goal is to merge the renminbi with the Hong Kong dollar, it is not likely that the Hong Kong dollar will lose its U.S. dollar peg.

Currency depreciation has lowered production costs in various Southeast Asian countries and Korea. So, will China become less competitive for its vital export markets? Currency depreciation will lower export costs in numerous Asia/Pacific countries, but only to the extent that they do not need imported components (most do, though).

This means that short-term competition with China for exports and possible long-term competition for foreign investment will come from Southeast Asian countries and Korea. However, there are even broader issues facing China, including the currencies and economies in neighboring countries, which are highlighted as follows:

 ©1998 Dataquest

- Raising the competitiveness of its faltering domestic companies, especially state-owned enterprises, before entering the World Trade Organization
- Countering the serious slowdown in foreign investments resulting from rising costs of doing business in China
- Maintaining 7 percent to 10 percent GDP growth and raising the rate of domestic consumption to absorb excess capacity and overdependence on exports
- Dealing with a slowdown in Japanese imports of consumer electronics and PCs from Asia/Pacific. China may be hurt most because its currency has not depreciated, and therefore its costs are increasing relative to other countries.
- Responding to the heavy reliance on exports by Korea and other affected countries as they try to pull themselves out of their economic turmoil

The following factors will help China counter these major challenges and maintain relatively strong electronic growth:

- A large proportion of Chinese electronics companies are successfully competing against major multinational corporations, particularly in the computer and consumer equipment markets. The priority for the government is to improve efficiencies and quality; therefore, information technology will continue to be rapidly deployed as an infrastructure necessity.
- Although total investment was down in 1997, production capacity of the large multinational corporations and local electronics manufacturers has increased by more than 50 percent. Furthermore, the two main reasons for investing in China remain intact: to develop the long-term potential of the domestic market and to take advantage of an abundant, inexpensive labor force.
- Inflation was the major concern in 1996; now deflation is the top priority of the government. Interest rates are likely to fall to stimulate growth.
- Japanese manufacturers are shipping goods worldwide from China. Exports of electronics to Japan from China represent 10 to 15 percent of China's total electronics exports. Therefore, Japan's slowdown in consumption has a minor effect on Chinese production.
- Korean and other affected Asia/Pacific electronics and semiconductor companies may have an increasing currency advantage for exports relative to China in the short term. However, these companies are being seriously hurt by increasing debt-service costs.

In summary, China/Hong Kong has not been affected significantly by this financial crisis in the short term because of the stable renminbi and Hong Kong dollar, which are backed by about U.S.$200 billion in combined foreign reserves. However, Dataquest has outlined the deflation and investment challenges within China. Most notably, Southeast Asia and Korea are likely to receive increased investment in the future that would otherwise have

©1998 Dataquest

gone to China (after four years of very high foreign investment levels in China). However, the power of the Chinese market and its production prowess for international markets will continue to attract investment, enabling it to extend its lead as the largest and fastest-growing semiconductor market in Asia/Pacific.

Competitive Analysis

A Comprehensive Analysis of Compaq's Acquisition of Digital Equipment

Abstract: *On January 26, Compaq Computer Corporation announced an agreement to acquire Digital Equipment Corporation for $9.6 billion, the largest acquisition in the history of the computer industry. The ramifications of this merger impact every corner of the IT industry. This Perspectives provides a Dataquest-wide analysis of the effects of this acquisition on the IT market, the competition, and on the future of Compaq and Digital Equipment.*

By Dataquest Analysts

Introduction

This Perspective represents a Dataquest-wide effort to explore the significance and meaning behind Compaq Computer Corporation's acquisition of Digital Equipment Corporation. This acquisition is touted as the largest deal ever to take place in the history of the computer industry, thus catapulting Compaq to new heights as one of the world's top computer companies. The following pages explore the impact this merger will have on the industry, the competitive landscape, and the future of Compaq and Digital Equipment.

The Largest Acquisition in the History of the Computer Industry

On January 26, Compaq Computer Corporation and Digital Equipment Corporation announced, to a somewhat surprised public, that Compaq will acquire Digital Equipment. The deal, worth $9.6 billion, is the largest acquisition in the history of the computer industry. This announcement came amidst ongoing speculation that Compaq was talking with Digital

Dataquest

Publication Date: February 9, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Equipment, but many industry pundits would have bet that the resulting deal was for Digital Equipment's profitable services business, as opposed to the entire company. Under the terms of the agreement, Compaq will complete the purchase with a combination of stock and cash. Digital Equipment shareholders will receive $30 in cash and about 0.945 shares of Compaq common stock for each share of Digital Equipment stock. Compaq will issue about 150 million shares of Compaq common stock and $4.8 billion in cash. Estimates indicate that the acquisition cost works out to between $60 and $65 per share. Pending approval by Digital Equipment's shareholders and clearance under antitrust laws, Digital Equipment will become a wholly owned subsidiary of Compaq.

The true cost of Digital Equipment to Compaq, however, is much less. Digital Equipment, at the end of December 1997, had just over $2 billion in cash—making the net cash outlay only $2.8 billion and the 150 million shares representing 19 percent of Compaq's shares outstanding. This means that if Digital Equipment produces no earnings, Compaq's earnings per share would be diluted by 19 percent. However, if Compaq is successful in making whatever parts of Digital Equipment it keeps, as profitable as the rest of Compaq, there will be no dilution. As a result, Dataquest expects Compaq to act swiftly in realigning the parts of Digital Equipment it will keep and spinning off whatever remains.

Who Is the Biggest of Them All?

As part of its announcement, Compaq made the claim that once combined with Digital Equipment, the resulting company will be the second largest computer company in the world after IBM; Table 1, in some ways, supports Compaq's boast. In total revenue, Compaq combined with Digital Equipment comes in fifth place. Backing out noncomputer revenue is difficult at best. However, Dataquest's best estimate shows the combined revenue of computer-related products from Compaq and Digital Equipment to be second only to IBM. Table 1 and Table 2 present a breakout of this data.

Table 1
Total Worldwide Company Revenue, 1996 and 1997 (Millions of Dollars)

Company	1996	1997
IBM	75,947	78,508
Hitachi	65,207	68,735
Hewlett-Packard	38,420	42,895
NEC	34,904	39,907
Compaq and Digital Equipment	34,572	37,646
Fujitsu	29,160	36,318

Note: All numbers are Dataquest estimates.
Source: Dataquest (January 1998)

Table 2
Total Worldwide Computer Revenue, 1996 and 1997 (Millions of Dollars)

Company	1996	1997
IBM	72,222	74,777
Compaq and Digital Equipment	32,593	35,800
Hewlett-Packard	31,559	35,449
Hitachi	34,174	35,325
Fujitsu	23,286	30,887
NEC	27,340	30,540

Note: All numbers are Dataquest estimates.
Source: Dataquest (January 1998)

For Compaq to maintain its role as the second largest computer company, it must effectively integrate Digital Equipment's operations into its own with minimal cannibalization, while continuing to grow at its stated growth rate of 25 percent per year or better. Clearly, Compaq will not be able to keep all of Digital Equipment's market share in PCs and low-end servers, making the combined companies' revenue not completely additive. However, even with an assumed loss of 75 percent of Digital Equipment's PC revenue, Compaq is still ahead of Hewlett-Packard Company after backing out HP's test and medical equipment revenue (but not by much). In essence, the race for the No. 2 position in the computer industry is a dead heat between the combined Compaq and Digital Equipment, HP, and Hitachi. Fujitsu and NEC are not far behind.

A key benefit for Compaq is Digital Equipment's core enterprise business, which occupies a market position that Compaq has been unsuccessful at penetrating because of its Intel-based architecture. However, Digital Equipment's Alpha business is the clear technical leader in large computing system hardware, but it has been unsuccessful in a marketing sense. Compaq can take the Alpha systems business and dramatically accelerate it through Compaq's powerful sales and marketing skills. If it succeeds, the prize will be large—Table 2 indicates that there is plenty of money in this particular pot.

How Does the Acquisition Impact the Competition?

Prior to the acquisition, Compaq competed against IBM's and HP's products. Today and in the future, the battle will be waged over solutions that Dataquest defines as the strategic bundling of products and services. IBM is still by far the world's largest computer company. However, its hardware revenue is dominated by aging legacy systems such as S/390 mainframes, AS/400 midrange systems, and its UNIX-based RS/6000 products. The inevitable maturation of Windows NT should have a profound effect on IBM's ability to keep its business from shrinking. Compaq's acquisition of Digital Equipment puts increasing pressure on IBM to decide whether to aggressively pursue a Windows NT-based product and services strategy as have HP and Compaq. If IBM continues to shy away from a similar strategy,

 ©1998 Dataquest

its customers may become fodder for HP and Compaq's growth. The ultimate key challenge for Compaq is to create its own solutions methodology, thus moving away from a products-only strategy.

As for PC companies, Compaq has moved significantly ahead of its traditional competition. Dell Computer Corporation must decide whether to become a computer company or stay a very efficient channel for PC products. A major risk for PC and other systems vendors is that Compaq, IBM, and HP will become the primary product and service suppliers for end users. Customers may not see the need to include more than three vendors on their short lists. This may have force other competitors to become niche solution providers.

How Will the Acquisition Impact Products and Technologies?

A Dataquest analyst made the analogy that "the merger of these two enterprises and cultures will be like two galaxies colliding: slow to happen, and some worlds may collide and be destroyed." This comment reflects the multitude of perceived product overlaps within Compaq, Tandem, and Digital Equipment. Understandably, these redundancies will be remedied—the perceived outcome is the eradication of certain products and technologies. Perhaps the more interesting question is which products and technologies have enough brand and market value to succeed under the new Compaq regime. Dataquest briefly explores these questions by product and technology type.

Workstations

With the workstation market in a period of major transition, Compaq's acquisition of Digital Equipment has the potential to significantly change the balance of power. Although it is relatively new to the workstation business, Compaq has shown itself to be one of the movers and shakers in the rapidly growing Windows NT workstation market. By comparison, Digital Equipment has not been doing as well—not only losing market share in the stagnant UNIX market, but more importantly losing ground in the Windows NT segment where it was one of the early leaders. Digital Equipment workstation customers stand to gain from Compaq's leadership and momentum. Almost immediately, Compaq can challenge HP more effectively for the No. 1 position in the Windows NT market segment by pooling the market share of both companies (Compaq and Digital Equipment).

Compaq also gains significantly on the technology front with a technically credible UNIX offering. The most significant impact of this could be in the graphics area. Until now, Compaq has had no graphics strategy of its own, relying upon third-party cards while HP and Intergraph have been able to differentiate their Windows NT product lines with proprietary high-end graphics capabilities. Along with Digital Equipment's workstation business, Compaq has gained the high-end graphics technology from Megatek, which Digital Equipment acquired in 1996. Compaq has the opportunity to add the

 ©1998 Dataquest

fruits of this venture to its workstation business potentially filling one area of weakness.

Servers

The issues dealing with the operating system of choice take place most predominantly in the server space. Compaq supports Windows NT, SCO UnixWare, and Novell's NetWare; Digital Equipment provides Windows NT and its proprietary UNIX, as well as systems based on VMS. The third element of the new company, Tandem (acquired by Compaq in June 1997), has its proprietary NonStop Kernel (NSK), a small investment in UNIX, and Windows NT. Also there is a mix of processors (that is Intel, Alpha, and MIPS) within the new company and the operating system decision goes jointly with the chip selection.

Dataquest foresees that Compaq will opt to keep Tandem's high-end systems and operating system while at the same time maintaining Digital Equipment's UNIX variety. There may be an opportunity to migrate the NSK operating system to an Intel design in the future, but it is well after the turn of the century. The Alpha solutions gain credibility with Compaq's endorsement and can provide a path from IA 32-bit to the Merced technology. The real test of strengths will be the price/performance ratings of the processors and operating systems after Merced is stabilized and Microsoft's next generation matures.

Personal Computers

Through the first three quarters of 1997, Compaq sold roughly as many PCs every month as Digital Equipment did the entire period. This underscores the fragility of the Digital Equipment PC business as part of a much larger Compaq. Although Dataquest believes that Digital Equipment brings valuable technology and engineering to the table, these attributes will be more effectively leveraged in Compaq branded PCs. Therefore, Dataquest ultimately foresees the death of Digital Equipment branded PCs.

As customers' short list of vendors becomes dominated by IBM, HP, and Compaq, this may force other computer vendors (PC and otherwise) to target niche markets. Ultimately, this standardizes and simplifies the desktop, leading to a real commodity market where vendors must search long and hard to add significant value and differentiation. Whether customers will accept single vendor solutions is an open question.

As for the mobile portion of the PC business, there are no immediate magic bullets—it is truly a draw between the mobile technology of Compaq or Digital Equipment. Dataquest believes, however, that the acquisition may allow Compaq to finally get a shot at obtaining the kind of flagship product that instantly defines the entire line and its potential. Additionally, Digital Equipment design engineers and marketers have a chance to join a mobile team that has been one of the top three in the world for the past few years. Compaq has been vying for the top spot on the mobile PC vendor heap for almost as long as there have been mobile PCs. The addition of Digital Equipment's products and skills will help Compaq compete more effectively.

 ©1998 Dataquest

Microprocessors

Digital Equipment's Alpha chip will afford Compaq the chance to penetrate and grow its business in the data center environment. It raises Compaq to the elite ranks of HP and IBM as a provider of a full suite of systems and services and allows Compaq to let the PC business evolve into a box-delivery component of its overall system strategy. Compaq's server growth will no longer be limited by any perception that Compaq is just a PC company, and the opportunity to mate the advanced Alpha servers with Compaq's marketing and sales skills could lead Compaq to significantly higher overall margins by the end of the decade. Therefore, after the dust settles, there is a third major contender for the enterprise systems market as Compaq joins HP and IBM.

What's the Impact on IT Services?

The addition of Digital Equipment's services business to Compaq fills an immense void that has kept Compaq from becoming a significant player in the enterprise computing market. Compaq's distinct lack of a service business (especially in terms of field personnel), even with its acquisition of Tandem last June, had a "pigeonhole" effect on it as a product company. It could offer great technology that was admissible for workgroup computing, but would never fly in the enterprise because of the company's lack of mission-critical services infrastructure and IT integration and management skills. Compaq attempted to minimize its lack of robust enterprise services by crafting partnerships with Digital Equipment and Unisys. However, IBM and HP continually attacked this leveraged support model in competitive bid situations, even though they, too, used partners.

The addition of a direct service business is a major boost for Compaq. It now has a chance at the enterprise and may be able to give IBM and HP a run for their money, provided the integration runs smoothly and there is an increased focus on providing solutions. This move also places more distance between Compaq and its PC competitors, particularly Dell and Apple. Compaq can now go to market competing on product and service while most others will not be able to compete at this level in the services arena.

In terms of skills and resources, Digital Services Division consists of 22,000 service professionals split between its three service business units. These business units and the specific skills sets contained therein are as follows:

- Multivendor Customer Services (MCS): This group accounts for 66 percent of fiscal 1997 service revenue ($3.8 billion). MCS delivers hardware service, support, and maintenance services, as well as multivendor availability and management services that focus on providing technical expertise in UNIX and Windows NT for mission-critical environments. Compaq leverages the MCS organization as a global service partner. Overall, the MCS group will be challenged to maintain its vendor neutrality as a vendor-to-vendor service partner.
- Network and System Integration Services (NSIS): This group accounted for 24 percent of fiscal 1997 service revenue ($1.4 billion). It has

competencies in application solutions for mail and messaging, Internet/intranet services, electronic commerce, and manufacturing and telecomm industry solutions. Strong technology solutions have also been built around NT. Compaq made an initial foray into the network business with its acquisition of Thomas Conrad and Networth several years ago. To date, Compaq has not figured the nuances in delivering service for networks versus delivering services for desktops. This NSIS group will help better define Compaq's role as a network integrator.

- Operations Management Services (OMS): This group accounted for 10 percent of fiscal 1997 service revenue ($0.6 billion). Service offerings include operations support for distributed client/server environments, including desktop systems infrastructure management, application operations management, and Internet/intranet management. The services and skills in OMS will enable Compaq to offer life cycle management services to its customer base.

The integration of Digital Services into Compaq is, in theory, like finishing a puzzle—almost. Dataquest perceives certain weaknesses in Digital Equipment's services business that may directly translate into lost opportunity for Compaq. Specifically, Dataquest cites its lack of a mature applications integration practice as a major hole in Digital Equipment's capabilities. These skills are essential for a major play in the enterprise. As both companies are aware of this distinct lack, there is a chance that there may be additional acquisitions down the road.

Once the integration process gets under way between the two companies, Dataquest foresees a potential culture clash between product-oriented Compaq and the Digital Equipment's services business. Although Compaq's executives understand the need for services, there is a distinct lack of understanding about how to shift from a product to a solutions model. Compaq needs to make a concerted effort to leverage the knowledge and expertise housed within Digital Equipment in order to effectively make this transition. Compaq may very well end up integrating into Digital Equipment's service culture rather than the other way around. Dataquest believes Compaq's best bet is to let current Digital Services management remain in full control of services.

The existence of a Compaq/Digital Equipment service partnership prior to the acquisition may help move the integration process along. In fact, Compaq stated that talks between the companies first began because of the services partnership. However, there's a concern that Compaq will continue to be quite focused on the capabilities offered by Digital Equipment's Multivendor Customer Services (MCS) business unit, which are quite product support oriented. Compaq needs to expand its services vision and leverage the outsourcing and network services skills housed in Digital Equipment's other services units.

Lastly, there are several looming questions—the answers will directly impact the success of Compaq's merger with Digital Equipment and their future success as a unified company. Some of these key questions are as follows:

- How will Compaq manage its channel relationships given that it now has a direct service capability?
- Will Digital Equipment be able to sustain its reputation and viability as a multivendor service provider given that it is now a Compaq-owned company?
- Does Digital Equipment bring the right mix of service expertise that Compaq needs to deliver enterprise solutions to the Fortune 1000?
- How will Compaq integrate the Tandem and Digital Equipment professional services capabilities?

Dataquest believes that most of the elements are in place for Compaq to compete squarely in the demanding enterprise services arena. However, it needs to take a hint from IBM and HP: lead with solutions, not just products.

What's the Impact on the Channel?

The potential for product channel conflict is technology dependent. Clearly in an open technology market such as PCs, channel conflict is a key issue because a reseller can make the decision to switch brands if it is concerned that it is competing for business with the vendor. With Digital Equipment's PC business expected to be merged into Compaq's business, this should not be an issue—particularly since Digital Equipment's existing business is almost exclusively indirect.

Further up the technology curve, segmenting between direct and indirect channels is more difficult; it is a question that companies such as HP and Digital Equipment have struggled with, especially as WinTel technology has encroached into the workstation and midrange computer spaces. If technology is proprietary and demanded by users, then a vendor can operate through both direct and indirect channels. More difficult for vendors is how to stop and separate sales organizations from competing against each other. HP's solution is to put both sales organizations under the same umbrella. Compaq will need to move in this direction.

Channel relations regarding service could be a touchy subject, as Compaq now has direct service capabilities. However, considering Compaq's recent redesign of its Authorized Service Provider (ASP) program around customer requirements and satisfaction, and Digital Equipment's multivendor services accomplishment of integrating services at point of product purchase, there will be plenty of service opportunity for the channel. Current business partners focused on the services side of the equation have compelling reasons to stay the course or even upgrade their relationships with both companies.

Compaq needs the channel's support. Even with the Digital Services Division under its belt, the company still needs the channel's core competencies such as broad customer reach and custom software expertise. HP and IBM have recognized this and it is reflected in their channel

 ©1998 Dataquest

strategies. The Digital Equipment acquisition puts Compaq in a more powerful position when dealing with the channel, but there are alternatives that resellers can choose. Resellers will be watching Compaq very closely in the coming months.

What's the Impact on Sales and Marketing?

Neither Compaq nor Digital Equipment has as yet determined the overlap between accounts. Digital Equipment's MCS organization is already supporting many Compaq environments—all signs indicate that Compaq intends to preserve this vendor neutral asset. Digital Equipment's product and service top accounts map closely in Fortune 1000 market segments. Its services business has helped Digital Equipment penetrate Fortune 2000 and middle market segments with little overlap on the product side. Digital Equipment's strengths are in middle market and global enterprise organizations. Compaq views its markets slightly differently. Compaq clearly plays in the small office/home office segment and in what it labels the small/medium business, middle market, and global/mission-critical enterprises.

In terms of sales resources, Digital Equipment has about 1,000 dedicated service sales specialists worldwide who prospect for and close the company's service business. A number of these dedicated service sellers line up to strategic accounts and sell to end users as members of Digital Equipment's Enterprise Sales Force (ESF) account teams. They also include channel sales representatives who sell to, through, and with partners. ESF staffs about 2,000 people worldwide and sells the company's technology products; it segments into three types of selling orientations. One group is assigned to about 500 strategic corporate accounts, another group has a territory responsibility covering from two to 25 accounts, and the rest are devoted to prospecting for new business and generating leads for Digital Equipment's partners.

A potential concern however, before the acquisition and now, is the lack of sufficient consultative selling talent in both companies. Compaq's model is indirect through partners, with limited experience in the business solution sell at the top of the enterprise. Digital Equipment's only real engagement managers are in the OMS business and are already stretched. Pockets of excellence exist within Digital Equipment's service sales organization, with considerable talent in networks, business-critical support, migration, mail, and messaging. However, the new entity will require a prudent sales retention, conversion, and recruitment effort designed to bring the enterprise selling talent to a level commensurate with the new and considerable enterprise capabilities.

The new value proposition is one of client choice of highly engineered products and technology platforms, superb service capability, true global distribution and service infrastructure, and a wealth of experience in managing complex distributed computing environments. This proposition

 ©1998 Dataquest

gives the combined salesforce some powerful new selling opportunities that cannot afford to wait six months or even one year.

Dataquest Perspective: What's the Bottom Line?

Overall, Dataquest regards Compaq's acquisition of Digital Equipment as a positive move. Critical synergies exist that will greatly improve both companies' future positions and bring added value to existing and future customers. In the short term, Compaq will continue as it has been: driving NT over UNIX and proprietary systems, and leading the world selling PCs. Further down the road, Dataquest foresees significant product, technology, and service implications as a result of the acquisition.

One of the primary overlaps between companies is in the personal computer market. It is likely that Digital Equipment's PC business will be subsumed totally under the Compaq brand because of overlap and limited brand equity. Digital Equipment's mobile PC business will also be absorbed, but the company's pioneering work in low-profile large-screen products could combine with Compaq's solid mainstream devices to allow the combined company to challenge Toshiba from the No. 1 slot. Dataquest believes that Compaq will retain Alpha and Digital UNIX because they have the strategic implication of expanding Compaq's reach into the enterprise—that is until Intel's IA-64 architecture delivers a compelling alternative to the market (not until 2001 at the earliest) and NT matures. The combination of Tandem's NonStop Kernel, Alpha and Digital UNIX, and Compaq's PC contribution creates a powerful technology engine that will allow the combined company to compete against a wide variety of competitors.

On the services side, Compaq has historically been penalized for its lack of a substantial services business. With the acquisition, it gains a service giant, 22,000-people strong with global capabilities. Dataquest anticipates some form of a culture clash between the two companies as Compaq struggles to make room for services in its product world. Despite the addition of a formidable services business, Dataquest questions whether Digital Services has the precise array of services required to provide full solutions to enterprise customers. One of Digital Equipment's key weaknesses is its lack of application integration skills that are quickly becoming a requirement given the burgeoning enterprise resource planning market. Because both companies seem to be aware of this deficiency, Dataquest can't help but wonder if there are other acquisitions waiting in the wings.

Taken as a whole, the ultimate challenge will be the integration of products and technology with services. Compaq's goals of becoming one of the top three computer companies in the world and reaching $50 billion in revenue by the millennium are largely dependent on its success at solutions selling. Dataquest perceives that most of the working materials are in place to make the new Compaq a full solutions provider, with the exception of data center and application integration skills. Aside from these holes, Dataquest anticipates a success-filled future for Compaq as an enterprise player.

Semiconductors—Top Views
Market Analysis

Semiconductors Second Quarter 1998: A Buyer's Boon and a Supplier's Gloom

Abstract: *Since the release of Dataquest's spring worldwide semiconductor forecast, severe DRAM price erosion and economic downturns have begun to affect the revenue not only of MOS memory but also of all other major semiconductor product categories. The consumer and data processing electronic equipment markets are showing further signs of weakening. Capital spending forecasts have declined 15 percent. Weakened by economic turmoil in Asia/Pacific and financial weakness in Japan, prices on electronic imported goods arriving at Europe's and America's doorsteps have declined for seven consecutive months. The DRAM downturn that began in December 1995 is taking the rest of the market down. This very long downturn is reminiscent of the DRAM nosedive that began in January 1985. Many companies barely survived, and those that did were lucky to walk away bruised and battered. How do these events affect Dataquest's clients and current forecast?*
By Mary Ann Olsson

A Worldwide Forecast Update

For two and one-half years, there has been both decline and growth in semiconductor products. MOS memory devices have led the decline. In terms of historical volume and driving overall profit, DRAMs, the powerhouse products, have been pivotal to this decline (down 38 percent in 1996, down 20 percent in 1997). Judging from the decline in prices during the first half of 1998, there will be a third year of decline in DRAMs. This decline could go beyond 23 percent, taking DRAM revenue below $16 billion in 1998.

Although multiple forecasts and scenarios different from Dataquest's original forecast have been publicized, Dataquest has tried to avoid following the herd. This Perspective offers the most likely scenario for the market and, possibly, moments of sanity that rise above soothsaying.

Publication Date: June 29, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

The spring publication of Dataquest's worldwide semiconductor forecast for semiconductors and ICs showed the optimistic forecast; the most likely downside scenario for 1998 is shown in Table 1. Barring major economic downturns that even Dataquest cannot predict, we believe that the market will fall within this range.

Table 1
1998 Worldwide Semiconductor Forecast Downside Scenario (Millions of Dollars)

	Actual 1993	Actual 1994	Actual 1995	Actual 1996	Actual 1997	Optimistic 1998	Most Likely 1998

Analysis and Assumptions

Since the first quarter of 1998, significant events have occurred that have affected not only industry dynamics but also Dataquest's initial forecast. The Asian financial crisis has worsened, weakening the financially struggling Korean semiconductor companies. Overcapacity is still prevalent. A price collapse continues to erode the DRAM market. Continued oversupply and unbalanced currencies in Asia/Pacific and Japan and competitive posturing by the 64Mb DRAM suppliers are the main cause of this erosion. Are those cries of dumping in the distance?

It is Dataquest's view that vendors will continue to lower prices, even to the point of selling at or below cost, to gain share or just to fill the fabs. The aggressive capital spending and overexpansion that continued through 1997 exacerbated the problems of a market already in the throes of overcapacity and accelerated DRAM technology die shrinks. In 1996, overcapacity in DRAM was about 20 percent, and it was rumored to be at 40 percent in 1997. With the shrink factor and the addition of net capacity over the last year and a half, the signs do not bode well for an 8 percent growth in 1998. Add to that a recent downward trend in microprocessor (MPU) and logic prices, and Dataquest's most likely scenario becomes more reasonable.

Buyers of semiconductor products are happy about these prices. But the risks are great. Building too much inventory in a shaky market with weak trading partners coupled with low import pricing could send the entire semiconductor industry spiraling into a recession. Many suppliers (merchant and foundry) are scurrying to fill fabs with non-DRAM products, offering lucrative contract pricing for products in the non-DRAM sectors. Many buyers are building low-priced inventories to keep up with pricing pressures while meeting demand for lower-end systems in the data processing, consumer, and communications sectors. Is the market spiraling out of control, and is this a market transition of electronic equipment demand growth from less sophisticated business sectors? Or is this simply a downshift in revenue growth as the equipment market becomes a commodity market?

Unless something miraculous happens during the next two quarters, stronger near-term semiconductor market growth is not expected.

Product Analysis

MOS Memory

DRAM has always been the key driver of growth and the key culprit in decline in the semiconductor industry. In the major DRAM and overall semiconductor market downturns, excess (capacity or strategic inventory) is the real culprit. There are many similarities between this market downturn and the market downturn that began in 1985. Some of these are listed in Table 2.

Table 2
Market Comparisons: 1985 through 1987 versus 1995 through 1998

1985-through-1987 Market	1995-through-1998 Market
Product hoarding/double-ordering led to supply excess, which precipitated price erosion.	Excessive capital spending added to overcapacity that precipitated price erosion.
Capital spending was depressed in the United States because of uncertainty about proposed tax reforms.	Capital spending was depressed in the United States, Japan, Europe, and Korea because of a capital spending binge.
International trade issues over product prices below fair market values led to antidumping duties on DRAMs and EPROMs.	Uncertainty about antidumping duties on DRAMs rises as rumors abound about dumping products at below cost to gain market share.
Damaged by price erosion, a depressed market, and aggressive competitors, Mostek, Intel, and Inmos disappeared from key market sectors.	Damaged by excessive spending, price erosion, and aggressive competitors, some DRAM suppliers are evaluating departure from the market.
A crossover point in price was reached between the 64K DRAM and 256K DRAM. The 1Mb DRAMs reached price-per-bit parity with 256K at the end of 1987.	In a dance of death, 64Mb DRAM chases the 16Mb DRAM. Price-per-bit parity could be reached by the end of 1998. A 4Mb-to-16Mb crossover could occur during this time.
There was a dramatic change in the yen exchange rate, from ¥254/dollar in 1985 to ¥128.4 at the end of 1987.	The yen/dollar exchange rate changed dramatically from ¥129.73 for the spring forecast period to ¥143 for 1999. The Korean won lost 50 percent of its value against the dollar, like the yen in 1985 through 1987.
Price erosion affected all memory products.	Price erosion affects the majority of ICs.

Source: Dataquest (June 1998

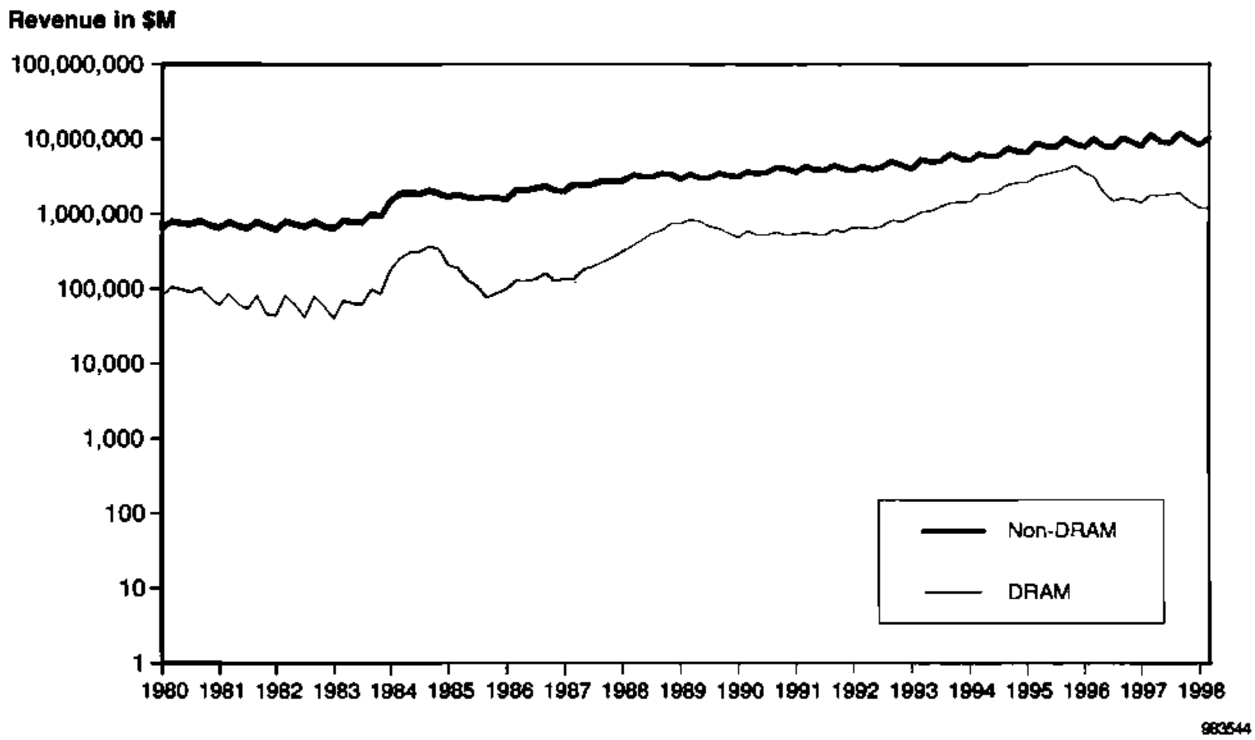
A stroll down memory lane might jangle some nerves but would help many to understand what is happening in the semiconductor industry. The DRAM market declined 52 percent, from $3.5 billion in 1984 to $1.7 billion in 1985. In 1984, suppliers hoarded products and buyers double-ordered on contracts to guarantee shipments. In 1985, as suppliers began dumping products and lowering prices, buyers canceled long-range contracts to reap the benefits of lower prices. Pricing wars raged until trading wars and dumping issues resulted in government intervention, and foreign market value (FMV) duties were imposed. The suppliers in this market suffered the worst losses and

 ©1998 Dataquest

faced the worst price erosion. Several companies made well-publicized withdrawals from the DRAM market during that year. The manufacturers that fared best were those well positioned in the 256K DRAM market, which enabled them to shift their revenue base as the 64K market declined.

The historical path of DRAM revenue versus non-DRAM revenue through the historical eyes of World Semiconductor Trade Statistics (WSTS) data reveals that a slowdown in market growth actually occurred in the last three months of 1984 (see Figure 1), before the DRAM market took a nosedive in January 1985. It took the market and its suppliers 27 months, from January 1985 through March 1987, to return to growth.

Figure 1
DRAM versus Non-DRAM Revenue over Time



Source: WSTS

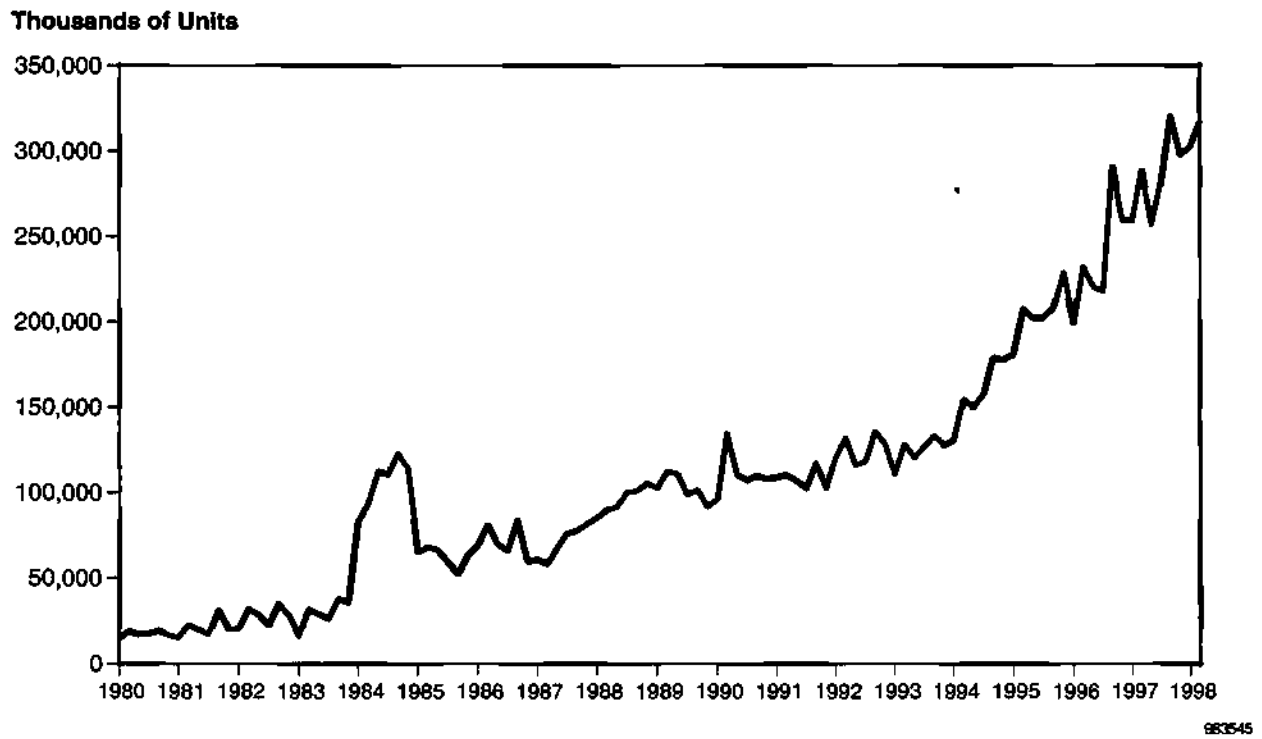
Today's market is very reminiscent of that downturn. DRAM growth slowed during the fourth quarter of 1995, and the decline began December 1995. From that time, it has been 29 months of more or less declining revenue. There was a brief respite in September 1996. There were gasps of minor growth in February and March 1997, growth mostly propelled by the Korean suppliers. There was a lull in April before revenue strengthened from May through September, and then the second downturn hit during the fourth quarter of 1997.

Figure 2 shows that DRAM shipments over time were very smooth in the shortage years (1992 through 1995) but quite bumpy in times of oversupply (all other years). Do smooth shipments represent extremely tight allocation,

 ©1998 Dataquest

with factories operating at maximum efficiency? If this is true, then the bumpy times reflect opportunistic buying binges followed by times of feasting off the excess purchases. This figure has been extended to include the first four months of shipments in 1998. Given the fact that overcapacity remains, this period of decline could extend beyond 29 months into a 31-to-34-month decline in revenue.

Figure 2
Historical DRAM Shipments



Source: WSTS

There are two major differences between history (1986) and the present day. First, the 1997 market had about a six-month resurgence in spending in DRAM, which did not happen in 1986. On the bright side, the market for front-end equipment grew over 50 percent in 1988, which would correspond to 2000 in Dataquest's current forecast. Second, changes occurring now in the PC sector, the major area of consumption for all semiconductor products, not just DRAM, are exacerbating the situation even further.

Microcomponents

What are the lingering effects of this lengthy price pressure on the market? As with memory, microprocessor pricing is also in the throes of downturn. Some attribute this to increased competition from Advanced Micro Devices Inc. and Cyrix Corporation, while others blame the increasing visibility of sub-$1,000 personal computers. Dataquest argues that the real culprit behind microprocessor price erosion is the declining number of $2,000 and $3,000 personal computers in the sales mix. With the performance of today's low-

 ©1998 Dataquest

end and midrange machines, few users feel the need to pay top dollar for the fastest machines they can buy. Some of this desktop MPU price pressure may be offset later in the year as Intel introduces processors priced at $1,000, $2,000, and $4,000, specifically targeted at servers and workstations. Although sold in far smaller volumes than desktop MPUs, the new high-end devices could still contribute mightily to microprocessor average selling prices (ASPs). The combination of one $4,000 microprocessor and 38 $100 processors still results in a $200 average for the lot overall. If Intel's plan works as expected, the second half of the year will produce far stronger MPU revenue than the first.

Logic

Logic is also under pricing pressure and feeling the effects of the turmoil in Asia, but to a much lesser degree than DRAM and microprocessors. Programmable logic devices (PLDs) are a good leading indicator among logic products, and this market has slowed noticeably in the first half of 1998. Pricing pressure can be blamed to some degree, but this market has seen rapid price reductions for some time as suppliers bid for market share. The gate array market is most vulnerable because a large portion of these devices are consumed in Japan, so at least a 10 percent decline can be expected in this market in 1998. Cell-based ICs are still the shining star, but they too have slowed in the first six months of the year.

Price/Cost Analysis

Although megabytes of DRAM grew 77 percent in 1996 and 95 percent in 1997, price-per-bit and price-per-byte declines have eroded DRAM revenue growth potential. Non-DRAM products are expected to continue on a growth path through the end of the year, but pricing pressures in microprocessors, logic, analog, and discrete products have reduced the market's non-DRAM revenue potential from Dataquest's original estimate of $138.3 billion to a more likely scenario of $133.2 billion.

The price forecasts for the most popular 1Mbx16 DRAM part had a contract price value of $3.50 in first quarter 1998. The second quarter 1998 price dropped to $2.55 and could drop to $1.80 by the year's end. The 4Mbx16 DRAM part was $24.00 in first quarter 1998. By second quarter 1998, it had dropped to $11.40 (below Dataquest's $15.00 estimate) and is expected to decline to $8.00 by the end of the year.

Dataquest's original forecast was based on a price per megabyte averaging $2.37 in 1998. A quick review of WSTS worldwide DRAM data (note that revenue for February and April 1998 was restated) is an eye-opening documentation of the disastrous downturn the market has taken since our forecast (see Table 3).

 ©1998 Dataquest

Table 3
Price per Megabyte Stays below the Cost Line

Month	Price/Megabyte ($)	Growth (%)	Cost Trend ($)	Price/Cost Change (%)
October 1997	3.10	-9	2.99	104
November 1997	2.59	-16	2.89	90
December 1997	2.19	-15	2.80	78
January 1998	1.96	-11	2.71	72
February 1998	1.97	0	2.63	75
March 1998	1.67	-15	2.54	66
April 1998	1.63	-2	2.46	66

Source: WSTS, Dataquest (June 1998)

Specific densities show even more cause for concern. Units of 16Mb DRAMs have declined significantly, while 64Mb units increased less, causing an overall decline in bit shipments of 11 percent from March 1998 to April 1998.

Application Market Analysis

Economic growth in Asia/Pacific and now Japan is grinding to a standstill, and that will almost certainly lower electronics demand even further. Japan's deteriorating economic circumstances are particularly distressing. Most forecasters now expect Japan to experience a sharp contraction in economic activity this year. If recent estimates of this contraction (a drop of 0.2 to 0.9 percent) are realized, then Japanese electronics demand will decline precipitously. This downward tumble in Japan would not only affect Japan's already hobbled electronics industry, but it would also seriously affect Asia/Pacific's export production.

The falling yen compounds this problem. The yen recently fell below ¥140 to the dollar and appears well on its way to falling even further, U. S. Treasury Department intervention notwithstanding. To be sure, the continuing depreciation of the yen could provide some stimulus to Japan's sagging economy. However, it is likely to reduce dollar-valued Japanese electronics activity. Moreover, by making Japanese exports less expensive, it almost certainly increases the economic stress of Japan's afflicted Asia/Pacific competitors. In the worst case, a deflating yen could raise the specter of competitive currency devaluation between Japan and its Asia/Pacific neighbors (notably China) that could depress both electronics and semiconductor activity well beyond 1998.

Given all these potential developments, it is not too unreasonable to believe that Dataquest's electronic equipment forecast, shown in Table 4, could also have a most likely scenario that may go well below 4.4 percent. When analyzing semiconductor activity from an end-use perspective, it is important to remember that semiconductor growth is ultimately driven by growth in electronics production and the semiconductor content of electronics. In short, the formula is as follows:

Semiconductor Growth = Electronic Equipment Growth + Semiconductor Content Growth

For 1998, a no-growth scenario is possible if (dollar-valued) electronics production slows significantly and average semiconductor content is reduced. Slower electronics growth now seems very likely, given economic circumstances in Japan and Asia/Pacific. A decline in the average semiconductor content of electronic equipment also appears highly likely, given the apparent inelasticity of DRAM demand in the face of falling DRAM prices. Added to that, Dataquest believes that the growing price competition in several key electronics markets (PCs!) is likely to curtail average semiconductor content as manufacturers struggle to preserve margins by holding the line on semiconductor consumption.

Inventory was a real issue for some PC suppliers during the fourth quarter of 1997 and the first quarter of 1998, and they have slowed their chip orders significantly in the second quarter of 1998. Added to this, server systems are sluggish as spending on these is being cut in favor of funding year 2000 software consultants. The cost concerns of year 2000 issues could be enormous if the additional cost hits from insurance protection and litigation potential are included.

More worrisome is the state of the rigid disk drive business. This sector remains in a prolonged overcapacity as prices and production plans continue to be cut. This pain has also been passed along to the semiconductor suppliers.

In the communications sectors, LAN and Internet access systems saw even worse price pressure than expected. This also affected the semiconductor suppliers because they were also pressured into lowering prices.

The segment that should come under close scrutiny in all regions is consumer electronics. Reports now indicate that the consumer sector is faring worse than expected as the financial turmoil in Japan and Asia/Pacific cuts spending in that area.

Table 4
1998 Electronic Equipment Production Forecast Downside Scenario (Billions of Dollars)

	Actual 1997	Actual 1998	Most Likely 1998 Scenario
Electronic Equipment Production	906.6	968.9	946.5
Growth (%)	6.8	6.9	Greater than or equal to 4.4

Source: Dataquest (June 1998

Regional Analysis

Asia/Pacific

The overall business climate in the Asia/Pacific region is weak and unstable. It is Dataquest's opinion that the Korean semiconductor market is dead. Korean semiconductor capital spending as a percentage of Asia/Pacific capital spending has traditionally been very aggressive. Korean DRAM suppliers originally gained access to the DRAM market during the government negotiations between Japan and U.S. DRAM suppliers during the trade wars of 1986 and 1987. Korean companies accounted for just over 14 percent of all capital spending worldwide in 1997, but it now appears that all new Korean semiconductor investment projects have stopped. Dataquest's capital spending forecast assumes that Korean companies will cut spending 40 percent in U.S. dollars. This is a total of about $3.3 billion for the big three companies (Hyundai Electronics Company Ltd., LG Semicon Co. Ltd., and Samsung Electronics Company Ltd.). DRAM price drops caused by the Asian turmoil are changing the outlook for 1998 DRAM growth in the region. DRAM, which originally was expected to contract 0.7 percent, is now expected to drop 31.0 percent. This could translate to a 0.6 percent contraction in Asia/Pacific semiconductor revenue for 1998. Asia/Pacific is a trade-intensive region that is basically in a trade recession. Its largest trading partner, Japan, has now become its largest trading competitor. China and Taiwan appear to be the more stable areas of the region. However, capital spending in Taiwan has begun to slow this quarter compared with the previous quarter.

Japan

The analysis from Japan does not bode well for a quick return to market growth. The biggest change has been felt in price declines in various MOS digital products—not just DRAM but also flash memory, microprocessors, microcontrollers, and application-specific ICs (ASICs). In the logic product markets, there have been mild price changes in cell-based ICs, while prices for application-specific standard products (ASSPs, the "other MOS logic" category) are falling rapidly. DRAM prices have come down below cost. In the microprocessor and logic product markets, vendors are offering aggressive prices that could bring revenue growth down substantially from the levels forecast at the beginning of 1998. It now appears that the yen/dollar exchange rate, assumed for Dataquest's spring forecast to be ¥129.73, will be closer to ¥138 for 1998 and ¥143 for 1999. This translates to a 6.3 percent yen depreciation against the spring forecast assumption. During recent interviews with Japanese semiconductor vendors, they gave estimates for growth in Japan ranging from a 5 percent contraction to flat for 1998. Contacts in the consumer applications believe that there may be a yen-based total semiconductor contraction this year.

Europe

The continued decline in DRAM pricing is affecting all device categories for European vendors, although analog, discrete, and optoelectronic product growth appears to be more robust than that of the more complex products. Microcomponent growth is down, even though unit demand continues to

©1998 Dataquest

grow. Regional PC demand in the first quarter was unexpectedly strong, with first quarter 1998 shipments up 26 percent over the first quarter of 1997. Demand has been weaker in the second quarter. The third quarter is historically weakest; however, strong fourth quarter demand should hold the year to the 14.3 percent PC unit growth forecast.

Production of other high-volume products, such as digital cellular handsets, remains robust, with the equipment manufacturers reveling in low prices, short lead times, and minimal inventories. A de facto just-in-time ordering system seems to be the norm on commodity products, with equipment manufacturers happy to have the semiconductor vendors acting as their warehouses and transferring products to their own ownership at the last possible moment. This has enabled them to decrease their inventories, but this is a dangerous game because, when the upturn comes, lead times will rise overnight, leaving less astute purchasers without adequate backlog coverage.

The current forecast for Europe is for 8.6 percent growth, but that the change in circumstances makes this an unlikely occurrence. On the basis of the reasonably strong end-equipment growth still forecast for Europe, Dataquest expects the region to outperform the worldwide market with growth, at best, at about 3 percent for the year.

Americas

The Americas region, originally forecast to grow around 10.9 percent, could instead decline to growth of about 4 to 5 percent. Americas investment in DRAM is minor compared with that of Asia/Pacific and Japan. The major price declines in other memory products (SRAM, flash, and EEPROM), microprocessors, and logic/ASIC devices are an indirect result of other market downturns and DRAM system price pressures. All the major North American semiconductor and front-end equipment suppliers are posting declines in quarterly earnings. Some have chosen more drastic measures, layoffs, to stem the revenue decline. National Semiconductor Corporation, Motorola Incorporated, and Applied Materials Inc. have all announced major layoffs. Lam Research Corporation has chosen a two-week plant shutdown. Even with the U.S. Federal Trade Commission breathing down its back, Intel Corporation has buckled under the system pricing pressures and announced price reductions of up to 20 percent on various MPU products. The automotive and consumer application markets are stable, but the communications sector, especially the cellular telephone market, has weakened.

What about Capital Spending Now?

A "technology" spending cycle during 1997, normal in the middle stages of an oversupply-driven downturn, was much stronger than expected, driven by the sheer momentum of an increased number of new and inexperienced players in the market. The correction in spending is now under way, following very closely, and perhaps exceeding, the downside scenario presented by Dataquest in January ("Wafer Fab Equipment Market Forecast

Update: Question Marks for 1998," SEMM-WW-DP-9801, and "Conference Call on Capital Spending and Wafer Fab Equipment Year-End Forecast Update," SEMM-WW-DP-9803). A revised capital spending forecast will be released in mid-July; however, the current view is that 1998 spending is likely to be 14 to 16 percent lower in 1998 than 1997. The weakness is the underlying chip market in 1998 should delay a recovery in spending until 2000, meaning that 1999 should be a single-digit growth year, at best.

Dataquest Perspective

The tried and true survivors of the semiconductor industry understand the angst of these memory boom-to-bust death cycles. The length of this DRAM downturn will weaken the growth potential of 1999. At this time, Dataquest does not expect memory IC revenue to return to 1995 growth levels until after 2000, when balance returns to the market. Despite the ups and downs of the semiconductor industry, semiconductors are fundamental to information technology. The market has seen revenue set back for the last two and one-half years. This may turn into a full three-year downturn or it may be temporary, unless the markets in Asia/Pacific and Japan weaken further.

Is there a bright side somewhere? A return to growth could come from many of the top 10 emerging consumer, communications, and data processing equipment markets. These are expected to account for about 70 percent of semiconductor consumption through 2002. The PC market is undergoing an intense transition from the high-end desktop products to the low-end, low-priced systems. There is concern about demand for the system above 300 to 400 MHz, which will drive DRAM megabyte growth. Is real demand developing for high-end thin servers and workstations? Intel could make that demand real, based on its recent price decrease efforts. Prices for various 300-to-400-MHz devices have recently been cut from 12 to 20 percent. The wireless and new digital consumer application markets continue to drive digital signal processor, embedded, and digital ASIC growth.

Dataquest will continue to closely monitor regional, product, and application events as they occur. Comments on updates are always welcome.

Asian Financial Crisis: Status Report

Abstract: *To keep our clients up-to-date on the impact of the Asian financial crisis (AFC) on the semiconductor industry, Dataquest is providing a high-level view of the current state of the AFC, looking briefly at how the AFC is affecting the major countries in the region.*
By J. H. Son, Jerry Yeh, Chang Soo Kim, Ken Ng, Daniel Heyler, and Yoshihiro Shimada

Asia/Pacific Regional Overview

The Asian financial crisis (AFC) can be compared to the tornado that sweeps through the Eastern part of the United States almost every year. Once it lands, it destroys everything indiscriminately, including buildings, automobiles, and road construction. Its direction is unpredictably random, and it moves anywhere depending on atmospheric phenomena. The financial crisis is taking place when the economic situation is unstable, and like a tornado, it can travel to any country, depending on the conditions.

To keep our clients up-to-date on the impact of the AFC on the semiconductor industry, Dataquest is providing a high-level view of the current state of the AFC, looking briefly at how the AFC is affecting the major countries in the region.

The AFC that we are facing seems to have originated when most Asian countries did not respond quickly enough to the fast-changing world economy. While the world economy required rapid globalization and democratization, most of Asian countries couldn't keep pace with these trends. In addition, they neither caught the right direction of the international fund flow nor secured enough international confidence from the West. Also, they were inattentive to the revolution bringing about a new,

Dataquest
Program: Semiconductors—Top Views

Publication Date: July 20, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

economy-oriented society. This eventually resulted in the Asian countries' financial crisis.

The AFC, which started in July 1997, landed in Thailand first. After that, it traveled to Indonesia, and then Korea. It destroyed those countries' economies, and its power was extended to Japan, Singapore, Malaysia, and many other Asian countries. Fortunately, China has not yet been influenced by the AFC as deeply, but it may be subject to damage if the value of the yen continues depreciating. As the duration of the AFC lengthens, it shows symptoms of expanding to Russia, Europe, and the United States. This crisis seems not to be finished with the Asia/Pacific region.

The AFC will cause the gross domestic product (GDP) of most Asian countries to drop in 1998. Specifically, Indonesia, Thailand, and South Korea are expected to show negative growth in 1998, and Japan will again record under 1.0 percent growth this year. The other Asian countries will record positive numbers, but much lower growth rates than in 1997. Average GDP growth rate in 1997 was 5.0 percent, and it is expected to be 2.5 percent in 1998, which is just half of 1997 growth. Dataquest forecasts that this poor growth will not recover even in 1999. The details are referred to in Table 1.

Table 1
Real GDP Growth for Asia/Pacific Countries (Percent)

	1997	1998	1999
Indonesia	4.6	-6.4	-1.7
Thailand	-0.5	-3.5	1.5
South Korea	5.5	-1.8	2.2
Japan	0.9	0.6	1.7
Malaysia	7.8	2.0	3.0

China	8.8	7.0	7.5
Vietnam	8.7	9.0	9.4

Source: Dataquest (June 1998)

The AFC's first effect was the depreciation of local currencies in Asia/Pacific region. Table 2 shows the average exchange rates of local currencies against the U.S. dollar for 1997 and 1998. Among the 13 local currencies, the renminbi (also called the yuan) is the only currency to keep positive value against the U.S. dollar. The other Asian currencies lost value against the U.S. dollar, and the currencies in Indonesia, South Korea, Malaysia, and Thailand are experiencing deep depreciation in this year.

Table 2
Foreign Currency per U.S. Dollar (Annual Average)

Country	1997	1998*	Change (%)
Indonesia (Rupiah)*	2,872.61	11,525.00	-75.1
South Korea (Won)	954.14	1,450.74	-34.2
Malaysia (Ringgit)	2.82	3.86	-26.9
Philippines (Peso)*	29.47	39.16	-24.7
Thailand (Baht)	31.07	41.13	-24.5

China (Renminbi)	8.32	8.31	0.1

* Estimate
Source: Dataquest (June 1998)

The AFC has also influenced stock market prices. High depreciation of local currency requires higher interest rates, which badly affect the management of companies. Foreign investors have a tendency to withdraw their money from the stock market to avoid losing more value. For this reason, the local currency has depreciated, and stock market prices are falling. Table 3 shows how much stock prices dropped during the past year. As in the case of exchange rates, China is the only country that showed an increased stock price index in Asia/Pacific region. The price indices of the other countries all show negative numbers. Indonesia, Malaysia, South Korea, Thailand, Singapore, and the Philippines have a stock price drop of more than 50 percent within a year. Stock prices in June dropped much more than in February, which means that the AFC is getting more serious.

In the early days of the AFC, manufacturing in the Asia/Pacific region increased a little more than before the beginning of the AFC. This was because the higher exchange rate created greater profit margins and increased competitiveness. As the AFC lasts longer, however, it has shrunk capital spending and resulted in falling growth rates for the electronics market as well as the semiconductor market. Dataquest has reflected this in the recent revision of the semiconductor market forecast.

In the spring, Dataquest estimated that the semiconductor market would reach $159 billion with 8.2 percent growth in 1998. Recently, however, the 1998 forecast was revised to $149 billion for 1.4 percent growth. This is a $10 billion reduction from the April version of the forecast (see Table 4). As for the $10 billion, the DRAM reduction will share 50 percent. The worldwide DRAM growth rate in this year was estimated at 1.0 percent in April, but Dataquest revised it by negative 22.9 percent in its latest forecast.

Asia/Pacific	32,534	35,899	32,330

Source: Dataquest (June 1998)

Dataquest's spring 1998 forecast was for the Asia/Pacific semiconductor market to grow 10.3 percent. Recently, however, we reduced the growth rate to negative 0.6 percent, considering the AFC situation. The main reason for this decrease is the DRAM price drop, which is much more serious than our original estimation. We estimate that the DRAM market in Asia/Pacific will be reduced by 31.0 percent in 1998.

Among the countries in the Asia/Pacific region, South Korea will be influenced by the AFC the most, followed by Singapore. China and Taiwan are less influenced than the other Asian countries. Table 5 shows each country's revised market forecast.

South Korea

Electronics Industries Are Staring at External Surroundings, Especially Japan's Yen

Economic Trends

The weakening yen and a possible devaluation of the Chinese renminbi are also posing an enormous threat. Reflecting the dismal sentiment, the Daewoo Securities financial institute projected in its latest report that Korea's economy would be reduced by up to 5 percent this year because of surging import prices and negative economic growth, adding that unemployment will exceed 8 percent. The institute expected this year's trade surplus to range from $27 billion to $31 billion. But the state-run Korea Institute for Industrial Economics and Trade issued an even gloomier forecast, saying that the trade surplus will amount to a mere $10 billion this year and less than $10 billion next year.

At the current exchange rates, according to financial experts, a 1 percent loss of the yen's value against the dollar, or the won's 1 percent gain against the dollar, will raise the won's strength against the yen by about W11. The nation's auto and electronics firms, which are competing fiercely with Japanese rivals in global markets, expect a 10 percent fall in the yen's value to cut their export profits by W1.1 trillion and $630 million, respectively.

Electronics Production Trends

Korean products will be able to keep their price competitiveness over Chinese products at least for the next two years, even after the Chinese government imposes a devaluation of its currency. The nation needs to sharpen the competitiveness of products that are in direct rivalry with China in the global market to cope with the cheaper Chinese currency.

©1998 Dataquest

As the Japanese yen depreciated to the level of ¥140 to the U.S. dollar, Korean exporters were on alert over a loss of competitiveness that had increased with the fall of the won. Most analysts in Korea predicted that if the yen fell to ¥150 per U.S. dollar, then annual exports from Korea would be reduced by $4.63 billion and imports by $920 million.

Korea's electronics industry's exports are expected to grow by 6 percent this year, according to the Korea Institute for Industrial Economics and Trade. The institute estimates that the recent low growth in exports is the result of difficulty in trade financing, a rise in trade incidentals, falling export prices, retrenchment of the Asian economy, and fiercer competition. Other elements slowing exports in this area are insufficient restructuring of operations and excessive dependence on semiconductors.

Korea as Semiconductor Consumer

Although exports of Korea's electronics equipment products are expected to grow by 6 percent this year, the electronics industry may be heading for its worst economic difficulties in the latter half of this year, according to the current situation. Signs of an imminent collapse of the industrial base are rampant in consumption and the factory operating rate. With the average factory operating rate sinking to 60 percent lately, especially for small and medium-size companies, sluggish domestic demand and sky-high interest rates have forced industrial companies to cut equipment investment by 40 percent. As a result, the production of data processing equipment is expected to decline by 2.1 percent this year and production of consumer electronics is expected to decline by 5.1 percent. However, communications products will grow at 12.2 percent, owing to expanding digital cellular phone and mobile systems. The growth rate of the combined production of data processing, communications, and consumer electronics is expected to be below 1 percent this year.

Dataquest's spring forecast had assumed that DRAM prices would bottom out at about manufacturers' variable costs. Unfortunately, DRAM prices have sunk below cost and have not yet hit bottom. At this rate, DRAM revenue could decline 44.8 percent in Korea. Assuming non-DRAM products grow a slight 1.1 percent, the total semiconductor market would decline by 3.3 percent in 1998 because of a slowdown in overall electronic equipment production and severe global price erosion. Dataquest will continue to update clients on the Korean market. Dataquest's fall forecast for the Korean semiconductor market, available in the fourth quarter of 1998, will present an in-depth analysis of the situation and will include itemized product forecasts for all semiconductor devices.

Korea as Semiconductor Supplier

Semiconductor exports including assembly business during the first quarter of this year reached $4.08 billion, an increase of 12.8 percent over the same period last year. Exports of semiconductors are expected to increase only by 6 percent this year because of weak prices of memories. Domestic semiconductor manufacturers' exports of nonmemory products are increasing, including media processors and chip designs such as system-level integration (SLI), Alpha, and quadrature phase shift keying (QPSK).

 ©1998 Dataquest

LG Semicon, which developed the MPACT media processor chip with Chromatic of the United States, produces 200,000 chips. LG's Java chip, which it plans to ship in the second half of this year, can be used for a variety of network-based information technology appliances, including network computers, Internet TVs, and Internet set-top boxes. Exports of SLI chips by Samsung Electronics increased from $200,000 in January to $5 million in April. Samsung plans to expand SLI chips to SRAMs and flash memories. The company also forecasts that its revenue from Alpha chips will increase substantially in the future. Although Hyundai Electronics recently sold Symbios, its nonmemory subsidiary in the United States, Hyundai intends to enter the market for CMOS image sensors this year and will ship QPSK modules for satellite broadcast receivers. Hyundai's revenue target for these nonmemory products is $5 million this year.

Korea's semiconductor manufacturers are placing more emphasis on marketing their nonmemory or system integrated circuit products in the domestic market. Dataquest estimates that this is part of their strategy to make up for declining revenue from memory chips sales overseas and enhance the competitiveness of their nonmemory products in the domestic market, which is dominated by imports. While recognition of Korean semiconductor companies as memory chip producers brings difficulties in expanding exports of nonmemory chips, these products are gaining popularity among domestic electronic appliance manufacturers because of their improved price competitiveness.

Dataquest Perspective

Korea's financial crisis has resulted in local electronics vendors not being able to sustain the sales volume necessary to maintain their competitiveness and justify continued investment in the electronics industry. As a result, the local electronics vendors are experiencing massive core business restructuring, corporate mergers, acquisitions, and downsizing this year.

Having overcome a dangerous liquidity crisis in March, Korea must diligently continue with the reform under way to leave the crisis behind. Potential obstacles include political infighting among the nation's leaders, social unrest resulting from layoffs and a high unemployment rate, and less than genuine restructuring efforts by the nation's conglomerates. Any of these factors can result in delay on the road to recovery, potentially plunging the country further into crisis. However, the international financial community has sustained confidence in Korea's ability to recover, as demonstrated by Korea's brisk and successful sale of U.S.$4 billion of bonds in the U.S. financial market in April. The first positive effects of successful restructuring should be felt by the beginning of 1999, if all goes well.

Under the terms of the International Monetary Fund (IMF) emergency loan extended to Korea in late November 1997, the economy will undergo massive and fundamental restructuring in 1998. The economy can be expected to experience low growth, high unemployment, and high interest rates this year. The nation's conglomerates, having already instituted deep cuts throughout their business units, will continue to implement radical self-reform measures and increase financial transparency. The financial sector

 ©1998 Dataquest

will be deeply affected, as banks and other financial institutions with massive amounts of bad or underperforming loans will be shut down or seek mergers and acquisitions. Domestic vendors will also focus their energies on boosting exports in order to improve their balance sheets while reaping the short-term benefits of lower product prices in overseas markets because of the devalued won.

By Chang Soo Kim (Asia/Pacific Semiconductor Group), changsoo.kim@dataquest.com

Taiwan

New Storm near Taiwan, Asian Crisis Spreading

Another wave of financial crisis is building in Asia as the negative influences of the financial storm gradually spread across the region. The Taiwanese government has started planning to prevent another wave of the financial storm, which has been on the horizon since March, from swamping Taiwan. Under the circumstances, the public is concerned about whether the Taiwanese economy is able to maintain steady growth. Taiwanese exports to Southeast Asian countries, as well as South Korea and Japan, dropped considerably in the first four months of the year. Taiwanese export and import trade with those countries during this period declined 6.7 percent and 3.2 percent, respectively, from the same period last year. The phenomenon indicated that Taiwanese international trade has been under the influence of the Asian financial crisis since the middle of last year.

Tables 6, 7, 8, and 9 provide a same-period comparison. Table 6 provides Taiwanese exports by region for the January-through-April period of 1997 and 1998. Table 7 shows Taiwanese exports by country in the Asia/Pacific region. Table 8 covers Taiwanese exports by commodity. Table 9 shows the Hsinchu Science-Based Industrial Park exports classified by commodity (January through April 1997 and 1998).

Dataquest Perspective

Taiwan has seen its exports decline for the first time in the past 10 years, which has been a warning signal for the year-long AFC. AFC and economic

©1998 Dataquest

recession in the region, including Japan, is reducing the number of electronic products imported from Taiwan. Some production shift to Taiwan from Southeast Asia/Pacific is occurring because of the AFC's turmoil (such as the Indonesian political and economic crisis). However, this additional strength cannot overcome the impact of sluggish import demand from the major industrial countries. The impact has begun to shake this trade-driven island since the first quarter of 1998. Electronics exports show a single-digit decline, but this dramatic change (compared to previous years) is significant. Fortunately, the island has credit available for expansion, the economic fundamentals are healthy, and most local companies have a well-controlled financial performance. Also sufficient capital exists to support local companies during the crisis, and the government has more than U.S.$80 billion in reserves. Is Taiwan safe, in the eye of the storm? Someone may get hurt, but should survive.

Singapore

AFC Hits Singapore

Lower Growth

Singapore's economy is headed for lower growth in 1998 as a result of the Asian financial crisis. Regional economies have not recovered yet despite adopting measures recommended by international institutions. With the worsening Japanese situation, fears abound of an impending round of currency devaluation among the Asia/Pacific economies. The Singapore government has earlier forecast a GDP growth rate of between 2.5 percent to 4.5 percent for the year. However, the government is now looking to revise official growth rates toward the lower end of the forecast range. Dataquest estimates that Singapore's economy is likely to record 2.5 percent growth. The Singapore government's consistent budget surpluses should allow the city state to better weather the financial crisis compared to other regional economies.

Lower Electronic Exports

Singapore's electronics sector is a key component of the island's export-driven economy. Nonoil domestic exports, as measured in local currency terms, declined 1.6 percent in April (see Table 10). Exports of electronics products drove the decline, decreasing by 3 percent. Electronic exports have fallen more significantly in U.S. dollar terms when we take into account the 18 percent depreciation of the Singapore dollar since February this year.

Trade data for the first few months of 1998 has shown an evident slowing down of electronic exports. This trend reflects the negative impact on demand and increased pricing pressure for electronics products brought on by excess capacity and the AFC. Oversupply and increased competition has hit Singapore's major export earners. Rigid disk drives (RDDs), the single largest export item, have shown weak growth this year. Major RDD manufacturers, such as Seagate and Western Digital, have reacted to the slowdown by cutting their workforce. Even the high-growth semiconductor industry has succumbed to the trend despite new investments in capacity

 ©1998 Dataquest

and equipment. Personal computers registered consistent declines in export value as a result of declining prices and inventory corrections.

Table 10
Singapore Trade Growth (Year-on-Year Percent Change)

	January 1998	February 1998	March 1998	April 1998
Nonoil Domestic Exports	-0.8	28.1	9.6	-1.6
Electronics	-2.4	24.0	8.3	-3.0
Rigid Disk Drives	-6.5	12.2	2.6	-0.4
ICs	5.8	41.1	21.2	1.8
Personal Computers	-15.9	0.1	-1.3	-28.8

Source: Trade Development Board and Dataquest (June 1998)

The regional economic outlook appears to be bleak going forward. With more bad news than good news on the horizon, hopes of an export-led recovery in Singapore this year are fading.

By Ken Ng (Asia/Pacific Semiconductor Group), ken.ng@dataquest.com

China/Hong Kong

Assessing the Downside Risk of China's Electronics Industry and Semiconductor Demand in 1998

This section assesses the potential threat that the Japanese and Asian economic slowdown pose to China's electronics industry and semiconductor demand in 1998. In revenue terms, China/Hong Kong is the largest and fastest-growing semiconductor market in Asia/Pacific, accounting for over 20 percent of consumption and 26 percent of electronic equipment production in 1997. In the current downturn, while most of the region is contracting, vendors are turning to China for growth. Although Dataquest will publish a detailed Market Trends report on the subject in July, this is an executive summary of key findings.

Currency Devaluation

The currency devaluation created critical problems for Asia/Pacific semiconductor suppliers and users that are almost entirely dependent on imports. Although most vendors denominate their prices in dollars, cash-flow problems—attributed to rising credit costs and falling sales—have resulted in weakened demand from local manufacturers. Indonesia's currency was devalued more than 80 percent during the past six months, and its equity market dropped more than 80 percent. As a result of the financial turmoil, stock markets in Korea, Thailand, the Philippines, and Malaysia declined by more than 60 percent. Equity markets in China and Hong Kong have also dropped, but their strong cash account reserves have enabled them to support the Hong Kong dollar and Chinese renminbi.

Few economists expect a devaluation in 1998, but there are concerns in the region that falling exports and a slowing economy will force China to devalue, potentially sparking another round of disastrous currency depreciation in Asia. It is a question of time. Of course, China will devalue, but whether it is before or after the region has recovered is the issue. In 1998, the Chinese government is under extreme pressure to maintain strong economic growth and create new jobs because of the dismantling of state-owned industries, which is creating millions of surplus workers. So far, the Chinese leadership has responsibly held its currency at the expense of economic growth, in addition to committing U.S.$250 billion in infrastructure spending projects to increase GDP vis-à-vis domestic consumption.

GDP Forecast

Data from the Organization of Economic Cooperation and Development (OECD) forecasts China's economy to grow between 7.5 percent and 8.0 percent. However, because of the region's worsening economies and slowing exports, GDP is expected by a number of sources in Hong Kong to fall between 6.5 percent and 7.5 percent. GDP in the first quarter of 1998 slowed to 7.2 percent and is expected to slow to 7.0 percent in the second quarter. The trend is expected to continue, with the second half of 1998 averaging less than 7 percent. One of the advantages China has over the rest of Asia/Pacific is that its economy is far more diversified, with economic expansion taking place in heavy industries, manufacturing, electronics, services, and agriculture. This broad-based growth, including electronics, has been an important buffer to Asia's economic woes. In fact, the major growth burden has been from the state-owned enterprises (SOEs) that account for about 60 percent of the economy. Prime Minister Zhu Rongji is in the process of structuring SOEs, which is the main factor behind slower growth and rising unemployment. However, China depends heavily on foreign capital and markets to sustain its current growth rate.

Foreign Investment

In addition to increased efficiencies in Chinese companies, economic growth has been boosted by direct foreign investment. Foreign investments need to continue to flow into China for it to achieve a 7 percent GDP growth. Hong Kong, which has been hurt financially by its falling stock market, accounted for 59 percent of foreign-invested capital in China from 1980 to 1997. Contracted investments in China declined from $88 billion in 1994 to $72 billion in 1997. However, the actual utilized investment increased from $33 billion to $44 billion during this period. There is uncertainty in 1998, and most forecasts indicate a decline in utilized investments, to $35 billion, for the first time in at least five years. However, Dataquest continues to see communications, computer, and consumer electronic companies maintaining a high strategic interest in investing in manufacturing in China for long-term needs: to increase market access, reduce distribution costs, and improve time to the market.

Trade

China is exposed to the Asian financial crisis by about 11 percent because 11 percent of its exports go to Southeast Asia and Korea. In the past few years, China's exports to Japan have declined to about 15 percent of total exports, but exports to Europe, North America, and Taiwan increased to more than 60 percent. Based on export exposure, a dramatic trade downturn as experienced by the rest of Asia is not likely. The free-falling yen was clearly a threat, but China still holds a (dangerous) wild card: devaluing the renminbi. So when China hinted at devaluing its currency as the yen collapsed without response, the United States and Japan quietly negotiated overnight to support the yen.

Electronic Equipment Production

Dataquest has lowered its electronic equipment production growth for China/Hong Kong from 19.8 percent to 16.3 percent because of slower investments, domestic consumption, and exports than previously forecast. Of China's $190 billion exports, 12 percent related to electronics, and the sector is increasing in total share. With the United States and Europe occupying about two-thirds of China's electronic equipment exports, the only major downside is Japan and Southeast Asia, which account for about one-fourth of exports. Slower exports and China's consumer electronics glut mean that production will expand by only 13 percent, while communications and consumer will have a combined growth of 23 percent.

The most dramatic falls in PC consumption in Asia/Pacific during the quarter were in Indonesia (with revenue shrinking 82 percent), Thailand (negative 62 percent), and South Korea (negative 46 percent). PC sales in 10 key Asia/Pacific markets shrank 25 percent in the first quarter, compared to a year ago. Only China and Singapore showed positive revenue growth, of 21 percent and 19 percent, respectively. However, China represents one-third of Asia/Pacific consumption.

The inevitable, long-term market is continuing to attract multinationals to invest in manufacturing, even during the current uncertainty. It is these investments that will enable accelerated growth in 1999 and beyond. The main reason for continued confidence is that China is not only the largest consumer electronics market in Asia/Pacific, it is the largest consumer of computer and communications equipment. Currently, China represents 30 percent of PCs shipped to Asia/Pacific and about 40 percent of all cellular handsets. The Internet is booming in China. Nationwide, there are about 1 million accounts. In Guangzhou, 1,000 new users sign up for the Internet every month. In five years, the number of users is expected to hit 10 million. Intel Corporation estimates that China will overtake Germany this year and become the world's third-largest PC market. And 11 million new telephone lines are installed every year, which is equal to starting a new regional Bell operating company every 12 months. Nokia Corporation, Motorola Incorporated, and Ericsson all have multiple major manufacturing facilities in switching, handsets, and other communications equipment and continue to announce expansion plans. Recently, Cisco Systems Inc. announced an investment plan involving $100 million to accelerate its technology transfers to China, including a solely owned networking technology company in Beijing and a network laboratory. Other semiconductor and IT vendor investments—by companies such as Intel Corporation, Texas Instruments Inc., NEC Corporation, and IBM—are expanding beyond manufacturing investments to R&D ventures, which are serving both local and global R&D requirements.

 ©1998 Dataquest

In summary, Dataquest believes that of the $54 billion in electronic equipment production in 1998, an estimated 52 percent, or $28 billion, will be exported. Overall electronic equipment production will slow from 21 percent in 1997 to 16 percent in 1998. Dataquest has established that the exports' downside risk per se is moderate, as long as the domestic consumption of key equipment sustains current growth levels, and the economy sustains a slower, but reasonable, growth level of 6 percent to 7 percent.

Semiconductor Market Forecast

Dataquest believes the China/Hong Kong semiconductor market will fall short of 1997's impressive 19.5 percent growth because of a slowdown in overall electronic equipment production and severe global price erosion. Dataquest's spring forecast had assumed that DRAM prices would bottom out at about the level of manufacturers' variable costs. Unfortunately, DRAM prices have sunk below cost and have yet to hit bottom. At this rate, DRAM revenue could decline 27 percent in China/Hong Kong, despite expected PC unit production growth of more than 40 percent. Assuming non-DRAM products expand by 10 percent, the total semiconductor market would achieve only 6.3 percent growth in 1998. Dataquest considers this forecast to be at the low end of its overall forecast range, while 15.5 percent growth is at the high end, with DRAMs achieving flat growth (which is unlikely). Dataquest will continue to update clients on the Chinese market. Stay tuned. Dataquest's July Market Trends report will present its in-depth analysis of the situation and itemized product forecasts for all semiconductor devices.

Dataquest Perspective

The effect of the global DRAM glut on the Asia/Pacific and Chinese semiconductor markets is the greatest threat to overall revenue growth. However, there is a wide variance in growth prospects across semiconductor products, which Dataquest will highlight in subsequent reports.

The financial crises and economic recessions across Asia/Pacific are expected to recover in two to three years. Despite China's mammoth economic challenges, its management of the economy has, thus far, avoided Southeast Asia's fate. Semiconductor demand continues to be robust, but global overcapacity will dim hopes of another year of double-digit revenue growth in China. However, China will be relatively better off than the rest of Asia/Pacific because of the following obvious fundamental advantages:

- A diverse electronics production base spread across various major sectors in the computer, consumer, and communications industries
- An emerging domestic market, which now consumes almost half of overall electronics production. The other half is exported (of which 31 percent is shipped to the healthy European and U.S. markets, while only 26 percent is exported to Japan and Asia/Pacific).
- Continued confidence and desire to invest by foreign investors, owing primarily to optimistic long-term prospects of the Chinese economy, rising disposable income, and evident market prospects

 ©1998 Dataquest

- Unwavering government support, with financial resources to spare, for IT adoption in infrastructure development (and the localization of domestic content for communications and computer equipment)
- Rising exports of equipment to the United States and Europe, which account for more than 31 percent of China's total production

By Daniel Heyler (Asia/Pacific Semiconductor Group), dan.heyler@dataquest.com

Japan

What's Going on in Japan after the AFC?

Starting with electronics equipment production of Japanese companies in Asian countries, the equipment targeted at internal consumption continues to show low production levels, including audio and video consumer products, as well as that related to PCs, such as storage. Video CDs are still suffering from excess inventory, which is rumored to be a few million units.

On the contrary, image scanner production in Taiwan is booming, and the fast increase in orders for charge-coupled device (CCD) image sensors has resulted in shortage of CCDs, while other semiconductor products suffer excess inventory because production of scanners is now forced to be lower than originally planned.

To take advantage of depreciated currencies, there are notions of intra-Asian shift of production sites. One Japanese audio equipment company decided to move its minicomponent production from mainland China to Malaysia, reportedly for the following two reasons:

- Lowered costs in member countries of Association of Southeast Asian Nations (ASEAN)
- High defect rate at Chinese production site of about 5 percent compared to about 1 percent at the Malaysia site

However, some industry contacts indicate infrastructure problems in ASEAN countries, especially the lack of human resources and of water supply.

These production site shifts, as well as the depreciation of the yen, prompted buyers of semiconductors at the Japanese affiliates to ask their colleagues in Japan to buy Japan-made semiconductors. The currency situation has made initial public offerings (IPOs) difficult for the time being because many Japanese companies assumed ¥130 to 135 to a dollar in their business plan for fiscal 1998. Further yen depreciation—especially if it becomes a constant trend—will make the purchase shift a solid move. (Usually the direct effect of rapid currency change becomes felt in about three to six months, depending on foreign exchange reservations.)

Another factor that is driving the purchase shift is the shortened order cycle. Seeing the fast-falling prices of semiconductors, buyers are unwilling to place long-term orders. Excess capacity in the semiconductor industry is another factor that is encouraging purchasing managers to withhold long-term orders. To cope with the short order cycle, "buying near production site" is preferred, while it is becoming important for semiconductor vendors to produce near the consumption site.

Along with the price fall of DRAMs, Japanese semiconductor companies' revenue outlook in the Asia/Pacific countries is becoming gloomy again, and it looks like the second wave of AFC impact has arrived. The first wave was, of course, all the turmoil caused by the sudden changes in currencies, and the plummeting economy. The second wave is the stage when the AFC hits both countries and corporations (within and outside Asia/Pacific) that are trying to change tactics and strategies to incorporate the new business environment, while the overall economic situation remains turbulent in selected countries.

Japanese semiconductor companies' capital spending this year is decreasing by more than 20 percent on the whole, with a couple of major companies cutting their expenditure in half.

The AFC has hit the semiconductor manufacturing equipment companies hardest here in Japan. The industry association in this area is reporting a reduction of over 40 percent in production of equipment, and the decrease is coming both from domestic semiconductor companies and Asian companies. Especially in Korea, there are indications that Japanese companies with their careful attitude are withholding shipment and future contracts while non-Japanese counterparts are being flexible in terms of trade. Wafers do not seem to suffer as much, but photoresist demand has been lowered substantially.

Looking at the Japanese domestic situation, consumption of end-user products in Japan continues to be sluggish, and even some digital consumer products, such as digital still cameras, seem to be suffering from lowered growth. Infrastructure-related industries, including automobiles, are being affected by reduced demand in various Asian countries.

Market Analysis

How Long Will DRAMs Remain a Quagmire?

The pending sale by Texas Instruments of its memory business to Micron Technology throws the global spotlight on DRAMs. This report provides a comprehensive third quarter 1998 outlook for the worldwide DRAM market. The report provides estimates of 4Mb, 16Mb, and 64Mb DRAM quarterly unit shipments by vendor for the 1998-1999 period. It shows the quarterly DRAM supply and demand outlook for this time frame including detailed analysis of PC DRAM consumption. This Perspective is based on the Executive Summary of **DRAM Supply/Demand Quarterly Statistics: Third Quarter 1998 Outlook** *(DSDR-WW-MS-98Q2).*
By Ronald Bohn, Jim Handy, James Seay, and Masahiro Suzuki

Introduction

This report provides the third quarter 1998 outlook on worldwide DRAM supply based on the results of recent DRAM vendor surveys and related information. The report sets out the DRAM supply/demand scenario for the period from first quarter 1998 through fourth quarter 1999, including detailed analysis of the 16Mb and 64Mb markets. The report also analyzes DRAM demand in detail, based on a forecast of worldwide production of electronic equipment, including PCs, and estimated DRAM megabytes (MB) consumed for each category of equipment.

Objectives

The objective of this forecast and market trends information is to serve as a basis for near-term planning concerning worldwide and regional DRAM manufacturing, sales, and procurement tactics; long-term strategic planning for DRAM product strategy and supply base management; and decision making concerning DRAM capital formation.

Key Findings

Highlights from the analysis are as follows:

- DRAM vendors should prepare for a 25 percent DRAM bit oversupply in 1998.
- DRAM market conditions likely will improve little for vendors during 1999, which will be another year of large DRAM oversupply.
- DRAM suppliers are aggressively ramping 64Mb output while also producing a large supply of 16Mb devices.
- The oversupply means strong price competition among vendors of 16Mb and 64Mb DRAM—and extreme pressure on these suppliers.

Suppliers' Strategies

Major DRAM manufacturers have achieved two top priorities: the development of high-speed DRAM for PC100 and 64Mb DRAM die-size reductions (or shrinks). The current priority is to achieve higher production yields on high-speed 64Mb parts.

Major manufacturers, especially Japanese companies, will accelerate their shift to 64Mb DRAM and away from 16Mb this year. By contrast, Korean manufacturers will not only increase 64Mb production this year but also maintain a high level of 16Mb production.

The pending sale of Texas Instruments Inc.'s memory business to Micron Technology Inc. indicates that additional company consolidation will occur in the worldwide DRAM market should the severe oversupply continue for another 18 months, as is expected.

16Mb

Suppliers of 16Mb DRAM have forged two main strategies:

- **Moderate shift from 16Mb DRAM**—One approach is to maintain 16Mb production at a relatively high level while proceeding to reduce production moderately. These suppliers have already completed the 16Mb chip shrinks, but low 16Mb pricing means profitability problems. Unless major DRAM manufacturers sharply reduce 16Mb production, the 16Mb market will remain largely oversupplied as forecast.
- ■ **Rapid shift to 64Mb DRAM**—The other approach calls for as rapid a migration to 64Mb and away from 16Mb as possible. These suppliers have focused on 64Mb die shrinks (and not on 16Mb die shrinks). These suppliers face the challenge that 64Mb capacity far exceeds demand, a problem that is exacerbated by low pricing and large supply of 16Mb parts.

 ©1998 Dataquest

64Mb

The large 16Mb oversupply causes a continual decline in 64Mb pricing. Oversupply in 16Mb has caused vendors to seek any means to avoid the profitless bloodbath in 16Mb pricing. Their efforts have spread the oversupply and the corresponding price erosion to 64Mb as well.

The key applications for 64Mb DRAM are PCs and high-end computers, including PC servers and workstations. Although the 64Mb DRAM provides four times more capacity than 16Mb DRAM, the main memory size of PCs and other computers has increased by less than a factor of four. The result, if DRAM manufacturers ramp their 64Mb production as expected, will be a large 64Mb oversupply.

Even so, major DRAM manufacturers will ramp 64Mb production to keep and increase their market share. This is the basic reason that the DRAM market encounters such a large oversupply. This situation happens historically whenever total DRAM production capacity far exceeds the magnitude of demand.

Currently, there are four kinds of 64Mb DRAM in the market: extended data out (EDO) DRAM, 66-MHz synchronous DRAM (SDRAM), 100-MHz SDRAM (CAS Latency 3, or CL3), and 100-MHz SDRAM (CAS Latency 2, or CL2). The main player as of mid-1998 is the 66-MHz SDRAM. For 1999, that role shifts to the 100-MHz SDRAM, especially the CL2 version. There is some price premium for 100-MHz SDRAM, but that premium will erode gradually toward the end of this year because production capacity will balance with demand for this part by year-end 1998.

4Mb

Major DRAM manufacturers continued to reduce total 4Mb supply; however, they increased the production rate for 256K x16 DRAM. This shift caused an oversupply and a sharp price decline for the 256K x16 part.

DRAM Market Trends

DRAM production capacity continues to clearly exceed DRAM bit demand as of the third quarter 1998. In part because of factors like the Asian crisis, the large DRAM bit oversupply should persist well into 1999. If this prediction proves true, the DRAM oversupply will endure for a longer period (1996-1999) than ever in history. What explains the likelihood of a three-year DRAM oversupply?

Oversupply Factors

The factors involved in this probable oversupply are as follows:

- Factor 1. DRAM manufacturers avoided capital spending reductions as much as possible; this tendency keeps current DRAM production capacity at a high level.

 ©1998 Dataquest

- Factor 2. Japanese DRAM vendor/manufacturers also use foundries (that is, contract manufacturers), a practice that enables these vendors to maintain high levels of shipments without large investments. Capital spending by Taiwan foundries in effect increases the total DRAM capital spending.
- Factor 3. DRAM manufacturers historically linked DRAM die shrinks to their process technology road map. The chip-shrink methodology was a "linear scaling" type of technology. But most DRAM manufacturers changed their die shrink strategy because of the strong re-emergence of Micron during the mid 1990s. Now, most DRAM manufacturers actively focus on new DRAM shrink technology, with the result being smaller DRAMs (and more bits).

In addition, major DRAM manufacturers have accelerated the use of advanced process technologies for chip shrinks. Historically, process technologies were updated every three years, but this period dramatically shortened starting in 1997. This trend will persist into 1999.

Two-Stage Oversupply

The oversupply that started in 1996 reflects two stages. The first stage is the historical pattern of an overcapacity caused by excessive capital spending. As indicated, the newly emerged second stage results from advanced die-shrink technology, which enables increases in DRAM production without increases in silicon usage.

The DRAM market stands as of mid-1998 at the beginning of the second stage. Barring dramatic organizational change among major DRAM manufacturers in the near future (à la the Micron-TI deal), the oversupply situation will continue until the end of 1999.

64Mb Die Shrinks

A key DRAM supply-side issue centers on the die size of 64Mb DRAM. Major DRAM manufacturers are working aggressively to shrink their 64Mb DRAM die. They plan to develop a 50mm-square, 64Mb die by the end of this year. Dataquest believes the development is possible for major manufacturers.

However, DRAM manufacturers will find it difficult to use the 50mm-square device for mass production at the end of this year because of the lack of appropriate production equipment. A more reasonable 64Mb die size for year-end 1998 mass production will be around 80mm square. If manufacturers rapidly shrink the 64Mb die to 50mm square, some will likely encounter low production yields. (For reference, the advanced 16Mb chip size announced by leading manufacturers was about 60 to 65mm square with 0.35-micron design rules; the size of the 4Mb chip was just under 50mm square.)

 ©1998 Dataquest

High-Speed DRAM for PC100

As noted, there are two kinds of DRAM for PC100 now. One is the CAS Latency 2 (CL2) and the other is the CAS Latency 3 (CL3).

Originally, Intel expected to have the CL2 version for PC100, but DRAM manufacturers found the device difficult to produce. As a result, Intel accepted a compromised specification (the CL3 version). In order to produce the CL2 version, a 0.27-micron (or less) type of process is likely to be necessary. Both CL3 and CL2 will be used for PC100 during the second half of 1998, but the main player in 1999 will be CL2. If the chip shrink proceeds, the current CL3 version will satisfy the specification of CL2.

Inventory control means PC vendors prefer to use the mainstream device whenever possible, so they will not use CL2 until the CL2 supply capacity is sufficient. Under the current oversupply situation, the DRAM price for PC100 will decline toward the end of this year.

The possible stages of this price decline will be first a CL3 price decline, followed by a CL2 price decline. Eventually, the CL2 version will be used for all PC100 systems in 1999. Therefore, all DRAM manufacturers have to accelerate, as soon as possible, the development and high-yield production of CL2.

As noted in Dataquest's second quarter 1998 report, high-speed DRAM could be a difficult design choice for DRAM users. Users cannot easily switch their high-speed DRAM demand among different manufacturers. For this reason, DRAM manufacturers that release high-speed DRAM before other manufacturers do—and that win device qualification from DRAM users—should secure a better business position. Thus the best strategy for DRAM manufacturers might be to aim for an early release of CL2 so as to win device qualification from PC vendors ahead of the competition.

128Mb DRAM

Dataquest does not include 128Mb DRAM in this report yet because the product is not in mass production. DRAM manufacturers have announced that more than eight manufacturers will develop 128Mb DRAM. Dataquest conservatively forecasts that 24 million units of 128Mb will ship in 1999.

The forecast assumes that the target applications for 128Mb DRAM will be PC servers or higher-level computers and high-end notebook PCs. Just several suppliers could generate 25 million units next year. If eight or more DRAM manufacturers enter the 128Mb market, the market will become oversupplied and the price will drop.

 ©1998 Dataquest

In terms of pricing, the 128Mb sweet spot for targeting PC servers and high-end notebook PCs will be a price that is just 1.5 to two times more expensive than the 64Mb equivalent. If the bit price of 128Mb declines below this range, the 128Mb device might secure adoption in desktop PCs. In that case, the consumption of 128Mb DRAM would dramatically increase—but so would 128Mb bit supply.

This situation could lengthen the DRAM oversupply beyond the year 1999. At the same time, DRAM price declines will accelerate. If this scenario happens, Dataquest believes that DRAM business will remain unprofitable into the year 2000.

Dataquest Predicts

The Semiconductor Slump: Is There Light at the End of the Tunnel?

Abstract: *The semiconductor industry is mired in a slump that has lasted for several years and shows no sign of immediate relief. Worse than the depth of this down cycle is the growing uncertainty about how long it will be before the industry begins to turn around. In this Perspective, Dataquest analyzes qualitative supply and demand factors affecting semiconductors and what might happen to turn the industry back toward health.*
By Jordan Selburn

Widespread Uncertainty in the Industry

The current semiconductor downturn has continued longer than almost anyone had predicted. Recently, there seems to have been a fundamental change in attitude among industry leaders and watchers. The story at the quarterly financial announcements used to be, "This quarter is flat, we have limited visibility into the following quarter, but things should pick up after that." This has changed to, "This quarter is flat, we have limited visibility into the following quarter and very little idea about what will follow." The uncertainty about the duration of the downturn is widespread, and very few semiconductor companies—certainly no major companies—have escaped its effects.

The question of when semiconductors will pull out of the current slump is on everyone's mind. One approach to finding an answer would be to analyze previous downturns and chart typical semiconductor cycles. However, the factors that have driven past cycles (if there have been common causes in the past, a debatable assertion) are certainly different from those driving the current cycle. A much more rigorous approach, and that taken in this Perspective, is to examine first causes and analyze the supply and demand

Dataquest

PublicationDate: September 28, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

factors for semiconductors. Only when these two components have shifted will there be any change in the semiconductor market.

As part of Dataquest's regular forecast cycle, a number of analysts covering all aspects of semiconductors meet to discuss the factors driving the industry. This Perspective represents the qualitative thinking leading to the actual forecast. The quantitative results of the forecast have been published in a Dataquest Alert on September 22, 1998, with detailed results to be published in a Focus Report in October.

Demand Factors

The Economy

Global Conditions

Asia's economic troubles have definitely thrown the global economy for a loop. In short, the current situation is not pretty. The economic woes that first engulfed Korea and Southeast Asia last summer appear to be spreading throughout Asia. Economic activity has slowed across the region, and most Asian economies now find themselves battling a host of seemingly intractable economic ills. The deteriorating situation in Japan compounds matters. Japanese economic data leaves little doubt that Japan has lapsed into its worst recession since World War II. Added to that, the yen continues to gyrate downward against the dollar, putting devaluation pressure on currencies around the world. Meanwhile, Asia's ills have begun to impose punishing economic strains on economies elsewhere. The effects have been hitting especially hard in emerging economies dependent on industrial commodity exports, notably oil, and inflows of foreign capital. Mexico, Russia, and Brazil top the list of emerging economies victimized by Asia's troubles. Even advanced economies such as the United States and Canada, once judged immune to Asia's woes, have suffered economic bruises. The good news is that the outlook for 1999 looks better. Economic forecasters generally expect an upturn in global economic activity next year. However, most caution that the strength and breadth of this upturn very much depend on how 1998 plays out.

Naturally, all this is taking a toll on the global semiconductor market. Macroeconomic turmoil primarily affects semiconductors on the demand side of the market. There is strong evidence that changes in global gross domestic product (GDP) impact the demand for electronics. This, in turn, affects electronics production and the demand for semiconductors. Macroeconomic upset can also exert secondary effects on the supply side of the semiconductor market through its impact on credit and the availability of capital. Dataquest anticipates a strong adverse impact on semiconductor demand this year because of the economic troubles in Asia and Japan. Economists are virtually unanimous in the belief that gross world product (GWP), valued in U.S. dollars at current exchange rates, will decline in 1998. Worse, they expect especially strong GDP contraction in the Asia/Pacific region and Japan. Indeed, the latest global economic forecast from the WEFA Group indicates that the combined GDP of Asia/Pacific and Japan will decline some 11 percent. Given the size and significance of Asia/Pacific and

 ©1998 Dataquest

Japanese electronics consumption, these results suggest that semiconductor demand will suffer a substantial setback in 1998.

Macroeconomic-related supply-side impacts are harder to figure and document. The potential for significant macroeconomic supply-side effects certainly exists in Asia. Capital inflows to the region have given way to significant outflows, and there is ample indication that credit has become extremely scarce and costly within the region. Still, aside from anecdotal evidence, there is little clear indication that Asian semiconductor producers face binding macroeconomic-related supply-side constraints.

Fortunately, the economic outlook for 1999 at this point suggests the makings of a turnaround for semiconductors, at least for the demand side of the market. Economists generally agree that world GWP will rise next year. More important, most expect renewed GDP growth for Asia and Japan. For its part, the WEFA Group forecasts that world GWP could jump 7 percent next year (versus a projected decline of 0.4 percent for 1998), with combined GDP growth in Asia/Pacific and Japan pushing 7.5 percent. Should it occur, growth of this sort would provide a powerful demand-side boost to the semiconductor market. Renewed growth in Asia would also greatly ease any macroeconomic-related supply-side constraints that Asian producers currently face. For all their optimism, however, these forecasts can hardly be considered sure bets. As noted earlier, the outlook for 1999 very much depends on how 1998 plays out. On this score, four economies in particular merit close watching through the end of the year: Japan, China, Russia, and the United States.

Russia

Russia could well provide the spark needed. The Russian ruble has faced strong devaluation pressures more or less continuously since last fall. Although the ruble has successfully withstood three aggressive speculative assaults to date, there is growing doubt that it could withstand a fourth. Russia may be resolved to uphold the ruble, but Russia's means to do so are growing dangerously small. Russia is low on foreign reserves and strapped for hard-currency export revenue. The issue is not so much whether the ruble devalues, but how. The greatest fear of economists is that any speculation-induced devaluation of the ruble would be sudden, very chaotic, and virtually without limit. Given the anxious state of international financial markets, a free fall of the ruble would likely induce a panic in equity and currency markets around the world, with devastating effects. As this Perspective was being written, Russia had announced plans to "float" the ruble between R6 and R9.5 to the dollar through at least the end of 1998. (Note: the ruble had already depreciated below R12 to the dollar as of the date of this document and is fluctuating wildly as political events unfold.) Since the value of the ruble will almost certainly "float" downward under this plan, the policy effectively amounts to a devaluation. Whether Russia's new policy will be successful in controlling the ruble's descent is open to debate. Russia's economy remains plagued by a swarm of structural ills that will continue to worry international investors. Added to that, investors will justifiably remain nervous about the impact of woefully depressed oil and natural gas prices on Russian tax and export revenue. Without efforts to

©1998 Dataquest

address these concerns, Russia's latest policy move is unlikely to assuage international anxiety about the ruble. And that spells added danger for semiconductors in the months ahead.

United States

What of the United States? Economists have been changing their tune about the impact of Asia's woes on the U.S. economy over the last few weeks. At the onset of Asia's troubles last fall, the general consensus was that the United States would escape reasonably unscathed. Now many forecasters are not so sure. The Commerce Department's second quarter GDP estimate was the most recent of a series of economic data releases indicating that the U.S. economy has been impacted by Asia far more than first expected. On balance, it still looks as if the U.S. economy as a whole is benefiting from the economic difficulties in Asia and Japan. On the plus side, the influx of less expensive Asian and Japanese imports, together with the lower prices for imported oil that have followed in the wake of Asia's difficulties, are helping to keep U.S. inflation in check. What is more, reduced Asian and Japanese demand for U.S. exports is helping to counterbalance the economic impact of unprecedented growth in U.S. domestic spending. On the minus side, U.S. corporate earnings have begun to slow in response to sagging Asian demand and the general effects of a rising dollar. More important, the U.S. trade deficit is ballooning, and the United States' current account is soaring to levels that could trigger a move against the dollar in world currency markets. Economists fear that both these developments could abruptly reverse the stock market boom that appears to have fueled much of the domestic consumer and capital spending responsible for recent U.S. economic growth. In fact, some see the stock market's recent weakness as the beginning of a recession-inducing downturn. Unfortunately, Asia's ills have been less kind to the U.S. semiconductor industry. U.S. semiconductor and semiconductor equipment makers have suffered sharp slowdowns and, in some cases, significant losses. A downturn in U.S. economic activity at this juncture would be very unwelcome indeed.

In sum, the macroeconomic prospects for a near-term semiconductor turnaround range from poor to fair. A turnaround before the end of 1998 seems highly unlikely. The situation in Asia and Japan is simply too distressed to allow the demand growth the market requires. A turnaround in 1999 seems a better bet but is certainly less than sure. We expect semiconductor demand to revive next year provided the global economy can successfully overcome the threats to renewed 1999 GDP growth. In general, two things must be accomplished. Asia must be revived, and the risk of new currency turmoil must be reduced, if not eliminated. To date, policy efforts aimed at these goals have been carried out on a country-by-country basis. It increasingly appears that this piecemeal approach has failed. Indeed, if anything, the approach appears to have created more problems than it has solved. Many economists now believe that resolving these matters requires altogether new policy prescriptions that stress multilateral and cooperative solutions. These new prescriptions will undoubtedly require rethinking the notions of moral hazard and economic culpability that have dominated the unilateral approaches tried so far. The semiconductor industry would be wise

 ©1998 Dataquest

to support these new efforts since the future health of the semiconductor market ultimately depends on the vigor of the world's macroeconomy.

Japan

The International Monetary Fund (IMF) announced in August a forecast for Japan of a 1.7 percent GDP contraction over the previous year. This recession is being caused by decline in various factors, such as private consumption, private investment, residential construction, and both exports and imports. Along with the additional stimulus package including ¥10 trillion of additional public spending and ¥7 trillion in tax cuts, as well as measures for financial stability, it will be vital for Japanese domestic private consumption and investment to regain momentum.

The Japanese semiconductor market is still suffering from oversupply and subsequent weak pricing. The economic sluggishness weakened demand for semiconductors because electronics equipment produced within Japan has, over the recent few years, become primarily dependent on the domestic market. Therefore, the key to recovery lies in increasing demand stemming from emerging applications in digital consumer and communication areas. Both electronics companies and semiconductor companies have taken whatever measures they themselves can take, including developing new systems and bringing prices down quickly. Now the electronics industry is beginning to feel that the growth of electronics production, hence the growth of semiconductor consumption, depends on an overall recovery in the global economy. An increase in private consumption will also mean an increase of imports from Asia/Pacific countries, helping them secure the path for recovery from the Asian financial crisis.

The yen has been depreciated to a level unseen since early 1990s, discouraging imports that were already affected by reduced domestic demand. In electronics, yen depreciation is not expected to bring the great advantages it might have in the 1980s because goods exported to overseas markets are now manufactured at foreign sites—mostly in Asia/Pacific countries. The falling yen is likely hurting Japan more than helping it. To be sure, the yen's fall is helping to stimulate Japanese exports, but it is also intensifying domestic uncertainty and encouraging capital outflows from Japan. More important, it is imposing substantial economic punishment on Japan's troubled Asian trading partners. Despite some recent strength, a reversal in the overall trend of the yen's weakening with respect to the dollar is not expected in the foreseeable future, and the majority of economists expect the exchange rate to hit ¥150 or more to the dollar by the end of 1998. Further deterioration in the yen-to-dollar exchange rate will pose threats to the currencies of Asia/Pacific countries, hampering economic recovery in those countries.

Japan's long-term economic prosperity is inextricably linked to the economic health and vigor of its Asian neighbors. The weak yen, however it may improve terms of trade for exports, cannot be translated into an increase in exports from Japan at the expense of slowing economies in Asia/Pacific, because further deterioration in other Asian economies will affect Japan. The continuing fluctuation in exchange rates has made Japanese semiconductor

©1998 Dataquest

users tend to buy semiconductors in Japan, even though they use the parts in their electronics production sites overseas, mainly in various Asian countries. Stability in the yen exchange rate itself will encourage a return to global semiconductor purchasing.

China

Although China remains a relatively minor electronics consumer and semiconductor producer, it could make the one move in 1998 that would almost certainly break the 1999 semiconductor market: devalue its currency, the renminbi-yuan. Economists generally agree that a Chinese devaluation would likely plunge both Asia and the rest of the world into an economic crisis that could rival the Great Depression of 1929. Their concern is that a renminbi-yuan devaluation would set off a disastrous round of competitive currency devaluation around the world that would paralyze financial markets and freeze international trade. To date, China has steadfastly maintained the value of its currency, albeit at significant economic cost. China has seen its growth slow, its exports contract, and its competitiveness erode as Asia's troubles have deepened. The question of devaluation is not black and white, because simply devaluing the currency does not solve China's growth challenges. It is the combination of domestic spending, foreign investment, government projects, and exports that determines growth in China's large economy. Exports account for less than 25 percent of industrial output and less than 20 percent of GDP. But no one gets something from nothing. A weaker yuan obviously means higher import costs, which China's exporters depend on in the form of key components and raw materials (semiconductors, textiles, steel and so on). Unlike Taiwan, Japan, and Korea, China's industries are not fully integrated. Hence, economists in Hong Kong and China are against devaluation at this point. There are geopolitical concerns as well. Because China is running a huge trade deficit with the United States, its main trading partner, sudden devaluation would no doubt result in a congressional backlash.

But there are concerns that falling exports *and* a slowing economy will force China to devalue, potentially sparking another round of disastrous currency depreciation in Asia. It is a question of time. Certainly, China will devalue, but whether it will be before or after the region has recovered is the issue. Japan's yen is at the center of China's currency question. A weaker yen will seriously hurt China's economy, which is why China continues to hint at devaluing each time the yen falls. China's efforts to restructure its economy require growth. If Asia continues to falter or the yen falls too much more, China may reach a point at which it feels it has sacrificed enough and may move to devalue.

In 1998, the Chinese government has been under extreme pressure to maintain strong economic growth and create new jobs because of the dismantling of state-owned industries, which is creating millions of surplus workers. So far, the Chinese leadership has supported its currency at the expense of economic growth and is using infrastructure spending (and microeconomic levers), not currency-driven exports, to foster growth. Recently, the government committed some U.S.$250 billion in infrastructure spending projects. Dataquest cannot make a direct connection between communications equipment spending and a yuan valuation. If spending is needed to bolster the economy, then these outlays will continue to be made, especially since they are viewed as long-term necessities (to modernize the economy).

Korea

Korea has been greatly impacted by the Asian financial crisis and the continuing free fall in DRAM prices. The Korean won has depreciated by over 50 percent versus the U.S. dollar over the past year, and the overall Korean trade surplus could drop to $10 billion in 1998, according to the Korea Institute for Industrial Economics and Trade.

The weakening yen poses a particular threat to the Korean semiconductor industry. Some estimates show that each 1 percent loss of the yen's value versus the dollar could result in a $630 million decrease in Korean exports; for example, a fall in the yen to ¥150 per dollar could reduce Korean exports by over $4.5 billion. Until the economic situation solidifies in the rest of Asia, particularly Japan, it is unlikely that Korea will see a major upturn. Offsetting the current regional stagnation, however, are two trends. First, the global reduction of DRAM manufacturing capacity now beginning should stabilize DRAM pricing, which will disproportionately help Korea. Second, the potential merger between Hyundai's and LG Semicon's semiconductor groups could allow for cost reductions and greater profitability in the Korean electronics industry, helping the Korean economy as a whole.

Semiconductor Application Markets

Consumer

The prior Dataquest forecast for consumer electronics relied on legacy consumer electronics markets eroding minimally while digitally enhanced and next-generation products drove overall growth. However, legacy products are declining at a more rapid pace, and digitally enhanced products are not compensating for this drop. In the next-generation category, price pressure is again causing reduced expectations. The brightest spot in the next-generation category is digital set-top boxes, driven by new opportunities in digital cable. However, video games will have a negative impact on the market in the next two years. In 1998, video games, which have been a major driver of next-generation growth over the past three years, will grow only slightly, hitting a peak before the start of a new video game market cycle, which will result in overall video game hardware market declines for the next 24 months or longer.

Digital set-top box shipments are undergoing rapid growth. However, the price erosion of semiconductors is dampening the growth of the associated chip market. In 1999, this should begin to change some as new, more sophisticated digital cable boxes come to market that have more valuable semiconductor content. This will help the digital cable box semiconductor market to grow and will serve as an engine of overall consumer semiconductor growth over the next several years.

 ©1998 Dataquest

Wireless Communications

The high-flying wireless semiconductor market growth crashed to earth in 1998. During the past three or four years, the strong growth in the semiconductor market for mobile communications has been dominated by the ramp-up in the digital cellular handset market. The growth in production of associated mobile communications infrastructure has also contributed to this growth. These product categories have been the dominant drivers of strong double-digit growth for semiconductors from 1994 through 1997. Although Dataquest still forecasts relatively strong growth for production of digital cellular handsets, the severe price erosion for semiconductors in these handsets, along with integration trends, is placing a major damper on semiconductor market growth expectations. The mobile communications category does not include cordless handsets, which are grouped in the premise telecommunications category. The increase in the popularity of digital cordless products such as DECT and 900-MHz digital and spread-spectrum handsets is expected to add some growth to the overall wireless communications semiconductor market in the near term, but this will fade as a growth driver in 2000 and beyond. Dataquest is predicting that wireless semiconductor market growth will drop into the high single digits in 1998 and 1999.

A number of elements are taking shape that Dataquest expects will help boost the growth of the wireless communications semiconductor market into double digits beginning in 2000. First, it is anticipated that semiconductor prices in handsets will start to stabilize about this point. Also, there will be increased opportunity for creating additional value for functions such as global positioning system (GPS) location services and higher data rate services in handsets. There is a great deal of discussion revolving around the introduction of third-generation (3G) wireless services starting in 2000, but Dataquest is very skeptical about this timeline. Dataquest does not expect a significant 3G wireless market to take shape before 2003. Even though there have been a number of semiconductor product announcements related to 3G products during 1998, this segment of the market will be delayed beyond current industry expectations. However, new initiatives and products related to home and personal wireless networks, such as Shared Wireless Access Protocol (SWAP) and Bluetooth, do show promise for boosting wireless growth in 2000 and beyond. These efforts could help wireless semiconductors penetrate a wide range of electronics products in an increasingly networked environment.

Wired Communications

During 1997, enterprise networking created strong demand for 10/100-Mbps Ethernet solutions. Although this upgrade cycle is continuing, competition and ASP erosion will keep growth in check. There is no really hot new technology waiting to take the enterprise networking area by storm in the next one to two years. Gigabit Ethernet is expected to remain a backbone technology until at least 2002. If copper Gigabit Ethernet proves to be successful, there could be some upside in about 2001, but prices must fall significantly first. Home networking is not expected to have significant market impact before 2000, but this outcome depends to some extent on a single "killer application": distributing Internet bandwidth in the home.

When all is said and done, unit demand for converged voice/data/video networks remains very strong from a unit perspective. The LAN segment remains on track; although this is good for current market participants, it also means that the semiconductor industry cannot look to wired communications to single-handedly turn the overall market around.

Personal Computers

The excitement in PCs lately has come from the emerging sub-$1,000 machine. These inexpensive boxes have maintained the market's unit growth, but a significant part of the cost cutting that makes these PCs so attractive has come from the semiconductor content. One of the reasons that the sub-$1,000 PC is flourishing is the impressive computing power a few dollars buys. In the home at least, but to some extent in businesses as well, there is little need for a processor beyond today's low-cost entry-level chips from Intel (the Celeron) and its competitors, principally Advanced Micro Devices (the K6) and Cyrix. These processors can easily handle the vast majority of today's computing tasks, giving customers little reason to spend more for a state-of-the-art PC. Renewed growth in the overall PC market will be driven by new applications, such as voice recognition, that push desktop data processing to the limit and force users to ante up for a new high-end personal computer.

Supply Factors

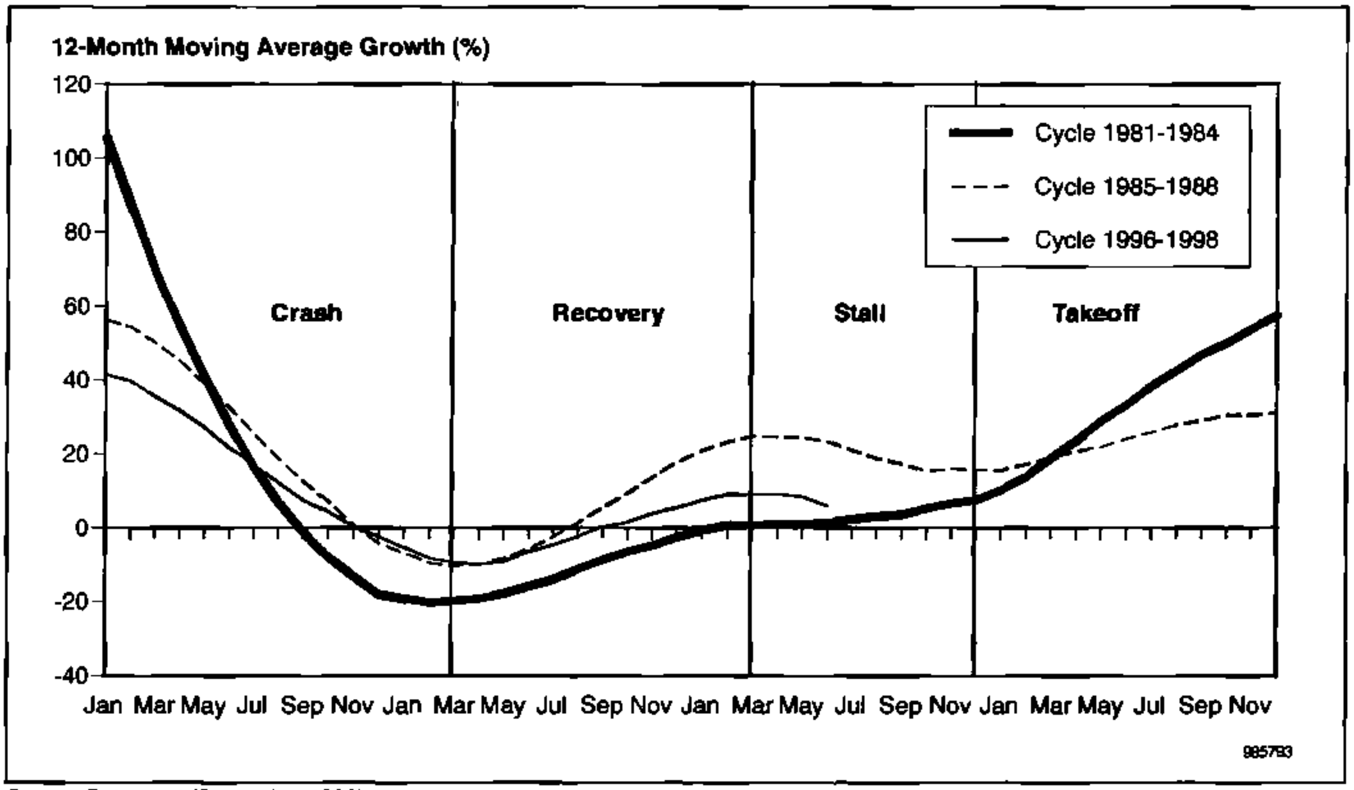
Semiconductor Devices

DRAM

While many semiconductor industry watchers are predicting a fundamental change and an end to cyclicity (where have we heard that before?), a few are beginning to suggest that an upturn may be just round the corner. The last time an end to cyclicity was mooted was in 1995, at the end of a prolonged growth cycle, when it seemed impossible that the market could crash ever again. But crash it did, principally because of a huge buildup of DRAM capacity. Many are convinced that something new is going on because the current DRAM recession has resulted in an unprecedented third consecutive year of revenue contraction—about a 40 percent drop in 1996 and a 20 percent drop in 1997, with a further decline of 20 percent forecast for 1998. What is more interesting, though, is the rolling annual growth profile during the past three years. Here, a more familiar story is unfolding. Figure 1 shows the current semiconductor market downturn, which began in 1996, superimposed on the two previous market downturns, which began in 1981 and 1985. All three of these downturns were DRAM induced, and it is possible to deduce a common rolling annual growth profile split into four sections: crash, recovery, stall, and takeoff. Not only that, there is common seasonality as well. So, maybe the current semiconductor market downturn is not unique, and a common trend is being masked by the absolute level of annual growth measured at the end of a particular year.

 ©1998 Dataquest

Figure 1
Comparison of Semiconductor Industry Cycles



Source: Dataquest (September 1998)

It must be remembered that the semiconductor industry is influenced by the DRAM market more than by any other product category. And DRAM is pure commodity—the balance between supply and demand is critical and the link to capital spending inextricable. So, when forecasting the growth prospects of the semiconductor industry as a whole, DRAM market conditions are key. Sophisticated arguments about macroeconomic conditions, GDP growth, end-user equipment demand, and structural changes in the semiconductor industry (for example, the trend toward system-level integration, or SLI) all have their place and should be considered during the forecast process, but special consideration should be given to how they affect the core growth influence: the DRAM market. The latest slump in the semiconductor market was caused primarily by DRAM overcapacity and a resulting price crash; the overcapacity was driven by the first causes mentioned earlier. It should be noted that the demand for DRAM, as measured by the bit growth rate, continues to be relatively strong, with only the overcapacity driving prices down.So one of the most important factors in a semiconductor industry recovery is a reversal of the DRAM market conditions that caused the malaise.

Assuming that the number of DRAM bits shipped continues to increase at a rate consistent with history (about 70 percent, for the sake of argument), then it is the level of production capacity that will determine whether the DRAM market is oversupplied or undersupplied and whether prices, revenue, and margins are low or high. The continuous increase in DRAM bit demand sits uneasily with short but intensive bursts of periodic investment, and it is this relationship that causes DRAM market cyclicity. As with all commodities, today's investment affects tomorrow's market, and the recent switch in DRAM capital investment will have its effect. Demand will catch up with supply, and a period of improving market growth will begin in late 1999/early 2000 and last through 2002. In today's oversupplied DRAM market, prices remain depressed and continue to decline, and it is all too easy to continue to predict a gloomy outlook. Forget all the rational arguments and all the reasons why a recovery may not happen—trust in the industry cycles and look forward to a DRAM boom.

Analog

Given the analog IC industry's characteristics of broad-end application market exposure, relatively stable pricing, and high gross margins, analog IC companies have been largely immune to the semiconductor downturn until now. In fact, since 1996, the analog IC market has been outperforming the general semiconductor market. In 1996, the total semiconductor market declined 6 percent, compared with a 10 percent growth rate for analog ICs. In 1997, analog ICs grew 19 percent, while the overall semiconductor market grew a mere 4 percent. The analog IC market has declined progressively since April 1998, and many companies have cited the U.S. and overseas distribution channels as contributing significantly to the weakness. Distribution typically accounts for 40 to 50 percent of a company's total analog IC sales, and a large portion of the sales through distribution goes to the industrial sector. As a result, the health of the analog IC market is closely linked to the strength of the industrial sector or the GDP growth rate. While the U.S. economy remained robust through the first quarter of 1998, it slowed considerably in the second quarter as the Asian economic crisis deepened. U.S. GDP grew a mere 1.4 percent in the second quarter, compared to the 5.5 percent registered in the first quarter. The U.S. industrial sector slowed considerably in the second quarter from the first quarter, as measured by the purchasing managers' composite index of industrial activity. Dataquest believes that the slowdown of U.S. industrial activity in the second quarter has contributed significantly to the decline of the analog IC market (which also started in April).

Distribution sales typically account for 30 to 50 percent of a company's total analog IC sales, and a large portion of the sales through the distribution channel goes to the industrial sector. Therefore, the distribution weakness signals a reduction or pause of demand from the industrial OEMs. This is likely caused by the weak economic conditions in Asia/Pacific and Japan, and the effects on U.S. industrial companies.

Analog IC companies have finally become victims of the semiconductor downturn. Does this mean that the downturn will become prolonged now that the most resilient companies have surrendered? Historically, analog IC company performance tends to lag behind the decline of the semiconductor market because of the industry's unique characteristics. Therefore, if history is of any relevance, it is less likely that the current weakness of the analog IC market signals the beginning of a much-prolonged downturn than that it signals the proximity of the trough.

 ©1998 Dataquest

However, this downturn might be unique in that global economic conditions, especially in Japan and the emerging markets, could be different from those in historical downturns. If Japan and the emerging economies from Asia to Russia to Latin America could avoid a worsening of the crisis and regain stability, then an end to the semiconductor decline might indeed be close. On the other hand, if the turmoil were to deepen and spread, this would not be likely to result in healthy demand for electronics equipment, and hence the road to semiconductor recovery could become longer. The next few months will be crucial in determining which scenario is likely to occur, and Dataquest will be watching closely.

Semiconductor Manufacturing Equipment

Suppliers of equipment and materials to the semiconductor industry have been suffering now on and off for two years as the semiconductor industry dealt with a severe case of overcapacity. Flowering in the second half of 1997 was the Asian financial crisis, which has caused the economies of that region to grind to a halt, along with the semiconductor consumption that goes with it. If the industry cannot get off this falling elevator, it must at least try to find the "up" button—the fundamental issues that will get the semiconductor industry and spending back on track.

Aggressive investment in 0.25-micron technology throughout 1997 has only exacerbated the persistent overcapacity in the industry. Dataquest has been calling for a W-shaped recovery pattern in wafer fab equipment, with the second-phase downturn being caused by the fundamentals of overcapacity and with financial health eventually winning over the desire for technology. As this second phase now unfolds with very deep spending cuts in 1998, the questions begin for 1999. Were the cutbacks deep enough to correct the oversupply? When can a sustainable recovery really begin? What will fundamentally bring it back?

We can now say, for the first time in the last several forecast cycles, that we see the fundamental issue that will bring the next spending boom in 2000 and 2001, starting in about the fourth quarter of 1999. The main fuel for the 2000-2001 boom will be the return of DRAM spending resulting from an undersupply that will emerge.

In DRAM, there has been a net addition of capacity in the last two years beyond the requirements for silicon area. At present, Dataquest is estimating the overcapacity in DRAM to be between 20 and 25 percent. The movement of the industry to the more silicon-efficient 64Mb density will sustain the oversupply throughout 1999. Our silicon demand model shows that, with the forecast 60 to 70 percent bit growth rate in 1998 and 1999, about 6 to 9 percent less silicon will be required by the end of 1999 than is now consumed.

However, net supply will be tending to decrease as well over the next 18 months as capital spending cuts make their mark on reducing the rate of supply increase. As time passes, larger line-width capacity naturally exits the market, and Dataquest is estimating that this "attrition" will actually outpace new supply. In addition, we expect capacity to actively exit the market, meaning that fabs now in commission will be closed or mothballed. This could take several forms, including companies leaving the market, consolidation in the industry, and outright mothballing of fabs. A recent example is the net loss of the TwinStar fab in the United States, which was part of the sale of Texas Instruments' memory business to Micron Technology. This fab is being mothballed as a result of the consolidation of capacity, and the equipment is being reallocated and sold. The situation should set up nicely for a shortage of capacity in 2000.

Silicon consumption in the DRAM market accounts for 13 to 16 percent of silicon consumption, and, in order to meet the bit demand in 1999, about 8 percent less silicon will be required at the end of 1999, compared to the end of 1998, primarily because of the silicon efficiencies generated by the 64Mb density. As the DRAM density transition is completed, sequential silicon demand should accelerate into 2000, giving continued double-digit millions of square inches (MSI) growth rates through 2001. The reduced capital spending pattern of 1998 and 1999 should actually set net capacity in the DRAM area on a downward trend. In 2000, these two trends meet to produce an undersupply.

The foundry market has also made a transition to overcapacity. Unfortunately, the stall in semiconductor demand has made the forecast oversupply much more acute, and it is now calculated to be between 30 and 40 percent. Foundry suppliers have reacted to this oversupply much faster than DRAM suppliers by planning to cut back spending heavily for the remainder of 1998. The growth of total spending in 1998 for foundry suppliers is now estimated at 20 percent, compared to earlier estimates of 40 percent. We expect 1999 spending to be cut significantly, perhaps 20 to 30 percent below 1998 levels, in the foundry area.

Today's excess foundry capacity is also technologically mismatched, with the current demand creating a "technology glut." The greatest oversupply exists in the leading-edge technology. This is confirmed by recent trends in wafer processes, where the most severe declines could be seen first in 0.35-micron and now in 0.25-micron wafers.

Compared to Dataquest's forecast of six months ago, the picture has changed. Both the upswing and the start of the next down cycle have been pushed out by one year. Why? The answer is that semiconductor demand has stalled in 1998. Economies in Japan and other Asian countries have slowed tremendously in recent months, and this has impacted electronic equipment demand in consumer electronics and automotive, with a slight impact on computing.

One way to view 1998 is that the semiconductor industry demand profile has inserted a one-year "holding pattern," as well as a one-year delay, in any recovery that was previously forecast. This has made the secondary downturn we were expecting appear much more severe, because the industry will be making only minimum investments during the next 12 months. Because a sustainable recovery in spending and the equipment market must come from capacity buying, there must be a healthy chip market in 1998 if the equipment market is to grow in 1999. It does not appear that the

 ©1998 Dataquest

chip market can mount a recovery until next year, so we have downgraded the 1999 wafer fab equipment forecast to be essentially flat from 1998 levels.

As with Dataquest's year-end forecast process, the midyear forecast was being developed against the background of a rapidly changing picture in capital spending, emanating from changes in semiconductor demand and the present downward spiral in spending levels. Despite what feels to the industry like falling off a cliff, Dataquest believes that the downturn will reach bottom in the third quarter of 1998, with a slight uptick in the fourth quarter. The uptick is motivated by seasonality as much as by a possible increase in Japanese spending as Japanese companies head into the second half of the fiscal year, having "underspent" in the first half. There is even some upside potential, although we believe that the probability of the upside occurring is only 15 percent.

In this time of gloom, thinking of an upside potential might seem odd. Yet an examination of the history of wafer fab equipment shipments reveals that this industry does not normally make small moves from quarter to quarter. And change can happen relatively fast.

The upside scenario is based on the possibility that the PC market, which is the strongest driver of semiconductor consumption, shows unexpected signs of life in the second half of 1998. Recent DRAM order surprises from PC manufacturers lend some credence to the scenario. If the PC market strengthens, it would lead to an uptick in semiconductor demand overall and, in particular, in DRAM demand. The consequences are clear. Increased semiconductor revenue could arrive after a delay of six to nine months as capital spending levels increase.

Overall, Dataquest assumes in the 1999 upside scenario that capital spending could grow by nearly 12 percent, compared to about 4.5 percent in the forecast mentioned earlier. The assumption about which companies would differentially increase spending is directly related to the assumption that PC unit shipments will be unexpectedly strong in the second half of 1998. Under this scenario, it is quite conceivable that Intel could accelerate capacity spending in the second quarter of 1999, rather than the fourth quarter of 1999, as assumed in the forecast. Further, since the PC market accounts for 70 percent of fabless company shipments, an increase in foundry demand over Dataquest's forecast could renew spending in the second half of 1999. Our current forecast for foundry spending throughout all of 1999 calls for spending at the rate of the second half of 1998, leading to a year-over-year spending cut of about 20 to 30 percent. Renewed second half 1999 spending could essentially make year-over-year comparisons flat. These assumptions mean that logic-oriented spending will be favored in the upside scenario over DRAM spending, because Dataquest believes that the DRAM oversupply will persist in the face of a better-than-expected market.

What is the probability of the upside scenario coming to pass? Dataquest believes that it is low, only about 10 to 15 percent. But it is a possibility.

 ©1998 Dataquest

Dataquest Perspective: Where Is the Balance?

The semiconductor industry has been mired in a slump for longer than most participants would have predicted. Of even more concern is the uncertainty that the industry faces: Is this a cyclical slump, such as has been seen in the past, or is there a fundamental change in the industry? It is possible, after all, that the semiconductor market is maturing and that average annual growth of about 17 percent will no longer be seen. Some of the signs of a mature market are already here. There has been and continues to be a great deal of consolidation in the industry as medium-size companies seek to survive by becoming major players and large companies seek to maintain their competitive position and attain even better economies of scale. Not unlike the automobile industry, in most segments of the semiconductor industry, the top few companies represent the dominant part of the market. Even given some of these trends, it is unlikely, for now at least, that the semiconductor industry will achieve the status of a mature industry. There are still too many opportunities for growth, and the primary question is "when," not "if." New markets such as home networking and digital video seemed poised to expand rapidly when overall economic conditions permit.

When will the semiconductor industry break out? Dataquest will publish the detailed quantitative forecast in the near future, but barring any of several "killer asteroid" events, such as a complete collapse of the Japanese economy, the most likely scenario points to the second half of 1999 as the start of the turnaround for semiconductors, with manufacturing equipment following six months to a year later. Other major events, such as the ubiquitous year 2000 problem, could shift this turnaround substantially either way. This means that lean times will continue for the next year or slightly longer and that 1999 overall will not be a spectacular year. However, the pieces are in place for a return to better times when the new millennium arrives. Although a return to the heady days of the mid-1990s is unlikely, from today's perspective, the 17 percent historic norms for semiconductors look quite attractive indeed.

Semiconductors Worldwide

Technology Analysis

Next-Generation High-Density Packaging Technology

Abstract: *Low-cost chip scale package (CSP) technology is now entering its growth stage as a package for system-level integration ASICs, memory, and standard logic devices. Demand from compact and lightweight systems, such as mobile communications and digital consumer equipment, is a major driver for the growth of CSP and other emerging package technologies, such as ball grid array and flip chip. This Perspective analyzes these new technologies, which hold the key to the miniaturization and successful implementation of next-generation submicron devices.*

By Yoshihisa Toyosaki and Mary Ann Olsson

Emerging Package Technology Drivers

The economic turmoil in Asia, coupled with the financial troubles in Japan, resulted in tremendous price pressure on electronic goods being shipped to Europe and the Americas during the past 12 months. The industry downturn that began in December 1995 continues to depress the pricing of most devices. A handful of semiconductor companies are reporting early signs of improvement in sales of new low-voltage, high-performance products. However, most semiconductor suppliers, including fabless suppliers, are still in the throes of a serious demand and pricing slump. System-pricing pressure has forced many competitors to increase the pressure on manufacturing margins for several key electronics products. Declining system average selling prices (ASPs) in many applications are putting pressure on semiconductor makers. Although volume demand is good in many communications, consumer, and data processing segments, declining ASPs are damaging system revenue growth and putting pressure on the dollar value of semiconductor content.

Publication Date: December 28, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

To increase their profit margins and distinguish their value-added products, many semiconductor manufacturers are positioning their emerging products and technologies for growth. They are offering new cost-effective, high-performance value-added product and technology solutions that meet various price points for both high-end and low-end systems. Manufacturers are concentrating their efforts on growth opportunities in the top emerging consumer, communications, and data processing equipment markets. In particular, wireless and digital consumer applications have the potential to enhance growth of digital signal processors (DSPs) and embedded and digital application-specific IC (ASIC) products. A large proportion of these value-added solutions will come from new and emerging package technologies. Figure 1 highlights selected applications that are revenue opportunities for new fine-pitch packages. These applications, in addition to next-generation digital consumer applications, PC cards, memory modules, switches and routers, base stations, thin server workstations, and notebook and laptop PCs, are increasing demand for small form-factor packages.

Emerging Package Developments

The greatest package challenge in 1979 came from two electronics sectors. First, the consumer sector began its initial phase of growth of semiconductor content. Valued at less than $5 billion in the United States in 1970, the consumer sector's semiconductor content represented about 5 percent of total semiconductor consumption. Between 1970 and 1975, this percentage grew to 12 percent, which precipitated one of the greatest changes in semiconductor package technology. Through-hole technology remained king of the computer, industrial, and military sectors. Hybrids were the mainstay technology for communications and automotive equipment. However, the need for low cost and miniaturization drove the consumption of new small outline (SO) and chip carrier surface mount technology (SMT) packages that offered up to 5:1 area reductions and up to 84 input/output (I/O) pins. The improved parameters offered by SMT became critical in the consumer sector in watches, calculators, video games, clocks, handheld radios, disk cameras, and TVs. Development of these systems would not have been possible without SMT.

Second, the semiconductor industry's shift to VLSI technology and the rapid entry of Japanese companies into the DRAM markets pushed through-hole technology to its limits. SMT technology offered not only low cost and reduced board space, but also high I/O capability, improved electrical performance characteristics, and ease of handling by automated assembly processes. Japanese companies, by virtue of their majority share of the consumer business, their lead in automated assembly, and their strong SMT focus on SO for logic and memory devices, led the charge and changed the course of package history.

Current Market Status

Today's semiconductor package industry is in the throes of another major upheaval. Volume production is currently focused on shrink versions of existing SO and quad flat packages (QFPs). Advanced area array packages and attach techniques such as ball grid array (BGA), flip chip, multichip module (MCM), direct chip attach (DCA), column grid array (CGA), and chip scale package (CSP) formats are being designed in at a faster pace than previously forecast. Widely used in new applications, these packages meet the increased demand for miniaturization, lower cost, and improved electrical performance. Because of their chip-size appearance, many of these package techniques are lumped into the very popular market category now referred to as CSP.

By industry definition, a true CSP is a die size no larger than 1.2 times the size of the chip design. The Ultra BGA, microBGA and other advanced BGA packages with flip chip attach are advertised as CSPs. This marketing cognomen adds even more confusion to a market already overburdened with package-acronym proliferation. From a density point of view, a CSP by any other name is positioned between standard packages and wafer-level techniques such as flip chip, chip stacks, and DCA. These various technical idiosyncrasies or nuances will eventually be surpassed by volume design wins. Given the industrywide trend toward increasingly high-density ultra-VLSI designs, most of the latest CSP and BGA designs are feasible solutions for a wide range of applications. Figure 2 illustrates the evolution of some of these ultra-VLSI and system-level interconnect designs. Table 1 shows new technologies implemented by some of the major semiconductor companies.

Traditionally, the time scale involved from package technology acceptance to implementation has been substantially longer than a semiconductor device or system application life cycle. To illustrate the time required for market penetration of a new package technology, the cycle has been divided into four phases, as shown on Table 2. We have attempted to position the new package categories (area arrays, CSPs, flip chip, and wafer level interconnects) in this time line.

Table 2
Emerging Package Technology Timeline, 1992 to 2010

Category/Description	Year of Adoption
Development	
Preliminary package design, selection of materials, process development, standards development	1992 to 1997
Prototype Use	
Sample shipment, reliability testing, socket and manufacturing equipment developments	1995 to 1998
Application Development	
Product evaluation, supply of printed circuit board and CAD tools	1996 to 1999
Volume Production	
Enhancement of product offerings, diversification of printed circuit board and CAD vendors, diversification of test tools	1998 to 2010

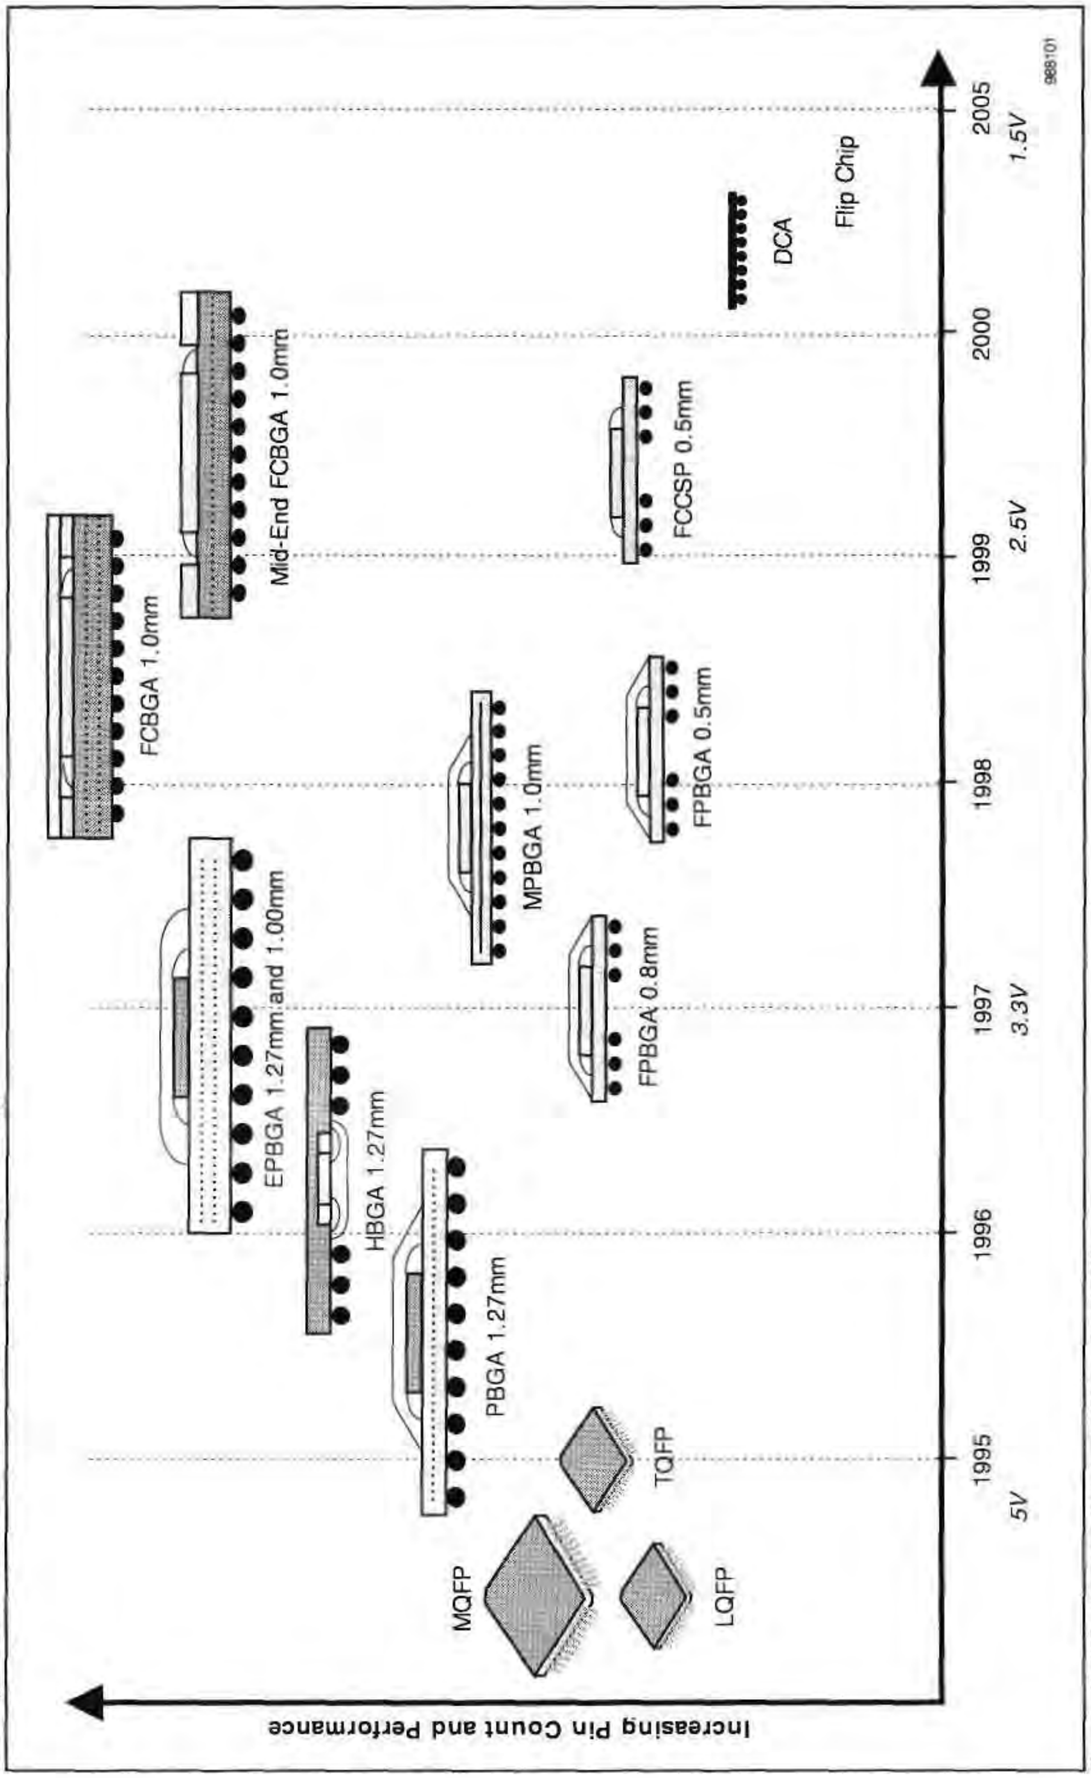
Package Opportunities

From a demand side, the largest group of users of new miniature, below-100 I/O CSP designs will be suppliers of passive, discrete, flash memory, RDRAM, and optical components, IC cards, and memory modules. According to Amkor, about 80 percent of CSP designs have involved lead counts of between 28 and 48 pins.

The second-largest group of users for fine-pitch or CSP designs is the high-I/O ASIC suppliers. Figure 3 illustrates a road map littered with new CSP designs that will satisfy form factor requirements for ASIC users. This market is being driven by system cost, form factor and size, feature set, and time to market. VLSI Technology is shipping ASIC devices in 0.8mm fine-pitch BGAs (FPBGAs), in volume (over 1 million) in the fourth quarter of 1998. The second-generation 0.5mm FPBGAs will be shipped in 1999. These products were designed for the wireless/portable market. Suppliers such as VLSI Technology, LSI Logic, and Xilinx and equipment manufacturers such as Ericsson, Nokia, QUALCOMM, and Motorola all agree that the new FPBGAs, which will represent 10 percent of the handset market in 1999, could represent almost 50 percent of that wireless market by 2000. For many of the ASIC designs in the high-lead arena, current FPBGAs are priced at 1.2 times the cost of a thin quad flat package (TQFP) design.

 ©1998 Dataquest

Figure 3
A High-Density Fine-Pitch Package Road Map



Source: VLSI Technology, Dataquest (November 1998)

In the memory category, flash memory suppliers entered the CSP market using various microBGA designs. The larger-volume DRAM suppliers could turn the tide of capacity challenges when and if they switch package designs from thin small-outline packages (TSOPs) to some of the new, smaller BGA designs. As cost per lead of CSPs and BGAs reaches parity with comparable TSOP and QFP designs in 1999, the capacity of advanced packaging technologies could become constrained.

In the memory area, some of the most recent announcements from Mitsubishi include new molded CSP (M-CSP), multichip package (MCP), and stacked MCP (S-MCP) designs for SRAMs and flash memories. Mitsubishi and Sharp are collaborating on common pin compatibility and package size configurations. Xicor has introduced the XBGA for EEPROM. Toshiba and Fujitsu have jointly agreed on the BGA MCP design, which allows mounting of both SRAM and flash in a single package. This new configuration takes up about 70 percent less space than two TSOPs. In volume production, the new MCP will be priced the same as a flash and an SRAM in separate TSOP packages.

In the logic area, Integrated Device Technology, Philips Semiconductors, and Texas Instruments have jointly agreed to source several logic device designs in new low-profile fine-pitch BGAs (LFBGAs) with 0.8mm 96-lead designs. Compared to thin shrink small-outline packages (TSSOPs), the new LFBGAs reduce board space up to 65 percent for the same functionality. The companies have announced that these new designs are up to 50 percent more efficient at dissipating heat than TSSOPs.

Technology Advantages and Disadvantages

It is not the role of Dataquest to sing the praises or assess the capability of one supplier's or subcontractor's package over another's. It is important to report the user concerns about the advantages or disadvantages of various technologies. Many of the advanced BGA and CSP designs proliferating in the market pose multiple challenges, obstacles, and advantages that need to be addressed before complete market acceptance is reached. Some of these obstacles include the following:

- Limited test techniques and higher test costs
- Narrow terminal pitch width
- Increased costs of wiring patterns on PCs
- Lack of standards on lead and package design
- Test socket connection
- Standardization on tape and reel
- Assembly-handling equipment
- Visual inspection equipment requirements
- Routing, signal integrity, thermal, and mechanical issues

Some of the advantages include the following:

- Smaller form factor than standard SO and QFP packages

- Board space savings from miniaturization
- Higher chip performance because of electrical and thermal characteristics
- Lower power consumption in application
- Lower system board cost

Some of the design challenges result from increased demand for alternative technologies, which now include flip chip attach and known good die. Most of the latest advanced BGA and CSP designs have reached the 0.8mm-to-0.5mm ball pitch required for the 0.35-micron-to-0.25-micron device regime. The high cost of substrates, assembly techniques (either flip chip or wire bond), smaller die, and smaller pad pitch require a more advanced regime of testing, handling, and inspection and CAD tools not readily available. Ultimately, the level of market penetration will govern the price. A technology cannot achieve the lowest possible cost unless it follows the learning curves determined by very high-volume production. Any advanced package technology involves certain risk until official standards or pseudo-standards are established to determine a "technological winner."

Dataquest Perspective

The semiconductor industry has entered the age of system-level integration (SLI) for ASICs and embedded applications for memory, microprocessor, DSP, and other logic products. It has become imperative for semiconductor suppliers and package subcontractors to respond effectively to the needs of application equipment vendors. Advanced package developments, analyzed in this light, promise to be a haven for profit and growth. Historically, most semiconductor companies have developed products on the basis of supply-side dynamics, but they lacked the marketing savvy to serve the needs of the application market. Their future success will be based on their ability to cooperate with subcontractors (foundry and assembly). The shift from 0.8mm to 0.5mm and below pitch packages will involve a tremendous technological challenge over the next few years. The differences among the various BGA- or CSP-type designs and standards being proposed clearly indicate that all efforts must be directed toward package miniaturization, increased lead counts, and low cost. As the industry drives semiconductor process technology into the realm of 0.18-micron geometries between 2005 and 2010, the next package challenge will be faced by the users and developers of the DCA and flip chip technology platforms.

Market Analysis

Mergers and Acquisitions in the Analog and Mixed-Signal IC Industry

Abstract: *This Perspective reviews the mergers and acquisitions in the analog and mixed-signal IC industry and provides analysis of their strategic implications. The long-term trend for mergers and acquisitions in the analog and mixed-signal IC industry is also discussed.*
By Jim Liang

Introduction

The analog IC market is a unique segment of the semiconductor industry in that there are more than 60 players with annual revenue larger than $20 million, 40 of which are based in North America. Moreover, competition in the analog IC market is diffused, with no single company occupying more than 11 percent of the total market. Factors contributing to the diffused competition include low capital requirements for analog IC companies, diverse end markets for analog ICs that give rise to many niche-oriented small companies, and relatively high and stable margins on analog ICs, which allow many companies to be consistently profitable.

Although the analog IC market has been growing at a compound annual growth rate (CAGR) of over 17 percent since 1975, the industry's growth rate has slowed in recent years to about 15 percent per year, in line with the overall semiconductor market. Dataquest projects that the analog IC market will grow at a CAGR of 13.4 percent between 1997 and 2002. It is likely that the analog IC industry is entering into a more mature stage, together with the overall semiconductor industry.

On the other hand, analog ICs have revived their importance in the digital age. As the world goes more and more digital, the demand for analog ICs has

Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

actually increased. This is because the digital revolution has dramatically reduced the cost of the systems and, in turn, stimulated larger demand for digital systems. Moreover, in every digital system, analog ICs are needed to interface with the real world. In particular, the demand for power management ICs such as voltage regulators has soared in both portable systems, such as cell phones and notebook PCs, and in desktop PCs. As a result, there have been many new players entering the market in the past few years to capitalize on the growing need for analog ICs used in digital systems. These are mostly smaller players with revenue of around $50 million and who are targeted toward a specific niche market.

Mergers and acquisitions have been increasing in the analog IC market space, partly as a result of the large number of small players and partly because the industry's growth rate is not as fast as before. This Perspective takes a look at the merger and acquisition activities in the North American analog IC market and analyzes the outlook.

Industry Overview

In order to understand merger and acquisition activities in the analog IC industry, it is important to study the industry landscape first. The North American analog IC industry can be divided into three segments: the large-capitalization companies, the small-capitalization companies, and the medium-capitalization companies. Listed next are the major companies in the three segments. These companies all have analog IC sales as a major portion of their total revenue.

The large-capitalization companies include the following:

- Analog Devices (ADI)
- Motorola
- National Semiconductor
- Texas Instruments (TI)

The small-capitalization companies include the following:

- Elantec
- TelCom Semiconductor
- Linfinity Semiconductor
- Supertex
- Exar
- IMP
- Integrated Circuit Systems
- Unitrode
- Micro Linear
- Sipex

 ©1998 Dataquest

- Cherry Semiconductor
- Dallas Semiconductor
- IC WORKS
- IMI
- Siliconix
- Anadigics
- TriQuint Semiconductor
- Pericom Semiconductor
- Power Integrations
- Impala Linear
- Calogic
- CP Clare

The medium-capitalization companies include the following:

- Linear Technology
- Maxim
- Micrel
- Semtech
- Burr-Brown

The three segments represent very different business strategies and characteristics. Table 1 outlines the major differences between the three segments.

Table 1
Business Strategies and Characteristics for Analog IC Companies in the Three Segments

Segment	Strategy	Characteristic
Large-Capitalization Companies	Provide both digital and analog IC solutions and develop systems-level chips for mass markets by integrating both digital and analog ICs on the same chip.	Are diversified in terms of end markets and have more stable revenue growth rates. All have significant digital IC expertise. TI, Motorola, and ADI have digital signal processing (DSP) technology. National has microprocessor technology.
Small-Capitalization Companies	Focus on a specific high-growth end market and become a niche supplier to that market.	Can have a very high growth rate when the targeted end market is growing quickly but could falter once that end market slows.
Medium-Capitalization Companies	Focus on multiple high-growth end markets and provide proprietary high-performance analog ICs to those markets.	Recognized as the leading high-performance analog IC suppliers, they have the highest gross margins and fastest growth rates and, as a result, the highest valuation multiples in the analog IC industry.

Source: Dataquest (December 1998)

©1998 Dataquest

Now that we understand the industry landscape, what kind of merger and acquisition activities have occurred in the analog IC industry recently? The following section offers an analysis of the major merger and acquisition activities in the analog IC market in 1998.

Mergers and Acquisitions

Unitrode and BENCHMARQ Merge to Tackle the Portable Power Market

On March 2, 1998, Unitrode Corporation and BENCHMARQ Microelectronics Inc. announced a definitive merger agreement under which BENCHMARQ shareholders will receive one share of Unitrode common stock for each share of BENCHMARQ common stock outstanding. The combined company aims to accelerate penetration of the portable power market and increase growth opportunities in other rapidly growing markets.

Dataquest Analysis

Unitrode is one of the leading power management IC suppliers. Of its 1997 revenue of about $170 million, more than 70 percent was supplied to the power management market, with the remaining going to the disk drive industry. In the power management area, Unitrode offers the pulse-width modulation (PWM) voltage regulation modules (VRMs) that are supplied mostly to the desktop PC market. The growing power requirement of the Pentium and the Pentium II processor modules has spurred the growth of the desktop PC power management market and benefited players such as Unitrode, Semtech, Harris Semiconductor, and Cherry Semiconductor that supply to the desktop PC market.

BENCHMARQ Microelectronics, with 1997 revenue of about $44 million, is a leading supplier of battery management ICs. Battery management products represented about 60 percent of BENCHMARQ's 1997 revenue and grew 30 percent from 1996 to 1997. The remaining revenue came from nonvolatile static RAM (NVSRAM) products. The battery management products are supplied to the portable electronics market, including the wireless phone and notebook PC market.

Dataquest views this merger favorably as a sound strategic move for the following four reasons:

- This merger has brought together two closely related product lines—the power management ICs from Unitrode and battery management ICs from BENCHMARQ—to create a broad-based power IC supplier.
- The merger offers the combined company the channel that BENCHMARQ has established with the portable electronics vendors, including the wireless phone and notebook PC suppliers, which gives the combined company an opportunity to make significant inroads into the wireless phone and notebook PC power management arena.

- BENCHMARQ's mixed-signal CMOS design capability should complement Unitrode's BiCMOS process technology and a new 6-inch wafer fab.
- The combined company overall will be less dependent on the disk drive and NVSRAM markets, which were experiencing difficult market conditions.

Semtech Acquires Acapella to Enter High-Speed Communications Market

On April 29, 1998, Semtech Corp. announced the acquisition of Acapella Ltd. in the United Kingdom, a designer of complex mixed-signal ICs for fiber-optic communications. Acapella also provides design consultancy services for a wide range of electronic companies. Semtech has exchanged 175,000 shares of its common stock for all outstanding shares of common stock of Acapella.

Dataquest Analysis

Semtech has transformed itself from a military-focused company a couple of years ago to a largely commercial manufacturer today. Military business accounted for 40 percent of its business four years ago and accounts for about 10 percent today. The transformation of Semtech started with its move into the analog power management market for PCs. In 1997, Semtech was among the leading suppliers of power management ICs for the Pentium and Pentium II processor modules. To further diversify its business, Semtech acquired Edge Semiconductor in 1997 and entered the Automatic Testing Equipment (ATE) IC market. The acquisition of Acapella is Semtech's latest endeavor to diversify, this time into the high-speed communications market.

Acapella is a fabless design house with about 12 designers focused on providing IC solutions for the emerging fiber local loop market. Acapella has developed a proprietary technology to implement time-division multiplexing (TDM). It named this technology "Ping Pong" because just as a ball goes back and forth between two ends in a ping pong game, the Acapella technology is about fiber-optic transceivers deployed at the two ends of the fiber that can both transmit (convert electrical signal to optic and send to fiber) and receive (receive from fiber and convert optical to electrical) signals. Given the potential emergence of the fiber local loop technology, where fiber is used to replace copper as the signal carrier to dramatically increase speed and bandwidth, Semtech has a shot in pulling off another successful diversification move.

CP Clare Acquires Analog ASIC Vendor Micronix to Enter Analog IC Market

On July 6, 1998, CP Clare Corporation announced the acquisition of Micronix Integrated Systems Inc. Micronix, a privately held fabless analog ASIC company located in Aliso Viejo, California, had about $9 million in revenue for the year ending June 30, 1998. CP Clare paid $15.8 million in cash for all of the outstanding shares of common stock of Micronix.

Dataquest Analysis

CP Clare provides high-voltage discrete semiconductor components and packages, electromagnetic relays and switches, and surge protection devices, mostly for the communications market. Of its 1997 revenue of $156 million, about 45 percent came from high-voltage discrete semiconductor components. One of CP Clare's core competencies is its deep trenching technology to manufacture circuits with high-breakdown voltages approaching 300 volts.

Micronix is a specialized analog ASIC design house with about 10 experienced analog designers. This acquisition provides CP Clare with the analog IC design talents that are scarce today. Moreover, this marks an entry point for CP Clare to venture into the high-performance analog IC market for telecom applications. With Micronix's analog IC design expertise and CP Clare's high-voltage BiCMOS process technology and fab capacity, combined further with CP Clare's channel relationship with the communications OEMs, this marriage certainly makes strategic sense.

Micrel Acquires Synergy Semiconductor to Target the High-Speed Communications Market

On October 22, 1998, Micrel Inc. and Synergy Semiconductor Corp. announced that they entered into a definitive merger agreement whereby Micrel will acquire all of Synergy's shares for about $13 million in cash. Synergy, a provider of mixed-signal and digital integrated circuits for the communications, high-performance computing, and ATE industries, had about $28 million in revenue in 1998.

Dataquest Analysis

Micrel Semiconductor has emerged as one of the brightest stars in the "pure play" analog universe over the past few years. In the last three years, Micrel's revenue has been growing at a CAGR of over 50 percent. While the core competency of the company has been in supplying low dropout (LDO) regulators for the wireless market and has garnered great success in winning key business from wireless OEMs such as QUALCOMM, Micrel has been actively broadening its high-performance analog business portfolios. The company has not only expanded its LDO regulator business to other portable markets but has also become a leading supplier of power controllers for PC Memory Card Interface Association (PCMCIA) and universal serial bus (USB). In June 1998, Micrel ventured into the consumer radio frequency (RF) market with a radio transceiver product for remote actuation systems. With annual revenue of around $140 million, Micrel has until now grown its business without any acquisition.

Synergy, a privately held company founded in 1987, provides high-performance bipolar ICs for the networking, telecommunications, computing, and ATE markets. Synergy's products include communications transceivers, clock generators, clock recovery circuits, and high-speed logic and memory.

Micrel's ability to build on its core competency in power management design and process technology and aggressively identify and occupy fast-growing niche markets has been the key reason behind its rapid growth. In the meantime, Micrel's relatively small revenue base has been a contributing factor for the rapid growth rate. It is not inconceivable that the company's internal growth could slow down from the current rate as the company's revenue base hits $250 million and beyond. In that case, Micrel's internal growth rate would likely be more comparable to that of Linear Technology, which is around 20 to 25 percent per year. To realize the company's stated goal of becoming the leading high-performance analog IC manufacturer, Micrel needs to do more than just grow internally. This acquisition of Synergy is likely the first of more to come from Micrel.

This acquisition signifies more than just revenue expansion. What Micrel receives from the acquisition is about 16 analog designers, a 40 percent expansion of analog design resource for Micrel. Also, Micrel obtains Synergy's new 10,000-sq. ft., 6-inch bipolar fab, located in Santa Clara, California. More importantly, Micrel now has something that it did not have before—Synergy's high-speed bipolar technology called All Spacer Separated Element Transistor (ASSET). This patented technology makes possible high-speed circuits using the bipolar process, eliminating the need to go to subquarter-micron CMOS to achieve comparable speed. As a result, Micrel is now equipped to jump into the fast-growing SONET, Gigabit Ethernet, and Fiber Channel arenas and is now positioned to compete with companies such as Applied Micro Circuits and Vitesse Semiconductor. These competitors are certainly not amateurs, and Dataquest expects a fierce contest ahead.

Dataquest Perspective

With the analog IC industry growing at a slower rate than before and the small-capitalization segment crowded by many participants, Dataquest expects more consolidation to occur as the industry moves forward. The small-capitalization players, in an effort to diversify their end markets and lessen their business volatility, could potentially merge with other small players or be acquired by larger players. Private start-ups may seek strategic acquirers, rather than go public, to gain access to critical channels and resources. Ambitious medium-capitalization players, such as Micrel and Semtech, that are growing rapidly with the aim of joining the league of large-capitalization companies in the not-too-distant future will continue to seize opportunities to expand through acquisition. The large-capitalization companies, in an effort to maintain leading market shares and fend off competition from both medium-capitalization and small-capitalization players, are likely to be acquirers in the future. Digital IC companies may acquire analog IC companies in an attempt to add analog technology to their portfolios and provide single-chip mixed-signal solutions for high-volume markets. Leveraged buyout (LBO) firms, enticed by the analog IC industry's unique characteristics of high profit margin, high return on equity (ROE), and stable growth rate, combined with many companies' rich cash positions, may decide to invite themselves into the game.

Stay tuned.

Semiconductors Worldwide

Event Summary

1998 Analog and Mixed-Signal Applications Conference

Abstract: *This Perspective summarizes the Analog and Mixed-Signal Applications Conference held in July in San Jose, California. This Event Summary briefly relates all significant announcements and comments pertaining to key developments. Further details on technical presentations are available from the Dataquest inquiry service.*
By Jim Liang

Event Background and Overview

This year's Analog and Mixed-Signal Applications Conference, sponsored by *EE Times*, was held on July 13 and 14 in San Jose, California. The event was started in 1991 and has been held annually, except in 1993 and 1996. The conference addresses both traditional analog and contemporary mixed-signal issues in a variety of fast-growing market segments, including computer, communications, and consumer markets.

In addition to industry heavyweights Texas Instruments, Motorola, STMicroelectronics, Philips, and Lucent Technologies, conference presenters included not only traditional analog names such as National Semiconductor, Analog Devices, Linear Technology, Micrel Semiconductor, Cirrus Logic, Cherry Semiconductor, Burr-Brown, Harris Semiconductor, TelCom Semiconductor, and Micro Linear, but also new players, such as LSI Logic (a digital ASIC supplier), which is entering the mixed-signal field from the digital end.

Technical Session Topics

The following lists the technical session topics from this year's conference:

- High-speed communications
- Low power design
- Advanced electronic design automation
- Buses and motors
- Radio frequency (RF) and cell phone design issues
- Modeling techniques
- Pentium power supplies
- Analog-to-digital performance issues
- Multimedia
- Advanced integration issues
- Using operational amplifiers

There were a total of about 60 papers presented. Among them, Dataquest believes that the following two are worth an extra look because they represent key application trends for the analog and mixed-signal IC market:

- "Low-Dropout Regulators for Battery-Operated System Applications," from TelCom Semiconductor
- "A Comparison of High-Speed, Mixed-Signal VLSI Technologies for RF/Wireless Applications," from National Instruments

Low-Dropout Regulators for Battery-Operated Systems

The physical size of battery-operated systems, such as cell phones and personal digital assistants (PDAs), shrinks with each new generation. The decrease of system size results in the reduction of battery size, which in turn causes the battery's energy capacity to drop, forcing the system to operate on smaller amounts of current. A major performance benchmark in battery-operated systems is the operating time between battery charges. In order to achieve longer operating time, with decreasing energy capacity, power efficiency maximization has become an increasingly important task.

Low-dropout regulators (LDOs) are linear regulators capable of operating with small input-output voltage differentials (that is, dropout voltage). Low dropout voltage and low supply current make LDOs particularly attractive in battery-operated systems, because these characteristics result in better power efficiency. A major application of LDOs is in digital cellular phones, where battery life (or talk time) is of key importance. As discussed in the Dataquest Perspective "Analog and Mixed-Signal IC Applications in Digital Cellular

Phones," the market for LDOs used in digital cellular phones is estimated to be about $290 million for 1997, and is projected to grow at a compound annual growth rate (CAGR) of 18 percent to reach over $660 million by 2002. This strong growth is the result of the rapid expansion of the cellular phone market, combined with the increasing need for better power efficiency.

Although bipolar process technology traditionally is used to fabricate LDOs, there is an increasing trend toward using CMOS process technology. TelCom Semiconductor presented a paper comparing these two technologies.

A bipolar LDO uses either an NPN or a PNP series pass transistor, whereas a CMOS LDO generally uses P-channel MOSFET as the pass transistor. As a result, bipolar LDOs have the drawbacks of relatively high dropout voltage and high ground current. CMOS LDOs, in contrast, have the advantages of both low dropout voltage and low ground current. Also, CMOS LDOs allow for the possibility of future integration of LDOs with other digital circuitry. This integration could pave the way for system-on-a-chip solutions, such as single-chip cellular phones. TelCom Semiconductor performed side-by-side testing of the performance characteristics of both bipolar and CMOS LDOs and confirmed CMOS LDOs' advantages of low dropout voltage and low ground current. However, bipolar LDOs generally have better RF performance characteristics, such as lower noise and faster transient response. Therefore, in applications where battery life is more critical than noise characteristics, CMOS LDOs are the preferred choice.

Dataquest believes that there is room for further technology advancement to achieve LDOs with the ideal characteristics of low dropout voltage and low noise, because in applications such as cell phones, both battery life and RF performance are important.

VLSI Technologies for RF

RF semiconductors have emerged as one of the fastest-growing segments within the semiconductor industry, mostly as a result of the burgeoning wireless communications market . The semiconductors used in wireless systems can be partitioned into two major segments: RF semiconductors, which are used in the radio portion of a wireless system, and baseband semiconductors, which include microcontrollers, DSPs, microprocessors, memory, power management, and display semiconductors.

The explosive growth of the wireless communications market has driven the demand for systems with low cost, low power, and small size. In order to meet this demand, Dataquest expects the total semiconductor content of a typical wireless product, such as a digital cellular phone, to be reduced from $73 worth in 1997 to $40 worth by 2002. This reduction is driven by higher levels of CMOS integration in both the RF section and the baseband section. Furthermore, Dataquest expects that the RF section and the baseband section will eventually be integrated to achieve the lowest cost and power and the smallest size. Therefore, there will be an increasing trend toward integration in the RF section and ultimately in the entire system.

 ©1998 Dataquest

While the growth of the PC market has resulted in the advancement of digital VLSI technology in manufacturing memory and microprocessors, the growth of the wireless market is likely to advance VLSI technology for RF. However, the technical requirement for RF ICs, such as low noise, high gain, linearity, and power efficiency, are much more complex and do not necessarily improve with lithographic scaling or integration levels. Also, the typical RF section is made up of various components, such as amplifiers, synthesizers, transmitters, receivers, and switches. Each of these components tends to achieve optimum performance in widely different and incompatible technologies, which include silicon-based technologies such as CMOS and BiCMOS, gallium arsenide-based technologies such as MESFET and HBT, and silicon germanium-based technologies.

The optimum technology choice for an RF application is determined by issues of performance, wafer cost, level of integration, and time to market. National Instruments presented a paper comparing various technologies used for RF ICs.

Until recently, gallium arsenide (GaAs) technology was expected to dominate the RF IC arena because of its proven microwave performance. However, its limitations include higher wafer cost and lower level of integration. In fact, history has shown that silicon CMOS won out over GaAs for high-speed digital VLSI implementation, in spite of GaAs technology's superior material properties. This outcome was due primarily to the aggressive scaling of silicon CMOS, which allowed unprecedented levels of performance to be achieved. Silicon CMOS devices, through aggressive scaling, should be able to operate at speeds as high as those achieved with GaAs. However, GaAs MESFETs have a much lower noise figure than silicon devices. National Instruments' paper concluded that the ideal goal of a radio-on-a-chip will most likely be realized using silicon CMOS. In the near term, given the superior RF performance of GaAs, RF system designers will continue to push for hybrid solutions utilizing both silicon and GaAs technologies.

Industry Business Panel

Another highlight of this year's conference was a dinner panel discussion: "Business and Market Perspective on Analog and Mixed-Signal Semiconductors." The panel, moderated by the author, featured industry executives from National Semiconductor and STMicroelectronics, a security analyst from Hambrecht & Quist, the CEO of a startup, and a venture capitalist. The panel is probably the first of its kind to focus on high-level business and financial issues facing the analog IC industry.

The panel reviewed the landscape of the analog IC industry, which consists of two major segments—standard linear ICs and analog application-specific standard products (ASSPs). The standard linear IC industry is characterized by long product life cycles, low capital intensity, low selling prices, relatively stable pricing, high gross margins, broad application market exposure, and stable growth rates. The key factors for success in this industry include specialized analog design expertise and versatile analog process technology. The analog ASSP industry, on the other hand, has the characteristics of shorter product life cycles, higher selling prices, high volume, and high growth rates. Mixed-signal technology, systems know-how, and fast time to market are among the key success factors for this industry.

Companies that focus on the standard linear IC industry include Analog Devices, National Semiconductor, Linear Technology, Maxim, Micrel, Burr-Brown, and Semtech. Players that participate in the analog ASSP segment include vertically integrated companies such as Philips, Toshiba, SANYO, Sony, Siemens, and Motorola. Texas Instruments is unique because it participates actively in both standard linear IC and analog ASSP segments.

Looking at the stock performance of analog IC companies, it is evident that analog IC companies tend to outperform the semiconductor industry in general. Furthermore, the high-performance standard linear IC companies, such as linear Technology, Maxim, Micrel, and Burr Brown, have generated even higher returns than the overall analog IC industry. The primary reason is that these companies, as the "pure-play" high-performance analog IC suppliers, have shown high but stable growth rates over the years, with high gross margins at the same time. What more can a shareholder ask for?

There are two very different business strategies for success in the analog IC market: the profit strategy and the growth strategy. The profit strategy allows companies to position themselves as broad-based high-performance standard linear IC suppliers. The name of the game here is to capitalize on specialized analog design expertise and continually find niche applications in which high-performance analog design offers advantage. As a result of the proprietary nature of these analog designs, rich pricing premiums and high gross margins can be achieved. Linear Technology and Maxim have been following this strategy and have thrived on it.

To follow the growth strategy, companies attempt to identify high-growth and high-volume markets and to develop system-type products for these markets—although profit margins tend to be low because of the pricing erosion induced by high volume and fierce competition. Texas Instruments has been very successful in supplying analog ASSPs for the modem and cell phone markets. The downside of the growth strategy is the dependence of a company's fortunes on a narrow list of markets. In fact, Texas Instruments has modified its strategy and broadened the portfolio of its standard linear IC offerings in an effort to reduce this very risk.

Dataquest expects the standard linear IC suppliers to remain focused on the high-performance end of the market as new niche applications are constantly being identified. Also, Dataquest expects competition to intensify in this segment as newcomers, such as Micrel, Sipex, Semtech, Unitrode, and Power Integration, have grown significantly in the last few years by focusing on their respective niche markets. Today, these newcomers present an increasing challenge to the leaders, Linear Technology and Maxim.

For companies such as Texas Instruments and National Semiconductor, Dataquest expects that their drive toward system-level products will continue. Texas Instruments will continue to capitalize on its digital signal processing (DSP) technology and provide both analog and DSP solutions for

 ©1998 Dataquest

high-volume markets such as modems, cell phones, and disk drives, with the goal of achieving single-chip solutions for these markets in the future. National Semiconductor, in contrast, is trying to leverage both its in-house analog expertise and the acquired Cyrix x86 technology to build system-level products for low-cost PCs and other information appliances.

Dataquest Perspective

Analog ICs have regained vitality in recent years even though the world is increasing going digital. The primary reason is that the proliferation of digital technology has expanded significantly the demand for analog ICs. The digital revolution has dramatically increased the overall market size for digital systems and hence the demand for the analog ICs deployed in these systems. After all, every digital system requires analog ICs to interface with the real world. In other words, a world that is increasingly going digital is indeed a beautiful thing for the analog IC market.

In 1998, the analog IC market has taken a pause, as the demand for analog ICs and semiconductors in general has weakened as a result of the Asian economic downturn. Dataquest expects growth to return to the analog IC market in 1999, provided that stability can be regained in the emerging economies. Within the analog IC market, Dataquest believes that power management will lead the growth of standard linear ICs as the demand for power efficiency continues to be strong, and telecom ICs will lead the growth of analog ASSPs, driven by the expanding wired and wireless communications markets.

Dataquest expects the business landscape for the analog IC market to become increasingly interesting in the years ahead. How Linear Technology and Maxim can continue their high growth rates while maintaining high gross margins, in the face of increasing competition from the smaller niche players, remains an open question. Dataquest believes that the key to their continued success rests with their ability to continue to identify emerging niche applications where analog performance offers differentiated advantage. For system-level product suppliers such as Texas Instruments and National Semiconductor, Dataquest believes their success depends on their ability to get their system products to market quickly, as these high-volume markets continually shift to newer generations.

Semiconductors Worldwide

Market Analysis

It's Penny-Pinching Time for Semiconductor Spenders

Abstract: *Projected worldwide capital spending for 1998 is $31.6 billion, down 22 percent from 1997. This is a paltry sum in comparison to previous spending rates. For the industry, this represents a second year of decline for semiconductor capital spending. For the top 20 semiconductor spenders, which represent 68.3 percent of worldwide spending, total spending for 1998 is expected to reach only about $21.6 billion, which represents a 15.6 percent decline from the 1997 top 20 spending totals. Of the top 10, five companies have increased their spending over 1997 totals. Motorola, UMC Group, Advanced Micro Devices, IBM Microelectronics, and Winbond are posting a positive return to spending in 1998.*

By Mary Ann Olsson and Clark Fuhs

Capital Spending, 1998

FILE COPY:
MARIA VALENZUELA

The top 20 capital spenders in 1998, listed in Table 1, represent a sizable share of the industry's spenders and exemplify strengths and strategies. These top 20 represent a 68.3 percent share of the worldwide capital spending total. Their revenue share of $21.6 billion represents a 15.6 percent decline in spending from 1997. But for a few exceptions, a decline in the top 20 spending patterns reflects an industry that is still in a holding pattern expected to continue through 1998.

Of the top 20 companies listed in Table 1, only six are expected to post positive spending revenue in 1998. Motorola, UMC Group, Advanced Micro Devices, IBM Microelectronics, Winbond, and Micron Technology have jumped in ranking and in spending revenue in 1998. Also, three of the top 10 are foundry suppliers.

Current Industry Environment

Overall capital spending declined in 1997 by 9.9 percent. Dataquest expects this spending reduction to extend through the fourth quarter of 1998. The result would be an additional 22 percent decline over 1997 levels. This forecast reflects our belief that industry overcapacity will delay a sustainable capital spending growth pattern until at least late 1999. We would expect supply-and-demand dynamics to be corrected by late 1999 to early 2000, driving a robust resumption of growth in capital spending to about $77 billion in the year 2002, from nearly $31.6 billion in 1998.

Regionally, Americas capital spending remained more or less flat with 0.5 percent growth in 1997. For 1998, Dataquest expects that investment in advanced technology will continue in a "minimal investment" pattern. Spending in the region will decline by more than 17 percent. We are forecasting a modest recovery of 7 to 10 percent for U.S. companies in 1999. This recovery could be greater if the PC market shows signs of unexpected life in the second half of 1998. Preliminary worldwide PC vendor unit shipments (at 21.1 million units) posted a 13.9 percent growth in second quarter 1998 over second quarter 1997. The U.S. market sustained double-digit growth, increasing 12 percent. The Americas region is forecast to have the second-highest compound annual growth rate (CAGR) in capital spending for the period from 1997 to 2003 (12.1 percent), as foreign multinationals and foundry companies invest in capacity in the United States.

Japanese companies are reducing spending overall by 20 percent in yen terms. Continued weakness in DRAM and the depreciation of the yen affect dollar-based capital spending in Japan. With the yen weakness, this shift results in a 30 percent cut in U.S. dollar terms compared with 1997. Companies continue spending on 0.25-micron fabs for next-generation products, and their spending into the domestic sites will increase in proportion to other regions. The Japanese region on the whole will show milder growth in capital spending in the foreseeable future. Japanese companies will refurbish their fabs for "portfolio" production (mixed product manufacturing), with fewer dedicated DRAM, or logic, fabs. Most fabs will be ready to produce any products, thus closely following market trends.

The slowdowns that Europe experienced during 1996 continued in 1997 with a 19 percent decline for investments in the Europe region. We are expecting Europe to reflect the overall worldwide market because there is a good mix of multinational investment currently in the region. Europe is currently at equilibrium with the world, with a stable percentage of the demand and production mix. This stability is what has attracted more companies to produce in the region. Europe's long-term above-market growth and focus on specific projects in Europe during 1998, particularly the 300mm pilot facility in Germany, mean a more moderate spending decline than in other parts of the world.

Year-end DRAM declines and the dramatic Asian financial crisis show a nearly 12 percent decline in capital spending in the Asia/Pacific region for 1997. The market clearly overspent in this region, as is evidenced by the region's poor financial health. For 1998, constrained capital, especially by Korean companies, is estimated to result in a 27 percent decline in capital spending as the industry deals with capital constraints and the DRAM market remains under pressure. Over the longer term, we expect Asia/Pacific to rebound with aggressive growth in 2000 and 2001. The CAGR (at 11.6 percent for 1997 to 2003) should, however, be much closer to overall market growth rates than in the recent past.

Tied to the regional dynamics is the foundry market. Despite the competitive pricing environment that has existed for the past 18 months, dedicated foundry companies have managed to remain profitable. Yet, the foundry industry has shifted into an "acute" overcapacity situation. In a reaction to price pressure and decreased fab utilization, Taiwan foundries are rapidly

 ©1998 Dataquest

cutting back on spending. Their spending will grow only 20 percent in 1998, resulting in an overall decline in spending on the island of about 7 percent. For 1999, we are expecting DRAM spending to remain low and perhaps down, but foundry spending to be cut again, resulting in an overall island decline of roughly 20 percent.

The Outlook for 1999

The year 1999 is forecast to see only slight growth. Yet, the year is significant in the overall picture as it should mark the bottom point for the spending ratio in the current slowdown. From 1997 to 1999 and during 1999, semiconductor revenue will grow ahead of capital spending. In early 2000, the tide should turn and equipment revenue will start to grow again ahead of semiconductor revenue. Thus, another hot equipment market lies ahead. At that time "underspending" of the semiconductor industry not only will have resulted in a balance of supply and demand but the pendulum will have turned in the other direction, toward an undercapacity situation. Dataquest's forecast for 2000 and 2001 is for, respectively, more than 38 percent and 49 percent growth in capital spending while the industry should remain in a state of net underinvestment even in the year 2000. However, the year 2002 should bring the onset of the next down cycle, triggered by the industry transition to the 256Mb DRAM and overcapacity once again created by silicon efficiency.

Compared to our forecast half-year ago, the picture has changed in that both the upswing as well as the start of the next down cycle have been pushed out by one year. Why? The answer is that semiconductor demand has stalled in 1998. The Japanese and other Asian economies have slowed tremendously in recent months, and this slowdown has impacted electronic equipment demand in the areas of consumer electronics and automotive, with a slight impact to computing. Dataquest has recently reduced the electronic equipment production forecast for 1998 from 6.9 to 4.4 percent growth. This reduction has made a dramatic impact on semiconductor demand from a unit perspective, and our most likely forecast for semiconductors in 1998 now calls for a 1.4 percent growth—essentially flat.

One way to view 1998 is that the semiconductor industry demand profile has inserted a one-year "holding pattern," and likewise a one-year delay, in any recovery that was previously forecast. This condition has made the secondary downturn we were expecting appear much more severe, as the industry will be making only "minimum investments" during the next 12 months. Because a sustainable recovery in spending and the equipment market must come from capacity buying, we must have a healthy chip market in 1998 to have a growing equipment market in 1999. It does not appear to us that the chip market can mount a recovery until next year, so we have downgraded our 1999 wafer fab equipment forecast to be essentially flat from 1998 levels.

So 1998 is a gloomy year. Dataquest forecasts capital spending to decline by more than 22 percent (see Table 2). Strategic investments into new technologies continue to remain the focus, but there is a limit. Certainly, 300mm spending is not a savior for this year. In fact, after a lot of hype by semiconductor companies, the only words recently heard from these companies are "push-out" and "delay." Spending on 0.25-micron technology has been and should remain solid. However, we believe that with semiconductor revenue flat and overspending in prior years, there is frankly not much capital in the industry to be allocated for new equipment. Dataquest believes that the industry shifted in 1998 into a minimal investment pattern, which should last into the middle of next year. In this spending pattern, all purchases, even for 0.25-micron technology and strategic equipment, will be tightly scrutinized. Only what is really essential to move ahead and keep up with new technology developments will be purchased. This is quite a change for many segments, which were hot even during the initial phases of the down cycle.

In short, it all boils down to the question, "How much technology spending is enough?" Has the industry reached technology saturation—a technology glut? When one looks at foundry companies, the answer is yes. Although TSMC proclaimed at the beginning of the year that it was running at more than 100 percent utilization, the question remained: 100 percent utilization of fabs according to their technology capabilities or with any technology? We believe the latter to be the true situation, as foundries now admit they were running a lot of 0.5- and 0.6-micron products through their 0.35-micron fabs. When there is no money, even technology is hard to sell.

Turning to the tactical side, 1998 will be a year of minimal investment with a technology focus. Certainly, new fab construction is hard to find in these times. Yet, strategic investments also include any fabs that open up new production market locations and those that are tied to partnerships and joint ventures. Of particular interest are companies in new alliances, in which other factors, such as a strategic development or supply relationship, may be more important than the capacity being added. These two kind of strategic investments, although to some extent capacity-related, are historically less affected by an industry slowdown.

Table 2
Worldwide Capital Spending Forecast, 1997 to 2003, Including Merchant and Captive Semiconductor Companies (Millions of U.S. Dollars)

	1997	1998	1999	2000	2001	2002	2003	CAGR (%) 1997-2003
Worldwide	40,505	31,583	32,990	45,749	68,302	77,164	76,784	11.2
Growth (%)	-9.9	-22.0	4.5	38.7	49.3	13.0	-0.5	-

Source: Dataquest (August 1998)

Many fabs started or upgraded in 1997 fall specifically into these categories, including: the U.S. fabs being built by TSMC, Samsung, and Hyundai; the U.K. fab being built by Siemens; the array of initial joint venture fabs such as Dominion (IBM/Toshiba) and White Oak (Motorola/Siemens) in the United States; Taiwan companies Winbond, Powerchip Semiconductor, Nan Ya Technology, and Macronix, whose activities are tied to Japanese companies; Mosel Vitelic, which is tied to Siemens; and Texas Instruments' venture in

 ©1998 Dataquest

Korea (with Anam). In 1998, most of these fabs will not be stopped, but will likely have slower ramp rates than planned.

An exception are the Korean fab investments. In the near term, the liquidity crisis in Korea impacts these strategic investments. All new Korean semiconductor investment projects have stopped in their tracks, and nobody has definitive answers about when the situation will stabilize to the point that these projects can be restarted. In fact, the key issue to be looked at today is when and in what order planned projects will be restarted for Korean companies. In summary, we believe that the market will hit bottom in the third quarter of 1998, and a sustainable recovery should not be expected until the end of 1999.

Dataquest Perspective: Is There a Bright Side?

The industry is still in the throes of severe spending cutbacks, with many companies resorting to layoffs or shutdowns to rein in losses. Overspending in 1997 and softening in semiconductor demand have pushed out a sustainable recovery into late 1999. In the quarterly picture, we believe that capital investment will be in for sluggish business conditions after hitting bottom in third quarter 1998. There is a bright side, but it appears to be in the somewhat distant future. The fundamentals of capacity supply-and-demand balance simply do not support a major recovery occurring in the memory manufacturing segment before the end of 1999, unless capacity exits the industry. Dataquest believes that companies will continue to follow a "minimum investment pattern" with respect to technology, with shifting emphasis from 0.25-micron toward 300mm and 0.18-micron technology. Yet, the 300mm investment picture for 1998 has severely softened, as most investments have slipped into 1999. It appears that Japanese companies have adopted the strategy of investing in less capital-intensive extended R&D centers rather than full-blown pilot lines.

After increasing strength in the second half of 1997, every quarter of 1998 brought equipment revenue declines. This weakness is expected to continue through the third quarter 1998, before a slight, largely seasonally motivated uptick in fourth quarter 1998. Overspending during 1997 and the "holding pattern" in semiconductor revenue growth in 1998 have taken strength from any recovery in 1999.

More in-depth analysis on capital spending and wafer fab equipment can be found in the Dataquest Market Trends report *Midyear 1998 Forecast: Capital Spending, Wafer Fab Equipment, and Silicon Markets* (SEMM-WW-MT-9803).

Perspective

Semiconductors Worldwide

Market Analysis

European Inward Investment Opportunities

Abstract: *In this Market Analysis, Dataquest examines what the key factors are in attracting inward investment from the semiconductor industry and analyzes eight major locations. Funding is no longer the critical factor it once was, while educational infrastructure is playing an increasingly significant role.*
By Edmund Gemmell

Executive Summary

Most countries in Europe are interested in, and are actively seeking, inward investment from semiconductor manufacturers. With most countries offering broadly similar incentives by way of capital grants and taxation benefits, the battleground to win high-quality inward investment is shifting to skills management. The future winners in this battle will be those that offer a combination of the correct skills in the right numbers, as well as attractive financial packages. This calls for an integrated response by each country to the demands of the semiconductor industry.

Some countries have recognized this and are rising to the challenge of developing methods to meet these demands. These will be the countries that attract the added-value inward investment projects. Some countries or regions will continue to offer large grants, but as this becomes more expensive, and as their competitors become more differentiated, the quality of inward investment that these regions or countries attract will suffer. While the focus of this Market Analysis is the semiconductor industry, many of the financial and fiscal incentives described are equally applicable to other industries.

(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Introduction

The location of a wafer fabrication plant or assembly and test plant is a key decision made by semiconductor vendors when considering capital expenditure programs. Identifying where sufficient staffing, reliable infrastructure, and suitable land can be found is becoming increasingly important. At the same time, many countries in the European Union have realized the potential benefits of having semiconductor plants located within their borders, in terms of direct employment, indirect employment, enterprise creation, and regional regeneration. It is no surprise, therefore, that many countries, and specific regions in countries, are positioning themselves as high-technology centers and competing vigorously for new inward investment proposals. This report analyzes some of the regions that a semiconductor manufacturer might consider when deciding on a location in the European Union. This Market Analysis also provides details of appropriate staffing availability, as well as training infrastructure and an overview of the financial incentives and support available in each location.

The locations covered in this Market Analysis are as follows:

- Flanders, Belgium
- Southeast France
- Western France
- Eastern Germany (Saxony)
- Ireland
- Northern England
- Central Scotland
- Central and eastern Spain

Table 1 shows the regions that have been most successful in promoting themselves to the semiconductor vendor community.

Flanders

Recently, Flanders has been one of the more proactive regions in Europe trying to attract inward investment. The main focus of activity has been on attempting to attract a semiconductor wafer fabrication facility into the region. It is hoped that this will act as a catalyst for the further development of the semiconductor industry in the region.

One of the most interesting ideas being investigated by the Flanders Foreign Investment Office (FFIO) is the concept of building its own wafer fabrication plant and leasing this out to semiconductor vendors on a long-term basis. The model would have the Flanders government consortium managing the plant and issues such as chemical, gas, and waste handling, while the tenant vendor would be responsible for manufacturing development and core competencies. This business model is still being developed by the FFIO and Meissner and Wurst, a wafer fab design company.

Source: Dataquest (July 1998)

Flanders is home to two semiconductor fabrication facilities: Alcatel Microelectronics, which is based in Oudenaarde, near Gent, and Interuniversities MicroElectronics Center (IMEC), which has a smaller-scale facility in the region. IMEC is the largest independent microelectronics R&D center in Europe. IMEC's R&D activities are concentrated on the development of novel design methodologies, the development of processing technologies for the next generation of ultralarge-scale integration (ULSI) chips, and the support of the training of very large-scale integration (VLSI)

 ©1998 Dataquest

design engineers on behalf of both educational institutes and industry. IMEC also provides training facilities for industrial partners on request.

However, there are about 10 other fabrication modules located within 150km of Brussels. In addition to the semiconductor wafer fabrication plants and IMEC, Flanders has two other universities with specialist electronics faculties. The Flanders region also has 15 industrial engineering colleges that provide four-year electronics courses toward degrees.

The principal financial incentive offered by the Flanders government to inward investors is a series of cumulative direct subsidies. The first is a basic subsidy of 4 percent of total investment, which is available to qualifying investments that are the first operational unit by the company in Flanders. The second is a direct subsidy of up to 8 percent of the total investment, depending on the economic importance of the investment in the region. Given Flanders' eagerness to attract a semiconductor fabrication plant, it would be fair to assume that such an investment would be considered as being of great economic importance and, thus, would attract a significant part of this 8 percent. The third subsidy is based on employment growth and can be up to 9 percent of the total investment. The combination of these three subsidies means a total direct subsidy of 21 percent of total investments is available to any qualifying inward investment project.

In addition to the direct subsidies that are available as incentives, Flanders also offers several fiscal measures to increase the value of inward investment support packages. These measures include an exemption of real estate tax for the investment site for five years and accelerated depreciation programs. The FFIO will also participate in site acquisition and preparation.

The Flanders employment agency also participates in the sourcing of staff for any inward investment project. The Flanders employment agency, as part of an incentive package, will meet the expenses of new staff's first six to eight weeks of employment, when they usually will be in training.

France

In France, the regions of western France and Marseilles-Provence in the southeast are two of the primary high-technology and IT conurbations. Consequentially, both regions are being given a great deal of support from the Invest in France Agency. Philips Semiconductor, Temic Matra (now part of Atmel Corporation), and SGS-Thomson have all located wafer fabrication plants in western France. Marseilles-Provence hosts wafer fabrication plants belonging to SGS-Thomson and Atmel. Motorola Incorporated is nearby in Toulouse, and SGS-Thomson has more plants nearby in Grenoble.

The importance of this high level of wafer fabrication plants is that both regions have been acclimatized to the high levels of service that wafer fabrication investments need in terms of ground preparation requirements, planning permission, waste material management, traffic and customs infrastructure, and supply infrastructure. The regions also have an existing skill base and orientation toward high-technology industries.

Western France

As well as the wafer fabrication plants located in western France, the region has a high concentration of R&D facilities, including CNET (applied telecommunications research organization), CCETT (applied audiovisual research), and the microelectronics center for the west of France (CCMO), which is a collaboration among three electronics educational establishments in Rennes together with SGS-Thomson, Temic Matra, and SOREP Technology Corporation. CCMO provides R&D facilities as well as further training facilities and courses for workers in the electronics industry.

Western France is also home to more than 50 university- or engineering-school-based laboratories or departments with a high-technology orientation. These laboratories and departments are in 13 universities or engineering schools specializing in electronics, data processing, and telecommunications.

The primary financial incentive available to companies investing in western France is the regional development grant (PAT). Most areas in western France qualify for a subsidy of up to FF 50,000 (about $8,250) per job created, although some areas in the region qualify for up to FF 70,000 (about $11,500) per job created. PAT is available to all companies investing at least FF 20 million (about $3.3 million) and creating 20 permanent jobs over three years. Neither of these restrictions would pose much of a problem for a semiconductor vendor considering investing in a new operation. The PAT incentive is limited to 17 percent of total investment. Some exceptional levels of financial assistance are available from PAT in western France, however, because of the restructuring of the French defense industry.

In addition to PAT, other assistance is available for training programs and ensuring that manufacturing facilities are environmentally friendly. Full or partial exemption from business tax (a local tax) is negotiable for up to five years for inward investment projects. In PAT-qualifying areas, local authorities are also prepared to become involved in land acquisition and preparation and may provide a discount of up to 25 percent on purchase or lease costs.

Marseilles-Provence

The Marseilles-Provence region in the southeast of France has, as stated earlier, many wafer fabrication plants either in the region or close by. Additionally, the region has several technology parks serving the electronics industry, including Rousset, the Aixles-Milles industrial development park, the Chateau-Gombert science park, and the Arbois Europole project.

In these parks and the region's universities, 30 laboratories are carrying out research in various fields of microelectronics. These laboratories are based around the four universities in the Bouches du Rhone region. Also, Marseilles-Provence is home to the Microelectronics Regional Study Center on Silicon (CREMSI), which has some 40 members, including SGS-Thomson, Atmel, Gemplus SA, and DuPont Photomasks Inc., and 10 R&D laboratories. CREMSI is focused on furthering microelectronics in the Marseilles-Provence region and undertakes joint research for those companies involved. The Marseilles-Provence region also provides training programs and facilities for

 ©1998 Dataquest

the technicians and senior technicians required to populate semiconductor fabrication plants.

Financial incentives in the Marseilles-Provence region are structured as those for western France. Marseilles-Provence is one of the few regions in the southeast of France that qualifies for PAT. The PAT rate for Marseilles-Provence is FF 70,000 (about $11,500) per job created, subject to a maximum of 25 percent of total investment.

Ireland

Analog Devices Inc.'s investment in Limerick in 1976 was the catalyst for Ireland's interest in attracting electronics-related investment. Since then, in addition to attracting a prestigious investment from Intel Corporation, Ireland has attracted several other semiconductor-related inward investments in the form of design houses.

Ireland has focused its efforts to attract future inward investment by building an infrastructure to supply the key staff for future technology. The National Microelectronics Research Centre base at University College Cork has a 3-inch foundry, IC design group, and interconnect and packaging laboratory. In addition, Ireland has eight universities with electronic engineering faculties, which produce between 600 and 700 electronics engineering graduates per year. Also, the Irish government has put in place an Ir£50 million ($68 million) program aimed at developing additional engineering courses.

As well as its higher-education establishments, Ireland also has 12 regional technical colleges offering electronics-related courses. Included in these courses is one codesigned by Hewlett-Packard Company and Intel to develop a suitably educated pool of technician-level staff.

One of the major financial attractions for investing in Ireland is the level of corporation tax levied against companies. The standard corporate tax rate is set at 10 percent until 2010. From 2010 until 2025 the rate will be 12.5 percent, which is significantly lower than that of most other countries. Surprisingly, other financial incentives aimed at attracting investment are significantly lower than those that some other regions are offering. The Irish Development Agency (IDA) offered Intel about Ir£30,000 ($40,000) per job, which was significantly below some other offers, for a total commitment of 2,800 jobs, yet it still won the bid. This speaks volumes for the quality of staff on offer.

The IDA tends to work on an investment incentive per job created basis. However, once an amount per job has been fixed, it is broken down into three constituent parts: a capital grant based on the value of fixed assets; an employment grant, which, typically, would not exceed Ir£10,000 ($14,000) per job; and a training grant, which would cover up to 100 percent of agreed training costs.

Saxony, Germany

The former East German state, now one of the new German *Länder*, is positioning itself as the microelectronics center of eastern Germany. Since the reunification of Germany, Siemens Semiconductor has built a new DRAM wafer facility, in which it is planning its new 300mm pilot line, and Advanced Micro Designs Inc. is close to completing a new wafer fabrication plant for the manufacture of microprocessors. These developments are on top of the semiconductor infrastructure that existed when Saxony was part of East Germany. Zentrum Mikroelektronik Dresden (ZMD), which produces primarily memory products, has been located in Dresden since 1987. Before reunification, ZMD employed more than 3,000 employees in the microelectronics industry. Today it employs about 500, but the supply base for skilled employees, many of which worked in high-technology industries prior to reunification, remains.

Saxony, and Dresden in particular, offers a significant R&D and university infrastructure; Dresden has more than 30 educational and research institutes. Included in this number are the Institute for Semiconductor and Microsystems Technology, the Institute for Communications Systems, the Institute for Information Systems, and the Institute for Technical Informatics, all at the Technical University (TU) Dresden, which has 21,000 students. In addition to TU Dresden, these other institutions all offer IC design courses: TU Chemnitz, Freie Hoch Schule (FHS) Mittweida, FHS Zwickau, and FHS Zittau-Goerlitz. Dresden is also home to the Fraunhofer Institutes for Microelectronic Circuits and Systems, the Fraunhofer Institute for Material Physics and Layer Technology, and the Fraunhofer Institute for Integrated Circuits.

The financial incentives offered to inward investors in Saxony, and the new *Länder* of eastern Germany in general, are quite significant. Both Siemens and AMD received funding of about DM 800 million (about $450 million) to assist in their fabrication plant location decision.

Start-up grants can reach 28 percent for large inward investment firms in the surrounding areas of Dresden and Leipzig. In other regions of the new federal states, grants can reach 35 percent of total inward investment. These grants are from the Improvement of Regional Economic Structures Program, which is funded by the Saxony Government, the federal government of Germany, and the European Union.

In addition to grants, several tax incentives are available to inward investors. Included in these are an investment allowance and a special accelerated depreciation allowance. The investment allowance returns 5 percent of any investment in movable depreciable equipment. Given that the cost of setting up a state-of-the-art wafer fabrication plant facility is in the region of $1 billion, this allowance on its own is worth about $50 million. The special accelerated depreciation allowance allows companies to depreciate their capital equipment by between 20 percent and 40 percent above the normal depreciation rates.

 ©1998 Dataquest

United Kingdom

In the United Kingdom, three regions are focusing attention on attracting semiconductor inward investment. These regions are the central belt of Scotland, stretching from the east coast around Edinburgh to the west coast around Glasgow, northern England, and South Wales.

In 1996, semiconductor companies with manufacturing locations in the United Kingdom, along with the U.K. government, founded the National Microelectronics Institute (NMI). The NMI's role is to coordinate and enhance the activities of all parts of the United Kingdom semiconductor industry's support infrastructure. Included in this is the development of supporting industries and the coordination of further- and higher-education activities related to the microelectronics industry, as well as facilitating cooperation between companies in noncompetitive areas.

The NMI treats the three geographic areas as a single cluster, given their relative geographical proximity, coordinating all its activities to assist each area equally. The NMI has, with semiconductor vendors, developed two further-education courses designed to supply the semiconductor industry with appropriately qualified operators and technicians. To date, four further-education colleges in Scotland, and 10 in the United Kingdom, offer these courses. The NMI has also created and had accredited a microelectronics MSc qualification for the development of engineer-level staff.

The main financial incentives provided to those considering investing in any of the three regions are, in principle, the same, although in the last round of inward investment, a peculiar situation occurred of two regions within the cluster trying to outbid each other. Regional Selective Assistance (RSA) is the main financial incentive and applies to all three regions. "Locate in Scotland" (the inward investment agency) and the Northern Development Agency say only that RSA is negotiable on an individual basis, but is based on levels of capital expenditure and jobs created. In addition to RSA, all three regions have enterprise zones, which attract additional benefits of exemption from property taxes for 10 years and 100 percent depreciation allowance for buildings in the first year of operation.

Investors in the three regions will also be eligible for training and employment grants. Typically, these grants cover up to 50 percent of training costs, with a maximum of £4,000 ($6,500) per eligible employee.

An example that shows other potential benefits for investors is available in Scotland, where other substantial benefits including site acquisition and preparation, as well as considerable assistance with site management costs, have been made available. An example of these is Hyundai's ongoing (and delayed) investment in Dunfermline. It was reported that the assistance package, which totaled £151 million ($250 million) for a total maximum investment of £2.3 billion ($3.8 billion), included amounts of £9.6 million ($16 million) for site acquisition, £23.4 million ($39 million) for site preparation (including new road infrastructure), and £9 million ($15 million) for waste treatment facilities.

Central Scotland

Since the mid-1970s, when National Semiconductor Corporation opened its first fabrication plant in Greenock, Scotland has recognized the increasing importance of high-technology manufacturing as a driver of national growth and large-scale provider of jobs. Since the 1970s, central Scotland has tried to reposition itself as the high-technology center of Europe, going so far as to coin the term "Silicon Glen."

The central belt of Scotland is home to six semiconductor companies, which have a total of 10 wafer fabrication plants between them, and two more plants are in planning or under construction. Central Scotland is therefore very adept at dealing with the requirements of semiconductor wafer fabrication plants.

In addition to the NMI infrastructure, central Scotland also houses 11 institutes and research centers related to the microelectronic industry. These are based at eight universities throughout the central belt region. Four of these universities are participating in a project with Cadence Design Systems Inc. to establish the world's first system-level integration institute. There are also 46 further education colleges, in and around the central belt, offering two-year electronic or electronic engineering courses.

Northern England

In addition to the region's participation in the NMI, northern England has a significant electronics-oriented training infrastructure, which produces more than 800 electronics-related graduates per year. In early 1998, the North of England Microelectronics Institute, a joint venture between the region's universities, Siemens, and Fujitsu Ltd., opened in North Tyneside. The £16.5 million ($26 million) site includes laboratories for testing post-wafer processing reliability and design fault analysis, together with a new interconnection research project.

The region also has two universities: the University of Newcastle upon Tyne and Durham University, both of which have a number of research groups related to the microelectronics industry. The University of Newcastle upon Tyne includes the Semiconductor Technology Group, the Microelectronic Systems Design Group, and the DSP Group. Durham University includes the Centre for Molecular Electronics and the Centre for Electronic Systems. Durham University also manages a course developed by Fujitsu and continued by Siemens to fulfill the educational needs of both companies.

Spain

Spain appears to be something of an enigma in terms of winning inward investment from the semiconductor industry. Since attracting Lucent Technologies to Madrid in the late 1980s, it has not brought in any other major semiconductor fabrication investment.

Spain has set up two scientific parks focusing on the semiconductor industry. The first is Valles Technology Park located just outside Barcelona, and the second is Tres Cantos Technology park in Madrid, where Lucent

Technologies has its wafer fabrication plant. In and around Valles Technology Park are the Spanish National Microelectronics Center, the Regional General Testing and Research Laboratory, and the New Materials Center, which is part of the Higher Center for Scientific Research. The National Microelectronics Center also has a site in the Tres Cantos Technology Park.

The principal financial incentive offered in Spain is for investment in certain regions. This is offered by the state and varies from 20 percent to 60 percent of a project's capital expenditure. However, neither of the scientific parks mentioned above falls into one of the qualifying regions. Thus, these parks receive no regional incentive from the Spanish central government. In addition to the central government regional aid, each autonomous region offers its own smaller-scale investment packages.

Spain has also created a $420 million high-technology fund called the ATYCA initiative, which will run until the end of 1999. The program is financed by the Ministry of Industry and Energy and can provide funding for the improvement of the technology infrastructure and training.

Dataquest Perspective

Potentially useful manufacturing locations are essentially products for which there is a very small, but valuable, customer base. When Europe started attracting semiconductor inward investment, each country's offerings were essentially commodities, where, typically for commodities, price played the pivotal role in deciding which country won the inward investment. Price in this marketplace was represented by the amount of cash a region or country would pay to convince the prospecting company to move to their location.

However, the market has moved on; in the marketplace of inward investment, the emerging key differentiator is the supply chain for appropriate human resources. Those regions or countries that develop a coherent and integrated road map to supply sufficient numbers of appropriate graduates and other technical staff will be the winners in attracting the quality inward investment projects in most cases.

For some companies, though, location will still be a commodity product, and price (in the form of capital grants) will still have a key role to play. It could be argued that AMD's investment in Dresden, Germany was a case where "price" was the determinant factor. In contrast, Intel's investment in Ireland was an occurrence where the differentiator won out over the highest bidder—the differentiating factor being the availability of staff at all levels of engineering expertise.

Some regions are farther along the differentiation curve than others. For those lagging behind, price, in the form of subsidies, will continue to be their major attraction. For some companies this may be enough, although the dynamic is changing. Companies are beginning to want more than just a massive cash handout at the beginning of a project. They now want to ensure the long-term future of their plants and maximize the value they add to the

©1998 Dataquest

company. On the other hand, countries want more than a cash-for-jobs equation, especially as the amount of cash required to win becomes unaffordable. They want investment in their communities and participation in their educational infrastructure. We may not have seen the last of the bidding wars that occurred in the fight to attract inward investment in the 1980s and early 1990s, but they will be fewer, as will be the participants involved in the fight. The next step for the inward investment market may well be its segmentation, on both the part of the semiconductor vendor and the regions.

Technology Analysis

Analog and Mixed-Signal IC Applications in Digital Cellular Phones

Abstract: *Digital cellular telephones represent one of the most important application markets for analog and mixed-signal ICs. Total consumption of analog and mixed-signal ICs in digital cellular phones, excluding RF ICs, is projected to exceed $1.9 billion by 2002. This Perspective examines the forces driving the success of the wireless market and the use of analog and mixed-signal IC in digital cellular phones.*

By Jim Liang and Dale Ford

Cellular Telephone Market Overview

The number of worldwide cellular/PCS subscribers has grown tremendously in the last few years. As this growth continues, the wireless handset market will expand from 124 million units in 1997 to 293 million units in 2002. Worldwide production of cellular telephone handsets is projected to grow at a solid 19 percent compound annual growth rate (CAGR) during the next five years, as shown in Table 1. Although analog handsets represented 38 percent of total production in 1996, digital handsets, growing at a CAGR of 24 percent, will account for 98 percent of worldwide production by 2002.

The digital handset market exploded in Europe during the 1990s as the European countries agreed on the unified standard, called the Global Standard for Mobile Communications (GSM). The European market had experienced very low cellular penetration rates before then. With the introduction of the GSM standard, which allowed easier roaming among countries, the market took off and quickly became the largest digital cellular market in the world. Many countries in other regions have adopted the GSM standard. The Americas market has been slower than expected to adopt

digital technology; as a result, digital handset shipments accounted for less than 10 percent of the total Americas handset shipments in 1996. However, the digital handset market in the Americas region has grown rapidly in the last few years and should continue to experience strong growth.

Further insight into the wireless market is available in Dataquest's Market Trends Report *Communications Application Markets—Cellular/Broadband PCS and Cordless Telephones* (CSAM-WW-MT-9707, December 1997).

How Cellular Phones Work

Cellular telephones involve a relatively low-power handset corresponding with a local base station, of which there are many. The area surrounding the base station is called a "cell," and this can be visualized as a honeycomb. This simple concept yields powerful benefits. The handset can be small and light because it does not need to transmit over long distances. A large number of subscribers can be connected simultaneously because their signals travel only short distances and do not overlap with those in other cells. Traveling phones moving from one cell to another during a conversation can be accommodated by a central control's handing over responsibility for the handset from one base station to another.

Analog Cellular Phones

Analog cellular telephones were the initial standard deployed in the early days of cellular telephony. Voices are transmitted and received using a time-division multiplexing scheme, in which periodic samples of the voice are frequency modulated (FM) on a carrier frequency. The advantage of an analog approach is a straightforward, minimal design for both handsets and base stations. A disadvantage, it turns out, is a lack of security for both the information (the voice) and the control signals the phone uses to stay synchronized with the cellular network. This minor technical issue became a major financial opportunity for some ethically challenged members of society, who "clone" telephone serial numbers to circumvent usage fees. Another segment of society was able to listen in on, and record, phone calls with simple scanning receivers. A better solution was needed.

Digital Cellular Phones

Digital cellular telephones were the answer to these issues. Instead of transmitting the voice as an FM signal, the signal was digitized and sent as ones and zeros over a network optimized for digital traffic. A major benefit of this change is the ability to service multiple handsets with a single operation frequency instead of tying up a frequency slot per handset, yielding a dramatic increase in network call capacity. Digital handsets also have better energy efficiency, yielding longer battery lives. Furthermore, encryption was added for both serial number and voice data, making cloning extremely difficult. The initial digital standard was a European product using the GSM standard; since then, other digital standards—code-division multiple access (CDMA, or IS-95) and time-division multiple access (TDMA, or IS-54 and IS-136)—have emerged.

Figure 1 shows a block diagram of a typical digital cellular telephone, which comprises a radio frequency (RF)/intermediate frequency (IF) section, and a baseband section. The RF/IF section handles transmission and reception of RF signals. The baseband section processes communication signals at baseband frequencies.

Figure 1
Digital Cellular Telephone Block Diagram

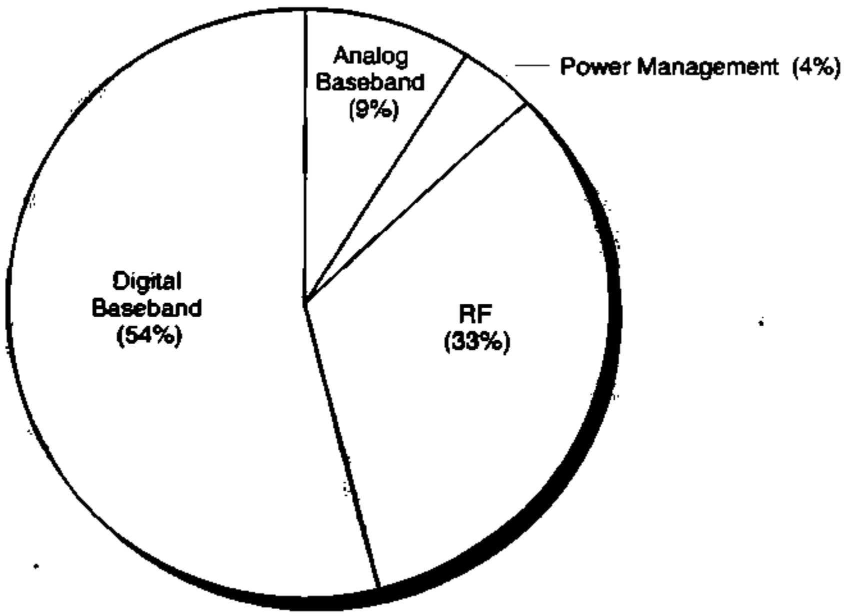
Analog and Mixed-Signal ICs in Digital Cellular Phones

The semiconductors used in digital cellular phones can be categorized into three major types: power management semiconductors, baseband semiconductors, and RF semiconductors. Power management semiconductors are involved in supplying power to the phone. Baseband semiconductors include digital baseband ICs and analog baseband ICs. RF semiconductors include RF ICs and discrete transistors and diodes. Figure 2 shows an estimated breakout of semiconductor content in today's typical digital cellular handsets.

Figure 2
Estimated Semiconductor Content in Digital Cellular Handset



Source: Dataquest (June 1998)

The digital baseband semiconductors include digital signal processors (DSPs), microcontrollers (MCUs), and memory. Power management ICs, analog baseband ICs, and RF ICs are the analog and mixed-signal ICs used in digital cellular phones, and these are discussed further in the following sections.

Power Management ICs

Power management in cellular phones represents one of the hottest applications for analog ICs, not only because of the growth of the cellular phone market itself, but also because of the increasing need for longer battery life (which translates into longer talk time) and higher performance.

Power management ICs in cellular phones, also called voltage regulators, provide regulated voltage supply to various sections of the phone. Voltage regulators convert one DC voltage to another DC voltage. In the broad category of voltage regulators, there are two subcategories: linear regulators and switching regulators.

Linear regulators can only step down, providing output voltage that is smaller than input voltage. Switching regulators, which consist of switch, inductor, rectifier, and capacitor, can either step up (or "boost") voltage or step down (or "buck") voltage. Linear regulators have the advantages of low noise and good transient response but the disadvantage of poor power dissipation on the pass element. Switching regulators, on the other hand, can provide higher levels of power with greatly reduced thermal problems, because the power transistor is on for only a small fraction of the total time.

As a result, switching regulators are favored today for use with Pentium II-based microprocessors because of the high power involved. In digital cellular phones, a special type of linear regulators called low dropout (LDO) regulators are used. This is because they not only have lower noise, which contributes to good RF performance, but they also provide very low dropout voltage, resulting in higher conversion efficiency. Typically, multiple LDO regulators are used in a cellular phone to supply voltages to different sections of the phone.

The drive toward longer battery life and higher performance has challenged LDO regulator suppliers. Longer battery life means high conversion efficiency from the LDO regulator, which requires low dropout voltage and low quiescent current; higher performance means good RF characteristics from the LDO regulator, such as high ripple rejection and low noise. LDO regulators have been available in three different process technologies: bipolar, CMOS, and BiCMOS. Bipolar LDO regulators provide low noise but have the disadvantage of high dropout voltage and high quiescent current, which contribute to shortened battery life. CMOS LDOs offer very low dropout voltage and quiescent current orders of magnitude lower than bipolar LDOs, but they have higher noise. BiCMOS LDOs employ a bipolar pass transistor for high ripple rejection and hence low noise and CMOS circuitry for reduced quiescent current, but they still fall short in the area of low dropout voltage, compared to CMOS LDOs. The BiCMOS solution probably offers the best performance of the three options, but the cost of using a BiCMOS process is higher than that of straight CMOS. There certainly exist ample opportunities for more innovative solutions that provide "ideal" LDO regulators for cellular phones at the lowest cost.

The major players participating in the power management arena for digital cellular phones include National Semiconductor Corporation, Micrel Semiconductor Inc., Linear Technology Corporation, Maxim Integrated Products Inc., Texas Instruments Inc., SGS-Thomson Microelectronics B.V., Toko Inc., and Impala Linear Corporation. Table 2 lists all the major players, with comments on their competitive positions. Dataquest does not provide power management IC revenue estimates for individual suppliers of ICs for digital cellular because they have not been surveyed at this detailed level.

The total power management IC market in 1997 is estimated to be about $2.5 billion, and the total value of power management ICs used in digital cellular phones in 1997 is estimated to be about $291 million.

 ©1998 Dataquest

Table 2
Major Players in Power Management ICs for Digital Cellular Phones

Companies	Comments
National Semiconductor	First to market with LDO regulator solution for wireless market; the current market leader
Micrel	Fast-growing new entrant; gaining market share
Linear Technology	Specializes in high-performance LDOs
Maxim	Specializes in high-performance LDOs
Texas Instruments	Made significant inroads in 1997 in power management to complement its DSP and mixed-signal leadership in cellular phone market
SGS-Thomson	Expertise in power processes; close relationship with Nokia and Ericsson
Toko	Specializes in low-cost LDOs
Impala Linear	Start-up company specializing in high-performance CMOS LDOs

Source: Dataquest (June 1998)

Although there is increasing trend to integrate separate functions of the cellular phone into a single chip, power management will likely remain independent because of the complexity of the analog processes involved in making power management ICs. Furthermore, the increasing need for longer battery life and higher performance will continue to stimulate the growth of power management solutions. As a result, power management ICs in digital cellular phones are projected to grow at a strong CAGR of 18 percent for the next five years, from $291 million in 1997 to $665 million by 2002.

Analog Baseband ICs

The analog baseband functions include voice coder/decoder (CODEC), and RF CODEC. The voice CODEC, linking the digital baseband to the microphone and speaker, sends a user's voice to the digital baseband and allows the received signal to be heard through the earphone speaker. The RF CODEC, linking the digital baseband to the RF subsystem, converts an outgoing digital data stream from the digital baseband into a modulation format appropriate to the transmission standard and converts an incoming signal received by the RF subsystem for further processing by the digital baseband. These two analog baseband functions, often referred to as baseband interface functions, provide an analog front end to digital communication systems and not only link digital baseband with users' voices and RF signals but also carry a great deal of the processing workload, such as maintaining signal quality, extending talk time, and improving overall system performance.

Unlike power management, where analog technology is key, the name of the game in supplying analog baseband CODECs is mixed-signal technology. Only companies with both analog and digital design and process expertise can compete well in this market. The major players that supply analog baseband CODECs include Texas Instruments, Motorola Incorporated, Lucent Technologies Microelectronics Group, NEC Corporation, Philips Semiconductors Inc., Siemens AG, VLSI Technology Inc., QUALCOMM Incorporated, DSP Communications Inc., and Analog Devices Inc. Table 3 lists the major players, with comments on their competitive positions.

©1998 Dataquest

Dataquest does not provide analog baseband revenue estimates for individual vendors because they have not been surveyed at this detailed level.

It is evident that all these suppliers have very significant mixed-signal expertise. And not surprisingly, the four leading DSP suppliers—Texas Instruments, Lucent Microelectronics, Analog Devices, and Motorola—are all active players, aiming to offer complementary mixed-signal DSP solutions for the wireless market. Furthermore, some of the players are vertically integrated wireless OEMs themselves, with in-house semiconductor business units that supply both internal and external customers.

The total analog baseband IC market for digital cellular phones in 1997 is estimated to be around $641 million. Since there is an increasing trend toward integrating the analog baseband CODECs and the digital baseband functions onto a single chip, the analog baseband ICs are projected to grow at a moderate CAGR of 14 percent for the next five years, from $641 million in 1997 to more than $1.2 billion by 2002.

Table 3
Major Players in Analog Baseband ICs for Digital Cellular Phones

Companies	Comments
Texas Instruments	Major supplier to first-tier OEMs Ericsson and Nokia; in-house DSPs
Motorola	Wireless OEM itself; in-house DSPs; trying to shift away from analog cellular and ramp up digital cellular
Lucent Microelectronics	In-house DSPs; announced an integrated DSP and voice CODEC chip for CDMA
NEC	Strong system-level ASIC technology
Philips	Wireless OEM itself with in-house semiconductor unit
Siemens	Wireless OEM itself with in-house semiconductor unit
VLSI Technology	Supplier of baseband ASICs for GSM
QUALCOMM	Wireless OEM itself; strong player in supplying baseband chipsets for CDMA
DSP Communications	Supplier of baseband ASICs for TDMA and CDMA; licensed CDMA technology from QUALCOMM
Analog Devices	Supplier of GSM chipsets to wireless OEMs such as Philips and Siemens

Source: Dataquest (June 1998)

RF ICs

RF ICs are mainly amplifiers, transmitters/receivers, and synthesizers. Amplifiers include power amplifiers for transmission of the radio signal and low-noise amplifiers (LNAs) for reception of a radio signal. Transmitters/receivers, along with synthesizers, handle many of the transceiver modulation/demodulation functions.

RF amplifiers represent the largest segment within RF ICs. A large portion of amplifiers, especially the power amplifiers supplied for cellular phones today, are based on gallium arsenide (GaAs), with the major players being Anadigics Inc., TriQuint Semiconductor Inc., and RF Micro Devices Inc. The other RF ICs, such as transmitters/receivers and synthesizers, are mostly silicon-based and made with a bipolar process. The major suppliers of transmitters/receivers include Hewlett-Packard Company, Motorola, Philips, Siemens, and NEC; the major suppliers of synthesizers include National Semiconductor, Motorola, Philips, and Fujitsu Ltd.

Texas Instruments has thrived on supplying baseband semiconductors for the digital cellular market. In a move to provide full solutions for the digital cellular market and lay the groundwork for the single-chip cellular phone, TI has announced its own RF products such as LNAs, receivers, and synthesizers, and is expected to announce power amplifier products in the near future. More detailed analysis of TI's wireless move is available in the Dataquest Perspective "Texas Instruments and its New Analog Thrust" (SEMI-WW-DP-9804, May 1998).

Silicon germanium (SiGe) technology has emerged as a potential alternative to GaAs and silicon technologies. The primary advantage of SiGe technology is that it leverages traditional silicon CMOS and bipolar processing to achieve higher-frequency performance and reduced power consumption. IBM has been the leading proponent of SiGe technology for the wireless market and has developed extensive SiGe technology in-house over the past few years. In a move to remedy its lack of wireless design expertise, IBM acquired CommQuest Technologies Inc., a chip design house known for its wireless communications design skills. With CommQuest's wireless know-how and its own pioneering SiGe effort, IBM has laid plans to provide single-chip cellular solutions, including RF and baseband parts, using its SiGe technology.

A more detailed analysis of RF semiconductors for wireless applications, including an RF IC market size forecast, will be available from Dataquest's Wireless Semiconductor Application Markets Worldwide (WSAM-WW) program, to be launched in July.

Analog and Mixed-Signal IC Market Size Estimate

Table 4 shows current market size estimates and growth projections for power management ICs and analog baseband ICs in digital cellular phones. Total consumption of analog and mixed-signal ICs in digital cellular phones, excluding RF ICs, is projected to exceed $1.9 billion by 2002. The RF IC market size and projections will be published by Dataquest's Wireless Semiconductor Application Markets Worldwide program.

Table 4
Digital Cellular Handset Consumption of Power Management and Analog Baseband ICs

	1996	1997	1998	1999	2000	2001	2002	CAGR (%) 1997-2002
Units (K)	48,789	98,600	131,200	165,185	205,705	247,550	288,925	24
Power Management ($M)	178	291	365	443	518	592	665	18
Analog Baseband ($M)	398	641	771	894	1,018	1,136	1,245	14
Total ($M)	575	932	1,136	1,336	1,537	1,728	1,910	15

Dataquest Perspective

Although the remarkable growth of the PC market in the last decade has been the driving force behind the growth of semiconductors, Dataquest believes the communications market, including wireless communications and wired communications, will join the PC market as driving forces behind semiconductor growth for the next decade.

The surge in sales of digital cellular telephones has provided tremendous profit opportunities for companies supplying this market. With further penetration of digital cellular in underdeveloped regions of the world, the digital cellular market will continue to expand. Dataquest believes that analog/mixed-signal and RF technologies will be among the key weapons that allow semiconductor vendors to win in this expanding wireless market.

Semiconductors Worldwide

Market Analysis

Integrated Circuit Packaging, 1998

Abstract: *As IC package design transcends to emerging flip chip, ball grid array (BGA), and chipscale package (CSP), proliferation of designs haunts both suppliers and users. It took the package industry over 10 years to shift its focus from through-hole to surface-mount technology (SMT). Package proliferation abounded with every new product and application. Package architectures became both product and application specific. It was a costly experience for both supplier and user. If this trend continues, what changes should one expect over the horizon?*
By Mary Ann Olsson

The Industry in 1997

If you are involved in any aspect of the semiconductor packaging world, then you are definitely experiencing a case of déjà vu. At a recent seminar on the use of advanced packaging materials challenges, arguments broke out about the proliferation of chipscale packages (CSPs), the lack of standards, and the probability of materials suppliers, package designers, and fab engineers working together to overcome today's package challenges.

The French have a great expression for this: *Plus les choses changent, plus elles restent le même,* which translates as, "The more things change, the more things remain the same." Surface-mount technology (SMT) entered the realm of semiconductor packaging in early 1970. The arguments over package proliferation, the lack of standards, and the advantages or disadvantages of small-outline (SO) packages over through-hole packages still held the industry in awe in 1984. The desire to compete with Japan and the shift in level of integration from large-scale integration to very large-scale integration (LSI to VLSI) prompted Texas Instruments Inc., Signetics Company, National Semiconductor Corporation, and Motorola Incorporated

Dataquest

Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

to invest heavily in surface mount equipment and assembly facilities. At that time, SO package costs were about 25 percent higher than the traditional through-hole designs.

By 1988 SMT package designs represented only 28 percent of all IC packaged devices shipped worldwide. By 1992 SMT reached 60 percent of IC packaged parts shipped. The level of integration was now in the middle of ultra-large-scale integration (ULSI), with device feature sizes dropping from 1.25 micron to 0.5 micron. Package proliferation was abundant as suppliers inundated users with numerous variations of SO and quad flat pack (QFP) designs. On the horizon, IBM projected a market of the future that would have to deal with 600-MHz microprocessors by 2000. Other mainframe and workstation vendors promoted the benefits of multichip modules and complex single-chip designs for 1997 and 1998 production. Wire bonder manufacturers and materials suppliers were in R&D stages, preparing for the onset of a flip-chip technology ramp-up by 2000.

It is now midyear 1998. The search goes on for the ultimate package. Motorola once described this as the universal package with only three leads: one lead for power, one for ground, and a third for a multiplexed fiber-optic link. However, the market remains inundated with multiple categories of package styles. Standards procedures are still long and arduous. However, there is evidence of change and improvement in how materials suppliers, package designers, and fab engineers work to form a cohesive process flow.

Table 1 represents the package categories for all semiconductor devices shipped in 1997. Each category has multiple subcategories of package styles and sizes that are too numerous to list in one Perspective.

Table 2 is an example of only one package subcontractor's capability in chip-size BGAs. Dataquest is not marketing one company's capability over another's. This is merely one example of package proliferation. Virtually every semiconductor supplier and package subcontractor now offers BGA and CSP package designs, as well as most other package styles listed in Table 1. Some have licensed other company designs, as well as patenting their own company designs.

The cost for manufactured plastic BGAs has reached parity with comparable plastic QFPs. The cost for CSPs varies by supplier and design and ranges by volume from 25 to 30 and even 50 percent higher than comparable thin small outline plastic (TSOP) and shrink small outline plastic (SSOP) designs, as shown in Table 3. If volume production ramps up in 1999 for CSP designs, especially in the low pad count range, CSPs could reach parity with some TSOP designs.

The Future of Packaging

Table 4 lists the unit shipment forecast for just IC packages. Table 5 lists the share of total shipments for IC packages. These tables do not include data for optical or discrete packaged devices. As noted in Tables 1, 4, and 5, SO packages dominate the market through the forecast period. The

 ©1998 Dataquest

microprocessor and ASIC devices will drive the need for high-performance and higher pin count (108-pin and above) package designs in both plastic and ceramic. The need will be for both single chip and multichip, using BGA and flip-chip attach, as well as older QFP and PGA designs.

The older PGA designs will decline in share while microprocessor giants such as Intel Corporation migrate to ceramic and plastic BGA and eventually even to advanced ceramic and plastic CSP designs. As noted by Evan Davidson (1998 IEEE Symposium, "Long Lossy Lines (L3) and Their Impact upon Large Chip Performance," IBM) at the 200-MHz MPU, internal delays on the clock rates were a problem; the effects worsened as the die grew larger and the ground rules got smaller. Many designers do not have the wire capacity allowances and cannot wire the design. Intel's Ricardo Suarez-Gartner suggested (1998 IEEE Symposium, "System Technology Challenges Facing the PC Industry") that the design challenge was to get the mostly small, multiple component suppliers to work together on the up-front design. With each process improvement, from 0.35-micron down to 0.09-micron, the component challenge would be a package challenge.

Beyond the Pentium II, Intel sees a heavy investment in flip-chip technology, but it admits that the magic will be the interaction of its chip's compatibility with the PCB and the other system components. What are future solutions for microprocessor and ASIC designers? Other solutions in R&D stages are die-packs or smaller cores. Die-packs are in reality small multichip modules (MCMs) that would use thin-film wiring in a BGA carrier. The BGA carrier would consist of four small chips instead of one big, complex chip. For ASICs, fine-line and enhanced BGA packages are addressing ASIC vendors' solutions to high input/output (I/O). These BGA designs are sufficient for complex ASIC designs with higher levels of integration and increased I/O counts that also need to address system-level miniaturization. An example of this type of development, from Altera Corporation, is shown in Table 6.

Table 3

The SO family of packages has long been the mainstay for memory, analog, standard logic and discrete devices. This has been the most cost-efficient and reliable surface-mount package available to the largest product sector of the market. It first grew in acceptance and in variation in Japan in the consumer electronics boom of the early 1980s and via selected digital products that required higher-density packaging. SO designs were the great contributor to memory module manufacturing and the eventual growth of the desktop PC market. On the horizon, CSP designs may be the package that displaces the SO.

The CSP package is now in production for flash memory devices. Some of the DRAM companies are evaluating CSP and lead-on-chip (LOC) designs for the 64M- and beyond generations of DRAMs. For many DRAM manufacturers, the SO and TSOP designs remain the most cost-effective, reliable product for most applications. CSPs are chip-size or slightly larger than chip-size in scale, as illustrated in Figure 1. In Xilinx Incorporated's complex programmable logic device (CPLD) product, the footprint of the 48-pin CSP is three times smaller than that of the 44-pin, very thin QFP.

Just as the consumer market initially drove the need for miniaturization of the devices in the 1980s, the new pocket-size consumer market, as well as portable and wireless applications, will drive the need and growth for this next generation of SMTs, the CSPs. Some of the new application designs incorporating the smaller CSP as well as BGA and flip-chip technologies are listed in Table 7.

Ultimately, 1997 was the turning point for increased demand for all of the new and emerging advanced package designs such as flip-chip attach, MCMs, BGAs, and CSPs. The new portable and consumer market applications were part of this enabling structure.

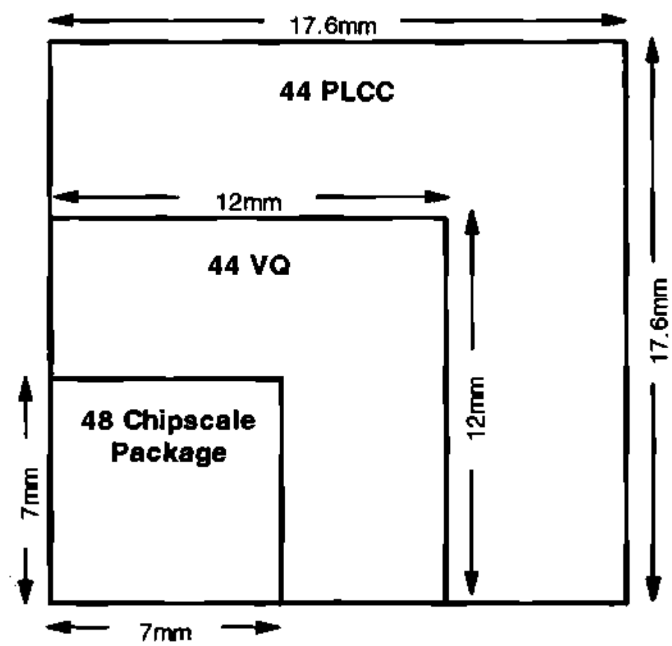
Challenges on the Horizon

Perhaps the biggest challenge for today's package designer is the shrinking cycle time. Proliferation of packages may be a marketing department's answer to addressing all customer and all application needs, but who will bear the cost, when the lowest cost is a major challenge. Equipment cycle time for many companies, especially those in the data processing and communications sectors, is now less than 18 months. Design cycles for equipment and semiconductor components are short and small. Even if a company could design something sophisticated or complex, does it have the time?

The semiconductor industry is in the throes of silicon transition. Whether designers like the transition or not, the users are making the calls. Intel is one company listening and heeding the call with leading-edge microprocessors in multiprocessing systems. Lucent, Texas Instruments, and Analog Devices Inc. are hot on the trail with embedded DSP, embedded microcontrollers, and embedded ASIC and mixed signal in ASSP devices. System-level integration, the enabler of smaller form factor and more feature-rich function, is according to Lucent Microelectronics, "the technical springboard that companies like cellular phone manufacturers need to differentiate their product." As the industry matures or shrinks, depending on one's outlook, the basic packaging infrastructure in place today may not be suitable to address the needs of the very near future.

Figure 1
Chipscale Package Size Comparisons



Source: Xilinx

In today's market, there is no time. More ICs are moving to modules or to self-contained units or cards. Modules are basically "idiot proof." They are easy to plug in anywhere. They plug into a cellular phone or a PC board, and they are present in every new application. The package industry of the future may look very much like a card I/O or an Intel kit.

If the package is indeed the primary barrier to development of many of the high-performance systems beyond 2000, how does today's industry improve or ready its infrastructure to survive the changes and challenges?

Flextronics International Ltd. is one of many companies that is building part of the infrastructure need. Other companies include Fujitsu Microelectronics Inc., IBM, and Flip Chip Technologies L.L.C., as well as most of the foundry companies such as Chartered Semiconductor Manufacturing Pte. Ltd., Taiwan Semiconductor Mfg. Co. (TSMC), and United Microelectronics Corporation.

Through either alliances or shared facilities, or as full turnkey manufacturers, these companies provide all levels of package integration: from wafer level through test and burn-in, through box, pack, and ship to customer types of services. Basically, they have become a one-stop shopping mall for the industry.

Flextronics has expanded its service developments during the last 18 months. It has increased its operational square footage to over 2 million, and as of the first quarter 1998, manufacturing facilities were running at full capacity. From product design to PCB fabrication, materials procurement and inventory management, final system assembly and test, packaging, and distribution, the company obviously fills the need for many customers.

Table 7
Emerging Package Application Opportunities

Products	Companies	Key Product Features	Key Package Features
Palm-Size PCs	Texas Instruments, Casio, Everex, Philips Electronics, 3Com	Voice command and voice recorders, alarms	CSP, MCM, BGA, flip chip
Handheld Portables	Philips Electronics, Sharp, NEC, Psion plc, Ericsson Mobile Computing AB, Hewlett-Packard, Geofox Inc., Casio, Compaq	Color screen, flash memory expansion slots, ROM card slots, PCS phone compatibility, camera card plug-in capability, touch-type keyboard, modem and memory expansion slots	COB, COF, flip chip on flex, CSP, MCM, BGA, TAB, SO
Smart Phones	Nokia Mobile Phones, Samsung Electronics, Alcatel, Philips Consumer, Motorola, Lucent, Hyundai, LG Information & Communication	Portable digital GSM, cellular CDMA, desktop, speech coding, security, PC card slots	Flip chip on flex, COB, CSP, MCM, BGA, TAB, SO
Automotive PC	Intel, Motorola, Microsoft, Chrysler, Daimler-Benz	Windows CE, connector card PC, desktop PC card slots, modem slots	COB, flip chip, CSP, MCM, TAB

Source: Dataquest (June 1998)

Flextronics and others have grown as a result of semiconductor suppliers outsourcing package design, manufacturing, and assembly services. In their own way they have leveraged their skills in materials procurement while reducing cycle time and costs for themselves and their customers. Package proliferation and standards chaos may be with us for quite a long time. The full-service provider, such as Flextronics, is gaining in popularity and may displace many of the small service providers along the way to growth.

Perspective

Semiconductors Worldwide

Market Analysis

Worldwide Semiconductor Quarterly Outlook: Spring 1998

Abstract: *Dataquest forecasts for worldwide semiconductor consumption are reviewed and analyzed in the context of the Asian financial crisis, delays in the production transition to 300mm technology, the booming U.S. economy, and trade issues. While the semiconductor industry as a whole appears to be healthy, with positive or recovering growth prospects in all regional markets during the current year, these optimistic forecasts should be tempered with some caution.*

By Junko Matsubara

Mixed Signals from the Industry

The U.S. economy appears to be on an upswing. Unemployment is at a 28-year record low, the stock market is at record highs, inflation is in check, and consumer confidence is responding to the positive conditions. This should translate into higher levels of domestic electronic hardware sales and thus generally benefit the semiconductor industry. Unfortunately, as has happened in the past, the semiconductor industry is not always in complete synchronization with the rest of the U.S. economy. This time the reasons are relatively clear. The semiconductor industry is trade intensive, and Asian markets for both chips and chipmaking equipment are depressed. The high contrast between the economic state of the United States and most of Asia has put some unusual forces into play in Silicon Valley. While some companies are being forced to reduce their workforce by double-digit percentages, other companies, notably Internet service providers, can't get enough new hires to fill all their openings. The shortage of affordable housing suggests that new job openings in the valley still outnumber the jobs being lost to downsizing.

FILE COPY:
MARIA VALENZUELA

Despite the outward appearance of prosperity and growth, there are reasons to be concerned. How long will the current conditions last? Will the high-

growth areas of the Internet lead to a rapid rebound for semiconductor equipment makers? If equipment makers found any signs of a recovery in the short term, it seems unlikely that they would submit their companies to the hardships of workforce reductions. Nevertheless, predicting these markets with the many underlying forces at work is becoming as complex as predicting weather changes, and Dataquest does not use supercomputers for its forecasting. Besides, even with its supercomputers, the U.S. weather service still failed to predict the tornado that touched down recently in the middle of Silicon Valley, for the first time in 50 years.

This Perspective discusses some of the salient issues that will help answer some of these questions. Dataquest forecasts for the five-year growth rate of the major semiconductor markets will also be reviewed.

Company Financials: Not Always the Complete Story

Table 1 shows the year-to-year change in the first quarter sales and gross profit margin for 16 major semiconductor companies. No Asian companies are represented because they do not generally issue quarterly results.

Table 1
Semiconductor Companies' Financial Results, Q1/97 and Q1/98 (Thousands of Dollars)

	Net Sales Q1/97	Net Sales Q1/98	Net Sales Change (%)	Gross Margin Change (%)	Net Income Q1/97	Net Income Q1/98	Net Income Change (%)
Micron Technology	876,200	755,400	-13.8	-22.0	16,565	-48,000	-389.8

Source: Company literature, Dataquest (May 1998)

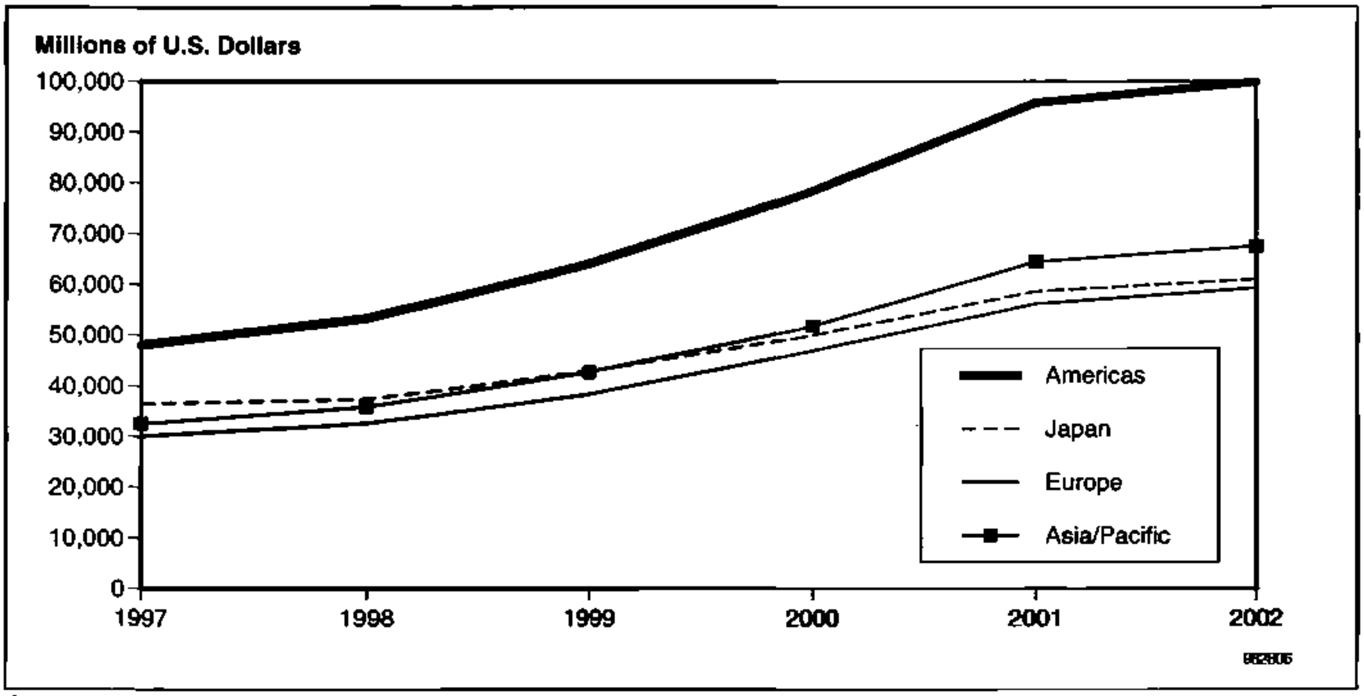
Based on these figures, it appears that Applied Materials Inc. and Lucent Technologies had the best performance through the first quarter, with strong growth in both sales and gross profit margins. Despite this performance,

 ©1998 Dataquest

Applied Materials and other equipment supplies are forecasting slower sales in the short term based on canceled or falling order rates. Lam Research Corporation also did well during the fourth quarter, recording the highest increase in growth profit margin of the 16 companies we investigated. However, Lam Research has already taken evasive action in preparation for revenue declines by having several rounds of layoffs. Its troubles are not unique, but rather a direct result of many chip manufacturers' decisions to delay upgrades to the new 300mm wafer-fabrication technology. This has delayed the return on the R&D investments that equipment manufacturers put into developing the new technology.

As Figure 1 shows, Dataquest forecasts that the Japanese, European, and Asia/Pacific regional markets will all be outpaced by the growth of the Americas semiconductor market in the next few years. This will have important implications for equipment manufacturers, which are the most dependent on international sales. For these companies, there will likely be a two-year slowing, followed by a rebound, assuming that Asian manufacturers solve most of their other problems related to their domestic economies.

Figure 1
Semiconductor Consumption Forecast by Region



Source: Dataquest (May 1998)

Among semiconductor vendors, Micron Technology Inc. derives the largest percentage of its revenue from commodity dynamic RAM (DRAM) memories, and it also showed the weakest financial performance in our roundup. The company's performance was indicative of the soft DRAM markets and probably representative of the declining profitability being experienced by both South Korean and Japanese semiconductor vendors. Although Micron remained profitable in the first quarter of 1998, it had only

©1998 Dataquest

a 3 percent gross profit margin, compared to the double-digit profit margins of the other 15 companies shown in the table.

Other DRAM vendors such as Texas Instruments Inc. and IBM fared significantly better, with more than 30 percent gross profit margins, mostly because of their size and diversified product lines. At the time of this writing, there is speculation that TI is preparing to exit the DRAM business by selling its facilities to Micron in exchange for Micron stock. This would serve to insulate TI's financial performance from the fluctuations in the DRAM markets, while still providing it with both an investment in, and future source of, DRAM products. A move like this would allow TI to focus its resources on its digital signal processing (DSP) and logic businesses to better compete with the likes of Motorola and the surging Lucent Technologies. Lucent registered net sales during the first quarter that exceeded even Intel Corporation's. Analog Devices, another major player in DSPs, also did well during the first quarter as one of the highest performing of the smaller semiconductor companies.

The year-to-year change in the first-quarter sales and gross profit margin were down substantially at microprocessor giant Intel and its most visible competitor, Advanced Micro Devices Inc. In Intel's case, the changes in sales and profitability are somewhat misleading. The company still had a 54 percent gross profit margin during the first quarter, the highest among the companies being reviewed. The declines in profitability are the result of the shift in the sweet spot of the PC markets to lower-cost machines. Many buyers are now finding that the performance of "value-line" machines is sufficient to meet their application needs while running on Windows 95. AMD's difficulties with low profitability stemmed more from manufacturing problems than from any flaws in its market or product strategy.

The Asian Financial Crisis

In the many ongoing debates about the impact of the Asian crisis on the U.S. economy, the majority of analysts now seem to speculate that the impact will be minimal. However, the reality of the situation is that no developed country or region can prosper indefinitely without robust trade with other countries. The last recession that the United States experienced in the early 1990s was due, in part, to the trade imbalance. Trading partners successfully exported their products into the U.S. market but failed to appreciate the importance of balancing their exports with a sufficient flow of imports of U.S.-made products into their own home markets. This led to a prolonged period of trade deficits and an unsustainable balance of payments, which eventually culminated in the loss of jobs and a slower economy in the United States. Inevitably, the U.S. recession resulted in a lack of funds to continue purchasing foreign-made imports, which, in turn, put a damper on trade with Asia. This sent Japan, in particular, into an even more severe recession than the one initially experienced by the United States. The circumstances that caused this chain of events could reoccur in the absence of a balanced flow of goods between the United States and its Asian trading partners. The

 ©1998 Dataquest

widespread decline of the Asian economies offers further substantiation of how dependent these economies are on trade.

The optimistic projections of so many U.S.-based analysts forecast minimal impact on the U.S. economy from the Asian crisis. However, it is important to recognize that these models implicitly depend on the recovery of Asian economies within a certain time frame. The longer the recovery takes to occur in Asia, the greater the impact on the U.S. economy. U.S. analysts have incentives to downplay the impact from Asia because no one wants to be the cause of an investor panic that results in a stock market "adjustment."

Moreover, the claims by many analysts that the U.S. economy is too healthy to be affected by the problems in Asia sound all too similar to the arguments put forth by Japanese analysts in the early 1990s just before the bottom fell out of their economy. Similar to current suggestions about the U.S. economy, those analysts claimed that the Japanese economy was simply too healthy and insulated to be affected by the U.S. recession. After all, Japan had a big trade surplus and lots of money. The problem with their reasoning was that Japan had basically accumulated too much money. The country was so cash rich that its trading partners had depleted their capacity to buy more Japanese products. Less cash meant reduced trade, and the rest is recession history.

Another way to think of the interaction is that if one country continues to export goods to another country without importing a similar amount of goods, the total number of goods available to the combined population is lower, and the standard of living of the combined population is therefore reduced. It doesn't matter whether the country exporting more than it imports does so because it finds no demand in its own markets for foreign goods, or because it genuinely has no funds with which to purchase imports. It is not cash that increases the standard of living of the global population, but total employment and high global productivity.

The trade conditions that now exist between the United States and Asia are similar to those that preceded the last recession in the United States. Americans are increasing their purchases of imported goods, while Asian countries are spending more conservatively, as expected, in these uncertain economic conditions. The result may well be a trade deficit with Asia that continues to expand as long as the Asian economies remain depressed. Consumer confidence in Asia will need to recover before U.S. exporters see a significant rise in demand for their products. While the circumstances for lower exports from the United States to Asia may be a bit different now than those that existed earlier in the decade, the impact on the U.S. economy is potentially the same.

Semiconductor Market Forecast

In semiconductors, Dataquest forecasts that the U.S. consumption rate will easily outpace the consumption growth rates in the other major areas of the world, which includes Europe, Japan, and the Asia/Pacific regions. This is shown in Figure 1 and Table 2.

Table 2
Semiconductor Consumption Forecast by Region (Millions of Dollars)

	1997	1998	1999	2000	2001	2002
Americas	48,086	53,326	64,133	78,388	95,782	99,906
Japan	36,499	37,397	42,943	49,988	58,610	61,093
Europe	30,046	32,627	38,425	46,927	56,152	59,336
Asia/Pacific	32,534	35,899	42,754	51,751	64,483	67,561
Total	**147,165**	**159,249**	**188,255**	**227,054**	**275,027**	**287,896**

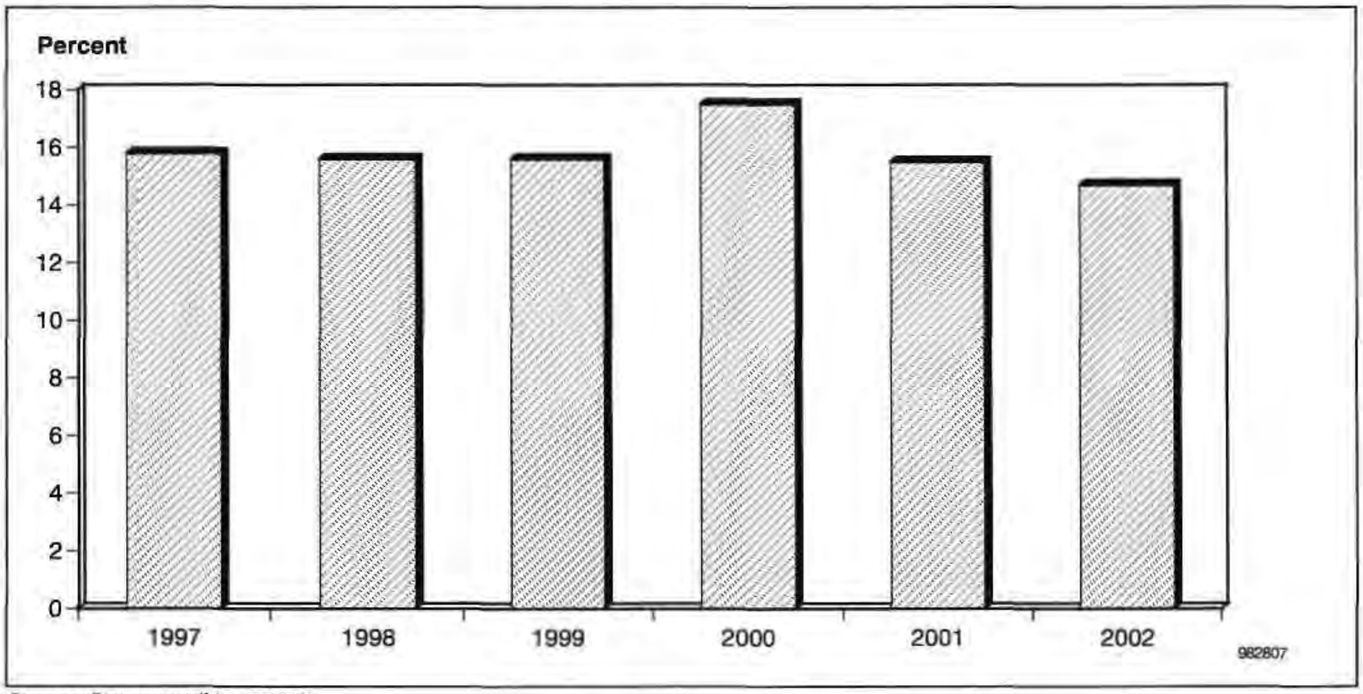
Source: Dataquest (May 1998)

Of the four major regions, Japan was the only one that experienced a contraction of its semiconductor consumption in 1997. Furthermore, Dataquest is anticipating that the Japanese semiconductor consumption will show far lower growth than the rest of the world during 1998, making the consumption curve nearly flat in Japan during the current quarter. The Americas semiconductor consumption level was roughly equal to the Japanese market in 1992, and by next year the Americas market is expected to have more than 1.5 times the semiconductor consumption level of Japan. Thus, the short-term outlook for Japanese system vendors, the consumers of semiconductors, is not encouraging. This escalating disparity in the consumption rates between the United States and all other countries is alarming in itself, even if it is just in the semiconductor sector. It suggests a growing trade imbalance that would naturally lead to economic resistance to further separation of the consumption rates.

Figure 2 shows the Dataquest forecast for the growth rate of worldwide PC shipments in the next five years. Over five years, beginning in 1998, the compound annual growth rate (CAGR) is expected to be 15.8 percent, which is in general agreement with the 14.6 percent CAGR of the worldwide semiconductor market over the same five-year period. A similar consistency exists between the Americas' five-year semiconductor market CAGR, at 15.7 percent, and their PC market CAGR of 14.8 percent for same time period. However, both the Asia/Pacific and Japanese regions have a greater disparity between their PC market CAGRs of 25.3 and 14.4 percent, respectively, and their semiconductor market CAGRs of 15.7 and 10.9 percent, respectively. In both cases, this forecast suggests that the supply of foreign-made PCs will grow at a faster rate than the sale of PCs made by domestic firms, assuming that the growth of the semiconductor markets in these regions is a reasonable gauge of PC production growth.

Although it does seem clear that the Japanese have very different PC-buying practices from their U.S. counterparts, the slowdown of PC sales in Japan is disconcerting. Price barriers, which vanished a few years ago, have begun to reappear, despite the rapid declines in mainstream PC prices on world markets during the past year. A weak yen may be partly to blame, but cannot alone account for the lack of penetration in the Japanese home markets. The Internet is apparently not driving PC sales in Japan to the extent it is in other countries, where sub-$1,000 Internet-ready PCs are the volume leaders. In contrast, mobile computers, particularly mininotebooks, appear to be the PC product leaders in Japan. The average selling price in Japan is closer to $2,000. These facts may confirm the hypothesis that Internet-browsing performance is a primary consideration in determining the suitability for home PC purchases in the West and hence has helped push the sub-$1,000 PC into the mainstream. Since the Internet is less pervasive in Japan, consumers there are not yet using these criteria in their buying decisions. Therefore, Japanese purchasers are more skeptical of the lower-cost machines in the way that U.S. buyers were once wary of some of the first-generation PCs that targeted the home markets.

Figure 2
Worldwide PC Shipment Growth Rate Forecast



Source: Dataquest (May 1998)

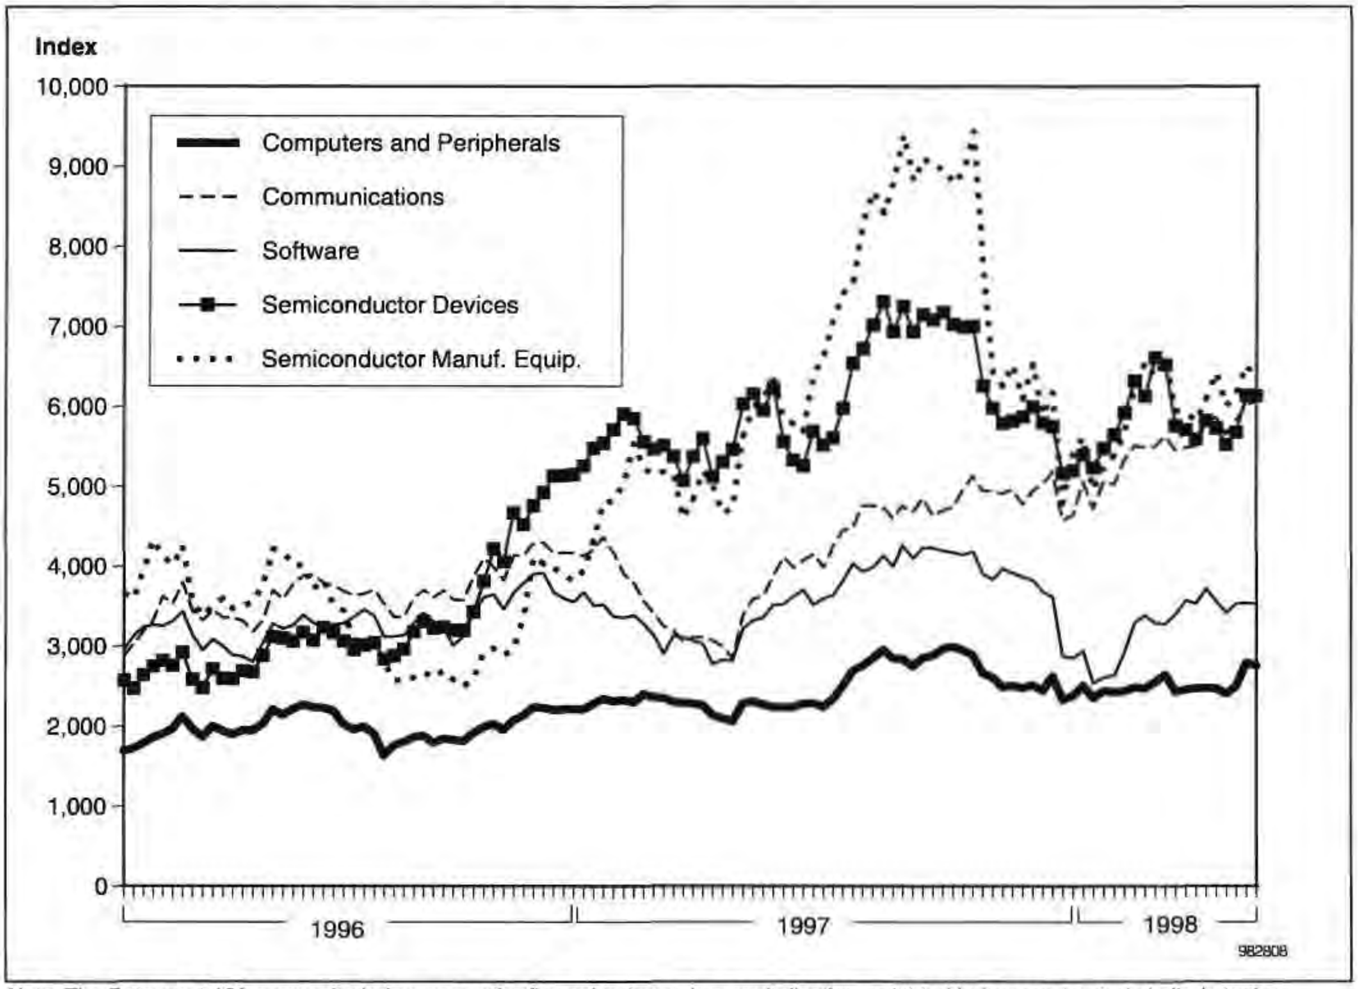
Dataquest projections for semiconductor market growth suggest that the annual change in the growth rate of global consumption will remain positive for at least the next few years. The expected deceleration of growth around 2001 would coincide with the end of a silicon growth cycle that began in 1995. If this prediction materializes, historical trends would then show that the so-called silicon cycle would have slowed in frequency, with an average period of four years during the 1980s to a 50 percent-larger, six-plus-year period during the 1990s.

Silicon Valley Stocks: The Internet Frenzy

Components of the Dataquest 100 high-technology stock index are found in Figure 3, which shows the average weekly stock performance of Silicon Valley companies from the semiconductor, equipment, PC, software, and telecommunications industries as separate curves.

 ©1998 Dataquest

Figure 3
Dataquest 100 Weekly Index, 1996 to Q1/98



Note: The Dataquest 100 composite index, as are the five subindexes, is a capitalization-weighted index constructed similarly to the Standard & Poor's S&P 500 Index. The indexes are set equal to 1,000 in the base period December 31, 1992. A list of companies included in the Dataquest 100 is available on request.
Source: Dataquest (May 1998)

The stock prices of equipment and semiconductors manufacturing companies have shown a distinctly downward trend since the beginning of the fourth quarter of 1997. In contrast, communications companies maintained strong market valuations, mostly because of high investor confidence in the Internet and related industries. Even companies remotely identified as pertaining to networking have enjoyed high market capitalization to earnings ratios. However, the business models of many of the fastest-growing Internet companies, particularly the search engine companies with their now astronomical market valuations, have yet to prove that the large amount of investing that has gone into these companies is justified. Not that long ago, Netscape Communications Corp. was perceived as a high-flying start-up with unlimited promise as a World Wide Web pioneer. Today, the company is still worth billions, but it continues to struggle to identify sources of growth and long-term revenue and, as a consequence, has experienced both layoffs and reorganization. In its latest moves to find itself, Netscape is attempting to capitalize on the current market love affair with search engine companies by boosting its role as a service provider. However, in doing this, Netscape appears to be merely following the investor dollars in a desperate attempt to buoy its stock price.

The Internet is an efficient medium for trade, so it shouldn't be too surprising that there are growing parallels between the business practices of some Internet companies and many of the export-minded Asian electronics giants that have stumbled so badly in recent years. Many would say that the stereotypical Silicon Valley Internet start-up company couldn't be culturally more distinct from traditional Korean or Japanese companies. However, both classes of companies have operated under a common assumption: If you export sufficient quantities of product at any price (at cost in the case of some commodity memories and largely free in the case of services provided by most Internet companies), then prosperity must follow.

Internet investors are buying into this concept in a big way, but one has to wonder whether the earnings potential of some of the most active segments of the Internet industry can justify the large investment levels. Almost the first question any new user on the Internet asks is: Who is paying for this? The standard response is the businesses that advertise on the Internet. But the real answer will depend on the future. Stock investors are paying for a lot of Internet expansion and services with the hope that it will eventually lead to higher levels of commerce on the Internet, and hence greater returns on their investments.

It is certainly true that some companies have already successfully capitalized on the efficiency of the Internet to improve their electronic mail order businesses, such as build-to-order computer manufacturers (Dell Computer Corporation, for example), booksellers, adult entertainment providers, and business-to-business transactions. However, there may also be some businesses that will benefit only minimally from the new medium. These industries may even find that their advertising budgets are better spent on print or TV media than on the Internet. It still has to be determined how the Internet will affect individual buying habits. Right now it is basically a big experiment being fueled and financed by speculative investors. In the meantime, the semiconductor industry is benefiting from the surge of networking and computer hardware investments associated with businesses building up their presence on the Web and from individuals who are purchasing Internet-centric PCs and communications gear.

The important thing to recognize for the semiconductor industry is that if investor confidence in the Internet subsides, the speculative investments that are fueling hardware consumption could quickly vanish. There are definitely many Internet users that are not paying for the services rendered via their own purchasing or consumption habits. In the extreme case of those individuals who are known to be actually addicted to Internet surfing, much of their time spent on the Internet is a loss of productivity that necessarily lowers everyone's standard of living.

©1998 Dataquest

Dataquest Perspective

There are unknowns that may ultimately cause corrections to the semiconductor consumption levels that Dataquest has forecast. Trade issues and regional economic conditions are difficult to incorporate into a forecasting model, but nevertheless may have a significant impact on the eventual market sizes. Moreover, new application drivers and technological advances are always parameters that are difficult to anticipate or quantify. The economic boom in the United States is in stark contrast to the economic gloom of most of Asia, and the difference in prosperity is a bit ominous. It may be the calm before the storm, or it may be that the economic momentum of the United States is so great that the prosperity will simply pull Asia out of its slump by virtue of high demand for Asian products.

It is important for Asian countries to recognize that although raising export levels will boost their employment levels, imports are required to sustain those export levels. The projected acceleration of the U.S. semiconductor consumption rate relative to other parts of the world in the next half decade is somewhat astonishing. It suggests elevated levels of imports to the United States from Asia, without an obvious pattern of growth in Asian consumption levels. In five years, the United States is projected to consume more than one-third of the world's production of semiconductors. This percentage is still below the level achieved by the United States in previous decades, but probably would never have been anticipated just five years ago. At that time, the U.S. and Japanese semiconductor markets were nearly equal in size, and the European and Asia/Pacific markets appeared to be gaining ground on the two leading markets.

Vendor Analysis

Texas Instruments and Its New Analog Thrust

Abstract: *Texas Instruments surpassed SGS-Thomson and became the No. 1 supplier of analog ICs in 1997. The strategic moves and competitive position of Texas Instruments in the analog IC market are reviewed and analyzed in this Perspective.*

By Jim Liang

The Less-Known Story

If we go back in time and look at Texas Instruments Inc. at the beginning of the 1990s, we see a multifaceted company, with business activities scattered in such diverse markets as calculators, DRAMs, notebook PCs, defense, and electronics contract manufacturing. Since then, TI has transformed itself into a well-focused company. Many might say that the focus is digital signal processors (DSPs), given TI's pioneering work and dominant position in the DSP market. However, that is only the better-known story.

The less-known story has to do with TI's analog thrust. Ranked as the No. 9 supplier of analog ICs in 1991, TI overtook SGS-Thomson Microelectronics B.V. and became the No. 1 supplier of analog ICs in 1997, with analog IC revenue exceeding $2 billion. Shown in Figure 1 is TI's analog IC revenue and growth rate history, compared with the growth rate of the overall analog IC market. It is evident that TI has outgrown the total analog IC market every year since 1992. The compound annual growth rate (CAGR) for TI's analog IC revenue from 1991 to 1997 was 30 percent, more than twice the 14 percent growth rate for the total analog IC market. The acquisition of Silicon Systems, which added more than $400 million to TI's analog IC revenue, contributed significantly to TI's analog momentum and propelled TI to the No. 2 position of analog ICs in 1996. However, TI's internal growth has been just as remarkable. Without the SSI acquisition, TI's analog IC revenue grew

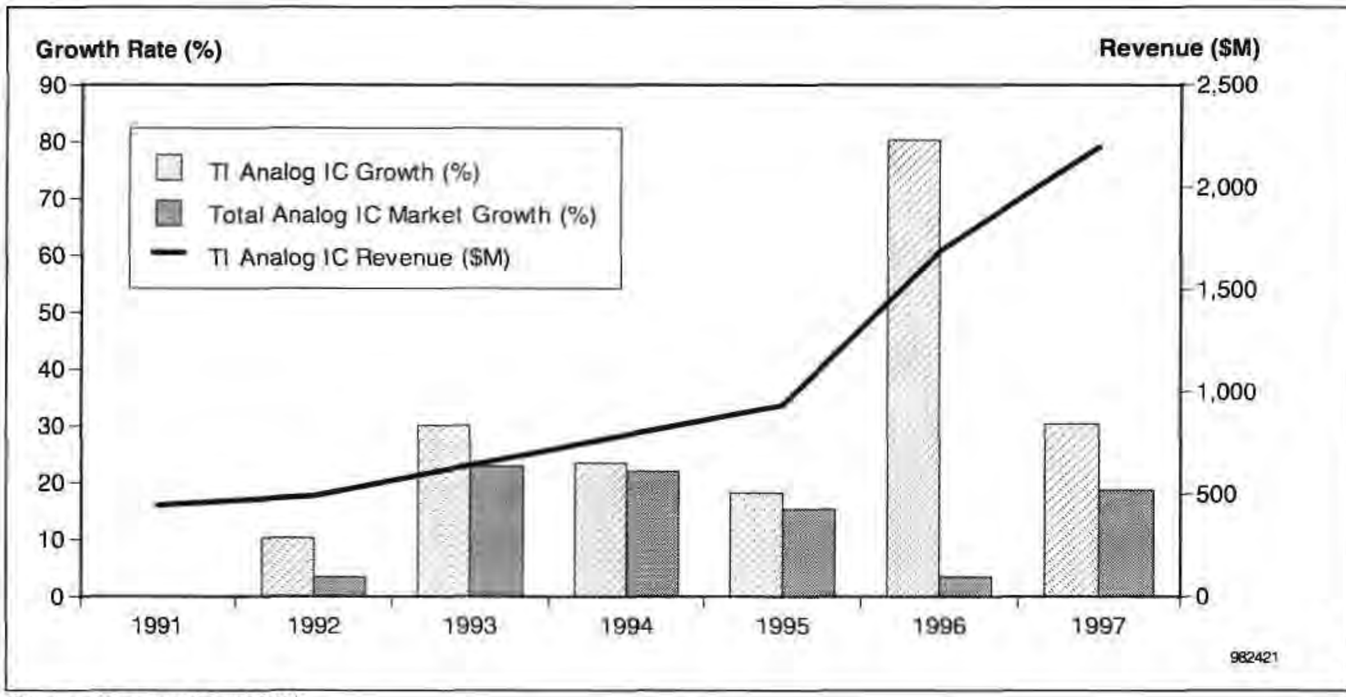
Publication Date: May 18, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

at a CAGR of approximately 25 percent from 1991 to 1997, still significantly higher than the 14 percent growth rate of the overall market.

Figure 1
TI's Analog IC Revenue and Growth Rates Compared with the Total Analog IC Market Growth Rate



Source: Dataquest (May 1998)

Analog ICs include linear ICs (pure analog ICs) and mixed-signal ICs. The mixed-signal IC segment has been growing rapidly. From 1991 to 1997, the mixed-signal IC market grew at a CAGR of 18 percent, which makes mixed-signal ICs one of the fastest-growing segments in the semiconductor market. This rapid growth is mostly the result of the "pull" effect from digital technology. In each digital system, mixed-signal ICs are needed to interface between the real analog world and the digital world. The proliferation of digital technology has expanded the overall market demand for mixed-signal ICs. Digital technology is driving new applications into a more affordable range, which dramatically increases market size.

TI's analog story is indeed about its focus on the mixed-signal IC market. From 1991 to 1997, TI's mixed-signal IC revenue is estimated to have grown at a phenomenal CAGR of 40 percent! Even without the acquisition of SSI, the internal growth is estimated at a solid 31 percent. In comparison, the 1991 to 1997 CAGR for TI's linear ICs was estimated at 14 percent, and about three-quarters of TI's analog IC revenue came from mixed-signal ICs in 1997.

TI's mixed-signal IC growth is a result of its business model, which is tailored toward high-growth end-equipment markets. In 1991, TI put together teams of system, application, marketing, and design experts to focus on high-potential end-equipment markets. In 1992, TI entered the analog baseband market for cell phones. In 1996, TI acquired SSI and became the

 ©1998 Dataquest

No. 1 supplier to the mass storage market. For a more detailed analysis of TI's current moves in the mass storage IC market, please refer to Dataquest Perspective "TI DSP Also Acts like an MCU for Disk Drives" (MCRO-WW-DP-9805, code # 64438). In 1997, TI introduced the x2 modem chipset, including an analog front end and bus interface circuits. The result of these efforts has been TI's remarkable success in supplying mixed-signal application-specific standard products (ASSPs) to three huge end-equipment markets: disk drives, modems, and cell phones. Today, TI has become a strategic supplier to 3Com Corporation, Ericsson, Nokia, Seagate Technology Inc., Quantum Corporation, and Western Digital Corporation—all dominant OEMs in their respective markets.

The TI story is really about both DSPs and mixed-signal ICs. In fact, DSPs and mixed-signal ICs combine synergistically into what TI calls "Digital Signal Processing Solutions (DSPS)." The TI strategy has been to push for the acceptance and penetration of DSPs, which in turn expands the end market for mixed-signal ICs. DSP, with its low cost and high performance, shifts the market demand higher for end systems with DSPs; this in turn not only expands the demand for DSP itself, but also for the accompanying mixed-signal ICs.

The Weapons

The weapons to succeed in the mixed-signal ASSP market include mixed-signal design talent, mixed-signal process technology, and systems expertise. Having both digital and analog functions on the same chip is a unique challenge; it is difficult to make high-precision analog components using the standard digital submicron CMOS process, which is not optimized for analog circuits. Moreover, the switching in digital circuits generates noise that can interfere with the analog circuits on the same chip. Both specialized design capability and process technologies, such as BiCMOS, are needed to overcome these problems. Because these ICs are designed for specific mass applications, it is crucial to have in-house systems expertise to provide value to major OEMs in these application markets.

Given the synergy between DSPs and mixed-signal ICs, it is beneficial for a vendor to offer both technologies, or better yet, a complete solution that includes both DSPs and mixed-signal ICs.

TI's success came from its development and early deployment of these weapons to grab market share leadership. This is not the end of the story; in fact, this is probably only the beginning. Other significant players have jumped into the game, which brings us to the competition.

The Competition

The three biggest competitors for TI are probably Lucent Technologies, Analog Devices Inc., and Motorola Incorporated. All three have both DSP and mixed-signal technology. In 1996, TI was the No. 1 supplier of both DSPs and mixed-signal ICs. Lucent Technologies was the No. 2 supplier of DSPs and the No. 7 supplier of mixed-signal ICs. Analog Devices was the No. 3 supplier of DSPs and the No. 4 supplier of mixed-signal ICs. Motorola was the No. 4 supplier of DSPs and the No. 6 supplier of mixed-signal ICs.

TI and its competitors have staged significant battles. Lucent Technologies and TI have squared off in 56K modems. TI joined forces with U.S. Robotics Inc. (now part of 3Com), the world's No. 1 manufacturer of modems, and came up with X2 protocol. Lucent Technologies teamed up with Rockwell International Corporation and pushed a protocol called K56flex.

Analog Devices, on the other hand, attacked TI's dominance in supplying chipsets to 3Com's X2-based modems. ADI worked with 3Com and developed the industry's first single-chip solution for X2-based controllerless modems. In this solution, ADI utilized a standard 0.5-micron CMOS process technology to integrate DSP, memory, and analog front end (AFE) on the same chip. Building on its leading sigma-delta data converter and voice codec technologies, ADI was able to successfully integrate the AFE and DSP core without degrading the performance of the analog functions.

As the market for communications and consumer products such as modems, digital cellular phones, digital cameras, and digital video discs gains rapid momentum, so will the drive toward higher speed and reduced size, weight, cost, and power consumption. The ability to provide single-chip, mixed-signal DSP solutions for these products will become a key factor for success in these markets. ADI fired a shot by offering a single-chip modem, and this has significantly raised the bar for competitors.

Motorola has traditionally been strong in supplying semiconductors for the wireless market, given its position as a leading OEM for cell phones. In 1996, Motorola was the No. 1 supplier of wireless baseband semiconductors. TI has been gaining momentum in the wireless markets in recent years and went from the No. 4 supplier of wireless baseband semiconductors in 1995 to No. 2 in 1996. TI has established a dedicated strategic business unit for the wireless market. TI's wireless endeavor so far has been in providing DSPs and mixed-signal baseband solutions. The next move for TI is to become a leading supplier of power management and radio frequency (RF) solutions. TI has already delivered power management and small-signal RF products and is expected to enter the power RF market in 1998.

SWOT Analysis

Table 1 summarizes a strengths, weaknesses, opportunities, and threats (SWOT) analysis of TI's position in the analog and mixed-signal IC market. TI's strengths, as well as weaknesses, come from its business concentration on key mass markets.

Strong competitors with both DSP and mixed-signal technology will certainly pose a threat to TI. However, the biggest threat to TI's continued success in the analog/mixed-signal arena, as it is for other leading suppliers of these ICs, is the potential lack of analog/mixed-signal design talent. It usually takes years to train graduating engineers before they can handle analog and mixed-signal design projects, since design automation is not as prevalent in analog design as in digital design. To some extent, analog design is more of an art than a science, and it takes years for a new designer to get a handle on that "magic." Furthermore, engineering schools today are turning out far fewer analog designers than their digital counterparts. The lack of analog talent will limit the growth potential of analog ICs and make analog technology the bottleneck for digital systems. This in turn will limit the growth potential for the overall market. This threat is more significant to TI, as the market leader needs the most design talent.

Dataquest Perspective

Now that TI's opportunities have been identified, how can TI exploit them and maintain its leadership position? Dataquest offers three recommendations.

First, TI needs to increase the total market for digital signal processing solutions. Since TI has the biggest market share, it is in the company's best interest to expand the total market; an increased total market always benefits the market leader the most. Therefore, TI needs to play a leading role in identifying and enabling new mass markets for DSP solutions. We shall name this strategy "beyond disk drives, modems, and cell phones."

Second, TI needs to work with leading engineering institutions around the world to help to cultivate future analog and mixed-signal design talent. TI already has active programs in place to encourage the education of DSP design at universities, and the same needs to be accomplished for analog and mixed-signal design.

Table 1
SWOT Analysis of TI's Analog/Mixed-Signal Market Position

	Issues
Strengths	Complementary DSP and mixed-signal/analog offerings, and strategic relationship with key OEMs in the three major mass markets: disk drives, modems, and cell phones
Weaknesses	Concentration of business on a few mass markets, with the likelihood of being severely affected if these key markets take a dive; today's hot application markets may become saturated tomorrow
Opportunities	Emerging new mass-markets that require both digital signal processing and mixed-signal technology, and the potential to enter the high-end standard linear IC market
Threats	Attack from strong competitors with both DSP and mixed-signal technology, and the potential lack of analog/mixed-signal design talent to fuel growth

Source: Dataquest (May 1998)

 ©1998 Dataquest

Finally, TI could launch an offense into the high-end standard linear IC market. Even though the linear IC market has been growing at an unspectacular 11 percent per year, the high-end segment of the linear IC market has been growing at a much faster rate. This is partly because the price erosion in the high-end segment has been less severe than for low-end commodity-type products. Also, the linear IC market has the attractive characteristics of long product life cycles, high gross margins, and relatively stable pricing (as compared with the more cyclical DRAM pricing). The high-end standard linear market is where companies such as Linear Technology Corporation and Maxim Integrated Products Inc. have thrived. Although TI is not yet a leading player in this market, the company's advanced analog process technology and design expertise should allow it to mount a formidable challenge.

Semiconductors Worldwide

Technology Analysis

Evolution of Packaging Technology for SLI ASICs

Abstract: *The low-cost ball grid array package has gained wide acceptance for 0.35-micron system-level integration ASICs. As gate counts reach 500,000 to 1.5 million and system frequency exceeds 100 MHz, a cost-effective package design is critical. To maximize performance of these devices, package designs need to be 200 to 350 pins, with external operating frequencies of 66 MHz to 150 MHz. ASIC vendors are using low-cost BGAs at or below the cost of conventional PQFPs. This has accelerated BGA market growth and the implementation of other new package technologies, such as chip-scale packages and flip-chip attach.*

By Yoshihisa Toyosaki

Evolution of High-Density Attach Technology

Increased use of high-density attach technologies has emerged with new information equipment markets, such as personal digital assistants (PDAs), cellular phone, and mobile computers, and with new consumer electronics markets, such as digital camcorders and digital still cameras. Growth of small-form-factor and handheld equipment designs increased demand earlier than expected for new chip-scale packages (CSPs), ball grid arrays (BGAs), combinations of BGAs with flip chip, as well as direct chip attach (DCA) and known good die (KGD). To house leading-edge packages and KGD printed circuit board (PCB) developments such as surface laminate circuit (SLC), a buildup substrate technique developed by IBM Japan is being widely adopted in numerous applications that require miniaturization. Dataquest believes, however, that there are hurdles to these new package and substrate technologies. Some of the hurdles include a limited number of buildup substrate suppliers, high design costs, and delay in the effort to develop package standards between Japan and the United States for CSPs and BGAs.

(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Figure 1 shows a road map for leading-edge packaging technologies to 2001. The evolutionary path is based on the system block frequency required for each generation of MPU, which is closely associated with application-specific ICs (ASICs), and the key technologies required to implement the designs.

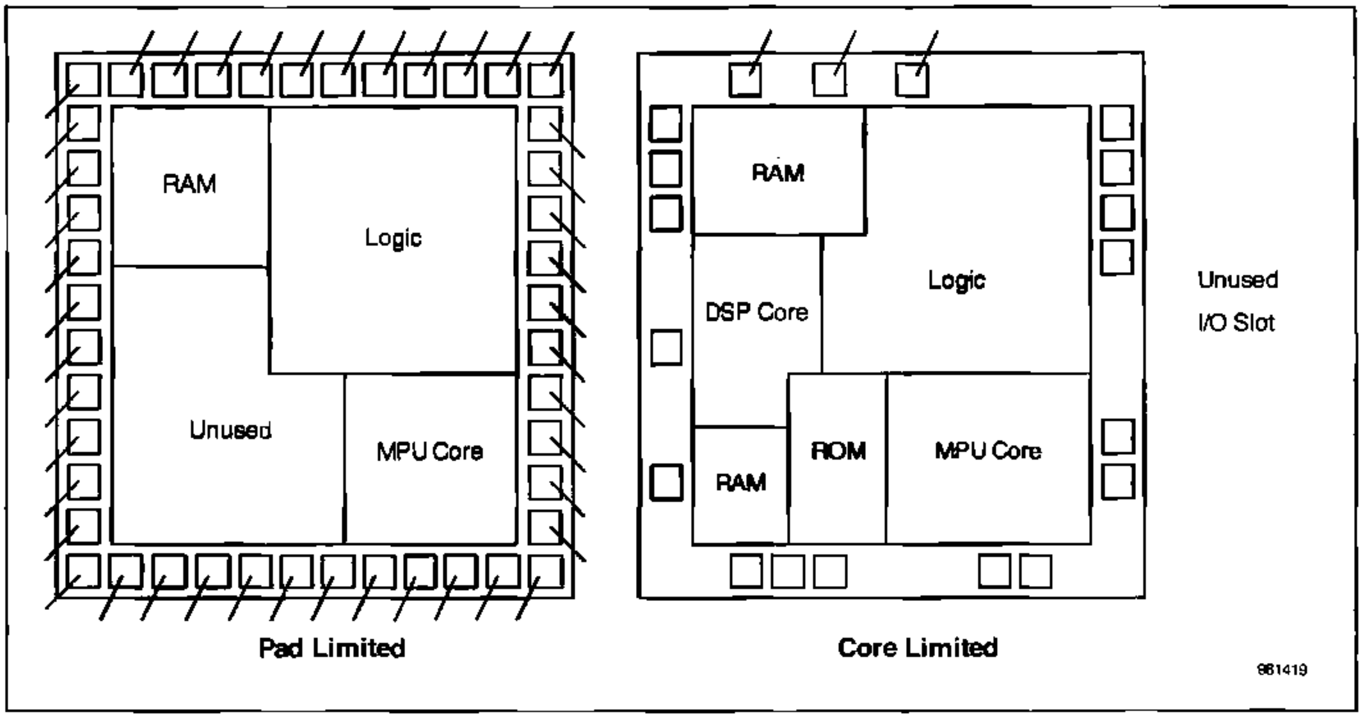
Pad-Limited and Core-Limited Designs in SLI ASICs

Although finer process technologies lead directly to an increase in gate counts accommodated in the same die size, Dataquest sees a risk of "I/O pad-limited design," where the die size is governed by the number of I/Os in some applications. Interconnect technology varies with package type, but the ability to reduce the I/O pad size required for bonding a die and a package is limited. The area of the die per side (in square millimeters) needed to secure the required I/O counts is a physical limitation resulting in a larger die area than that designed (see Figure 2). This design trend is frequently seen in gate arrays. Previously, "core-limited designs" were common. Applications limited by die size have declined with the pervasiveness of 0.5- to 0.35-micron process technology and commercialization of a 0.25-micron high-density ASIC process technology. Nevertheless, core-limited designs will persist in some applications, such as DVD encoders that require large circuits and switching systems demanding large DRAM capacities (memory space switchlike applications). In particular, Dataquest believes that this need will continue in consumer applications in which single-chip implementation using system-level integration (SLI) ASICs is an important goal.

Figure 2
Situation of Pad-Limited and Core-Limited Designs



Source: Dataquest (March 1998)

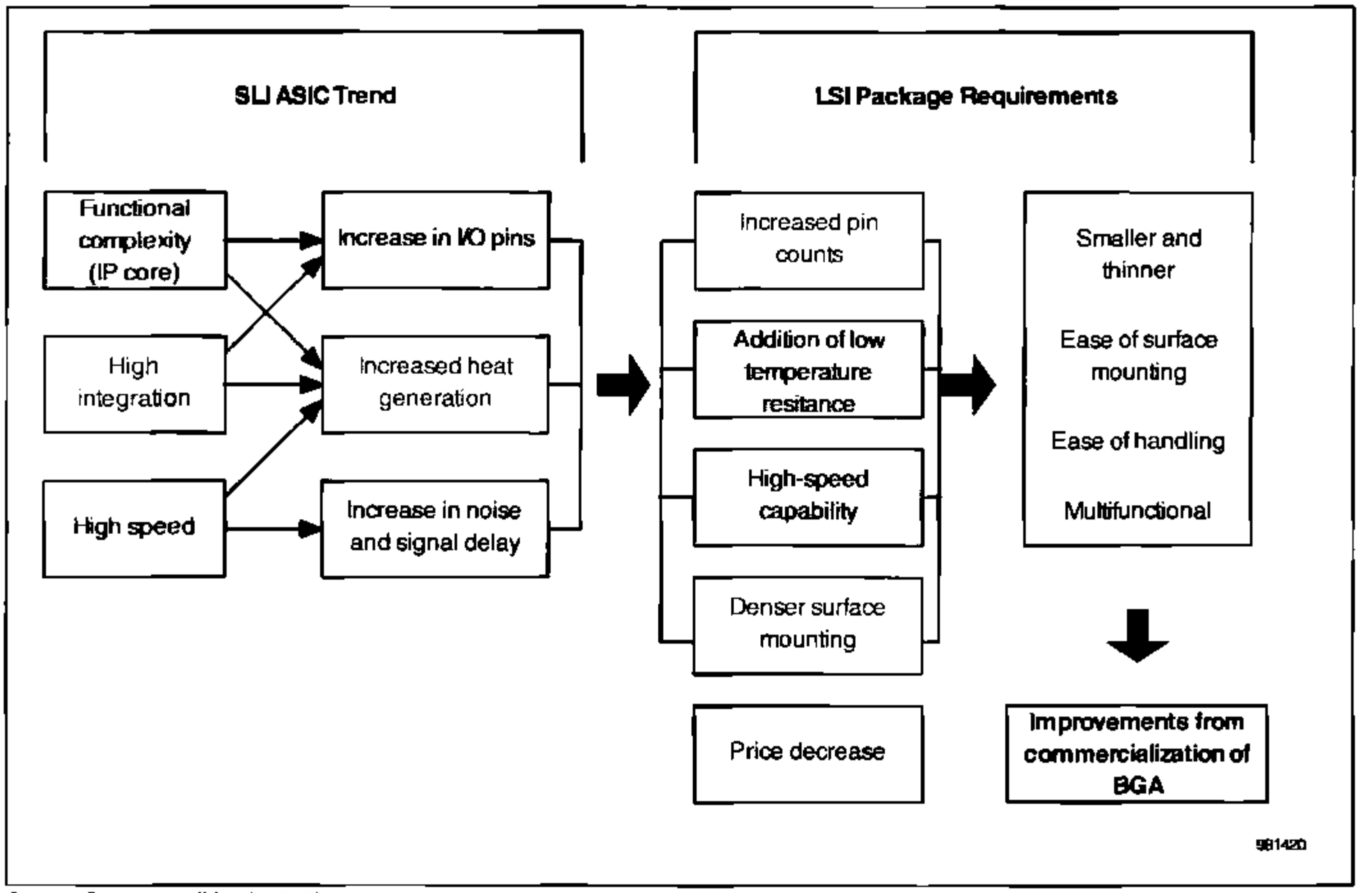
BGA Package and Development Targets

Conventional plastic quad flat packages (PQFPs) are generally limited to 304 pins and 50 MHz by inductance issues. BGA technology raises limitation levels to 750 pins and 200 MHz.

In the plastic ball grid array (PBGA) package structure, the chip surface area contains circuitlike die attach patterns and signal patterns. The chip is mounted by using a die bonder and epoxy-based silver paste. The package is characterized by a single-side resin sealing structure that allows an array of solder balls (I/O and power source) to reach the lower side of the IC, resulting in a wider pitch and enabling a smaller and thinner package. Major characteristics of the low-cost BGA (overmolded plastic pad array, or

OMPAC) developed by Motorola Incorporated, currently the mainstream BGA package design, are shown in Figure 3.

Figure 3
BGA Package for ASICs



Source: Dataquest (March 1998)

Current State of CSP

CSP is a compact package with a size more or less equivalent to the die area. Although many CSP technologies have been developed, most of them have a common feature, which is to provide a dense area array on the underside of a package. Compared to BGAs, CSPs offer better marketability because they occupy a relatively smaller area on a PCB, resulting in a cost advantage, especially for portable applications. Size reduction also leads to improved electrical performance.

Major markets for the CSP include consumer applications such as digital camcorders and portable DVD and communications applications such as modem cards and mobile phones. As designs for these applications face increasingly strict size and cost demands, the CSP must also satisfy other requirements. Emerging applications require relatively small pin counts (176 or fewer as of 1997), and many of these are limited by the height, length, and width of a package. CSP, the smallest package, is primarily used for memory products such as flash and SRAM, as well as for discrete devices. These

 ©1998 Dataquest

devices have variable die sizes and yet require very small pin counts (50 or fewer). This makes them highly suitable for the chip-size CSPs.

Naturally, there are various problems with CSPs. Obstacles include a higher initial packaging cost and limited wiring patterns on a PCB. These are important design considerations in consumer applications. Higher equipment costs could delay full acceptance of the CSP, but suppliers must meet user demands for package miniaturization and the most cost-effective package solution. Some of the current solutions include the narrow-pitched low quad flat pack (LQFP) as well as the BGA. As the industry's infrastructure improves, CSPs will gradually move into mainstream applications with high pin counts. CSPs are now used in digital camcorders, which use PCBs with six to eight layers with buildup substrates.

The CSP is best suited to applications that require mounting of devices with low pin counts on very small, very dense PCBs. Some of these applications use PCB designs with 176 or fewer pins (see Table 1 and Figure 4). DVD manufacturers set the highest priority on small form factor and light weight, using SLC, a high-cost laminate substrate. This design application enables CSP packaging in an area array pattern. However, CSP is unsuitable for computing and communications applications that use very large PCBs with high pin counts. CSPs used in memory applications are expected to go into volume production late 1998. This will accelerate development of the infrastructure and widen market acceptance for CSP technology.

The CSP design of Sharp Electronics Corporation and Texas Instruments Japan is an extension of existing technologies, rather than a technological breakthrough. The primary goal is to minimize costs and development risks. Technological advances include a ball pitch of less than 1.27mm—for example, 1.0mm, and 0.8mm. The package size will continue to be reduced until the die becomes a limiting factor.

Table 1
Expected Pin Counts in Digital Camcorders by Generation

Digital Camcorder Manufacturer	First Generation	Second Generation	Third Generation
Company A	64 to 144 pins	80 to 144 pins	100 to 120 pins
Company B and Company C	80 to 164 pins	100 to 176 pins	176 to 256 pins
Company D	100 to 160 pins, mainly 144 pins	176 pins	208 to 304 pins, single chip

Source: Dataquest (March 1998)

According to digital camcorder designers, assembly cost for the LQFP package with about 100 pins is around ¥1 per pin. However, the cost of CSP assembly is relatively high because it is in the prevolume production stage (see Figure 5). Major cost adders include higher material costs, assembly yield, and new equipment requirements (including tooling, R&D, and

 ©1998 Dataquest

qualification costs). The CSP assembly cost acceptable to digital camcorder users is a maximum of 20 percent higher than the LQFP cost.

Flip-Chip Technology

Flip-chip technology is being viewed as another advanced attach solution for high-performance and high-pin-count application markets. Yet, there are many issues to be overcome before commercial application of the flip-chip technology to ASICs. Some of these issues are summarized as follows:

- A limited number of designers and engineers who have experience in development and volume production of flip-chip products
- Restriction on package assembly technology using the new flip-chip technology, including internal wiring (often conflicting with package patents held by IBM, Tessera Inc., Matsushita Electrical Industrial Company Ltd., and Hitachi Ltd.)
- Production capacities of suppliers and subcontractors, as well as their business strategies and investment in flip-chip technology
- Additional cost incurred according to structure, varying with package type and design (mask cost and turnaround time)
- Failure analysis requirements attributable to design (circuit and bump, among others)
- Issues related to alpha particles and electric coupling, attributable to design
- CAD systems (to establish layout methods for internal core and I/O cells)
- Wafer sort (high-cost probe guard, long lead times, and customized development because of the nonstandard footprint)
- Establishment of flip-chip technology and package qualification methods

Figure 6 shows flip-chip technology road map trends required for the technology to evolve through each generation and mature at a low cost.

IBM's Controlled Collapse Chip Connection (C4) flip-chip technology, now licensed by many semiconductor suppliers, is widely used in advanced computer and emerging communications handset applications. Major characteristics of flip-chip technology developed by IBM include the following:

- Ease of securing high contact points: Electrical contacts can be placed over the entire surface of a semiconductor device in an array pattern. Although the present basic designs are limited to a 250-micron pitch and a solder ball diameter of 100 microns, further shrinkage is feasible by taking into account the consistency of coefficient of thermal expansion between the device and the substrate and selection of a soldering material.
- Ease of high-performance design: Contacts can be placed on any location over the entire surface of a device. The ability to minimize inductance or impedance leads to electrically advantageous designs.
- Enabling higher integration on the device: By allowing formation of contacts on an active area of a device, the flip-chip design enables finer-geometry design for a die.
- High productivity: High-quality batch bonding by reflow methods facilitates the reworkability of a device.

©1998 Dataquest

- High reliability: In addition to field-proven highly reliable soldering, the self-alignment effect created by surface tension as the solder melts assures highly precise and reliable bonding of a small form factor.

In spite of the technological challenges of flip chip, leading-edge ASIC companies are stepping up their efforts to commercialize flip-chip technology in order to leverage its advantages, which are being demanded by systems companies.

Figure 6
Evolution of Flip-Chip Technology and Cost Trends

Technical Requirements for ASIC Packages by Market Segment

Tables 2 through 4 show technical requirements for ASIC packages by major applications in each market segment. Table 5 shows market requirements for high-speed I/O, an important factor in package development.

Performance requirements for packages from the system side are shown in Table 6 and rated on a five-point scale. Table 7 shows the relative importance of packaging characteristics for data processing, communications, and consumer applications. Figure 7 illustrates package and mounting technologies for advanced ASIC designs.

Table 2
Packaging Technology Requirements in the Data Processing Market

	Mainframe/ Supercomputer	Server	Workstation	Desktop/ Notebook PC	Personal Digital Assistant
Gate Count/ Memory Integration	400,000-3,000,000	100,000-500,000	200,000-1,500,000	50,000-100,000	2,000-300,000

Environment of Attach Technology

Traditionally, suppliers have generated revenue by supplying customer-specific designs. However, to achieve high-density mounting at a lower cost, packages having area array terminals on the rear side, such as BGA and CSP, have emerged. Dataquest believes that the future package development should be based on the concept of reducing total system cost.

 ©1998 Dataquest

Packages and high-density printed circuit boards, including buildup substrates, will be offered by multiple suppliers. Buildup substrates with 100-micron wiring pitch have been introduced for bare die attach, intended for multichip modules (MCMs).

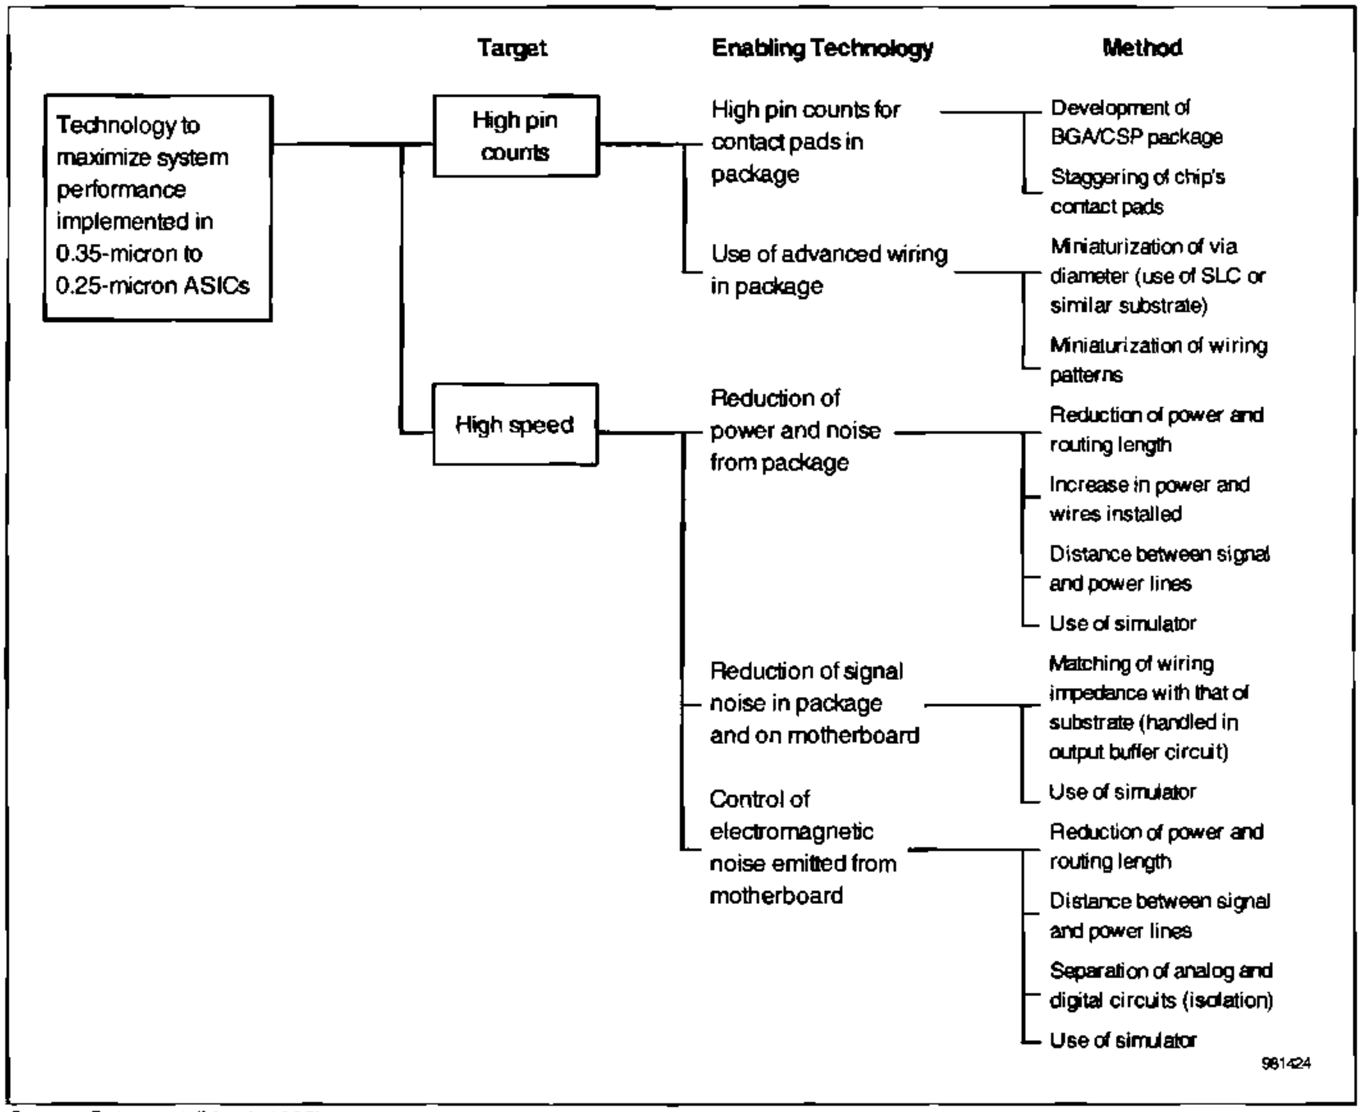
Figure 7
Package and Mounting Technologies for 0.35- to 0.25-Micron ASICs



Source: Dataquest (March 1998)

Technological Challenges for ASIC Packages

Increased function and integration at the system level, as well as miniaturization and lower power consumption, now require higher integration, higher speed, higher pin counts, and enhanced functions from ASIC products. The ASIC package domain has often been relatively neglected, compared to the process, library, and intellectual property core areas. However, system design specifications for ASIC products, packages, and attach technologies are becoming critical. Technical challenges for ASIC process and package designs include the following:

- Accurate analysis of stress produced in the fab process, such as oxidization and diffusion, as well as analysis of electrical characteristics of circuit devices that vary according to the degree of stress

 ©1998 Dataquest

- Thermal stress related to the complexity of multilayer plastic packages composed of multiple materials. The packaged device goes through many thermal processes, so it must be robust enough to withstand destruction of the composite materials by thermal stress—for example, destruction of a die by thermal stress, destruction of resin by thermal fatigue, and destruction of a passivation film. Also, increased use of smaller and thinner ASIC packages makes destruction by external forces at the time of mold separation and lead forming an important issue.

Given the diverse technological challenges, if the ASIC business is to change from the traditional custom production approach, ASIC vendors will have to establish standard procedures for package design and analysis that go beyond the realm of the traditional single-chip package.

Dataquest Perspective

In 1997, when 0.35-micron process technology became the mainstay, the integration level of LSIs was driven by finer geometries. SLI ASICs, led by cell-based ICs, increased demand for high-performance packages with smaller and thinner form factors and high reliability. This technology development demanded higher pin counts, higher heat emission, electrical characteristics that match the increase in I/O counts, lower power consumption, and higher speed. The traditional QFP and tape automated bonding-based lead frames and films were reaching their limits of pitch, heat emission, and electrical characteristics.

Packages with an external contact pitch of 0.4mm for miniaturization and higher-pin-count system ICs required a finer pattern. To meet higher-performance system requirements, new packages were developed, such as BGA and CSP, and new solder bump techniques progressed rapidly. CSP technology has overcome major obstacles, but many challenges remain for volume commercialization of CSPs.

In theory, direct chip attach to the substrate is the most effective means of maximizing performance of ASIC products. For this reason, many companies have been working with MCM designs. Nevertheless, the supply of bare die, especially for known good die, involves increased technical challenges, reliability issues, and additional test costs.

The development of an optimum ASIC package requires further understanding of system user requirements. ASIC vendors need to further analyze the needs of the entire application market and decide on the applicable technical solution for these products to ensure the optimum package design. Ultimately, this would guarantee a "true" SLI ASIC that would meet the user's needs.

To reduce package cost, ASIC vendors should employ a more flexible strategy, possibly involving an alliance with a subcontractor with a leading-edge package. Such a joint technology effort could be critical in meeting the shorter time to market required by customer cycles.

Perspective

Semiconductors Worldwide

Event Summary

ISSCC 1998

Abstract: *This Perspective summarizes the 1998 ISSCC that was held in February in San Francisco, California. In this Event Summary, Dataquest briefly relates all significant announcements and comments pertaining to key developments. Further details on technical presentations are available from the Dataquest inquiry service.*

By Jim Liang

Event Background and Overview

This year marked the 45th session of the International Solid-State Circuits Conference (ISSCC), which is sponsored by the Institute of Electrical and Electronics Engineers (IEEE). This is one of the most important conferences of the year for those semiconductor companies and universities around the globe involved in research and development of solid-state circuits. It creates a forum for open discussion among engineers and allows for dissemination of information that may help advance the technology and design concepts within the semiconductor industry.

This year's conference was held February 5 through 7 in San Francisco, California. There were 159 technical papers presented in 25 sessions, eight discussion sessions, six tutorial lectures, and a short course. Forty-eight percent of the papers are from North America, 18 percent from Europe, and 34 percent from Far East. Of these papers, 70 percent are from industry, 18 percent from universities, and 12 percent from industry-university collaborations.

(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Discussion Sessions

The following is a listing of the discussion session titles from this year's conference:

- Three Decades of DRAM Development, Debates, and Distinction
- How Much Analog Is Going to Survive on Large Digital Chips?
- Deep Sub-1V, SOI, or Bulk CMOS?
- Will Power Limit Microprocessor Performance?
- Will CMOS Image Sensors Survive Scaling?
- How Will Media Signal Processors Dominate the Next Decade?
- LSI Solutions and Enabling Technologies for Mobile Multimedia Devices in the Year 2002
- Global Communications: the Good, the Bad, and the Ugly

Tutorials

The six tutorials at the 1998 ISSCC were:

- High-Speed SRAM Design
- How a Spread-Spectrum Radio Works
- Op Amp Compensation for Low-Voltage, Mixed-Signal Designs
- FIR-1001: Architectures and Applications
- MEMS for the Circuit Designer
- High-Speed Clocking for Large Digital ICs

Short Course

- xDSL Broadband Communication via Plain Old Telephone Service

Plenary Session

"Global Communications" was the main theme for the 1998 ISSCC. The infrastructure for global communications is broad and includes technologies of voice, data, and video. Papers spanning each of these topics were included in this year's conference. Furthermore, all three papers at the plenary session were devoted to this theme, and they are as follows:

- Challenges in Semiconductor Technology for Multimegabit Network Services
- GSM and Beyond—The Future of the Access Network
- The Global Positioning System: Challenges in Bringing GPS to Mainstream Consumers

 ©1998 Dataquest

The first paper, from Hitachi Ltd., highlighted the semiconductor technologies currently employed in network systems such as backbone broadband transmission, Asynchronous Transfer Mode (ATM) switching, and mobile communications. The paper then outlined the technology advancements required to realize future multimegabit network services: advanced microfabrication techniques, novel circuit technologies, and sophisticated system-level integration architectures.

The second paper, presented by Alcatel Microelectronics, examined the future of network access and provided a vision of how the competition between wireline and wireless cellular would play out in the future.

The last paper came from SiRF Technology Inc. and was focused on global positioning system (GPS) technology. The paper discussed the history of GPS, its potential applications, and the technological challenges that need to be overcome in order that GPS becomes a mainstream consumer product.

Significant Announcements

Two significant announcements took place at the 1998 ISSCC. The first was the 1-GHz microprocessor announcement from IBM Corporation. In the announcement, IBM said that it successfully demonstrated an "experimental CMOS processor" that runs at speeds up to 1,100 MHz. Its engineers implemented a working subset of a PowerPC microprocessor, using conventional 0.25-micron manufacturing technology. While the pace of microprocessor speed improvement in the past few years has been clearly ahead of the software industry's ability to build more ambitious applications that consume the available computing power, Dataquest expects it is going to be only a matter of time for the applications demand to grow and meet the processor speed capability. For more detailed analysis, please see Dataquest Alert, "To One Gigahertz and Beyond" (PSAM-WW-DA-9804, February 1998).

The second announcement was Alcatel's formation of a new division, Alcatel Microelectronics, to market intellectual property (IP) and system-on-a-chip application-specific standard products for wireline and wireless access solutions worldwide. Alcatel Microelectronics has also joined forces with electronic design automation tool vendor Synopsys Inc. to refine its systems-on-a-chip design environment. In the wireline access arena, Alcatel Microelectronics is aimed at the asymmetric digital subscriber loop modems market, and in the wireless access arena, it is targeting the Global System for Mobile Communications (GSM) solutions market. Alcatel Microelectronics' manufacturing strategy is to support the IP and system-on-a-chip marketing efforts with a hybrid approach: focusing on Alcatel Microelectronics' mixed-signal and radio frequency (RF) BiCMOS manufacturing technology for designs requiring the highest level of analog and digital functionality on a single chip, while utilizing a network of CMOS foundries for lower costs when advanced mixed-signal capabilities are not required. Over time, Alcatel microelectronics plans to contract with low-cost foundries for production of its digital CMOS and to return all the manufacturing capacity to mixed-signal and RF. Dataquest believes that Alcatel's strategic move reflects the

©1998 Dataquest

continuing growth of the telecommunications market, which drives the growth of telecommunications chips. Furthermore, Dataquest believes that Alcatel Microelectronics' shift to mixed-signal and RF manufacturing technology illustrates the growing importance of mixed-signal and RF technology to system-on-a-chip solution providers as the key differentiating factor.

Technical Papers Worth Highlighting

Besides the IBM paper describing the first 1-GHz microprocessor, the following papers caught Dataquest's attention because they represent significant technology breakthroughs:

- "A 480MHz RISC Microprocessor in a 0.12-Micron CMOS Technology with Copper Interconnects," by IBM, about the first microprocessor using copper interconnect technology
- "40Gb/s Analog IC Chipset for Optical Receiver Using SiGe HBTs," by Hitachi Ltd., about a 95-GHz SiGe-based heterojunction bipolar transistor (HBT) used to realize building blocks for 40-Gbps optical links
- "A 128Mb Early Prototype for Gigascale Single-Electron Memories," by Hitachi Ltd., about a 128Mb single-electron memory targeting minimum-bit-cost technology
- "A 200mW 3.3V CMOS color Camera IC Producing 352x288 24b Video at 30Frames/s," by Lucent Technologies, about CMOS sensors for virtual reality and Internet conferencing applications

Analog and Mixed Signal

Analog and mixed-signal ICs are gaining importance in this digital age as getting data to and from the real world becomes the gating factor of digital systems. The reduction in cost and size of digital systems has stimulated market demand, which in turn has driven the growth of analog and mixed-signal ICs. Dataquest projects that analog and mixed-signal ICs will grow at a compounded annual growth rate (CAGR) of 15 percent for the next four years. Reflecting this growing importance, the 1998 ISSCC devoted the following four technical sessions to this topic:

- Oversampling Converters
- Analog-to-Digital Converters (ADCs)
- Analog Techniques
- Amplifiers

Significant advances were reported in the analog technology area, including 400-Msamples/sec 6-bit CMOS analog-to-digital converters from both Texas Instruments and Fujitsu Ltd., a 10-bit 250-Msamples/sec CMOS digital-to-analog converter from Broadcom Corporation, and a 113dB signal-to-noise ratio oversampling digital-to-analog converter utilizing sigma-delta technology from Analog Devices.

Wireless and RF

One of the fastest-growing application segments within the semiconductor industry is wireless communications. The wireless semiconductor market can be partitioned into two major segments, RF semiconductors, which are used in the radio portion of a wireless system, and baseband semiconductors, which include microcontrollers, digital signal processors, microprocessors, memory, power management, and display semiconductors. RF semiconductors such as RF amplifiers, synthesizers, transceivers, receivers, and switches have experienced strong growth in the last few years as a result of the burgeoning wireless communications market, and Dataquest expects this trend to continue into the foreseeable future. At this year's ISSCC, four technical sessions were dedicated to wireless and RF:

- Transceivers and Power Amplifiers
- Wireless Receivers
- Advanced RF Circuits
- Wireless Building Blocks

Among the papers presented at these sessions, Dataquest felt that three were particularly interesting: The first was from Toshiba Corporation, about a single-chip CMOS RF transceiver utilizing standard 0.25-micron CMOS technology; the second was from University of California, Los Angeles regarding a 900-MHz/1.8-GHz CMOS receiver for dual-band applications, and the third was from Stanford University, about a 115mW CMOS GPS receiver implemented in an analog 0.5-micron CMOS technology.

Dataquest Perspective

The remarkable growth of the computer market during the last decade has been the driving force behind the growth of semiconductors. As a result, PC components such as microprocessors, logic, and memory have been the main focus of ISSCC in the past. However, this year's ISSCC has chosen "global communications" as the main theme. This reflects Dataquest's belief that the communication markets will join the computer market as the driving forces behind semiconductor growth for the future.

As a result of this rapid emergence of communications market, mixed-signal ICs and RF ICs will become increasingly important. It will be companies with expertise in mixed-signal and RF design and manufacturing that possess the key weapons to succeed.

Semiconductors Worldwide

Market Analysis

Alliance Activity in 1997: Another Year of Acquisitions

Abstract: *Acquisition was the name of the investment game in 1997. Overall alliance activity was not as robust as in 1996, as Dataquest captured only 289 known or published alliance agreements, in comparison to over 450 listings in 1996. The alliances listed in this document involve all aspects of the global semiconductor industry—components, front-end equipment, materials, foundry, assembly, and end-system equipment.*

By Mary Ann Olsson

Investment for Some, but Takeover for Others

Most electronics companies will remember 1997 as the year of falling DRAM prices, tougher competition, and shrinking design cycle times. In reality, profit margins became everything. To head off the competition and to keep the shareholders at bay, companies bought their way into technology and regional markets through acquisition.

In 1997, as in previous years, agreements between U.S. companies were still the most numerous, as shown in Figure 1. The growth of alliances between U.S. companies and U.S. and European companies was substantial in comparison to previous years. By company, Siemens AG was the most active in forming alliances worldwide. Founded in 1847 by Werner von Siemens, Siemens AG is celebrating its 150th year in business and holds the No. 12 position in semiconductors for 1997.

As shown in Figure 2, investment agreements surpassed license and joint-development agreements in 1997. Table 1 lists all the alliance activities by company and region. The order of appearance in either column A or B is random.

Dataquest

Program: Semiconductors Worldwide
Product Code: SEMI-WW-DP-9801
Publication Date: March 2, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Figure 3 shows alliance activity by product function, contract assembly, front-end equipment and foundry, electronic equipment systems, software, materials, and others. The "others" category includes products that are not included in specific categories currently collected by Dataquest. Figure 4 illustrates the application market selections. Not all the alliances listed in Table 1 are application specific. Each agreement is coded according to a Dataquest classification. Dataquest classifies all of the alliances listed in this table as follows:

- License agreements (LA): License agreements are defined as legal permission to utilize a company's patents or proprietary technology for a fee or royalty payment. This could also include a cross-licensing agreement where the companies involved have legal permission to another company's patents or proprietary technology.
- Second-source agreements (SS): Second-source agreements allow companies to manufacture a product designed and developed by another company as a second source of supply for customers.
- Sales agreements (SA): Sales agreements provide companies with exclusive or nonexclusive rights to sell the partner's original products to which value is added, in specified markets.
- Fab agreements (FA): Fab agreements involve the use of another company's fabrication facilities to manufacture a product.
- Assembly and test agreements (AT): Assembly and test agreements involve a company's manufactured components and parts that are shipped to another company for assembly and test.
- Technology exchange (TE): Technology exchange involves an exchange of proprietary technologies that may or may not involve a transfer of money.
- Joint venture (JV): Joint ventures involve two or more companies that jointly form a company to develop, manufacture, or market new products.
- Joint development (JD): Joint development agreements are between two or more companies that decide to combine forces and capabilities to develop new products or technology.
- Investment (IV): Investment alliances are made among regional companies or foreign companies for the purposes of gaining access to technology or acquisition of small start-ups or innovative companies.
- Coordination (CO): Coordination of standards are agreements on common or compatible technical standards that would link devices and systems and users of different components, systems, or tools.
- Procurement (PC): Procurement agreements are commitments by companies to purchase certain quantities of specific goods or services over a contracted time.
- Other types (OT): Other types of agreements could include visitation and research participation where researchers visit, observe, and participate in the R&D activities of the allied company. An original equipment manufacturing (OEM) agreement might involve the manufacturing of a product for another company that will label it with its name or logo and will also handle all of the business aspects of that product, such as its marketing and service. Service agreements are those provisions of follow-up service of the product in foreign markets.

Semiconductors Worldwide

Market Analysis

Alliance Activity in 1997: Another Year of Acquisitions

Abstract: *Acquisition was the name of the investment game in 1997. Overall alliance activity was not as robust as in 1996, as Dataquest captured only 289 known or published alliance agreements, in comparison to over 450 listings in 1996. The alliances listed in this document involve all aspects of the global semiconductor industry—components, front-end equipment, materials, foundry, assembly, and end-system equipment.*
By Mary Ann Olsson

Investment for Some, but Takeover for Others

Most electronics companies will remember 1997 as the year of falling DRAM prices, tougher competition, and shrinking design cycle times. In reality, profit margins became everything. To head off the competition and to keep the shareholders at bay, companies bought their way into technology and regional markets through acquisition.

In 1997, as in previous years, agreements between U.S. companies were still the most numerous, as shown in Figure 1. The growth of alliances between U.S. companies and U.S. and European companies was substantial in comparison to previous years. By company, Siemens AG was the most active in forming alliances worldwide. Founded in 1847 by Werner von Siemens, Siemens AG is celebrating its 150th year in business and holds the No. 12 position in semiconductors for 1997.

As shown in Figure 2, investment agreements surpassed license and joint-development agreements in 1997. Table 1 lists all the alliance activities by company and region. The order of appearance in either column A or B is random.

Dataquest

Program: Semiconductors Worldwide
Product Code: SEMI-WW-DP-9801
Publication Date: March 2, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Figure 3 shows alliance activity by product function, contract assembly, front-end equipment and foundry, electronic equipment systems, software, materials, and others. The "others" category includes products that are not included in specific categories currently collected by Dataquest. Figure 4 illustrates the application market selections. Not all the alliances listed in Table 1 are application specific. Each agreement is coded according to a Dataquest classification. Dataquest classifies all of the alliances listed in this table as follows:

- License agreements (LA): License agreements are defined as legal permission to utilize a company's patents or proprietary technology for a fee or royalty payment. This could also include a cross-licensing agreement where the companies involved have legal permission to another company's patents or proprietary technology.
- Second-source agreements (SS): Second-source agreements allow companies to manufacture a product designed and developed by another company as a second source of supply for customers.
- Sales agreements (SA): Sales agreements provide companies with exclusive or nonexclusive rights to sell the partner's original products to which value is added, in specified markets.
- Fab agreements (FA): Fab agreements involve the use of another company's fabrication facilities to manufacture a product.
- Assembly and test agreements (AT): Assembly and test agreements involve a company's manufactured components and parts that are shipped to another company for assembly and test.
- Technology exchange (TE): Technology exchange involves an exchange of proprietary technologies that may or may not involve a transfer of money.
- Joint venture (JV): Joint ventures involve two or more companies that jointly form a company to develop, manufacture, or market new products.
- Joint development (JD): Joint development agreements are between two or more companies that decide to combine forces and capabilities to develop new products or technology.
- Investment (IV): Investment alliances are made among regional companies or foreign companies for the purposes of gaining access to technology or acquisition of small start-ups or innovative companies.
- Coordination (CO): Coordination of standards are agreements on common or compatible technical standards that would link devices and systems and users of different components, systems, or tools.
- Procurement (PC): Procurement agreements are commitments by companies to purchase certain quantities of specific goods or services over a contracted time.
- Other types (OT): Other types of agreements could include visitation and research participation where researchers visit, observe, and participate in the R&D activities of the allied company. An original equipment manufacturing (OEM) agreement might involve the manufacturing of a product for another company that will label it with its name or logo and will also handle all of the business aspects of that product, such as its marketing and service. Service agreements are those provisions of follow-up service of the product in foreign markets.

Chapter 1
Executive Summary

Dataquest forecasts that worldwide semiconductor revenue will decline by 6 percent in 1998, a number that represents a downgrade from our previous expectations for the year. The worldwide semiconductor market should grow by 12 percent in 1999 and total $155 billion. The economic crisis in Asia, including Japan, remains a major concern. For the long term, Europe and the United States will lead the growth. The world market should grow at an 11.5 percent compound annual growth rate (CAGR) for 1997 through 2002, reaching $254 billion in the year 2002.

Objectives

This forecast and market trends information serves the following objectives:

- Near-term planning of worldwide and regional semiconductor manufacturing, sales, and procurement tactics
- Long-term strategic planning of semiconductor product strategy and supply base management
- Capital formation process decision making in debt and equities markets

Forecast Outlook

Worldwide semiconductor revenue will grow by 12 percent in 1999, totaling $155 billion. This growth will follow the unexpected revenue decline of at least 6 percent for 1998. By the year 2002, worldwide semiconductor revenue will total just over $250 billion, which marks an 11.5 percent-plus CAGR for the five-year period from 1997 through 2002.

The industry is now moving toward the end of its third straight year of lackluster performance . The prior expectation had been that the product market would rebound in 1998. The Asian financial crisis and low pricing for DRAMs, cell-based ICs (CBICs), and analog ICs, among other parts, thwarted semiconductor revenue growth this year. Few product segments will achieve more than marginal 1998 revenue growth, and year-end results remain a concern.

The 1999 forecast assumes sluggish demand in Asia, at best, but also stable DRAM pricing. Most product markets will not strengthen until mid-1999, so next year's growth will be concentrated in the second half of 1999. Also, the long-term growth rate is slower than was previously forecast.

Key Growth Metrics

Table 1-1 provides growth rates and revenue totals by product for the period from 1997 to 2002, including the five-year CAGR.

Semiconductor Forecast with and without DRAM

Figure 1-1 provides a different look at the forecast. The figure shows worldwide semiconductor growth rates for 1997 through 2002 for the total semiconductor market, the DRAM market, and the non-DRAM semiconductor market.

The figure shows somewhat more stable and flatter long-term semiconductor growth when DRAMs are excluded. The figure also highlights the more volatile growth expected for DRAM.

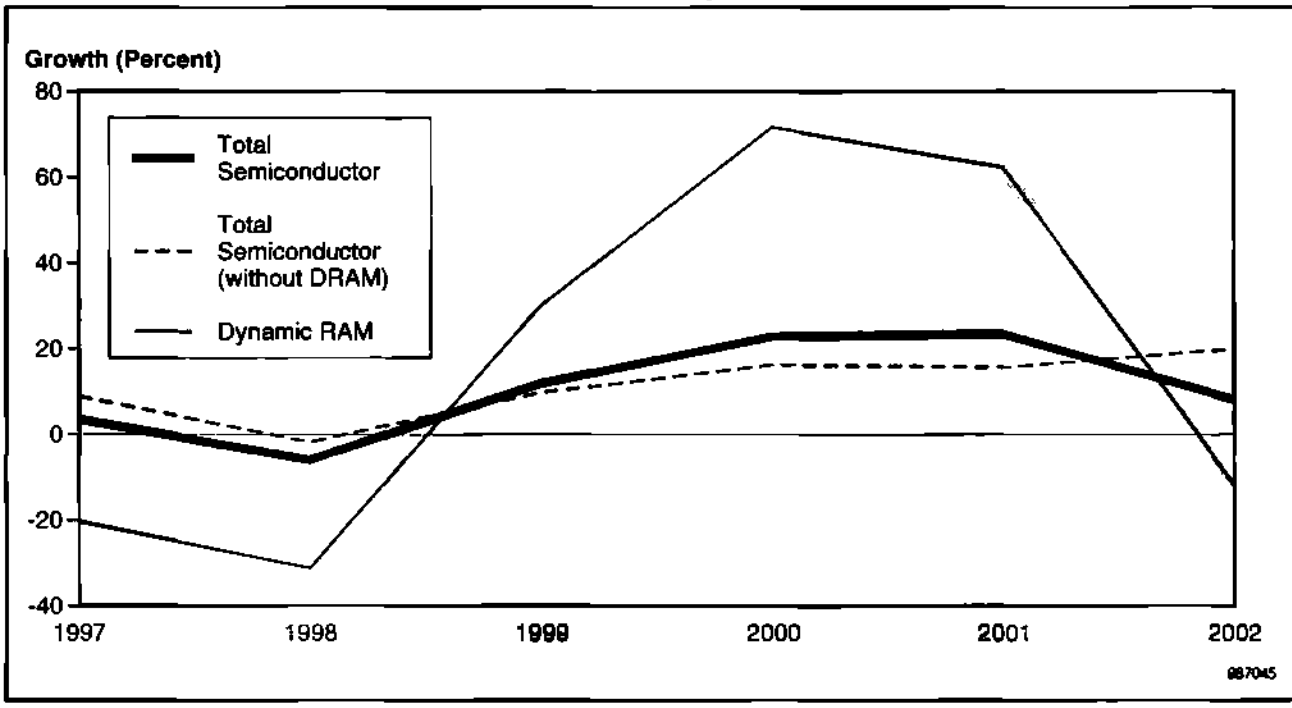
Figure 1-1
Worldwide Semiconductor Forecast, 1997 through 2002



Source: Dataquest (September 1998)

Electronic Production Forecast Analysis

As a first step in the forecast process, Dataquest combined worldwide electronic equipment production numbers for 1997 to 2002 with semiconductor input/output (I/O) analysis. This process generated the following worldwide semiconductor forecast (with the final forecast shown in parentheses):

- 1998: $148 billion for the production-based estimate of semiconductor consumption (versus the final forecast of $138 billion)
- 1999: $165 billion for the production-based estimate of semiconductor consumption (versus the final forecast of $155 billion)
- 2000: $196 billion for the production-based estimate (versus a $190 billion final forecast)
- 2001: $230 billion for the production-based estimate (versus a $235 billion final forecast)
- 2002: $242 billion for the production-based estimate (versus a $254 billion final forecast)

The forecast methodology process uses this information as a central input and "reasonable test" for generating the final semiconductor forecast.

 ©1998 Dataquest

Forecast Methodology

The worldwide semiconductor revenue forecast consists of an interlinked set of regional product consumption forecasts. A team of product and regional experts generate regional product forecasts. The experts are chosen on the basis of their knowledge of key application trends, unit growth rates, and local economic factors. The team also has expertise on capacity, pricing, and related factors.

Each regional product forecast (for example, the Asia/Pacific digital signal processor [DSP] forecast) is rolled into a single worldwide product forecast. Also, the regional product forecasts (for example, Japanese consumption of DSP, DRAM, and so on) are rolled into a single regional forecast. As noted, the interlinked forecasts ultimately are rolled into the worldwide product forecast.

The basic methodology is as follows:

- Under the aegis of the worldwide product director, a regional product expert provides a "first-pass" regional product consumption forecast to the worldwide product director; for example, the microcontroller (MCU) expert in Japan provides a five-year forecast of MCU consumption in Japan to the worldwide MCU director; the worldwide director compiles the full set of MCU regional forecasts and then reviews the resultant worldwide MCU revenue totals and growth rates.
- Concomitantly, under the aegis of a regional forecast director, the first-pass regional product forecasts are also sent by the regional product experts to the regional forecast director. For example, the MCU expert, the DRAM expert, and so on in Japan also send their Japanese consumption market forecasts to the Japan regional forecast director. The regional forecast director compiles the regional product forecasts into a regional forecast and then reviews the resultant regional revenue totals and growth rates.
- The process remains interactive as the regional product forecasts are fine-tuned. When agreement has been reached on these regional product forecasts, a "proposed" worldwide forecast is reviewed by a team of worldwide and regional product analysts. This process typically requires selective modification to worldwide product forecasts, including regional forecasts. The process includes scrutiny of worldwide growth rates, product growth, regional growth, supply and capacity, pricing, potential forecast accelerators or inhibitors, and related factors.
- By consensus, the final worldwide and regional semiconductor product forecasts are then generated and published from the forecast database.

Perspective

Three straight disappointing years have challenged semiconductor industry confidence. The Asian crisis and its spreading impact outside Asia heighten near-term concern. Recent semiconductor company consolidation resulting from overcapacity contributes to this concern. The next six to nine months mark a critical period as the industry tries to rebound and re-establish revenue vitality.

 ©1998 Dataquest

This forecast analysis identifies specific assumptions that serve as the basis for the semiconductor product and regional forecasts. The analysis also includes factors that could accelerate or inhibit the forecast rates of growth. Under current economic conditions, the near-term inhibitors are likely to capture attention.

For example, if Japan's economy becomes weaker than expected, then China might revalue its currency in 1999 in order to maintain export competitiveness. In turn, this move could make the Asian crisis deeper and more prolonged than expected—with obviously negative implications for near-term semiconductor demand and pricing. At this point , multiple factors could restrain semiconductor revenue growth during late 1998 and well into 1999.

By contrast, our long-range forecast assumes that semiconductors will retain market vitality and expand over the next five years. For the long term, worldwide information technology (IT) spending should grow at a CAGR of 11 to 12 percent. Semiconductors will have to compete against software and IT services for a share of corporate spending budgets. Even so, semiconductors will win a place in many systems demanded by business and consumer users.

The semiconductor market should grow at a rate similar to the growth in the IT market, partly on the long-term assumption that the DRAM oversupply will continue into 2000. As noted, under current economic conditions, it is easy to overlook factors that could accelerate the forecast rates of growth. For example, it is not early to predict the emergence of the next PC or Internet-based "killer application." Certainly no such application seems to be on the near-term horizon. Although such developments are hard to predict, the forecast analysis recognizes that microprocessor- or DSP-based killer applications could accelerate long-term growth well above the 12 percent rate. Also, the forecast anticipates an eventual but mild DRAM shortage (versus the 1995 experience). Although hard to envisage now, a post-1999 DRAM shortage akin to 1995 would mean accelerated long-term growth.

Chapter 2
Worldwide Product Forecasts

The tables in this chapter provide the complete five-year forecast by product type for the worldwide semiconductor market. This chapter also provides semiconductor demand expectations for the PC, communications, and consumer application markets.

Worldwide Semiconductor Product Forecast and History

Table 2-1 provides the five-year forecast through 2002 by product type for the worldwide semiconductor market. We term this the "most likely" forecast for each product. This table shows total semiconductor market growth including DRAM and also without DRAM. Table 2-2 shows revenue history by product type for the 1992-1997 period.

The tables show that the worldwide semiconductor market should grow at a 12 percent-plus CAGR during the five-year period from 1997 to 2002. This growth rate contrasts with the much stronger 18 percent CAGR for 1992 to 1997.

Assumptions: Most Likely Forecast, Accelerators, and Inhibitors

The forecasts in this report provide the most likely forecast for that product or region. Each most likely forecast includes a set of assumptions that serve as the basis for the forecast. Near-term assumptions generally refer to the late 1998-to-1999 period, whereas long-term assumptions usually pertain to the post-1999 time frame.

Also, the forecast analysis includes a set of factors that could accelerate the forecast rate of growth plus a set of factors that would inhibit and lower the forecast growth rate.

Assumptions for the Most Likely Forecast

The following are the high-level assumptions for the most likely worldwide forecast:

- Worldwide PC unit shipments will grow about 15 percent per year; however, PC average selling prices (ASPs) will continue to fall. At best, PC revenue will grow annually at a single-digit rate.
- The semiconductor market will continue to confront oversupply; the foundry oversupply will persist for the next 18 months and the DRAM oversupply until mid- or late 2000.
- Despite continuing oversupply, DRAM pricing should stabilize during 1999 following the price collapse of the 1996-to-1998 period.
- The Internet will drive the wired communications chip market in both the near term and the long term; the Internet should mean growth for high-end microprocessors (MPUs) used in computer servers.
- Europe should experience strong growth in PC and digital cellular handset production.

Source: Dataquest (September 1998)

©1998 Dataquest

- Demand throughout Asia, including Japan, for semiconductor-based products will remain sluggish at best.
- Good growth in consumer electronics in the Americas, especially the United States, will be offset by weaker demand in other world regions.
- The impact on semiconductor demand from broader information technology market trends, such as corporate spending on year 2000 (Y2K) solutions and European Monetary Union (EMU) conversion, remains uncertain.

Potential Accelerators to Growth

Although today's economic conditions cause more concern about market inhibitors, several factors could accelerate worldwide semiconductor revenue growth to a CAGR of more than 11.5 percent.

Strong Emerging Economy Demand for Communications and Consumer Electronics

As noted, the most likely forecast expects sluggish Asian demand for the next several years. Semiconductor growth would accelerate if demand for new communication systems and consumer products proves stronger than expected in the emerging economies of Asia, Eastern Europe, and Latin America.

Faster Adoption of Digital Consumer Electronics

The most likely forecast anticipates the emergence of DVD, digital TV, and other consumer digital systems and appliances. The trend has been "stop and start," with expectations often exceeding market results. If the pace of adoption accelerates, so would semiconductor growth.

Voice Recognition

Voice recognition technology has existed for years but has never quite made a dramatic market impact. The most likely forecast expects voice technology to have growing yet nondramatic impact on semiconductor demand. Accelerated adoption of voice technology by digital users would boost semiconductor growth.

Killer PC and Multimedia Applications

The most likely forecast is not based on the expectation that some amazing killer PC or multimedia application will emerge over the next several years. Even so, it is plausible that in the year 2000 or so, a semiconductor-intensive product will sweep worldwide or regional markets. Internet-based computing, communication, and consumer appliances come to mind. If such an unpredictable killer application emerges, semiconductor growth would accelerate.

©1998 Dataquest

Potential Inhibitors to Semiconductor Growth

As noted, following the 1998 decline, worldwide semiconductor revenue should increase by nearly 12 percent in 1999 and at an 11.5 percent CAGR for the 1997-to-2002 time frame. The following factors could, however, cause slower semiconductor market growth.

Deeper Decline and Slower Recovery in Asia

Although the most likely forecast assumes Asian economic weakness during the 1998-to-1999 period, conditions in Asia could deteriorate even more than expected. In the near term, recession might become depression in many Asian countries, meaning weaker-than-expected 1999 semiconductor demand and pricing. The long-term restructuring of Japan's banking system could have a sharp impact not only on exchange rates but also on Asian trade.

U.S. Economic Downturn

The most likely forecast assumes steady-to-strong American demand for systems that use semiconductors. For example, a U.S. economic downturn, in a ripple effect from Asia, could thwart semiconductor revenue growth.

Fierce Competition That Drives Down ASPs

The semiconductor market will remain highly competitive, and the most likely forecast assumes competitive long-term pricing. The forecast assumes, however, that semiconductor pricing in the near term will be less brutal for vendors than in the recent past. For example, the forecast assumes that factors such as industry consolidation (for example, the Hyundai-LG Semicon "Big Deal" and Micron's purchase of Texas Instruments' memory business) should moderate intense competition and extreme pricing pressure.

Any unexpectedly strong intensification of competition, by contrast, would inhibit post-1998 revenue growth by driving down semiconductor ASPs.

Delay of Access Technologies

The forecast explicitly assumes that the Internet will stimulate near-term growth and then sustain long-term expansion. Long-term semiconductor growth depends on the widespread availability of high-bandwidth technologies like digital modems, digital subscriber line (DSL) service, and the Rambus interface. Delayed access to high-bandwidth technologies would stifle revenue growth.

Semiconductor Demand Outlook by Application Market

As noted, the worldwide electronic equipment production forecast serves as a basis for the semiconductor product forecast.

PCs, wired communications, wireless communications and consumer electronics account for about 70 percent of semiconductor consumption. Trends in these application markets will determine near-term results and generate long-term growth in semiconductor revenue. For the long term, the PC remains the paramount application for compute MPUs and

 ©1998 Dataquest

DRAMs. Servers will eventually emerge as a key application for compute MPUs. Mobile communications , data communications, and digital consumer electronics, among other applications, should drive DSP, MCU, embedded MPU, and digital application-specific IC (ASIC) growth. Flash memory and EEPROM should also benefit from these trends.

The following sections summarize the outlook for the key semiconductor application markets.

Demand for PC Semiconductors

Table 2-3 provides the most likely forecast for semiconductor demand from PC applications. The PC-related market accounts for about 40 percent of worldwide semiconductor demand.

Table 2-3
Worldwide PC Semiconductor Revenue

	1997	1998	1999	2000	2001	2002	CAGR (%) 1997-2002
Revenue ($B)	41.79	38.37	44.18	60.65	78.02	76.03	12.7
Annual Growth (%)	NA	-8.2	15.1	37.3	28.6	-2.5	NA

NA = Not applicable
Source: Dataquest (September 1998)

Short-Term Assumptions for the PC Semiconductor Forecast

These assumptions guide the most likely 1998-to-1999 PC semiconductor forecast shown in Table 2-3.

- PC unit growth is expected to remain in the 13 to 17 percent range throughout the forecast period including 1999; by contrast, PC revenue will grow at a single-digit annual rate.
- The United States will continue to be dominated by a replace-and-upgrade cycle but the strong embrace of the sub-$1,000 PC will prompt more consumers to purchase their first home PC, boosting the penetration rate to more than 40 percent.
- The graphics chip market will face pricing pressure even as manufacturers continue to add features. The corporate computing market will continue to be slow to demand 3-D graphics features. Although it is difficult to buy non-3-D products today, the issue is one of corporate users buying down on the value scale rather than buying up.
- The audio market will face increasing competition from integrated designs with sound chips on the motherboard. Price pressure is extreme and will continue for at least one more year.

Long-Term Assumptions for the PC Semiconductor Forecast

These long-term assumptions guide the most likely PC semiconductor forecast shown in Table 2-3.

- PC unit growth will remain in the 13 to 17 percent range throughout the forecast period; however, PC ASPs will continue to fall. At best, PC revenue will grow annually at a single-digit rate.

 ©1998 Dataquest

- A cyclical upturn in DRAM revenue in 2000 and 2001 will be the primary drivers of overall PC semiconductor revenue growth.
- PC main memory sizes will track historic trends and grow in the range of 40 to 45 percent per year.

Accelerators to the PC Semiconductor Forecast

These assumption factors, if they occur, will accelerate the most likely forecast shown in Table 2-3. The result would be higher growth rates and revenue levels for PC semiconductors than those shown in the table.

- Continued attrition of vendors in key segments, including DRAM and graphics, could reduce competition to levels at which vendors regain the ability to charge substantial price premiums, increasing both semiconductor ASPs and profit margins.
- Sustained PC demand coupled with a leveling-off or increase in PC ASPs would lead to both an increase in dollars spent on semiconductor devices per PC and an overall increase in semiconductor revenue. The increase in semiconductor spending would be driven by device shortages caused by current light capital spending.
- Strengthening in the economies in the Asia/Pacific region and Japan, or increased Western European and U.S. consumption made possible by lower manufacturing costs in these economies, could drive higher consumption.

Inhibitors to the PC Semiconductor Forecast

The occurrence of these assumption factors would inhibit the forecast shown in Table 2-3. The result would be lower growth rates and revenue levels for PC semiconductors than those shown in the table.

- Corporate PC purchasers, stirred by the acceptance of the sub-$1,000 PC price category in the consumer segment, could force OEMs to bring down the mainstream feature set to sub-$1,000 PC and below. This development could severely limit semiconductor revenue as PC OEMs force semiconductor suppliers to take the brunt of the price drops. A similar impact would occur if PC OEMs choose to slow the acceptance of higher-priced leading-edge technologies.
- The transition to Direct Rambus main memory could proceed poorly and delay the introduction of a next-generation memory thus limiting perceived performance gains in the entire PC platform. PC buyers, seeing little compelling evidence of performance improvements from the new technology, might then choose lower-priced alternatives.
- PC growth in the developing Asia/Pacific and Latin American markets could slow because of economic issues stemming from the current financial crises.
- Changes in consumption trends driven by PC buying pattern changes and continued weaknesses in consumer spending could prolong overcapacity through more of the forecast period.

Demand for Communication Semiconductors

Table 2-4 provides the most likely forecast for semiconductor demand from wired and wireless communication applications

Table 2-4
Worldwide Communications Semiconductor Revenue

	1997	1998	1999	2000	2001	2002	CAGR (%) 1997-2002
Revenue ($B)	29.93	31.46	34.16	36.72	39.58	42.67	7.4
Annual Growth (%)	NA	5.1	8.6	7.5	7.8	7.8	NA

NA = Not applicable
Source: Dataquest (September 1998)

Assumptions for the Communications Semiconductor Forecast

These assumptions guide the most likely communications semiconductor forecast shown in Table 2-4. The communications market accounts for about 20 percent of worldwide semiconductor demand. This segment includes both wired communications and wireless communications semiconductor applications.

- Wireless communications semiconductors
  - There will be a modest recovery in the Asia/Pacific digital cellular market by the end of 1999.
  - Digital cordless telephones will retain continued popularity beyond 1999.
  - "Third-generation" cellular is not expected to have a significant impact on semiconductor consumption during the 1997-2002 forecast horizon.
- Wired communications semiconductors
  - Driven by Internet bandwidth upgrades, semiconductor consumption by the public infrastructure equipment market will remain strong.
  - Gigabit Ethernet remains a backbone technology during the 1997-to-2002 forecast horizon.
  - Cable modems and xDSL modems are on track for deployment in the 2001/2002 time frame.

Accelerators to the Communications Semiconductors Forecast

These assumption factors, if they occur, will accelerate the forecast shown in Table 2-4. The result would be higher growth rates and revenue levels for communications semiconductors than those shown in the table.

- Adoption rates
  - A dramatic pickup in demand for communications systems in the Middle East, Africa, and India.
  - A substantial uptake of wired and wireless home networking technology.

- Wireless communications semiconductors
  - The rapid adoption of enhanced feature phones, for example, smart phones
  - Significant deployment of 3rd-generation cellular products prior to 2002
  - Unimpeded high growth rates for digital cellular handsets and infrastructure in the Americas and Europe
- Wired communications semiconductors
  - Widespread adoption of Gigabit Ethernet (10/100/1,000-Mbps) to the desktop, especially physical layer devices for copper media
  - Significantly increased Internet bandwidth demand fueled by killer multimedia applications

Inhibitors to the Communications Semiconductors Forecast

These assumption factors, if they occur, will inhibit the forecast shown in Table 2-4. This would mean lower growth rates and revenue levels for communications semiconductors than shown in the table.

- Wireless communications semiconductors
  - A deeper Asian financial crisis with sharper negative impact on Asia/Pacific digital cellular handset and infrastructure deployment.
  - More severe price erosion fueled by fierce competition
  - Price erosion caused by breakthroughs in technologies such as silicon germanium (SiGe)
- Wired communications semiconductors
  - Standardization or implementation delays of next access technologies such as xDSL and cable modems
  - More severe price erosion fueled by fierce competition

Demand for Consumer Electronics Semiconductors

Table 2-5 provides the most likely forecast for semiconductor demand from consumer electronics applications. The consumer electronics market accounts for about 10 percent of worldwide semiconductor demand.

Table 2-5
Worldwide Consumer Electronics Semiconductor Revenue

	1997	1998	1999	2000	2001	2002	CAGR (%) 1997-2002
Revenue ($B)	23.77	24.86	26.54	28.22	30.46	33.1	6.8
Annual Growth (%)	NA	4.6	6.7	6.4	7.9	8.6	NA

NA = Not applicable
Source: Dataquest (September 1998)

Short-Term Assumptions for the Consumer Semiconductor Forecast

These assumptions guide the most likely 1998-to-1999 consumer electronics semiconductor forecast shown in Table 2-5.

- Growth in Asia/Pacific will be slower than expected; China will remain strong, while the rest of the region will sees slowing growth in gross domestic product or recession.
- Consumer electronics market saturation in Europe and recession in Japan will depress sales growth.
- Demand in the Americas, and especially in the United States, will be much stronger; for example, U.S. video and audio sales will rebound strongly in 1998 while TV sales growth will hit record levels.

Long-Term Assumptions for the Consumer Semiconductor Forecast

These long-term assumptions guide the most likely 1999 consumer electronics semiconductor forecast shown in Table 2-5.

- The Asian economy will recover; China will remain strong, and other countries will return to healthy growth and consumer electronics demand.
- Japan will remain in economic doldrums throughout forecast period.
- The consumer market in the Americas and Europe will gain strength with the popularity of new digital products.

Accelerators to the Consumer Semiconductors Forecast

These assumption factors, if they occur, will accelerate the most likely forecast shown in Table 2-5. The result would be higher growth rates and revenue levels for consumer electronics semiconductors than those shown in the table.

- Acceptance of digital TV (DTV) and digital set-top boxes in the Americas and Europe may be faster than expected; interactive television may explode.
- Asian economies may recover by the end of 1998 or early 1999; strong Asian New Year's sales may boost the market in 1999.
- The U.S. economy may grow faster than expected; Japan's economy may return to strong growth during the forecast period.
- Emerging economies (Africa, the Middle East, and India, for example) may experience a dramatic pickup in demand for consumer goods.

Inhibitors to the Consumer Semiconductors Forecast

These assumption factors, if they occur, will inhibit the forecast shown in Table 2-5. The result would be lower growth rates and revenue levels for consumer electronics semiconductors than those shown in the table.

- The economic downturn may continue in Asia/Pacific and Japan.
- The U.S. economy may weaken, especially because the Americas represent nearly 40 percent of the worldwide consumer electronics market.
- The Asian financial crisis may spread to China, which is a major factor in our most likely growth scenario.
- Digital products may fail; DTV and digital set-top boxes may stall.
- PCs may eat into the market share of video games and television.

 ©1998 Dataquest

Product Forecasts

The following section identifies the assumptions that serve as the basis for each semiconductor product forecast in Table 2-1. As noted, we characterize Table 2-1 as the most likely forecast for each product. In addition, the following analysis includes assumption factors that could either accelerate or inhibit each product growth forecast.

ASIC, Logic, and SLI Forecast

The forecast in Table 2-1 shows that worldwide logic/ASIC revenue will increase by 6 percent in 1999 and total $25 billion, following a sharp 5 percent decline for 1998. The ASIC market during 1998 experienced the worst percentage revenue change in history. Gate array revenue declined by nearly 20 percent, while revenue from programmable logic devices (PLDs) and CBICs marginally increased. In the long term, worldwide revenue will grow at a 10 percent CAGR and reach $40 billion by 2002. This growth will be fueled in part by the trend toward system-level integration (SLI).

Short-Term Assumptions for the ASIC Forecast

These assumptions guide the most likely 1998-to-1999 logic/ASIC forecast shown in Table 2-1.

- ASIC and logic market growth stalled during 1998 for three main reasons:
  - A general industry slowdown
  - The Asian financial crisis
  - An associated accelerated rate of ASP declines
- Logic markets will remain flat into 1999; there will be no significant increase in ASIC/logic quarterly revenue until the second or third quarter of 1999.
- Other logic—which includes application specific standard products (ASSPs)—should show strong unit growth, but also above-average price declines.
- Custom ICs are rapidly being replaced by ASICs because they offer shorter time to market.
- Standard logic has a small number of suppliers, and the market remains a relatively flat.

Long-Term Assumptions for the ASIC Forecast

These long-term assumptions guide the most likely logic/ASIC forecast, shown in Table 2-1.

- ASIC growth will be driven by CBICs and PLDs at the expense of gate arrays.
- SLI will fuel the growth of the cell-based IC market as MPUs, DRAMs, and other intellectual property (IP) blocks are integrated on-chip.
- Key ASIC/ASSP application market drivers include the following: disk drives, workstations, servers, digital cellular, LAN/WAN, premise and central office switching systems, set-top boxes, video games, digital camcorders, still cameras, and digital TV
- ASICs will be converted to ASSPs as application markets mature.

 ©1998 Dataquest

Accelerators to the ASIC Forecast

These assumption factors, if they occur, will accelerate the most likely ASIC and logic forecast shown in Table 2-1. The result would be higher growth rates and revenue levels for ASICs than those shown in the table.

- If application demand picks up in the first half of 1999, we could see a 10 percent upside in logic revenue for the 1999.
- In the longer term, if core standards for plug-and-play are put into practice in the next year, we could see more designs go to production in a shorter time period, thus taking up ASIC and ASSP revenue.
- Major consolidation in the industry could ultimately cause pricing to stabilize and increase long-term revenue growth.

Inhibitors to the ASIC Forecast

These assumption factors, if they occur, will inhibit the most likely ASIC and logic forecast shown in Table 2-1. The result would be lower growth rates and revenue levels for ASICs than those shown in the table.

- If near-term pricing aggressively declines because a vast number of suppliers target the same SLI markets, CBIC revenue will grow more slowly than expected.
- The rate at which SLI is adopted may slow.
    - SLI is the fastest-growing part of the logic market and is rapidly becoming the dominant part.
    - The move to SLI could be negatively affected by competitive pricing for other devices such as memory and microcomponents.
    - The move to SLI could be negatively affected by any limitation on the capability to design and produce SLI devices.
- ASIC growth rates would be negatively impacted by a major ramp-up in ASSPs.
- Unexpected changes in the growth of the major ASIC applications of cellular handsets, central office systems, and networking may occur.

Microprocessor Forecast

The forecast in Table 2-1 is that worldwide MPU revenue will increase by 11 percent in 1999 and total $27 billion, following growth of just 3.3 percent in 1998. Long term, worldwide MPU revenue will grow at a 10 percent CAGR and reach $38 billion by 2002.

Although MPUs are best known for compute applications, we provide additional assumptions for the embedded MPU segment.

Short-Term Assumptions for the MPU Forecast

These assumptions guide the most likely 1998-to-1999 MPU forecast shown in Table 2-1.

- Intel's high-end Xeon processors will begin to offset desktop MPU ASP erosion in the second half of 1998, but will not offset such erosion completely until 1999, when Intel offers support for four- and eight-way server configurations.

 ©1998 Dataquest

- As noted before, annual worldwide PC unit growth will remain in the 13 to 17 percent range for both the near term and the long term. PC ASPs, however, will continue to fall, so that PC revenue will grow annually at a single-digit rate.

Long-Term Assumptions for the MPU Forecast

These long-term assumptions guide the most likely MPU forecast shown in Table 2-1.

- Throughout the forecast period, general-purpose, "PC-like" devices will continue as the dominant mechanism for users to access the Internet and to perform other data processing functions in the home and office.
- As indicated, PC prices and ASPs will continue to trend down, as users see little reason to buy high-performance (and expensive) systems to use with current application software that places few demands on CPU performance.
- In the later years of the forecast period, new software applications and usage paradigms will evolve that will tax the processing power of the much faster processors then available and motivate users to replace older systems. Some of these new applications will expand the market by making computers relevant to users who previously had no need for such devices. Vast increases in communications bandwidth to homes and small office environments will enable many of these applications.

Accelerators to the MPU Forecast

These assumption factors, if they occur, will accelerate the most likely forecast shown in Table 2-1. The result would be higher growth rates and revenue levels for MPUs than those shown in the table.

- System purchasers may conclude—in large numbers—that they can afford to purchase more computing performance at current prices than they realistically need to do their jobs, thus stemming PC and MPU price erosion.
- Our MPU forecast presently does not expect either of the following technological capabilities to be widely deployed during the forecast period:
  - High-bandwidth communications facilities (including cable modems and DSL technology) may achieve critical mass sooner than expected.
  - Corporations may accelerate the conversion to more sophisticated computing environments, both in response to lower prices and to cover Y2K exposure resulting from continued use of mature software systems.
- New usage paradigms, in particular voice-based natural language user interfaces, may reach maturity more rapidly than Dataquest presently expects and facilitate the onset of new applications that tax processor performance.

 ©1998 Dataquest

Inhibitors to the MPU Forecast

These assumption factors, if they occur, will inhibit the forecast shown in Table 2-1. The result would be lower growth rates and revenue levels for MPUs than those shown in the table.

- PC growth in the developing Asia/Pacific and Latin American markets may slow more than expected because of economic issues stemming from the current financial crises.
- Corporations may defer computer purchases in order to fund software fixes to the Y2K problem.
- Improved communications bandwidth facilities may fail to emerge, as regulators and local exchange carriers continue to debate how such facilities will be funded.
- Technological dislocation may slow market growth—for example, such dislocation might occur should the U.S. government succeed in breaking up Microsoft, Intel, or both on antitrust grounds.

Assumptions for the Most Likely Embedded MPU Forecast

The following assumptions guide the embedded MPU forecast shown:

- Demand remains suitably strong for proven embedded applications such as office equipment, routers and hubs, video games, satellite receivers, and set-top boxes.
- High-performance MPUs have been offered at much lower prices than previously, so that $20 can buy nearly 200 MIPS.
- The attraction for building an ASIC with a deeply embedded MPU core will take away some embedded MPU business.

Accelerators to the Embedded MPU Forecast

These assumption factors, if they occur, will accelerate the most likely MPU forecast shown in Table 2-1. The result would be somewhat higher growth rates and revenue levels than those shown in the table.

- Vendors may develop sufficient peripherals integrated with processors to slow the move to custom solutions in SLI ASICs.
- Windows CE may spur enough developers to consider the platform for their ideas to really uncover a "killer application," and the hardware, software, service, and licenses may all be low-cost.

Inhibitors to the Embedded MPU Forecast

The occurrence of these assumption factors would inhibit the most likely forecast shown in Table 2-1 and result in lower revenue and growth rates.

- Microprocessor core availability in ASICs may become available from so many vendors that the value becomes minimal, lowering ASPs.
- Too many vendors may focus on network applications, so that prices for high-performance MPUs erode.

 ©1998 Dataquest

Microcontroller Forecast

The forecast in Table 2-1 shows that worldwide MCU revenue will increase by 7 percent in 1999 and total $10.4 billion, following a sharp 11 percent decline for 1998. In the long term, worldwide MCU revenue will grow at a CAGR of 10 percent and reach $17 billion by 2002.

Assumptions for the Most Likely MCU Forecast

These assumptions guide the most likely MCU forecast shown in Table 2-1.

- Prices for MCUs eroded badly during 1998, meaning low 1999 price levels.
- Growth for 16- and 32-bit MCUs will increase more quickly than previously expected.
- More exotic features such as flash memory will be offered at low adders.

Accelerators to the MCU Forecast

These assumption factors, if they occur, will accelerate the most likely MCU forecast shown in Table 2-1. The result would be higher growth rates and revenue levels for MCUs than those shown in the table.

- Vendors may pursue completely new markets in the low end, building the overall base.
- More configurations of existing MCUs may become available with one-time programmable and flash memories.
- Higher-performance 8-bit MCUs may become available, allowing 16-bit MCUs to retain higher prices.
- It may happen that 4-bit MCUs are more rapidly upgraded to slightly more expensive 8-bit MCUs.
- The United States may find a need for smart cards.

Inhibitors to the MCU Forecast

The occurrence of this assumption factor would inhibit the most likely MCU forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- More former DRAM vendors may get into the microcontroller business, improving margins for themselves but lowering margins overall, without significantly increasing overall market.

DSP Forecast

Table 2-1 shows that worldwide DSP revenue will increase by 19 percent in 1999 and total $5 billion, following 14 percent growth for 1998, which was below expectations. In the long term, worldwide DSP revenue will grow at a 22 percent CAGR and reach $10 billion by 2002.

 ©1998 Dataquest

Assumptions for the DSP Forecast

These assumptions guide the most likely DSP forecast shown in Table 2-1.

- Demand for cellular phones, modems, and disk drives is no longer increasing as fast as demand for DSPs.
- New architectures of high-performance DSPs reduce the cost-per-function in high-density DSP arrays.
- Digital signal processing can open a host of new applications for mobile and Internet communications and consumer interactivity.

Accelerators to the DSP Forecast

These assumption factors, if they occur, will accelerate the most likely DSP forecast shown in Table 2-1. The result would be higher growth rates and revenue levels than those shown in the table.

- Off-network data communications may continue to be upgraded as cheaply and as easily as the 56K modem allowed, without infrastructure changes or with infrastructure upgrades in lockstep.
- Dedicated DSPs may open significant new human interfaces to microprocessor-based equipment.

Inhibitors to the DSP Forecast

The occurrence of these assumption factors would inhibit the most likely DSP forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- Software development tools for the exotic DSP architectures may be inadequate for rapid acceptance.
- Microprocessors may be fast enough and well enough supported in digital signal processing techniques to severely reduce the number of applications that require separate DSP chips.

Memory IC Forecast

Table 2-1 shows that worldwide memory IC revenue will increase by 24 percent in 1999 and total $46 billion, following a steep 21 percent decline for 1998. In the long term, worldwide memory revenue will grow at a CAGR of 16 percent and reach $65 billion by 2002.

Short-Term Assumptions for the Memory IC Forecast

These assumptions guide the most likely 1998-to-1999 memory IC forecast shown in Table 2-1.

- Nearly all memory prices will continue to suffer because of an industry overcapacity situation.
- No near-term changes are anticipated in already-existing bit or unit consumption trends.
- The effects of embedded memory on existing markets will be negligible.

 ©1998 Dataquest

Long-Term Assumptions for the Memory IC Forecast

These long-term assumptions guide the most likely memory IC forecast shown in Table 2-1.

- DRAM consumption will catch up with capacity in 2000, and an undercapacity will occur in 2001, to be corrected in 2002.
- Flash memory will displace EPROM, but other memory markets will continue along their current paths: strong growth for EEPROM, modest growth for mask ROM and SRAM.

Short-Term Accelerators to the Memory IC Forecast

These assumption factors, if they occur, will accelerate the most likely memory IC forecast shown in Table 2-1. The result will be higher growth rates and revenue levels than those shown in the table.

- Market attrition could support price increases.
- Strengthening in the economies in Asia Pacific and Japan, or increased American or European consumption allowed by lower manufacturing costs in these economies, could drive higher consumption.

Long-Term Accelerators to the Memory IC Forecast

The occurrence of these assumption factors would accelerate the most likely memory IC forecast shown in Table 2-1 and result in higher revenue and growth rates.

- The DRAM shortage of 2000-to-2001 could be worse than anticipated, driving costs significantly higher.
- Vendor attrition or unprecedented consumption could exacerbate anticipated long-term shortages, meaning stronger and higher prices.

Short-Term Inhibitors to the Memory IC Forecast

These assumption factors, if they occur, will inhibit the most likely memory IC forecast shown in Table 2-1. The result would be lower growth rates and revenue levels than those shown in the table.

- Worsening of already-miserable market pricing practices could drive negative growth in 1999.
- Lower consumption stemming from depressed economies could cause usage to drop and competition to worsen.

Long-Term Inhibitors to the Memory IC Forecast

The occurrence of these assumption factors would inhibit the most likely memory IC forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- Changes in consumption trends driven by PC buying pattern changes and continued weaknesses in consumer spending may prolong overcapacity through more of the forecast period.
- DRAM overcapacity may cause manufacturers to invade and destroy all memory markets, causing recovery to be more difficult.

 ©1998 Dataquest

DRAM Forecast

Table 2-1 shows that worldwide DRAM revenue will increase by 30 percent in 1999 and total $19 billion, following a 31 percent plummet for 1998. In the long term, worldwide DRAM revenue will grow at a 17 percent CAGR and reach $46 billion by 2002.

Short-Term Assumptions for the DRAM Forecast

These assumptions guide the most likely 1998-1999 DRAM forecast shown in Table 2-1.

- Bit growth in the near term will be about average at 66 percent.
- Prices during late 1998 and 1999 will commence to level off, driven partly by the conversion to PC100 and partly by antidumping findings against Hyundai and LG Semicon.
- The current overcapacity will not resolve itself in the near term.

Long-Term Assumptions for the DRAM Forecast

These long-term assumptions guide the "most likely" DRAM forecast shown in Table 2-1.

- DRAM overcapacity will continue until demand meets capacity in 2000.
- The year 2001 will be marked by undercapacity, and the resultant profit cycle will be similar to those of 1980, 1984, and 1989; a repeat of the cycle of 1995 will not occur within our lifetimes.

Short-Term Accelerators to the DRAM Forecast

These assumption factors, if they occur, will accelerate the most likely 1998-to-1999 forecast shown in Table 2-1. The result would be higher growth rates and revenue levels than those shown in the table.

- Closure of significant DRAM fab capacity could have a very strong effect on increasing prices.
- Stronger than expected bit demand might drive spot shortages and combine with firming prices to make 1998 better than expected.

Long-Term Accelerators to the DRAM Forecast

The occurrence of these assumption factors would accelerate the most likely DRAM forecast shown in Table 2-1 and result in higher revenue and growth rates.

- Increases in PC consumption of DRAM over key historical averages could drive an earlier shortage of more important magnitude; historical averages have been 15 percent unit growth for PCs and 45 percent annual increases in system memory size.
- A shakeout in the market, accompanied by complete desertion by more than one major supplier, could reduce competition, making possible higher pricing.

 ©1998 Dataquest

Short-Term Inhibitors to the DRAM Forecast

These assumption factors, if they occur, will inhibit the 1998-to-1999 DRAM forecast shown in Table 2-1. The result would be lower growth rates and revenue levels than those shown in the table.

- Current below-variable-cost pricing could continue to erode, driving revenue to completely unsustainable levels.
- Current above-average bit growth in 1998 may dwindle down to below average, or 1999 bit growth may counterbalance the high bit growth of 1997 and 1998.

Long-Term Inhibitors to the DRAM Forecast

The occurrence of these assumption factors would inhibit the most likely DRAM forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- Acceptance of the sub-$1,000 PC may squeeze OEMs to the point that they cannot afford to put more memory into the PC, and per-PC megabyte growth may falter.
- Manufacturing efficiencies may accelerate, allowing today's capacity to exceed demand beyond 2000.

SRAM Forecast

Table 2-1 shows that worldwide SRAM revenue will increase by 16 percent in 1999 and total $5 billion, following a 9 percent increase for 1998. In the long term, worldwide SRAM revenue will grow at a 16 percent CAGR and reach $8.6 billion by 2002.

Short-Term Assumptions for the SRAM Forecast

These assumptions guide the "most likely" 1998-to-1999 SRAM forecast shown in Table 2-1.

- Depressed pricing will continue, despite consolidation of the PC cache market.
- Other end markets will move in a relatively predictable direction; however, the current oversupply will keep prices low.

Long-Term Assumptions for the SRAM Forecast

These long-term assumptions guide the most likely SRAM forecast shown in Table 2-1.

- A foundry overcapacity situation will keep prices from recovering.
- Bit growth, density migration, and speed improvement will continue along trends that have been in place for the past three years.

Short-Term Accelerators to the SRAM Forecast

These assumption factors, if they occur, will accelerate the most likely 1998-to-1999 SRAM forecast shown in Table 2-1. The result would be higher growth rates and revenue levels than those shown in the table.

- Greater consumption of electronics goods, driven by lower manufacturing costs in the troubled Asia/Pacific economies, could increase overall consumption in the western world.

 ©1998 Dataquest

- Possible adoption of level-three cache memories in Pentium II- and Celeron-based PCs could unleash new growth in the PC cache arena.

Long-Term Accelerators to the SRAM Forecast

The occurrence of these assumption factors would accelerate the most likely forecast shown in Table 2-1 and result in higher revenue and growth rates.

- A recovery in the Japanese economy, and commensurate increases in spending on high-end consumer electronics goods, could drive unpredicted consumption, resulting in higher unit consumption, faster density migration, and less competitive pricing.
- Movement to more complex interfaces such as Zero Bus Turnaround (ZBT), double data rate (DDR), and others could increase ASPs to account for the greater complexity of the part, the increased difficulty of test, and the fact that fewer vendors will be interested in participating in the market, driving competition down and prices up.

Short-Term Inhibitors to the SRAM Forecast

These assumption factors, if they occur, will inhibit the most likely SRAM forecast shown in Table 2-1. The result would be lower growth rates and revenue levels than those shown in the table.

- Further intrusion into the SRAM market by distressed DRAM suppliers could cause SRAM pricing to drop below cost, as in the DRAM market.
- Continuing financial woes in countries that consume large volumes of high-technology products could lead to sales shortfalls, affecting all suppliers that produce subassemblies and components used in these devices.

Long-Term Inhibitors to the SRAM Forecast

The occurrence of these assumption factors would inhibit the most likely SRAM forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- The adoption of DRAM into traditional SRAM applications could displace a large portion of the SRAM market. This possibility would be enabled by the increasing ease with which a DRAM controller can be added to an ASIC.
- Embedded volatile memory, either DRAM or SRAM, could be used to displace discrete SRAM chips in many applications, competing against discrete devices and displacing their market.

Nonvolatile Memory Forecast

Table 2-1 shows that worldwide nonvolatile revenue will increase by 16 percent in 1999 and total $5.9 billion, following a sharp 9 percent decline for 1998. In the long term, worldwide revenue will grow at a CAGR of 11 percent and reach $9.4 billion by 2002.

Flash memory and EEPROM will drive nonvolatile market growth. For example, EEPROM will surpass the $1 billion level in 1998 and approach $1.9 billion for 2002. This growth would result in an impressive five-year CAGR of 15 percent. Although flash revenue will decline in 1998 because of aggressive pricing, bit shipments continue to zoom. More stable pricing should enable worldwide revenue to grow at an 18 percent CAGR and exceed $6 billion by 2002.

Short-Term Assumptions for the Nonvolatile Memory Forecast

These assumptions guide the most likely 1998-to-1999 nonvolatile memory forecast shown in Table 2-1.

- The flash market will continue to be oversupplied in the near term, and competitive pricing of both flash and EPROM will reflect this oversupply. EEPROM and mask ROM will enjoy stable pricing.
- Flash and EEPROM bit consumption will continue to grow dramatically. ROM will continue to grow modestly, and EPROM will continue to be displaced by cheap flash memory.
- Flash will displace EPROM now that more attractive prices are available.

Long-Term Assumptions for the Nonvolatile Forecast

These long-term assumptions guide the most likely nonvolatile forecast shown in Table 2-1.

- The flash market will grow more from increased usage in new applications; however, it will also displace EPROM to a great extent over the term of the forecast.
- Mask ROM will continue to grow at a rate established before the great video game boom. The recent adoption of the Nintendo 64 system will not dramatically boost ROM sales.
- EEPROM will continue to grow substantially, driven by its use in smart cards, DRAM modules, and microcontroller-based equipment.

Short-Term Accelerators to the Nonvolatile Forecast

These assumption factors, if they occur, will accelerate the most likely nonvolatile forecast shown in Table 2-1. The result would be higher growth rates and revenue levels than those shown in the table.

- Pricing may stabilize because less fab capacity than needed comes on line in the near term.
- Greater consumption of electronics goods driven by lower manufacturing costs in the troubled Asia/Pacific economies could increase overall consumption in the western world.

Long-Term Accelerators to the Nonvolatile Forecast

The occurrence of these assumption factors would accelerate the most likely nonvolatile forecast shown in Table 2-1 and result in higher revenue and growth rates.

- A recovery in the Japanese economy, and commensurate increases in spending on high-end consumer electronics goods, could drive unpredicted consumption, resulting in higher unit consumption, faster density migration, and less competitive pricing.
- The video game market may move wholesale to the use of mask ROMs, driving this market back into prominence.

 ©1998 Dataquest

Short-Term Inhibitors to the Nonvolatile Forecast

These assumption factors, if they occur, will inhibit the nonvolatile forecast shown in Table 2-1. The result would be lower growth rates and revenue levels than those shown in the table.

- Further intrusion into the nonvolatile memory market by distressed DRAM suppliers could cause flash and mask ROM pricing to drop below cost, as in the DRAM market.
- Continuing financial woes in countries that consume large volumes of high-technology products could lead to sales shortfalls, affecting all suppliers that produce subassemblies and components used in these devices.

Long-Term Inhibitors to the Nonvolatile Forecast

The occurrence of these assumption factors would inhibit the most likely nonvolatile forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- Overcapacity from DRAM fabs converted for flash use and overinvestment in dedicated flash fabs and flash-capable foundry could prevent flash memory prices from recovering during the forecast window.
- Faltering new markets led by decreased consumption in the ailing Asian economies could stall consumption, leading both to lower usage and more competitive pricing.

Analog IC Forecast

Table 2-1 shows that worldwide analog IC revenue will increase by 16 percent in 1999 and total $26 billion, following disappointing marginal growth for 1998. In the long term, worldwide analog revenue will grow at a CAGR of 13 percent and exceed $40 billion by 2002.

Short-Term Assumptions for the Analog IC Forecast

These assumptions guide the most likely 1998-to-1999 analog IC forecast shown in Table 2-1.

- Demand has been slowing down in PC, communications, consumer, and industrial markets, among others.
- The Asian economic downturn and its rippling effects on the rest of the world are the main reasons for the slowdown in demand.
- A recovering Asian economy and continued growth in the Americas and Europe in 1999, combined with the inventory reduction at analog IC suppliers in 1998, should bring strong growth back to analog ICs in 1999.

Long-Term Assumptions for the Analog IC Forecast

These long-term assumptions guide the most likely analog IC forecast shown in Table 2-1.

- A semiconductor boom cycle starting in 1999 will continue to result in strong growth for analog ICs in 2000 and 2001.
- The year 2002 could see a slowdown in analog IC growth as the semiconductor market enters its next cyclical downturn.

 ©1998 Dataquest

Short-Term Accelerators to the Analog IC Forecast

These assumption factors, if they occur, will accelerate the most likely analog IC forecast shown in Table 2-1. The result would be higher growth rates and revenue levels for analog IC than those shown in the table.

- Stronger-than-expected recovery in the Asian economies would strengthen analog IC demand.
- Strength in the PC market may continue beyond the seasonally strong fourth quarter of 1998.

Long-Term Accelerators to the Analog IC Forecast

The occurrence of these assumption factors would accelerate the most likely analog IC forecast shown in Table 2-1 and result in higher revenue and growth rates.

- Strong emergence of new digital application markets
- Availability of more analog design talent

Short-Term Inhibitors to the Analog IC Forecast

These assumption factors, if they occur, will inhibit the most likely analog IC forecast shown in Table 2-1. The result would be lower growth rates and revenue levels than those shown in the table.

- Worsening turmoil in the emerging financial markets, triggering global crisis
- Slowdown of economic growth and industrial activities in the United States and Europe

Long-Term Inhibitors to the Analog IC Forecast

The occurrence of these assumption factors would inhibit the most likely analog forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- The commoditization of technology may cause the semiconductor market to grow significantly more slowly than in the past as a result of the much increased erosion in pricing.
- Cannibalization of the analog IC market may occur because of system-level integration.

Discrete Semiconductor Forecast

Table 2-1 shows that worldwide discrete semiconductor revenue will increase by 9 percent in 1999 and total $15 billion, following an unexpected 3 percent decline for 1998. In the long term, worldwide discrete revenue will grow at a CAGR of 8 percent and reach $20.5 billion by 2002.

Short-Term Assumptions for the Discrete Forecast

These assumptions guide the most likely 1998-to-1999 discrete semiconductor forecast shown in Table 2-1.

- Product price instability across all discrete devices, prevalent through the first half of 1998, has subsided. All discrete product groups are still in a state of ready availability. However, prices are returning to a state of stability.

©1998 Dataquest

- The worldwide discrete market revenue decline of 1998 was a direct result of a steep decline in product revenue for Japan.
- Continued instability in the consumer, data processing, industrial, and automotive sectors indicate a slower-than-normal growth path for discrete devices through the second quarter of 1999.

Long-Term Assumptions for the Discrete Forecast

These long-term assumptions guide the most likely discrete semiconductor forecast shown in Table 2-1.

- The delayed recovery in the semiconductor market may delay some competitor and user decisions to shift to the slowly evolving power discrete (MOSFET and insulated gate bipolar transistor [IGBT]) products. Although large suppliers in the Americas, such as Motorola, have lost product share to some of the European competitors, consolidation of vendor activities and new market entrants may change the balance of supplier share and product activity during the next two years.
- The long-term prospects for growth appear moderate as competitors and users move to power management devices. Consolidation or acquisition of competitors' products appear as developments of change and even more price instability for developing product areas.

Short-Term Accelerators to the Discrete Forecast

These assumption factors, if they occur, will accelerate the most likely discrete semiconductor forecast shown in Table 2-1. The result would be higher growth rates and revenue levels than those shown in the table.

- Stronger-than-expected recovery from Japan, especially in the power MOSFET and IGBT products, could improve the forecast outlook.
- Stronger worldwide demand plus improved pricing for power discretes in the industrial and automotive areas for power management functions could improve the long-term outlook for growth in all regions.

Long-Term Accelerators to the Discrete Forecast

The occurrence of these assumption factors would accelerate the most likely discrete semiconductor forecast shown in Table 2-1 and result in higher revenue and growth rates.

- Growth in demand for wireless communication products will increase demand for multiple discrete products.
- Entrance of new American competitors in the power discrete segment may improve the Americas share of the discrete market.

Short-Term Inhibitors to the Discrete Forecast

These assumption factors, if they occur, will inhibit the most likely discrete semiconductor forecast shown in Table 2-1. The result would be lower growth rates and revenue levels than shown in the table.

- Evidence of a slowdown in the European cellular and automotive markets could damage expected growth of discretes over the forecast period.
- A continued delay in the market's recovery could damage competitors' strength in the American market.

 ©1998 Dataquest

Long-Term Inhibitors to the Discrete Forecast

The occurrence of these assumption factors would inhibit the most likely discrete semiconductor forecast shown in Table 2-1 and result in lower revenue levels and growth rates.

- The declining market economies anomaly, which could spread into the European and Americas markets, could drive the industry into a recession, which would nullify growth throughout the industry.
- A transition by Americas competitors to ASSPs and embedded cores and transitioning to SLI technology could shrink the dollar volume in the market, driving the competitive field to further consolidation.

Optoelectronic Semiconductor Forecast

Table 2-1 shows that worldwide optoelectronic semiconductor revenue will increase by 6 percent in 1999 and total $5.6 billion. This follows an unexpected 1 percent decline for 1998. Long term, worldwide optoelectronic semiconductor revenue will grow at a 6 percent CAGR and exceed $7 billion by 2002.

Assumptions for the Optoelectronic Forecast

These assumptions guide the most likely 1998-to-1999 optoelectronic semiconductor forecast shown in Table 2-1.

- LEDs and laser diodes are key market drivers (60 percent-plus of revenue).
- LED growth has been moderated from the previous forecast by the general industry slowdown led by the Asian financial crisis.
- The laser diode market has been impacted negatively by the slow consumer markets and positively by the demand for bandwidth in the telecommunications market driven by the Internet.
- PC and wireless handset demand growth will return to higher levels in 1999.

Accelerators to the Optoelectronic Forecast

The occurrence of these assumption factors would accelerate the most likely optoelectronics forecast shown in Table 2-1 and result in higher revenue and growth rates.

- In the near term, successful resolution of the Asian financial crisis, especially in Japan
- In the longer term, acceleration of the automotive industry's switch to the use of LEDs for rear-window brake-light bezels and related applications
- Rapid long-term expansion of the Internet to developing countries

 ©1998 Dataquest

Short-Term Inhibitors to the Optoelectronic Forecast

These assumption factors, if they occur, will inhibit the most likely optoelectronics forecast shown in Table 2-1. The result would be lower growth rates and revenue levels than those shown in the table.

- In the near term, China may be impacted by the Asian financial crisis.
- In the long term, the U.S. and European economies may experience slower-than-expected growth.

©1998 Dataquest

Chapter 3

Worldwide Semiconductor Product Forecasts by Region

This chapter presents the worldwide total semiconductor forecasts by region.

Worldwide Semiconductor Forecast by Region

The total semiconductor revenue forecast by region—with and without DRAM—and the associated growth rates for the five-year semiconductor forecast are listed in Table 3-1. Chapters 4 through 7 provide top-level perspectives on the regional semiconductor forecasts.

Detailed regional product forecasts are contained in the appendix (Tables A-1 through A-12).

©1998 Dataquest

Table 3-1
Total Semiconductor Consumption by Region, Revenue Forecast, 1997 to 2002 (Millions of Dollars)

	1997 Revenue	1997 Growth (%)	1998 Revenue	1998 Growth (%)	1999 Revenue	1999 Growth (%)	2000 Revenue	2000 Growth (%)	2001 Revenue	2001 Growth (%)	2002 Revenue	2002 Growth (%)	1997-2002 CAGR (%)

Source: Dataquest (September 1998)

Chapter 4
Americas Forecast

Table 4-1 shows that semiconductor revenue from the Americas (that is, North America and Latin America) will increase by 13 percent in 1999 and total $52 billion, following a sharp 5 percent decline for 1998. Excluding DRAM, the market was flat in 1998 and should grow by 11 percent in 1999. In the long term, regional revenue will grow at a CAGR of 12 percent-plus and reach $88 billion by 2002.

Detailed regional product forecasts are contained in the appendix.

Short-Term Assumptions for the Americas Forecast

These assumptions guide the most likely 1998-to-1999 Americas forecasts shown in Table 4-1 and the appendix tables.

- A dramatic 1998 decline in DRAM revenue in North and Latin America means a decline in the semiconductor market; at best, non-DRAM product revenue in the Americas will be flat for 1998.
- The Americas markets, especially the U.S. market, will avoid recession in 1999, despite the economic chaos that threatens to spread worldwide.
- The market will experience price stability in 1999 and improved demand in all product sectors including DRAM; even so, market strengthening and recovery will not occur until the second half of 1999 or later.

Long-Term Assumptions for the Americas Forecast

These long-term assumptions guide the most likely North and Latin American forecast shown in Table 4-1 and the appendix.

- Although threats of recession for the Americas are on the horizon, barring any further major economic downturn in Japan and especially China (the Americas' largest trading partner), the Americas should avoid economic recession.
- Slower growth in machine tool production for the industrial sector, slower growth in semiconductor units sold to the automotive sector, and flat-to-no-growth in the consumer sector would be harbingers of a downturn spreading into the Americas market.

Short-Term Accelerators to the Americas Forecast

These assumption factors, if they occur, will accelerate the most likely Americas forecast shown in Table 4-1 and the appendix. The result would be higher growth rates and revenue levels than those shown in the tables.

- Robust return to growth in new data processing and communication applications could spur increased demand across all semiconductor product groups.
- Near-term stabilization and strengthening of product prices may boost market revenue.

©1998 Dataquest

Long-Term Accelerators to the Americas Forecast

The occurrence of these assumption factors would accelerate the most likely forecast shown in Table 4-1 and the appendix, resulting in higher revenue and growth rates.

- A return to stronger capital spending and investment is expected in late 1999 for future semiconductor products and technology.
- Increased demand for advanced semiconductor functions into new industrial, consumer, and communications sectors will grow the semiconductor revenue as forecast in the 2001-to-2002 time frame.

Short-Term Inhibitors to the Americas Forecast

These assumption factors, if they occur, will inhibit the forecast shown in Table 4-1 and the appendix. The result would be lower growth rates and revenue levels for the Americas than those shown in the table.

- Y2K fears, whether real or exaggerated, may interrupt revenue growth or the potential for return to growth during the later half of 1999. Investment dollars normally slated for semiconductor R&D may be diverted to other software and hardware business-related operations.
- If the economic downturn spreads to the Americas (and European) regions, a return to growth in 2000 will be delayed. A continued semiconductor market downturn will affect multiple competitors that have been weakened by the industry's lengthening malaise. Weakened company profitability may lead to further consolidation.

Long-Term Inhibitors to the Americas Forecast

The occurrence of these assumption factors would inhibit the most likely Americas forecast shown in Table 4-1 and the appendix, meaning lower revenue levels and growth rates.

- A shift to ASSP ICs and SLI may shrink the long-term value and growth of the semiconductor and electronic equipment industry.
- Industrywide consolidation and economic downturns could shift internal manufacturing to outsourcing of production. As a result, the Americas industry structure would change dramatically. This change would stimulate both the package and assembly industries as well as the foundry business.

 ©1998 Dataquest

Table 4-1
Americas Semiconductor Market, Revenue Forecast, 1997 to 2002 (Millions of Dollars)

	1997 Revenue	1997 Growth (%)	1998 Revenue	1998 Growth (%)	1999 Revenue	1999 Growth (%)	2000 Revenue	2000 Growth (%)	2001 Revenue	2001 Growth (%)	2002 Revenue	2002 Growth (%)	1997-2002 CAGR (%)

Chapter 5

Japan Forecast

Table 5-1 shows that semiconductor revenue in Japan will increase by 6 percent in 1999 and total $33 billion, following a dramatic 16 percent decline for 1998. Excluding DRAM, the market still declined by 13 percent in 1998 and should grow by just 4 percent in 1999. In the long term, regional revenue will grow at a CAGR of 7 percent-plus and reach $50 billion by 2002; growth is slightly lower when DRAM is excluded.

Detailed regional product forecasts are contained in the appendix.

Note that for 1998, the yen-to-dollar exchange rate (see Chapter 9) is assumed to depreciate by more than 10 percent, lowering revenue in dollar terms.

Short-Term Assumptions for the Japan Forecast

These assumptions guide the most likely 1998-to-1999 Japan forecast shown in Table 5-1 and the appendix.

Following the Japanese recession in 1998, a modest of recovery is expected in 1999.

- Key application equipment shows sluggish production trends highlighted by a 1998 decline in PC shipments into the domestic market.
- Weak pricing trends continue as oversupply in various semiconductor products persists through the first half of 1999. Improvements in pricing and recovery of revenue growth are expected in the second half of 1999.

Long-Term Assumptions for the Japan Forecast

These long-term assumptions guide the most likely Japan forecast shown in Table 5-1 and the appendix.

- Recovery in various aspects of the worldwide economy will increase production of semiconductor application equipment.
- In addition to computers and communication products, digital consumer products will drive the long-term growth of semiconductor demand in Japan;
- The year 2000 Olympic games should increase demand for satellite and terrestrial broadcasting service systems.
- The supply/demand balance changes from oversupply to mild undersupply in the year 2000, resulting in a peak year in 2001 when the market will see stable pricing trends. A mild downturn in pricing trends is expected in the year 2002.

©1998 Dataquest

Short-Term Accelerators to the Japan Forecast

These assumption factors, if they occur, will accelerate the most likely Japan forecast shown in Table 5-1. The result would be higher growth rates and revenue levels than those shown in the table.

- Stronger and more extensive economic recovery may come about in Japan as well as in other Asian countries.
- Among applications, lowered PC prices, and Windows 98 may result in stronger-than-expected demand toward the end of 1998, with the year 1999 in Japan marking the beginning of a recovery.
- Infrastructure construction may be accelerated in 1999 for digital satellite and terrestrial broadcasting systems in expectation of an audio/video system boom for the Olympic games.
- In the DRAM market, the move toward PC100 SDRAM is causing partial undersupply, which may lead to early stabilization of DRAM pricing.
- Increases in shipments of ASSPs for emerging digital consumer products such as MiniDisc, DVD, and digital still cameras may offset, if only partially, the negative growth trends for consumer application ASSPs.

Long-Term Accelerators to the Japan Forecast

The occurrence of these assumption factors would accelerate the most likely Japan forecast shown in Table 5-1 and the appendix, resulting in higher revenue and growth rates.

- Gigabit network backbone construction and cable television infrastructure integration may move forward, generating demand for various multimedia end products.
- Lowering PC selling prices may create stronger domestic demand in Japan, causing stronger PC semiconductor demand
- Digitization of consumer equipment may give the Japanese semiconductor market a chance to leverage on domestic system suppliers, accelerating trends toward SLI.

Short-Term Inhibitors to the Japan Forecast

These assumption factors, if they occur, will inhibit the forecast shown in Table 5-1 and the appendix. The result would be lower growth rates and revenue levels than those shown in the tables.

- Any failure in the recovery of the Japanese and Asian economies will pose an immediate threat to electronics production.
- With the penetration of Personal Digital Cellular reaching more than 30 percent, Japanese production of cellular phones may slow significantly.
- The stabilization of DRAM prices may slow down growth in PC DRAM megabytes, delaying a balancing of supply and demand.

 ©1998 Dataquest

Long-Term Inhibitors to the Japan Forecast

The occurrence of these assumption factors would inhibit the most likely Japan forecast shown in Table 5-1 and result in lower revenue levels and growth rates.

- If the quality of services cannot be improved because of incoherent and segmented service offerings, the result will be a slowdown in growth of digital consumer, communication, and data processing markets.
- SLI efforts may create excessive competition, dampening revenue growth in SLI ASICs.

Chapter 6

Europe, the Middle East, and Africa Forecast

Table 6-1 shows that semiconductor revenue in Europe, Middle East, and Africa will increase by 12 percent in 1999 and total $34 billion (surpassing Japan), following relatively flat 1998 revenue growth. Excluding DRAM, the market will increase by 6 percent in 1998 and should grow by 10 percent in 1999. In the long term, regional revenue will grow at a CAGR of 13 percent and reach $55 billion by 2002; growth is slightly lower when DRAM is excluded.

Detailed regional product forecasts are contained in the appendix.

Assumptions for the Europe, Middle East, and Africa Forecast

These long-term assumptions guide the most likely Europe, Middle East, and Africa forecast shown in Table 6-1 and the appendix tables.

- Two major applications—PCs and digital handsets—will drive regional revenue growth.
- PC memory fit continues to increase at a historic rate; this forecast assumes that impending major technology changes will not slow the rate down.
- Associated with PC memory expectations is the expectation that DRAM ASP fluctuations (in either direction) from assumed ASPs will result in changes in revenue.
- SLI migration will not be delayed because of declining ASPs of the main candidates for integration.

Accelerators to the Europe, Middle East, and Africa Forecast

These assumption factors, if they occur, will accelerate the most likely Europe, Middle East, and Africa forecast shown in Table 6-1 and the appendix. The result would be higher growth rates and revenue levels than those shown in the table.

- The inability of the industry to meet PC100 and Direct Rambus DRAM demand could drive up DRAM pricing in 1999.
- The negative impact from the Asian crisis on digital cellular handset production may be less severe than anticipated.
- Consumers may migrate to digital broadcasting more enthusiastically than forecast, increasing digital set-top box demand.
- The impact of sub-$1,000 PCs may be negated by demand for the higher processing power necessary for new killer PC applications.

©1998 Dataquest

Inhibitors to the Europe, Middle East, and Africa Forecast

The occurrence of these assumption factors would inhibit the most likely Europe, Middle East, and Africa forecast shown in Table 6-1 and the appendix, meaning lower revenue levels and growth rates.

- ASPs may continue to decline as the supply/demand imbalance continues to spread to products not currently affected.
- The industry may fail to regain investment momentum, delaying acceptance of new technologies.
- Pending liberalization of wireline communications may fail to have the expected inpact on central office and infrastructure sales.

Chapter 7
Asia/Pacific Forecast

Table 7-1 shows that semiconductor revenue in Asia/Pacific will increase by 15 percent in 1999 and total $36 billion, following a 4 percent decline for 1998. Excluding DRAM, the market will increase marginally in 1998 and should grow by 13 percent in 1999. In the long term, regional revenue will grow at a 13 percent CAGR and reach $61 billion by 2002. DRAM drives regional revenue, so the non-DRAM growth rate is quite similar.

Detailed regional product forecasts are contained in the appendix.

Short-Term Assumptions for the Most Likely Forecast

These assumptions guide the most likely 1998-to-1999 Asia/Pacific forecast shown in Table 7-1 and the appendix tables.

- The Asia crisis hit semiconductor demand and pricing hard in 1998; Pacific Basin economies should start to recover from the 1998 economic downturn during 1999 (1 percent gross domestic product growth).
- China's economy will grow about 8 percent in 1999.
- The Asia/Pacific semiconductor market is expected to post positive growth in 1999 because of increased electronic equipment production.
- Semiconductor consumption will gradually recover during the second half of 1999.

Long-Term Assumptions for the Asia/Pacific Forecast

These long-term assumptions guide the most likely Asia/Pacific forecast shown in Table 7-1 and the appendix.

- The highest growth rates will come from microcomponents and memory products, as a result of fast-expanding data processing and communications applications.
- Asia/Pacific semiconductor consumption growth will increase rapidly in 2000 and 2001, driven by higher revenue from the memory market. However, the balanced supply/demand situation is expected to tend toward oversupply by 2002.

Short-Term Accelerators to the Asia/Pacific Forecast

These assumption factors, if they occur, will accelerate the most likely Asia/Pacific forecast shown in Table 7-1 and the appendix. The result would be higher growth rates and revenue levels than those shown in the table.

- Communication equipment could generate stronger demand in the region, especially for ASICs, DSPs, ASSPs, and analog ICs.
- In the near term, mobile and wireless communications, plus digital consumer products such as digital set-top-boxes, could become quite strong.

- Strong production growth may occur in this region, especially for Pentium II, DVD, 3D graphics, Windows NT, and Windows 98.

Long-Term Accelerators to the Asia/Pacific Forecast

The occurrence of these assumption factors would accelerate the most likely Asia/Pacific forecast shown in Table 7-1 and the appendix, making possible higher revenue levels and growth rates.

- In the long term, any acceleration in demand from the region's most important semiconductor demand driver, the PC, would accelerate the forecast.
- Electronic equipment manufacturers in Asia/Pacific may gain competitiveness, winning more contract business from PC manufacturers.
- Electronic equipment production from new manufacturing investments, especially in data processing and communications applications, may grow.
- The memory market may recover earlier than expected; ASPs may strengthen because of consolidation in the industry.

Short-Term Inhibitors to the Asia/Pacific Forecast

These assumption factors, if they occur, will inhibit the Asia/Pacific forecast shown in Table 7-1 and the appendix. The result would be lower growth rates and revenue levels than those shown in the table.

- The Asian economic crisis may fail to improve in 1999; for example, Japan's economy may remain in a deep slump, and American and European export markets may exhibit reduced demand.
- Overcapacity in consumer electronics may continue.
- Related to an export slump would be concomitant slowing of local Asia consumption as a result of high unemployment.
- The lack of internal consumption would then probably bring down Asia's economy and ultimately the consumption of chips.

Long-Term Inhibitors to the Asia/Pacific Forecast

The occurrence of these assumption factors would inhibit the most likely Asia/Pacific forecast shown in Table 7-1 and the appendix, causing lower revenue levels and growth rates.

- Semiconductor vendors may lower prices even more steeply in response to intense competition in the high-growth device markets.
- Oversupply in commodity chip markets may occur earlier than 2002.

Chapter 8
Capacity/Supply and Pricing Environment

This section provides a top-level view of the semiconductor supply-side and pricing factors that guided the forecast process.

Capacity and Supply-Side Considerations

Aggressive investment in 0.25-micron technology throughout 1997 has only exacerbated the persistent overcapacity in the industry. Dataquest has been calling for a "W" recovery pattern in capital spending, with the second-phase downturn being caused by the fundamentals of overcapacity and the movement toward financial health eventually winning over the desire for technology. As this second phase now unfolds with very deep spending cuts in 1998, the questions now arise for 1999: Were the cutbacks deep enough to correct the oversupply? When can a sustainable recovery really begin? What will fundamentally bring about recovery?

DRAM Oversupply with Us into 2000, but the End Is in Sight!

We can now say, for the first time in the last several forecast cycles, what we see as the fundamental issue that will bring the next spending boom in the years 2001 to 2002, starting in about the third quarter of 2000. The main fuel for the boom will be the return of DRAM spending, resulting from an undersupply that will emerge.

In DRAM, there has been a net capacity addition in the last two years beyond the requirements for silicon area. Presently, we are estimating the overcapacity in DRAM to be between 20 and 25 percent. The movement of the industry to the more silicon-efficient 64Mb density will sustain the oversupply throughout 1999 into 2000. Our silicon demand model shows that with the forecast 60 to 70 percent bit-growth rate in 1998 and 1999, about 12 to 14 percent less silicon will be required by the end of 1999 than is currently consumed.

However, net supply will be trending down as well over the next 18 months as capital spending cuts have an effect in reducing the rate of supply increase. As time passes, larger linewidth capacity naturally exits the market, and we are estimating that this "attrition" will actually outpace new supply. Also, we expect capacity to actively exit the market, meaning that fabs currently in commission will be closed or mothballed. The exit of capacity could take several forms, including companies exiting the market, consolidation in the industry, and outright mothballing of fabs. Recent examples are the net loss of the TwinStar fab in the United States, which was part of the sale of Texas Instruments' memory business to Micron Technology, and the recent closing of the Siemens fab in the United Kingdom. The situation should set up nicely for a shortage of capacity in the year 2000.

Silicon consumption in the DRAM market accounts for 13 to 16 percent of silicon consumption, and in order to meet the bit demand in 1999, roughly 13 percent less silicon will be required at the end of 1999 compared to the end of 1998, primarily because of the silicon efficiencies generated by the 64Mb density. As the DRAM density transition is completed, sequential silicon demand should accelerate starting in mid-2000, yielding continued double-digit MSI growth rates through early 2002. About 50 percent more silicon will be required to meet the demand of early 2002 when compared to mid-2000. The reduced capital spending pattern of 1998 to 1999 should actually set net capacity in the DRAM area on a downward trend. In 2000, these two trends will meet to produce an undersupply condition.

Foundry Capacity Now in Acute Oversupply: Lower Prices

The foundry market has also made a transition to overcapacity. Unfortunately, the stall in semiconductor demand has made the forecast oversupply much more acute; it is now calculated to be between 30 and 40 percent. Foundry suppliers have reacted to this oversupply condition much faster than DRAM suppliers by cutting back spending heavily for the remainder of 1998. Total spending in 1998 is now estimated at 20 percent growth as a group compared to earlier estimates of 40 percent. We expect 1999 spending in the foundry area to be cut significantly, perhaps 20 to 30 percent below 1998 levels.

The excess foundry capacity that exists today is also technologically mismatched with the current demand, creating a technology glut. The greatest oversupply exists in the leading-edge technology. This observation is confirmed by recent trends in wafer process, where the most severe declines can be seen in 0.35-micron and now in 0.25-micron wafers.

Foundry overcapacity is expected to remain critical throughout most of 2000. Prices for foundry wafers generally are declining at a very rapid rate. Dataquest surveys pricing in this market every four months, and in our most recent survey showed prices declining 10 to 13 percent over four months. The markets for fabless companies, the main customer of foundry, tend to be very competitive. These fabless companies as a result cannot keep the benefits of the lower cost structure and are forced to pass on these cost reductions to the market. For the first time in history, the foundry market is having a major impact on semiconductor pricing in the logic and chipset areas. These assumptions have been factored into our semiconductor forecast for 1999 and 2000.

Dataquest expects some balance to return to the foundry market by 2001, as demand picks up generally and is accelerated by the delay of the movement to 300mm wafers. We expect the foundry industry to benefit from integrated device manufacturers choosing to outsource rather than build a 200mm fab that may have a short lifetime or a 300mm fab before processes are debugged. Therefore, pricing for foundry wafers in the 2001-to-2002 time frame should be firm.

Pricing

Pricing in the current market is very near or, in some cases, below cost levels for selected semiconductor devices. In this environment, price changes have very little space to move lower, while oversupply of most devices continues and demand is not expected to increase appreciably, causing a price hike. The current estimate for near term pricing is that pricing will continue to decline overall at a much slower rate than in the past two years. In some cases, new technology memory not yet in volume production may actually show very short-term increases, but as the tide of oversupply catches up pricing in these areas will also follow the declining trend.

Long-term pricing will follow the cyclical nature of capital spending patterns. The current overcapitalized market is expected to burn off the investments made over the past four years by the end of 1999. Renewed investment after that point will take time to come to market. In the interim, overall demand continues to pressure supply, and without continuous increases in supply, prices will begin to increase in the 2000-to-2001 time frame. By 2002, supply is expected to overshoot demand again, and another cycle of price cutting is expected to begin. It is hoped that investment for the next generation of capital equipment will be in better balance with overall demand levels to prevent the steep price declines that gross oversupply brings.

Chapter 9
Exchange Rates

We do not forecast exchange rates. The following exchange rate is used for the 1998 forecast:

- Yen: 136.35 per U.S. dollar

The following exchange rate is used for the 1999-to-2002 forecast:

- Yen: 140.79 per U.S. dollar

Table 9-1 shows exchange rates of the yen and European Currency Unit (ECU) versus the U.S. dollar for the period from 1980 to 1997. The appreciation of the dollar against these local currencies is given in the last two columns.

Table 9-1

Chapter 1
Executive Summary

Dataquest forecasts that worldwide semiconductor revenue will grow 8.2 percent in 1998, reaching $159 billion. The world market should grow at a 14.4 percent compound average growth rate (CAGR) from 1997 through 2002, reaching $288 billion in 2002.

Objectives

This forecast and market trends information serves the following objectives:

- Near-term planning for worldwide and regional semiconductor manufacturing, sales, and procurement tactics
- Long-term strategic planning for semiconductor product strategy and supply-base management
- Capital formation process decision-making in debt and equities markets

Forecast Highlights and Assumptions

The following are key assumptions and highlights of this forecast:

- Worldwide semiconductor revenue should increase by just over 8 percent in 1998 to a total of $159 billion. This modest recovery—which is a slower 1998 growth rate than originally expected—follows the slight 3.5 percent growth of 1997. The industry faces its third year of lackluster performance. The Asian financial crisis and low dynamic RAM (DRAM) pricing will hamper semiconductor revenue growth this year, although some product segments will achieve robust double-digit growth rates. In 1999, the market should grow by 18 percent to $188 billion. Long-term growth will be somewhat slower than in the previous forecast. By 2002, worldwide semiconductor revenue should total nearly $290 billion, which marks a 14.4 percent CAGR for the five-year period from 1997 through 2002.
- Worldwide PC unit shipments will increase by just over 15 percent in 1998 and exceed 90 million units. PC revenue will grow by just 6.4 percent this year, however, in part because of the emergence of the "sub-$1,000 PC." In the long term, the semiconductor forecast assumes that worldwide PC unit shipments will grow at a 16 percent CAGR for the five-year period and total nearly 170 million units in 2002. PC revenue, however, should grow at a slower 9 percent CAGR because of the decline in PC pricing.
- The semiconductor industry should retain long-term vitality. PCs, communications, and consumer electronics will continue to rank as the most important application markets. The trend toward system-level integration (SLI) bodes well for the industry. The impact of information technology (IT) market challenges such as the year 2000 (Y2K) problem and the European Monetary Union (EMU) remain uncertain. However, the effect of these on the semiconductor market will likely "filter" through their impact on the PC, communications, and related equipment sectors.

©1998 Dataquest

- The Asian crisis means somewhat lower near-term and long-term expectations for Japan and Asia/Pacific. Japan will remain behind the Americas region as the world's second-largest semiconductor consumption market until 2000, when Asia/Pacific should surpass Japan.
- The x86 architecture, as the central processor in the PC, serves as the major driving force for the PC and microprocessor (MPU) markets. As expected, MPU revenue growth will start to moderate following the extremely high growth of the 1992-to-1997 period. For 1998, worldwide MPU revenue should increase by just over 15 percent—and at a 16 percent CAGR for the 1997-to-2002 time frame.
- Microprocessors in embedded applications will continue to fuel the growth of MPUs for a wider array of vendors. For example, growth in video games, communications, and Internet appliances continues to drive the embedded RISC market.
- Digital signal processors (DSPs) rank among the highest-growth semiconductor products. These devices are the centerpiece of communications electronics such as cell phones, modems, and the emerging consumer digital electronics. DSP technology is vital in speeding up the information highway. Worldwide DSP revenue should grow at a 25 percent CAGR for the 1997-to-2002 period.
- Memory IC trends, especially DRAM pricing, serve as a key swing factor in both the near-term and long-term forecasts. In 1998, worldwide memory revenue should grow by a scant 1.4 percent; DRAM revenue will increase by just 1 percent this year.
- There will be a continuing oversupply of DRAM capacity through most of 1999. The long-term forecast, however, explicitly assumes a DRAM capacity shortage by year 2000 and a DRAM revenue surge for 2001. Associated assumptions are excess DRAM capacity by 2002 and a cyclical DRAM revenue downturn that year.
- Cell-based ICs (CBICs) will continue to be a fast-growing logic product and will be the product of choice for system-level integration. By contrast, gate arrays are entering the decline phase of the product life cycle.

Key Growth Metrics

Table 1-1 provides growth by product for the period from 1997 to 2002, including the CAGRs.

Semiconductor Forecast: With and without DRAM

Figure 1-1 provides a different forecast view.

The figure shows the worldwide semiconductor growth rates and revenue totals for 1997 through 2002 for the total semiconductor market, the DRAM market, and the non-DRAM semiconductor market (that is, total semiconductors, excluding DRAM).

Flatter, more stable semiconductor growth is seen when DRAMs are excluded. The figure also highlights the higher, more volatile growth expected for DRAM.

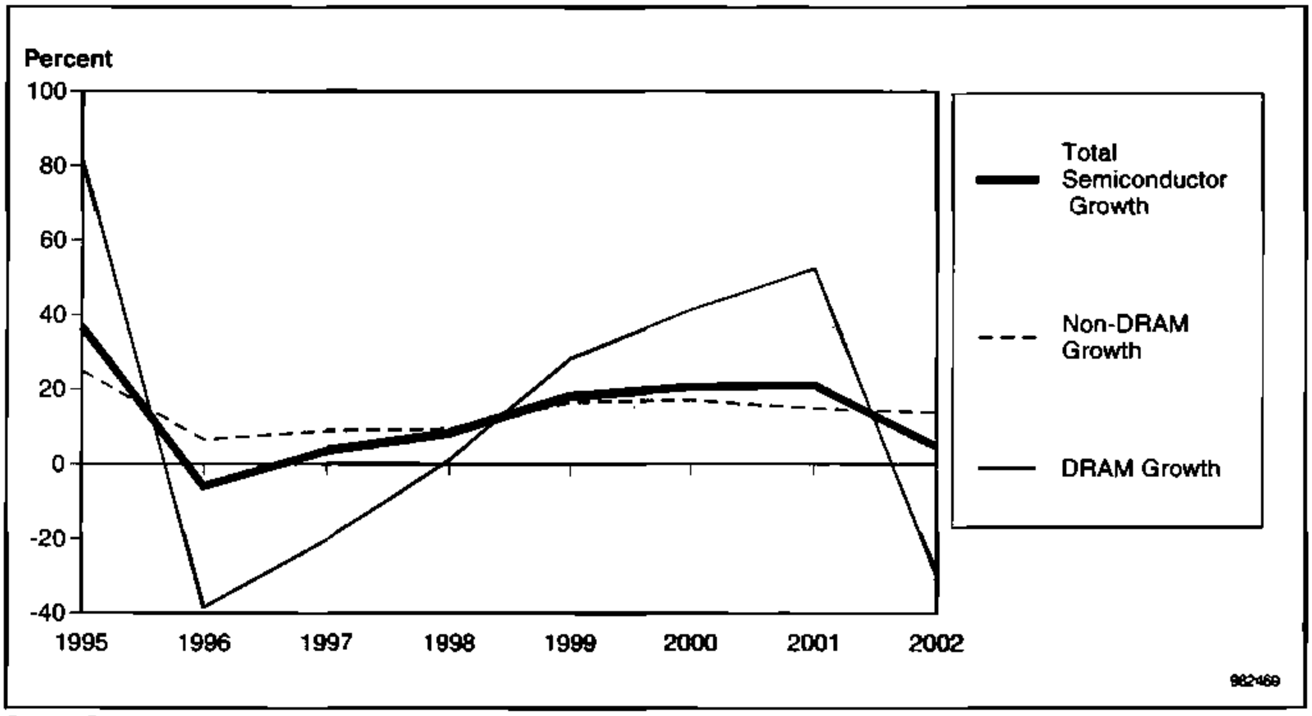
Electronic Production Forecast Analysis

As a first step in the forecast process, Dataquest combined worldwide electronic equipment production from 1997 to 2002 with semiconductor input/output (I/O) analysis. This process generated the following worldwide semiconductor forecast (with the final forecast shown in parentheses):

- 1998—$164 billion for the production-based estimate of semiconductor consumption (versus the final forecast of $159 billion)
- 2002—$262 billion for the production-based estimate (versus a $288 billion final forecast)

©1998 Dataquest

Figure 1-1
Worldwide Semiconductor Forecast



Source: Dataquest (May 1998)

The forecast methodology process uses this information as a central input and "sanity check" for generating the final semiconductor forecast.

Forecast Methodology

The worldwide semiconductor revenue forecast consists of an interlinked set of regional product consumption forecasts. A team of product and regional experts generate regional product forecasts. The experts are chosen on the basis of their expertise, including knowledge of key application trends, unit growth rates, and local economic factors.

Each regional product forecast (for example, the Asia/Pacific DSP forecast) rolls into a single, worldwide product forecast. Also, the totality of regional product forecasts (for example, Japanese consumption of DSP and DRAM, among others) roll into a single regional forecast. As noted, the interlinked forecasts ultimately roll into the worldwide product forecast.

The basic methodology is as follows:

- Under the aegis of the worldwide product director, a regional product expert provides a "first-pass" regional product consumption forecast to the worldwide product director. For example, the microcontroller (MCU) expert in Japan provides a five-year forecast of MCU consumption in Japan to the worldwide MCU director. The worldwide director compiles the full set of MCU regional forecasts and then reviews the resultant worldwide MCU revenue totals and growth rates.

- Concomitantly, under the aegis of a regional forecast director, the "first-pass" regional product forecasts are also sent by the regional product experts to the regional forecast director. For example, the MCU expert in Japan and the DRAM expert, among others, send their Japanese consumption market forecasts to the Japan regional forecast director. The regional forecast director compiles the regional product forecasts into a regional forecast and then reviews the resultant regional revenue totals and growth rates.
- The process remains interactive as the regional product forecasts get fine tuned. When agreement has been reached on these regional product forecasts, a "proposed" worldwide forecast is reviewed by a team of worldwide and regional product analysts. This process typically requires selective modification to worldwide product forecasts, including regional forecasts. This process includes scrutiny of worldwide growth rates, product growth, regional growth, upside/downside potential, and related factors.
- By consensus, the final worldwide and regional semiconductor product forecasts are then generated and published from the forecast database.

The Forecast Range

Market uncertainty means a forecast's results will be either higher or lower than the forecast. For this reason, this section provides a forecast range. Although the Asian crisis certainly tempers semiconductor market expectations, DRAM pricing predominates as the foremost swing factor affecting the semiconductor forecast range.

For the forecast range analysis, Dataquest assumes a set of low-side and high-side DRAM pricing assumptions. We also assume that DRAM bit growth will be quite predictable, despite pricing volatility.

For the low-side scenario, we assume low DRAM pricing. The market price is assumed to be at a "bottom-level," cost-based price, below which antidumping measures would be taken.

By contrast, under the high-side scenario, we assume very high DRAM pricing. Using historic patterns, we assume high markups for the market price, at as much as 1.7 times the cost.

The following summarizes the worldwide semiconductor forecast range for the 1999-through-2002 period, based on the DRAM price low/high assumptions (with the official forecast in parentheses).

Total Worldwide Semiconductor Forecast Range

The worldwide semiconductor forecast range is as follows:

- 1999—$186 billion to $201 billion ($188 billion forecast)
- 2000—$217 billion to $252 billion ($227 billion forecast)
- 2001—$249 billion to $291 billion ($275 billion forecast)
- 2002—$281 billion to $325 billion ($288 billion forecast)

 ©1998 Dataquest

Perspective

The worldwide IT market totaled $1 trillion for 1997. Inclusion of all telecom services and companies' internal information system (IS) spending would increase the 1997 total to more than $2 trillion. Either way, the IT market is bigger than most countries' gross domestic product.

GartnerGroup has identified the megatrends that will shape the worldwide IT industry for the next five years. The global semiconductor industry, as a key enabling technology for the IT marketplace, will directly benefit from several IT megatrends. These IT megatrends signal long-term vitality for the worldwide semiconductor market:

- Rise of the Internet:
  - 300 million active Internet seats are expected by 2002.
  - Semiconductors will build the infrastructure as well as equip and connect the users.
- Network computing happens—although "network computers" do not:
  - The network computer will fizzle, although it has stimulated interested in fully equipped sub-$1,000 PCs.
  - Networked computing, however, will continue to expand and use semiconductors in that process.
- Bandwidth demand explodes:
  - Bandwidth demand will grow 30 to 40 percent per year.
  - Networking functions will become integrated into semiconductors—although software solutions will be just as important.

Meanwhile, some IT market trends do not favor the semiconductor outlook. For the medium term, concern exists that solutions for the Y2K and EMU problems could divert business spending from PCs and other semiconductor-based products.

In the long term, worldwide IT spending should grow at an 11 to 12 percent CAGR for the 1997-to-2002 period. There will be a dramatic shift toward the added-value software and services segments—meaning lower revenue growth for hardware segments.

To put everything in perspective, however, the worldwide semiconductor forecast looks realistic. The services and emerging software segments will grow at CAGRs of 16 percent or higher over the next five years. By contrast, system hardware revenue will grow at a sub-10 percent CAGR. Driven by the trend toward system-level integration, the semiconductor market should grow at a "sort of intermediate" CAGR of 14 percent.

Project Analysts: Joseph Grenier, Kevin McClure, Mary A. Olsson, and Ronald Bohn

Chapter 2
Worldwide Forecast by Product

The tables of this chapter provide the complete five-year forecast by product type and by region for the worldwide semiconductor market.

Worldwide Semiconductor Product Forecast and History

The following tables show semiconductor product growth, both historic and forecast. Table 2-1 provides the five-year forecast through 2002 by product type for the worldwide semiconductor market. Table 2-2 presents the history of product growth for 1992 through 1997.

As noted in the tables, the worldwide semiconductor market should grow at a 14 percent-plus CAGR during the five-year period from 1997 to 2002. This is a realistic growth expectation when compared to the 18 percent CAGR from 1992 to 1997.

Forecast Summary: No Strong Recovery Yet

For many semiconductor companies, 1997 marked a year of modest revenue recovery following the 1996 revenue downturn. Memory segments like DRAM, however, did not recover in terms of revenue growth.

The forecast calls for modest worldwide semiconductor growth in 1998 and stronger growth over the long term. As noted, Dataquest expects the worldwide semiconductor market as measured in revenue to grow at a sub-10 percent rate this year. Our prior expectation for 1998 had been a more robust growth rate.

DRAM and the Asian crisis explain much of this change. For example, worldwide DRAM revenue should remain flat in 1998 at the 1997 level. The prior expectation was for a rebound in DRAM revenue growth this year. DRAM bit growth remains impressive, but excess capacity and low pricing combined with the Asian crisis mean scant DRAM revenue growth for 1998.

1998 Forecast Range

As noted, the worldwide semiconductor forecast calls for just over 8 percent this year. Applications market analysis, however, reveals that the 1998 forecast ranges from a low-side estimate of 3 percent growth to a high-side estimate of slightly over 10 percent growth.

Key Application Markets

PCs, communications, and consumer electronics will account for about 70 percent of semiconductor consumption. Trends in these application markets will determine near-term results and fuel long-term growth in semiconductor revenue. In the long term, the PC remains the paramount application for compute MPU and DRAM. Servers will eventually emerge as a key application for compute MPUs. Mobile communications, data communications, and digital consumer electronics, among other applications, should drive DSP, MCU, embedded MPU, and digital application-specific IC (ASIC) growth. Flash memory and EEPROM should also benefit from these trends.

Source: Dataquest (May 1998)

The following section summarizes the 1998 outlook for the three key semiconductor application markets: PCs, communications, and consumer electronics.

The High and Low of PC Semiconductors

Personal computers and workstations consume about one-third of the world's semiconductors and therefore have a tremendous impact on the market growth dynamics. Additionally, these applications consume 75 to 80 percent of all DRAM shipments and are somewhat elastic in terms of semiconductor demand as measured by revenue. This adds volatility to the overall semiconductor demand picture and particularly affects memory pricing trends.

Near-term volatility is minimal because we are already about one-third of the way through 1998, and we have a high level of confidence in our assumptions regarding PC pricing dynamics and the software application base (including operating systems) for PCs. We see minimal upside opportunities for our forecast in the near term unless system demand takes a dramatic uptick. Downside risk for 1998 is 5 percent on a revenue basis.

Long-term trends have greater volatility and hinge on four key "swing" factors. The low-side scenario would involve a 10 percent downward revision for PC semiconductor revenue in 1999 and 15 percent thereafter. Semiconductor spending as a percentage of the factory system average selling price (ASP) cannot be raised, so any dramatic upside opportunity can come only from higher-than-expected unit shipments or a stabilizing trend in factory system ASPs.

The key trends include the following:

- DRAM ASPs—The high-side scenario requires DRAM ASPs, as our memories forecast has DRAM and bit consumption according to the forecast. The low-side scenario has DRAM ASPs 20 percent lower than the target ASPs in the DRAM forecast.
- Consumer spending recovery in Asia—The high-side scenario involves a quicker recovery than Dataquest currently projects. The low-side scenario includes moderate recovery of consumer spending in Asia. The outlook is good for North America and Europe.
- The popularity of sub-$1,000 PCs in business environments—The high-side scenario includes limited acceptance of sub-$1,000 PCs in corporate environments. The low-side scenario has business acceptance of sub-$1,000 mirroring consumer excitement over that category. Falling ASPs for the PC industry cause PC makers to limit their semiconductor spending on a per-PC basis. Unit growth remains strong either way.
- Compelling new applications—The high-side scenario requires new applications to emerge that convince buyers to "buy up." Microsoft's Chrome product in the Windows 2000 operating system is an example. New versions of today's programs will only lead to the low-side scenario. Windows 98 arrives midyear, but it is unlikely to inspire dramatic changes. Windows NT 5.0 will not emerge until 1999.

 ©1998 Dataquest

The High and Low of Communications Semiconductors

The communications market accounts for about 20 percent of worldwide semiconductor consumption. In the near term, consumption for use in communications equipment on the low side could be 3 to 4 percent lower than the current forecast; on the high side, consumption could be 6 to 7 percent higher than forecast.

The following section summarizes the forecast range across different communications application segments:

- Premise telecom high and low range:
  - 1998 semiconductor consumption forecast ranges from 4 to 5 percent lower to just over 4 percent higher.
  - Downside would be mainly due to pricing pressures and Asian financial crisis.
  - Upside would be driven by 56Kbps modem "churn," acceptance of new wide area network (WAN) systems, and Y2K; the Y2K problem could cause companies to buy new premise telecom systems as their solution (versus a software rewrite).
- Public telecom high and low range:
  - 1998 forecast ranges from 3 percent lower to 3 percent higher.
  - Downside and upside both depend mainly on pricing and uncertainty.
- Mobile communications high and low range:
  - 1998 forecast ranges from 3 percent lower to more than 10 percent higher.
  - Downside would be due to lower demand resulting from the Asian crisis and European saturation.
  - Upside would be due to lack of negative impact from Asia crisis, strong subscriber growth, microcell and picocell infrastructure deployment, and possible strong code division multiple access (CDMA) ramp in the United States.

The High and Low of Consumer Semiconductors

Consumer electronics use about 10 percent of the world's semiconductors. In 1998, the forecast assumes just over a 9 percent worldwide increase of semiconductors for consumer electronics equipment. The following assumptions guide this 1998 forecast:

- Demand for next-generation consumer products will recover from the 1997 lull in demand. These products include digital set-top boxes (STB), digital TV, including high-definition television (HDTV), digital versatile disc (DVD), and 32-bit and 64-bit game players (Nintendo 64 and Sony Playstation).
- Legacy consumer product demand will increase slightly or else remain flat versus 1997. These older applications include color TVs, component stereos, analog audio/video systems, and household appliances.
- Semiconductor price erosion will moderate.
- Asian crisis will have moderate impact on consumer electronics sales.

©1998 Dataquest

Consumer Electronics Low-Side Scenario

For the near term, consumption for use in consumer electronics could on the low side be more than 10 percent lower than the current forecast. At worst, consumption by consumer applications could actually decline this year versus 1997. A similar result occurred in this application market during 1996.

The following assumptions would cause this negative 1998 scenario:

- The Asian crisis has major negative impact on consumer electronics sales.
- Demand for next-generation consumer products continues to fall below expectations.
- Legacy consumer product demand continues to decline.
- Semiconductor price erosion continues.

Consumer Electronics High-Side Scenario

On the high side, consumption could be 1 to 2 percent higher than forecast. The optimistic outlook says that consumer electronics applications can sustain the same near-11 percent consumption growth rate as experienced in the past several years. The following assumptions would cause this optimistic 1998 scenario:

- Fallout from the Asian crisis on consumer electronics demand is contained.
- The rate of demand for next-generation consumer products increases significantly.
- Legacy consumer demand rises slightly.
- Semiconductor price erosion moderates.

As noted, the 1998 forecast range based on applications analysis runs from a low-side estimate of 3 percent growth to a high-side estimate of slightly over 10 percent growth.

Product Forecasts

The following sections highlight trends that guide key product forecasts.

ASIC and Logic Trends and Forecast Assumptions

The worldwide MOS digital logic forecast calls for 7.3 percent growth in 1998. This is slower growth than originally expected. On a regional basis, the 1998 forecasts have been lowered in all regions to varying degrees, with the highest reduction in Japan, followed by Asia/Pacific.

The short-term forecasts on other MOS logic products have also been lowered. Supply exceeds demand for these products, which means downward pricing pressure. Standard logic remains relatively unchanged from our prior forecasts. ASIC product forecasts have been lowered only slightly.

Cell-based ICs, the system-level integration product of choice, will continue as the fastest-growing logic product. Gate arrays, however, are under serious pricing pressure and are entering the decline phase of the life cycle. CBICs are displacing gate arrays from high-end applications as programmable logic devices (PLDs) displace gate arrays on low-end applications. This translates into higher long-term growth in the CBIC and PLD segments and lower growth in gate arrays.

For 1998, the worldwide CBIC market should grow at a 22 percent rate. PLDs are suffering from rapid price erosion and slow demand, so we are forecasting only an 11 percent increase in 1998, the lowest growth rate in history. Gate array revenue will continue to decline and decrease this year by 7 percent. Full-custom ICs are on the most rapid decline, as they are being replaced by cell-based ICs and gate arrays to some degree. The mature standard logic market should increase by 5 percent. Other MOS logic products will grow 4 percent.

Long term, the CBIC market should exceed $30 billion by 2002, with an impressive CAGR of more than 27 percent for 1997 through 2002. PLDs will expand at nearly a 20 percent CAGR and exceed $5 billion by 2002. Other MOS logic products—which include some application-specific standard products—will grow at a respectable near-15 percent CAGR. The standard logic market will grow slowly, while gate arrays will decline.

Microprocessor Trends and Forecast Assumptions

The worldwide microprocessor revenue forecast remains largely consistent with prior expectations. As expected, MPU revenue should increase this year and over the long term, but at a slower rate versus the 1992-to-1997 period. The x86 architecture will continue its domination of the PC market. Business PC demand continues to drive MPU demand. The x86 MPU technology advances still stimulate PC demand from the key "early adopter" repeat buyers.

Key PC market dynamics, however, are changing as of first half 1998. For example, the "sub-$1,000" PC captured consumer market demand during late 1997. Business buyers now show growing interest in low-cost PCs, which means a long-term decline in the PC ASP. A sharp fall in the x86 MPU ASP, however, is not expected. Competition for Intel Corporation from competitors such as Advanced Micro Devices Inc. and National Semiconductor Corporation will not cause an x86 price war.

Why not? Although the price of MPUs for PC desktop applications will decline, the x86 ASP will rise somewhat as MPUs absorb other system functions. Also, Intel is creating workstation- and server-specific versions of x86 products that generate a much higher ASP (more than $500) than devices geared for PC markets. Internet appliances, communications (for example, cellular), and video games will fuel growth in the embedded RISC MPU market.

For 1998, worldwide MPU revenue should increase by 15.4 percent and reach $27 billion. Intel should lead a strong rebound in second-half 1998 in the worldwide MPU market. In 2002, worldwide MPU revenue should reach $50 billion, which represents a 16 percent CAGR for 1997 through 2002. This is a lower long-term MPU growth rate than the 30 percent-plus CAGR for the 1992-through-1997 period; this mirrors the slower long-term pace of PC revenue growth.

 ©1998 Dataquest

Microcontroller and DSP Trends and Forecast Assumptions

Our forecast continues to assume that non-PC applications such as digital cellular, digital consumer electronics, and data communications will drive demand for MCUs and DSPs, including embedded versions. The following is a summary of these product forecasts:

- DSPs should increase by more than 25 percent in 1998, exceeding $4.5 billion. By 2002, worldwide DSP revenue should surpass $11 billion, which translates into a stellar 25 percent CAGR for 1997 through 2002.
- Sharp price erosion for MCU products means lower 1998 revenue than originally expected. In 1998, worldwide MCU revenue will increase by just over 13 percent and total $12.3 billion. Long term, worldwide MCU revenue will total $22 billion by 2002. The forecast of a 15.3 percent CAGR for the 1997-to-2002 period is lower than previously expected.

Memory IC Trends and Forecast Assumptions

The DRAM market will remain volatile. The DRAM revenue forecast could swing widely for both the near term and the long term because of DRAM price fluctuations. DRAM bit consumption continues in line with our prior projections. This means that unit demand should be strong, although pricing might remain weak. As indicated, the semiconductor forecast assumes a cyclical upturn in 2001. The DRAM market peak in 2001, however, has been moderated to match similar historical peaks.

DRAM prices continue to hug a cost-based price curve, which means low pricing. This stifles the prospect for DRAM revenue growth. Dataquest expects this to remain the case through 1998 and into 1999. These prices are limited on the high side by DRAM oversupply and on the low side by antidumping regulations.

The effects of the current Asian crisis on DRAM prices will be "self-regulating" in that a temporary 1998 price downturn should shift market share to lower-cost producers. After this, the low-cost suppliers' capacity will be utilized, and DRAM prices will recover slightly.

The current overcapacity will continue through 1999 and into 2000. Capital expenditure did not slow in 1997 as we had originally anticipated. To reflect the impact, the DRAM market revenue peak originally expected for 2000 has been pushed out by one year to 2001. (Some manufacturing capacity may eventually exit the DRAM market, but this is not predicted in the current forecast.)

The DRAM high-side revenue forecast for 2002 is $78 billion. This would occur if there were a shortage in this year and bit growth followed its historical rate of 65 percent per year. Our low-side scenario, assuming as severe an overcapacity as we currently face, would be just $34 billion. By contrast, the DRAM bit growth trend has been extremely stable since the early 1980s, despite price fluctuations and the expected positive and negative influences of demand drivers.

The static RAM (SRAM) market is still oversubscribed, but conversion of cellular phones from analog to digital has dramatically increased SRAM usage in these phones. There is a big difference between this market and the

 ©1998 Dataquest

PC market, the last big SRAM stronghold. Cell phone manufacturers are much more selective about their supplier base; they use parts from top-tier suppliers and shy away from small, fabless companies. We still expect to see attrition in this market. Many companies that thrived in an open market for PC cache chips will shortly be excluded from this previously highly penetrable market and will not be able to participate in the cellular telephone market.

The nonvolatile memory market should see a continuing slow conversion from EPROM toward flash memory. Most of this conversion is happening in new designs and is therefore occurring at the higher densities. The flash memory market has moved from high profitability toward more competitive pricing as many competitors join the fold. However, unit growth remains strong. This new lower pricing has acted to enable the use of flash memory in a diverse array of new applications. Mask ROM has moved away from the "growth hump" that was characteristic of the game cartridge boom and is back on the less-dramatic, pregame growth trend.

Substantial growth should continue in the relatively small EEPROM market, fueled by this technology's use in everything from electronic commerce to microcontroller-based systems, including smart cards. New applications include Universal Serial Bus (USB) interfaces for the PC. The conversion of DRAM modules from single in-line memory modules (SIMMs) to dual in-line memory modules (DIMMs) will also help, as each new DIMM will contain one EEPROM to identify the attributes of the module.

The following summarizes memory IC product outlooks:

- DRAM revenue should increase by a scant 1 percent in 1998 and total $21 billion. By 2002, worldwide DRAM revenue should total $41 billion, which marks a 14.6 percent CAGR for 1997 through 2002.
- SRAM revenue will grow by 4.3 percent in 1998 and total $4.2 billion. In 2002, worldwide SRAM revenue will total nearly $10 billion, which means a 20 percent CAGR for 1997 through 2002.
- Flash memory revenue should increase by 10.2 percent in 1998 and reach the $3 billion level. By 2002, worldwide flash revenue will total nearly $6.4 billion, with an 18 percent CAGR for 1997 through 2002.
- EEPROM revenue will rise by 16 percent in 1998 and exceed the $1.1 billion mark. By 2002, worldwide EEPROM revenue should approach $2 billion, for a near-15 percent CAGR for 1997 through 2002.
- EPROM revenue should decrease by more than 30 percent in 1998, declining to just over $0.5 billion. By 2002, worldwide EPROM revenue will decline to only $0.22 billion.
- Mask ROM revenue will fall by more than 20 percent in 1998, declining to $0.8 billion. By 2002, however, worldwide mask ROM revenue will edge upward to the $0.9 billion level.

 ©1998 Dataquest

Analog Product Trends and Forecast Assumptions

Worldwide analog IC revenue during 1998 should grow by nearly 11 percent and total $24 billion. The Asian financial crisis should reduce consumer demand in the Asia/Pacific and Japan, which will slow the growth of analog products. By contrast, the analog market expanded by nearly 19 percent in 1997.

Analog IC revenue should grow at a CAGR of 14 percent from 1997 through 2002 and reach $41 billion by 2002. Looking at the long-term trends through 2002, mixed-signal ICs will experience solid growth, driven by application markets such as digital cellular. Also, new emerging applications in the consumer and communications market will contribute to the growth of mixed-signal ICs. In the more traditional, standard linear product area, voltage regulator products will still enjoy strong growth as the demand for smart power continues to grow, especially in the portable markets.

Discrete Product Trends and Forecast Assumptions

Worldwide discrete product revenue should rise in 1998 by nearly 7 percent to $15.2 billion. The discrete product market grew at a similar rate in 1997. The long-term forecast assumes a stable market. We forecast a CAGR of 10 percent in discrete products through 2002, reaching a total of $23 billion.

Regional vendors in the Americas, Europe, and Asia/Pacific are expected to maintain fairly strong growth and a share of the discrete market through the end of the decade. The Americas region's growth will be determined by prowess in the communications, automotive, and industrial sectors in the face of strong competition from Europe.

Optoelectronics Product Trends and Forecast Assumptions

Optoelectronic semiconductors have a number of factors that will affect overall and regional growth rates. Optoelectronic IC revenue should grow only 1.3 percent in 1998 and total $5.4 billion. This market grew by nearly 9 percent in 1997. By 2002, worldwide optoelectronics revenue will total $7.4 billion, which represents a moderate percent 7 percent CAGR for 1997 through 2002.

For the near term, the Asian economic crisis will reduce dollar growth in Japan and the Asia/Pacific region through lower demand or currency effects relative to the dollar. These effects are expected to be most severe in 1998. After this year, this region is expected to resume higher growth rates as worldwide and regional demand for new consumer electronics and personal communications products overcome the effects of the current economic conditions.

For example, long-term acceptance of DVD and multimedia disk consumer electronic products will raise growth rates of laser diodes. More expensive diodes are required for the new, high-capacity players. This long-term growth will benefit Japan and the Asia/Pacific region.

The growth in Japan will be mitigated by movement of production of consumer electronics products to the Asia/Pacific region as volumes increase and prices decrease. Digital cameras will drive demand for charge-coupled devices (CCDs). This will have a positive effect on demand for CCDs in Japan, but it will be insignificant compared to slower CCD growth in camcorder markets for the next five years until prices drop and picture quality improves. CCD demand in digital cameras will not have a large effect on the overall growth rate for CCDs or optoelectronics until the end of the forecast period.

The growth of the Internet also means positive long-term growth in this market. The Internet is creating extensive demand for high-bandwidth optical networks. This factor is particularly important in the United States. It will cause higher growth in laser diodes for fiber-optic modules for 155-Mbps through 10-Gbps fiber-optic networks. This will have a positive effect on growth in Europe as well as the Americas.

A third factor that is positively affecting demand for optoelectronics is automotive electronics. Automobile manufacturers are switching from incandescent lamps to LEDs for the rear braking lights in new car designs. This will give LEDs a positive push in all markets for the next several years as more car models adopt the new technology.

Figure 2-1 shows the impact of these varying rates of growth by product.

Chapter 3
Worldwide Semiconductor Product Forecasts by Region

This chapter presents the worldwide product forecasts by region.

Worldwide Semiconductor Forecast by Region

The worldwide semiconductor revenue forecast is broken into the four constituent regional forecasts in Figure 3-1. By world region, the forecast calls for the following CAGRs for 1997 to 2002 (regional revenue consumption for 2002 is shown in parentheses):

- Americas—15.7 percent CAGR ($100 billion)
- Japan—11 percent CAGR ($61 billion)
- Europe, Middle East, and Africa—14.6 percent CAGR ($59 billion)
- Asia/Pacific—15.7 percent CAGR ($68 billion)

As indicated, the long-term growth rates for Japan and Asia/Pacific have been lowered versus prior expectations.

Table 3-1 shows the regional revenue data and annual growth rates by region for the five-year semiconductor forecast.

The effect of this forecast on total market share by region is provided in Figure 3-2.

Semiconductor Product Forecasts by Region

This section builds on the product and regional analysis of the prior sections by focusing on the individual products and their regional segmentation.

Microcomponent IC Forecast by Region

Table 3-2 shows microcomponent product consumption by region for 1997 to 2002. Microcomponent growth should moderate somewhat to a 16 percent CAGR for 1997 through 2002. The Americas will remain the largest market, by far. Asia/Pacific, driven by MPUs and microperipherals (MPRs), will remain the second-largest regional market. Even so, as noted, the Asian crisis throws a pall over the outlook for Asia/Pacific and Japan consumption.

The large MPU market—$27 billion in 1998 and $32 billion in 1999—will grow at a 16 percent CAGR from 1997 through 2002. For 1998, Americas and Asia/Pacific should achieve the strongest growth rates among the regions. By 2001, each regional MPU market, led by the large Americas market, will exceed $10 billion, except for Japan.

Communications and digital entertainment applications, among others, will drive the DSP market to a 25 percent CAGR for 1997 through 2002. Rapid growth means an $11 billion market by 2002, led by the European and Americas regions.

©1998 Dataquest

MCUs continue to find new embedded homes in every conceivable electronic product, meaning stable long-term growth. The $11 billion MCU market of 1997 will double to $22 billion by 2002. The CAGR for 1997 through 2002 is expected to be 15 percent.

For 1998, Americas shows the strongest growth among the regions; all other 1998 regional forecasts have been lowered. Japan will remain the largest MCU market in the long term, with Americas and Asia/Pacific the fastest growing.

Memory IC Forecast by Region

Table 3-3 shows the memory product consumption forecast by region. Each region will show a double-digit CAGR over the forecast period. In 1998, however, each region shows negligible memory revenue growth.

The Asia/Pacific growth rate will *no longer* outpace other regions' memory growth. The Americas region will remain by far the No. 1 market for DRAM. The Americas region should also ultimately emerge as the leading consumer of nonvolatile memory. Asia/Pacific, Europe, and Japan will be important markets, however, for nonvolatile memory. For example, Europe's consumption will be driven by cellular phones that use EEPROM or flash.

Digital Logic Forecast by Region

Table 3-4 gives the digital logic forecast by region. For 1998, Americas and Europe should show the strongest regional growth. The Asian crisis means lowered expectations for Asia/Pacific and Japan. Japan will continue to rank with Americas as the two largest markets.

The worldwide digital logic markets will achieve a long-term 16 percent growth rate driven by strength in digital cell-based ICs and PLDs. The trend to system-level integration means that many formerly standalone MPUs will instead ship in the form of ASIC cores. By region, 1997-to-2002 CAGRs will range as follows:

- Japan—10 percent
- Asia/Pacific—15 percent
- Europe, Middle East, and Africa—18 percent
- Americas—19 percent

Analog, Discrete, and Optoelectronics by Region

Table 3-5 shows the regional forecasts for analog ICs, discrete semiconductors, and optoelectronic semiconductors. The products tend to be mature, as reflected in their slower, more stable growth rates. Optoelectronics consumption centers in Japan. The market for analog and discrete products has been geographically diversified.

Analog IC Forecast by Region

The movement to digital consumer electronics will be evolutionary, which means a stable long-term outlook for the analog IC market. As noted, the Asian crisis, among other factors, means somewhat lowered analog IC consumption expectations for Asia/Pacific and Japan in 1998 and in the long term. Even so, analog ICs historically show more equal distribution among the four regions than other products, and this stabilizes the worldwide outlook. Also, the increasing presence of analog ICs in computer and communications applications should stabilize worldwide growth.

Discrete Device Forecast by Region

Discrete semiconductors have been losing market share because of the relentless integration of components, yet the long-term outlook remains consistent with recent growth rates. For example, the discrete market had just under a 12 percent CAGR during the 1992-to-1997 period. Discrete semiconductors should grow at a somewhat slower but similar 10.3 percent CAGR for 1997 through 2002. The discrete semiconductor market remains viable because power and RF devices are not readily integrated. Power transistors represent about one-third of discrete device revenue and are expected to lead discrete device growth.

Asia/Pacific should ultimately surpass Japan as the world's largest market for discrete semiconductors. Each regional discrete device market—except Japan—should grow at a low double-digit CAGR through 2002.

The growing use of power discrete devices in power control and communications applications in the Americas and Europe indicates regional CAGRs of more than 12 percent in the next five years. The Americas and European markets for discrete semiconductors will remain at relatively the same size.

Optical Semiconductor Forecast by Region

Japan has been and should continue to be the largest regional market, by far, for optical semiconductors. Optoelectronics products are the most dependent of all semiconductor products on consumer entertainment-related applications. A major boom in the DVD application would mean stronger growth than currently projected for this product market (7 percent CAGR for 1997 to 2002). Meanwhile, computer and peripheral applications have an increasing impact on the optical semiconductor market. For example, scanners and copiers use charge-coupled devices (CCDs), CD-ROMs use laser diodes, and optical-fiber data links use semiconductor receivers and transmitters.

Chapter 4
Americas Forecast by Product Family

Semiconductor Forecast by Region

The semiconductor forecast calls for the Americas region (North America and Latin America) to grow at a 16 percent CAGR for 1997 through 2002. This growth will push the $48 billion market of 1997 to $100 billion by 2002.

The following section identifies the assumptions that guide the forecast.

Dataquest expects the Americas semiconductor market to grow by a moderate 11 percent rate in 1998. Stronger growth should occur during the 1999-to-2001 time frame. As of the first half of 1998, the major North American semiconductor vendors reported slower growth than expected in world markets, including the home region. Some have indicated slowdowns in key application segments such as desktop PCs, cellular handsets, and consumer markets. In the long term, these application markets should expand, which signals strong regional growth in the DSP, flash, and SLI product markets.

PCs will remain a kingpin application in the Americas region for both the near term and the long term. For example, MPU and DRAM product revenue represents over 40 percent of the Americas region's product revenue. For 1998, the Americas MPU market will grow by 17 percent and reach $12 billion. The Americas DRAM market will barely grow in 1998 because of low pricing, despite continuing DRAM bit growth. As indicated, Dataquest expects a rebound in the second half of 1998 in the Americas PC MPU market.

Also, Intel should successfully migrate the x86 architecture to server applications over the long term; this translates into a 15 percent CAGR for MPU revenue in the Americas region.

High-Growth Products

MPUs will remain the largest regional product market. The 1997-to-2002 CAGRs of the fastest-growing semiconductor products in the Americas region are as follows (with 2002 revenue in parentheses):

- DSPs—24 percent CAGR ($3.1 billion)
- ASICs—21 percent CAGR ($18.2 billion)
- SRAM—18 percent ($4.3 billion)
- Flash memory—17 percent ($1.9 billion)
- MPUs—15.2 percent ($21.6 billion)

Tables 4-1 and 4-2 provide details of the Americas semiconductor market.

Figure 4-1 shows the effect of the Americas forecast on the relative consumption by product. The Americas market will remain highly dependent on the health of data processing, especially PCs.

Chapter 5
Japanese Forecast by Product Family

Semiconductor Forecast by Region

Dataquest forecasts that the Japanese market will have an 11 percent CAGR for 1997 through 2002. The $37-billion market (in 1997) should reach $60 billion by 2002. This Japanese regional forecast of semiconductor consumption is lower than previously expected. Japan's economy both affects and is affected by the Asian crisis.

The following section identifies the assumptions that guide the forecast.

Market Weakness of Applications

On the demand side, electronic equipment production is expected to show 3 percent growth, which is lower than the fall forecast. This reduction comes from the decelerated domestic economy, as well as the decrease in demand in Asia/Pacific because of the macroeconomic crisis. PC shipments in Japan are experiencing sluggishness or even a decline in some months, and 1998 will see modest single-digit growth. Mobile communications did not slow down as expected in 1997—so the downturn is expected this year.

The CAGR of electronic equipment production for Japan in the years 1997 through 2002 is quite weak—less than 3 percent. Communications and consumer products will remain the leading applications, while industrial will see the highest CAGR over the period. Even with the introduction of all the digitized systems, the consumer category should remain the second-largest. Japan's consumer segment, however, should generate the slowest growth in semiconductor consumption for the coming five years.

Slower Semiconductor Product Growth

Japanese semiconductor consumption in 1998 will increase by just 3 percent in dollars, and at a somewhat higher rate in yen. With major applications slowing down, such as PCs, mobile communications, and audio/video equipment, as well as weak capital spending in most industries, Japanese semiconductor consumption is showing the lowest growth among all regions. In the coming five years, the weak growth in electronic equipment production will limit the growth of semiconductor consumption in Japan. As a result, Japan's 11 percent CAGR is the lowest of all the regions.

DRAM bit prices are declining faster than forecast during 1998 because of prolonged oversupply and the quick ramp-up of 64Mb supply. The shift from extended data out (EDO) to SDRAM may not contribute to DRAM price firming as much as previously expected. The current focus of interest is on the pricing premium of 100-MHz SDRAM, which remains to be secured for the first half of 1998 but will diminish in the second half as vendors increase supply.

Flash memory market will continue to be driven in both the near term and the long term by mobile equipment and IC card applications, such as cellular phones and digital still camera. As major memory suppliers emphasize flash memory in view of sluggish DRAM, the pricing of flash memories will continue to decline, and that will include 16Mb and beyond.

©1998 Dataquest

In the MOS microcomponent area during 1998, the MPU market growth in Japan will slow because of the sluggish Japanese PC market; the MCU market will experience somewhat stronger growth this year.

Four-bit MCUs will continue to enjoy expansion in application areas but will be replaced by 8-bit toward the end of the forecast period. MCUs with embedded flash will expand their market quickly and will lead to the introduction of embedded ferroelectric (FRAM) MCUs. Sixteen-bit MCU applications include emerging digital consumer equipment such as DVD, minidisc (MD), digital TV, and digital VCR. Both 32-bit and 64-bit products will continue to find applications in system-level integration.

DSP including media processors will continue to show the highest growth among microcomponent categories, finding applications in digital cellular, rigid disk drive (RDD), and DVD, utilizing advanced process technology of each generation.

In the ASIC area, system-level integration is becoming the norm for product development as well as applications. This trend is expediting the shift from gate arrays to CBICs and PLDs. In the Japanese market, because the domestic suppliers still put emphasis on gate arrays, this shift is taking place more slowly than in the worldwide market. CBICs in Japan are currently based on 0.35- to 0.25-micron processes, moving to 0.18-micron processes, as microcomponent, memories, and analog become embedded to offer SLI solutions.

Portable equipment applications in Japan are expected to drive low-voltage technologies as well as embedded memories and high-density packaging technologies.

Analog is expected to slow down in 1998 because of sluggish domestic markets for end products including consumer equipment. General-purpose analog such as amps and voltage regulators enjoyed proliferation as emerging new systems were introduced. However, as SLI becomes the norm for optimized system development, independent, general-purpose analog will be embedded in CBICs. RF and power products continue to enjoy sound growth in the forecast period, although 1998 should be a year of slow growth.

Similar market trends are expected for discrete semiconductors in Japan. For example, small signal products, which enjoyed an increase in volume in the past few years, will finally see slow growth as SLI products incorporate more system blocks. Here again, RF and power are the two functions that remain to be covered by independent ("discrete") discrete products, helped by mobile applications and digital consumer equipment. Steady growth is expected in optical semiconductors.

High-Growth Products

The 1997-to-2002 CAGRs of the fastest-growing semiconductor products in the Japanese region are shown here (with 2002 revenue in parentheses):

- DSPs—28 percent ($2.5 billion)
- SRAM—20 percent ($2.2 billion)

- Flash memory—18 percent ($1.5 billion)
- MPUs—16 percent ($5.6 billion)

Tables 5-1 and 5-2 provide details of the Japanese semiconductor market.

Figure 5-1 provides a product comparison for final revenue in the Japanese market.

Chapter 6
Europe, Middle East, and Africa Forecast by Product Family

Semiconductor Forecast by Region

The forecast calls for the Europe (including Middle East and Africa) market to grow at a 15 percent CAGR for 1997 through 2002. The market should grow by nearly 9 percent in 1998 to a total of $33 billion and reach $60 billion by 2002. The following assumptions guide the forecast with a focus on the near term.

The single most critical factor affecting the 1998 European semiconductor market will be DRAM average selling prices. A "side effect" of DRAM pricing and the excess capacity driving low DRAM pricing is the impact on the European pricing of other semiconductor products.

The prime application driver for Europe is the PC. For the near term, concern about "downside" forecast potential far outweighs upside potential. If European consumption of PCs is less than expected this year, MPU and DRAM revenue growth in the region would become lower than currently projected (about $0.5 billion).

A second major application driver in the European semiconductor market is mobile communications. The negative impact of the Asian crisis has been incorporated into the 1998 European semiconductor forecast. If the Asian crisis proves not as bad as expected, then the near-term European semiconductor forecast gains upside potential ($1.5 billion range).

Wireline communications mark a third key semiconductor application in Europe. France and Germany have started to "liberalize" their networks in 1998, which means increased semiconductor consumption. The European forecast is relatively pessimistic about the impact in this first year of new operators moving into the region. If the pace is faster than expected, then the European semiconductor forecast gains additional near-term upside potential.

Increasing Internet usage means growth in European data communication applications. The Internet now helps drive local European manufacture of switches, hubs, and routers by the major players. The current European semiconductor forecast is based on a conservative estimate of the regional production. The potential of faster growth means upside potential for the European semiconductor market.

By contrast, consumer digital applications create some downside forecast potential The current forecast expects strong growth in the set-top box market. Several pending European regulatory issues, however, might again delay European deployment of STB. This could lower European semiconductor consumption in this segment by about $100 million.

High-Growth Products

The products with the highest CAGRs in Europe over the five-year forecast period are as follows (with 2002 revenue in parentheses):

- DSPs—26 percent ($3.3 billion)
- ASICs—21 percent ($8.2 billion)
- SRAM—20 percent ($1.6 billion)
- Flash memory—17 percent ($1.4 billion)

Tables 6-1 and 6-2 provide details on the European semiconductor market.

Figure 6-1 shows the impact of the five-year forecast by product for the Europe, Middle East, and Africa market over the forecast period.

Chapter 7
Asia/Pacific Forecast by Product Family

Semiconductor Forecast by Region

Dataquest's forecast calls for the Asia/Pacific market to grow at a 16 percent CAGR from 1997 through 2002, which is lower than prior expectations. The market should grow by 10 percent this year to $36 billion and total $68 billion by 2002. The following assumptions guide the forecast.

The financial crisis in the Asia/Pacific region will have varying effects on semiconductor consumption in the region—many negative, but some positive. The effects also differ markedly on an Asian country-by-country basis. For example, growth has decelerated in countries such as Indonesia, Thailand, and the Philippines—but accelerated in China and Taiwan. Taiwan's electronics industry will fare well in this crisis, primarily because a larger percentage of components are supplied locally and because its financial sector is stronger than in the other countries.

All semiconductor vendors watch China. China's electronics equipment production will grow nearly 20 percent this year. China now stands as the largest semiconductor market in Asia/Pacific. China represents a huge consumer of communications and computer equipment, accounting for 25 percent of all personal computers purchased in Asia/Pacific. China's PC unit growth exceeds a 40 percent annual rate.

Although electronics consumption may be lower than previously expected in selected countries, the region as a whole will continue to enjoy the fastest growth rates in the world.

The semiconductor market for PC applications represents more than one-third of all semiconductor consumption and will continue as the key role for semiconductor growth. The Asia/Pacific PC production will maintain steady growth over the forecast period. PC production in Asia/Pacific should total 23 million units in 1998. The PC production growth in this region will be attributed to Pentium II, DVD, 3-D graphics, Windows NT, and Windows 98. Although much of the production is shipped elsewhere in the world, PC unit consumption in the region should increase by more than 20 percent this year and reach 12 million units.

In the long term, Dataquest expects the region's most important semiconductor demand driver, the PC, to sustain solid growth in Asia/Pacific production, with a CAGR of 23 percent over the five-year forecast period. As a result, PC production in Asia/Pacific will exceed 45 million units in 2002. PC motherboard production will also continue in the region.

In terms of regional consumption, PC unit consumption in Asia/Pacific will grow at a 25 percent CAGR for the period and total 30 million units in 2002. PC revenue will grow at a slower, but still impressive, 20 percent CAGR.

Communications equipment will also generate outstanding Asia/Pacific semiconductor growth over the forecast period. This application will support the demand growth for ASICs, DSPs, application-specific standard

©1998 Dataquest

products (ASSPs), and analog ICs. In the near term, most of the Asia/Pacific semiconductor market for communication in 1998 will be driven by mobile and wireless communications. Digital consumer products such as digital set-top-boxes will also begin to make a significant contribution to overall semiconductor demand.

The discrete device and optical semiconductor markets should be lower in 1998 than originally expected because of sluggish consumer equipment production, especially digital consumer applications. However, these markets will continue to achieve steady growth because of the post-1998 recovery in Asia/Pacific production of digital consumer equipment.

High-Growth Products

The following summarizes the CAGRs of the fastest-growing products in the region (with 2002 regional revenue shown in parentheses):

- DSPs—24 percent CAGR ($2.4 billion)
- SRAM—23 percent ($1.7 billion)
- Flash memory—21 percent ($1.6 billion)
- ASICs—22 percent ($4.4 billion)
- MPUs—20 percent ($11 billion)

Tables 7-1 and 7-2 provide details on the Asia/Pacific semiconductor market.

Figure 7-1 compares products in 1997 and 2002.

Chapter 8
Exchange Rates

Dataquest does not forecast exchange rates. The following exchange rates are used for the forecast for 1998 through 2002:

- Japan—¥129.73 per U.S. dollar
- European Union—ECU 0.8994 per U.S. dollar

Table 8-1 shows exchange rates of the yen and ECU versus the U.S. dollar for the period from 1980 to 1997. The appreciation of the dollar against these local currencies is given in the last two columns.

Table 8-1
Exchange Rates

Year	Yen per U.S. Dollar	ECU per U.S. Dollar	U.S. Dollar Growth versus Yen (%)	U.S. Dollar Growth versus ECU (%)
1980	227.00	-	3.6	-
1981	221.00	-	-2.7	-
1982	248.00	-	12.2	-

Chapter 1
Executive Summary

Two years shy of the year 2000 and a forecast of $227 billion, the semiconductor industry and its vendors stand precariously on the edge of an economic chasm. Will the industry recover in 1999, growing at more than 15 percent? Or will the financial crisis in Asia spread to Japan, pushing recovery into mid-1999? The move to institute 0.25-micron manufacturing capability, coupled with the retooling of fabs to migrate from DRAM to logic, was the main focus of investment in equipment in 1997. At the very high end of performance, companies such as Intel Corporation (300-MHz and above microprocessors), IBM (application-specific ICs, or ASICs, and 64Mb DRAMs), and Lucent Technologies (digital signal processors, or DSPs) are manufacturing products in 0.25- and 0.18-micron technology. Yet 40 percent of silicon is still consumed by discrete and optical semiconductor products for device geometries in the 1.0-to-0.5-micron range. The worldwide average wafer diameter for 1997 was 5.85 inches and for 1998 was 6.06 inches. Yet there are more companies and countries investing in 0.25-micron technology. Overinvestment and aggressive spending patterns plus overcapacity and accelerated die shrinks weakened the growth potential of the worldwide semiconductor market for 1998.

The Asian financial crisis, with its capital and credit constraints, has created tremendous uncertainty, with downside capital spending ramifications. Although capital spending is almost dead in Korea, Taiwan's financial situation is the healthiest in Asia. Taiwanese companies' capital spending is expected to increase about 13 percent in 1998 to $7 billion. U.S. and European regional companies are spending in the low 4 percent range, and Japanese companies will cut spending overall by 8 to 10 percent in yen (14 percent in dollars) over 1997. Overall, Japan's degree of strength or weakness and the effect of the Asian financial situation on the Americas and Europe will determine the ability of the industry to recover in late 1998. Table 1-1 shows the Dataquest's estimate of the future of the electronics industry.

Table 1-1
The Future of the Electronics Industry (Millions of Dollars)

	1997	2002
Silicon Wafers*	7,378	15,459
Wafer Fab Equipment	22,318	42,837
Semiconductors	147,165	287,895
Electronic Equipment	923,819	1,250,000

*Includes prime, test, and monitor wafers

Industry 1997: Technology and Applications

Data compiled from the more than 170 companies surveyed in 1997 indicated that the semiconductor industry had grown to $147.2 billion, up 3.5 percent from the $142.2 billion market of 1996. Capital spending declined 0.7 percent to $44.7 billion from $45 billion in 1996. Capital spending for 1998 is expected to decline to $43 billion, down 3.7 percent from 1997. The move toward 0.25-micron manufacturing capability, coupled with the retooling of fabs from DRAM to logic, has been the main focus of investment in fab equipment in 1997 and early 1998.

Table 1-2 shows a 10-year span of historical and forecast market share of semiconductor products. The 2002 data is based on Dataquest's spring 1998 forecast. Microcomponents will continue to capture the largest market share of all semiconductor products, based on demand from the data processing application segment—specifically, demand from the PC segment, a volatile equipment market. However, the communications segment, as shown in Table 1-3, will stimulate the growth of all other product categories as demand for components from the wired and wireless application segments expands. Semiconductor distribution in the electronic equipment base for 1997 is forecast in Table 1-4.

Table 1-2
Historical and Forecast Product Share of Semiconductors (Percent)

Product	1987 Market Share	1997 Market Share	2002 Market Share
MOS Memory	16	21	21
Microcomponents	14	33	36
MOS Digital Logic	17	17	18
Analog/Mixed-Signal	17	15	14
Discrete	18	10	8
Optical Semiconductors	5	4	3
Bipolar Digital	13	0	0
Total Semiconductor Revenue ($M)	**37,011**	**147,165**	**287,895**

Total semiconductor revenue does not include hybrid ICs.

Regional Suppliers

As shown in Table 1-5, the Americas and Japanese regions supplied 81.7 percent of semiconductors produced and shipped to the world in 1997. At $48.1 billion, the Americas region consumed 32.7 percent of semiconductors in 1997 (see Figure 1-1). Americas vendors also produced $72.3 billion in semiconductors (see Figure 1-2). Japan and Asia/Pacific owe their decline in revenue and product shares to continued drastic price declines in DRAM and to the lack of a substantial increase in DRAM bit growth to offset the lower average selling prices (ASPs).

Americas vendors maintained fairly significant growth in microcomponents, logic, and analog products. Americas vendors control 75.5 percent of microcomponents and increased their market share 21.4 percent from 1996 to 1997. They have a 48.7 percent share of logic, which grew 13.7 percent from 1996 to 1997. Americas vendors' analog share is 45.9 percent, with a 23.9 percent growth from 1996 to 1997. For European vendors, the strongest growth was in analog products. European vendors control 24.9 percent of the analog market and increased their revenue 17.8 percent from 1996 to 1997. The total regional forecast for semiconductors with actual production from 1997 is shown in Table 1-6. The specific product forecast detail for all regions can be found in Chapters 2 through 7.

In the final market share rankings for 1997, Intel led the worldwide semiconductor market. Intel captured 14.8 percent of the total market and led the top five vendors in all regions, as noted in Table 1-7.

Chapter 2
MOS Memory Market

At $30.9 billion, MOS memory revenue represented about 21 percent of worldwide semiconductor revenue in 1997. Figure 2-1 illustrates the growth and size of the memory market in relation to the total semiconductor market for 1997 through the forecast period. Worldwide memory revenue declined 18.6 percent. Overcapacity and continued cuts in DRAM ASPs drastically reduced DRAM vendor company revenue for the second straight year.

DRAM units grew 28.5 percent in 1997 over 1996 as total shipments reached 3.4 billion units. The 16Mb density, at 2.1 billion units shipped, captured the largest share. The overall DRAM ASP declined to $6.05 from $9.69 in 1996. If price declines continue through the first two quarters of 1998, the overall DRAM ASP and total revenue could be pushed well below the $6 ASP and $20.9 billion in revenue forecast for 1998. The average price per megabyte of DRAM in 1997 was $3.85, a 58.8 percent decline from $9.34 in 1996.

Of the SRAM products, unit shipments grew 10.6 percent to 1.2 billion units in 1997. The 256K devices totaled 514.8 million units for a 44 percent share of total SRAM shipments. Although price declines were not as severe in SRAM as in DRAM, the overall ASP declined 23 percent to $3.42 in 1997 from $4.45 in 1996. Factory revenue for SRAMs worldwide totaled $4.0 billion, declining 14.9 percent from 1996.

The nonvolatile memory segments totaled $5.6 billion in 1997. All four product segments (EPROM, flash, ROM, and EEPROM), declined in revenue. EPROM revenue declined 37.1 percent to $785 million in 1997. Flash revenue declined 3.2 percent to $2.7 billion. ROM revenue declined 19.1 percent to $1.0 billion. EEPROM revenue declined 7.9 percent to $967 million.

MOS Memory Product Forecast

The MOS memory market data shown in Table 2-1 includes factory revenue and product shares for total MOS memory products shipped to the worldwide market for 1997 through 2002.

Table 2-2 shows the regional shares of consumption and production revenue for MOS memory products. Table 2-3 shows the market share of the top five suppliers worldwide of MOS memory products to each region. Samsung Electronics Company Ltd. continued to dominate the MOS memory market worldwide, as well as the Americas, European, and Asia/Pacific markets. Samsung was also the No. 1 revenue supplier of DRAMs and SRAMs to the world. Table 2-4 shows the top five suppliers' share of worldwide revenue for the specific memory product categories.

Chapter 3
MOS Microcomponents

The MOS microcomponent market share of semiconductors was 33.3 percent in 1997, making that the largest segment of semiconductor devices. Dataquest's spring 1998 forecast expects microcomponents to capture 35.8 percent of the estimated $288 billion semiconductor market for 2002. A view of the MOS microcomponent share of the worldwide market forecast is illustrated in Figure 3-1.

MOS Microcomponent Product Forecast

The MOS microcomponent revenue forecast and market shares for each microcomponent sector are listed in Table 3-1. Microcomponent revenue reached $48,945 million in 1997. This represented an 18 percent increase from 1996. The Americas region remained the largest producer and consumer of the microcomponent products. The 1997 consumption and production data for microcomponents by region is listed in Table 3-2.

Microcomponent Market Share

Table 3-3 shows the top five suppliers' share of MOS microcomponents by region of consumption. Table 3-4 shows the top five suppliers' worldwide share of revenue for the specific MOS microcomponent segments. Further analysis on the markets and suppliers of microcomponents is available from Dataquest's Embedded Microcomponents Worldwide program.

Chapter 4
MOS Logic

The MOS digital logic segment (ASICs, custom ICs, MOS standard logic, and other MOS logic) is the third-largest product segment of the semiconductor market, after memory and microprocessors. Total MOS digital logic revenue grew 9.2 percent and reached $24.7 billion, or a 16.8 percent share of the world semiconductor market in 1997. Figure 4-1 illustrates the logic share of the semiconductor forecast through 2002.

Logic Product Forecast

The digital ASIC group of products—mixed-signal ASICs, cell-based ICs, programmable logic devices (PLDs), linear array ASICs, and gate arrays—representing the bulk of logic revenue, grew 11.7 percent to $16.5 billion. Revenue from custom ICs, MOS standard logic, and other MOS logic products combined represents $8.2 billion or a 33.2 percent share of MOS digital logic. Revenue by segments is shown in Table 4-1. MOS digital logic consumption versus production data by region in 1997 is shown in Table 4-2.

Logic Market Share

Tables 4-3 shows the top five suppliers' total revenue share of MOS logic products by region for 1997.

Chapter 5

The Analog Market

Analog ICs comprise linear ICs and mixed-signal ICs. Linear ICs, which are completely analog in nature, include amplifiers, comparators, regulators, references, and consumer and automotive ICs. Mixed-signal IC categories include data converters, interface ICs, telecom ICs, and mass-storage ICs. Although linear ICs have been growing at a slower rate, but a steady one, mixed-signal ICs have been growing at a faster rate because of the need to bridge the physical "analog" world with digital electronics. Analog ICs are found in all electronic equipment, even equipment that seems purely digital, such as digital computers. The major uses of analog ICs that will continue their growth are:

- Signal processing—purely analog or pre- and-post-DSP
- Conversion from analog-to-digital and digital-to-analog formats
- Providing regulated power supplies for electronics
- Providing drive to communication links and devices; providing signal conditioning for the receiving end
- Radio frequency (RF) communications

Figure 5-1 illustrates the analog share of the worldwide semiconductor market through 2002.

Analog Product Forecast

Worldwide analog semiconductor revenue grew 18.7 percent in 1997 to $21.7 billion. Dataquest projects analog IC revenue to grow at a compound annual growth rate (CAGR) of 13.8 percent between 1998 and 2002 and reach $41.4 billion by 2002. For 1998, Dataquest expects the analog IC revenue to grow 10.8 percent. In the long term, to 2002, mixed-signal ICs will experience solid growth, driven by application markets such as digital cellular. Also, emerging applications in the consumer and communications markets will contribute to the growth of mixed-signal ICs. In the more traditional standard linear product area, voltage regulator products will continue to enjoy strong growth as the demand for smart power continues to grow, especially in the portable applications. Table 5-1 shows the analog forecast for the world and each region. Table 5-2 shows analog production versus consumption for each region.

Analog Market Share

Texas Instruments Inc. overtook SGS-Thomson Microelectronics B.V. and became the No. 1 analog IC supplier in 1997. Table 5-3 shows the top five vendors of analog by region. Table 5-4 shows the top five analog vendors by specific analog product categories.

Chapter 6
Discrete Semiconductor Market

The term "discrete" refers to a packaged semiconductor device having a single "device," an electrical functional component such as a diode, transistor, or thyristor. These devices, unlike ICs, must be combined with other components to provide a basic electrical function such as amplification, switching, or latching. Discrete devices represent the ancient ancestral root of the IC business. Despite their age, discrete semiconductors, especially in the power transistor segment, continue to grow. The long-range forecast share of discrete products in relation to worldwide semiconductors is shown in Figure 6-1.

Discrete Product Forecast

Discrete products grew 5.8 percent to $14.3 billion in 1997 and represented 9.7 percent of the total semiconductor market. As noted in Table 6-1, a normal pattern of growth, around 10 percent, is expected in the period from 1999 through 2002. The 1997 consumption and production data for discretes by region is listed in Table 6-2.

Discrete Market Share

Motorola Incorporated maintained control of the No. 1 position in discrete with a 10.8 percent share of the total market, in spite of a 12.0 percent decline in revenue from $1.7 billion in 1995 to $1.5 billion in 1996. Besieged by capacity demands but limited in capacity through the first half of 1997, Motorola's strategic plan is to expand its fab capacity for discretes. Motorola has made investments in two European facilities (4- and 6-inch) for added capacity. The top five suppliers by region and specific discrete products are shown in Tables 6-3 and 6-4.

Chapter 7
Optoelectronics

Optoelectronic products represent the interface between light energy and electrical currents. Dataquest does not follow the total optoelectronics market, only the semiconductor optoelectronics sector. Nonsemiconductor products that are not covered are LCDs, CRTs, plasma displays, ceramic sensors, phototubes, or any optoelectronic product not fabricated on semiconductor material with semiconductor processing techniques. Because of this limited viewpoint, it may be more appropriate to discuss this segment as "optical semiconductors" rather than as optoelectronics. Figure 7-1 illustrates the growth of optical semiconductors in relation to the worldwide semiconductor market.

Optical Product Forecast

Optical semiconductor revenue reached $5.3 billion in 1997, an 8.6 percent increase over $4.9 billion in 1996. Applications for wired and wireless telecom, DVD, and digital cameras will be the major consumers of optical semiconductors such as lasers, charge-coupled devices (CCDs), and infrared (IR) products. Optical semiconductors are forecast to reach $7.4 billion by 2002. Table 7-1 shows the regional forecast for optical products, and Table 7-2 shows consumption versus production by region.

Optical Product Market Share

Desktop video digital cameras and camcorders, scanners, and LCD clusters for automotive communications and avoidance systems are just of the few application segments that drove regional and product-related revenue growth for the top five companies listed in Tables 7-3 and 7-4. Later in the forecast period, the wireless communications sector, optical scanners, surveillance/monitoring, wireless video, and robotics are expected to drive optical semiconductor product growth.

Appendix A
Product Definitions

Memory

The bipolar memory product category includes emitter-coupled logic (ECL) and transistor/transistor logic (TTL) random-access memory (RAM), and ECL/TTL programmable read only memory (PROM), first in/first out (FIFO) memory, and last in/last out (LIFO) memory.

The MOS memory product category is organized by volatile, nonvolatile, and specialty devices. Detailed definitions of all memory products are as follows:

- DRAM includes dynamic RAM, multiport DRAM (M-DRAM), video DRAM (V-DRAM), and new architecture DRAMs (NADs). NADs include Rambus, cache, enhanced, and synchronous DRAMs. These are volatile memories, and addressing is multiplexed. DRAMs have memory cells consisting of a single transistor and require regular externally cycled memory cell refreshes.
- SRAM includes static RAM, multiport-SRAM (M-SRAM), battery backed-up SRAM (BB-SRAM), and pseudo-SRAM (P-SRAM). SRAMs have memory cells consisting of a minimum of four transistors (P-SRAMs have memory cells consisting of a single transistor and are similar to DRAMs). SRAMs do not require externally cycled memory cell refreshes. Addressing is not multiplexed (except in the case of P-SRAM).
- The erasable programmable read-only memory (EPROM) product includes ultraviolet EPROM (UV EPROM) and one-time programmable ROM (OTP ROM). EPROMs have memory cells consisting of a single transistor and do not require any memory cell refreshes.
- Read-only memory (ROM) is often referred to as mask ROM because it is programmed by the manufacturer to a user specification using a mask step. ROMs are programmed in hardware rather than software.
- Electronically erasable programmable read-only memory (EEPROM) includes serial (S-EEPROM) and parallel (P-EEPROM) EEPROM and electrically alterable ROM (EAROM). EEPROMs have memory cells consisting of a minimum of two transistors and do not require memory cell refreshes. This product classification also includes nonvolatile RAM (NV-RAM), also known as shadow RAM. These products are a combination of SRAM and EEPROM technologies in each memory cell. The EEPROM functions as a shadow backup for the SRAM when power is lost.
- Flash memory includes products designated as flash EPROM/EEPROM that incorporate either 5V or 12V programming supplies and one-transistor (1T) or two-transistor (2T) memory cells with electrical programming and fast bulk/chip erase. These devices are considered nonvolatile memories.

- Other MOS memory accounts all other products not accounted for in the preceding MOS memory categories. Other MOS memory includes content-addressable memory (CAM), cache-tag RAM, first in, first out (FIFO) memory, last in, last out (LIFO) memory, and ferroelectric memory.

Microcomponent

The microprocessor (MPU), microcontroller (MCU), and digital signal processor (DSP) products of MOS microcomponents are similar in that they are designed to operate by program, fetching and running preprogrammed instructions (found either in software or firmware) to provide the desired logic function. The microperipheral (MPR) category differs in that its primary function is to provide specialized support to a host MPU, MCU, or DSP. The definitions for the four categories are as follows:

- A microprocessor IC includes an instruction decoder, arithmetic logic unit (ALU), registers, and additional logic. It may also contain instruction, data, or unified caches, memory management systems, and auxiliary ALUs for floating-point operations. An MPU's functions are determined by fetching and executing instructions and manipulating data held in registers, internal cache, or external memory.
- A microcontroller IC is designed for a standalone operation that includes a programmable processing unit, program memory, read/write data memory, and some input/output capability. The processing unit contains an instruction decoder, ALU, registers, and additional logic. The MCU's functions are determined by fetching and executing instructions and manipulating data held in on-chip program and data memory (not including cache memories).
- A microperipheral IC serves as a logical support function to an MPU in a system. This definition includes MPRs that comprise more than one device, such as PC or core logic chipsets.
- A digital signal processor IC includes a high-speed arithmetic unit (typically a multiplier-accumulator unit) designed to perform complex mathematical operations, such as Fourier transforms, manipulating digital representations of analog signals in real time. Most DSP functions, such as the multiply-and-accumulate function, are completed in single instruction clock.

Logic

Logic is an electronic function where bits (one and zeros) are processed. This bit processing is defined by hardwiring, mask programming, or field programming. Microcomponents and memory ICs are logic ICs, but they are logic ICs that are either dedicated to a function (such as microperipherals and memory ICs) or are software programmable (such as microprocessors and microcontrollers). Logic ICs also include customer-specific logic ICs.

 ©1998 Dataquest

The logic IC category includes application-specific ICs, or ASICs (gate arrays, programmable logic devices, cell-based ICs, full-custom ICs), standard logic ICs, and other logic ICs. ASICs are all IC products customized for a single user. ASIC products are a combination of digital, mixed-signal, and analog products. Customized ICs purchased by more than one user become standard products and are no longer counted as ASICs.

- Programmable logic devices (PLDs) are defined as ICs programmed after assembly. Memory devices such as PROMs and ROMs are not included in this market segment.
- Gate arrays are ICs that contain a configuration of uncommitted elements. They are customized by interconnecting these elements with one or more routing layers. Included in this category are generic or custom base wafers, which include embedded functions such as SRAM.
- Cell-based ICs (CBICs) are ICs customized by using a full set of masks and using automated place and route.
- Full-custom ICs are ASICs customized using a full set of masks and using manual place and route.

Analog

Monolithic analog ICs fall loosely into two categories—linear ICs or mixed-signal ICs. Dataquest defines linear ICs as those that are purely analog (having no digital data path or control functions). Linear products include amplifiers, comparators, references/regulators, special linear functions, and consumer-specific functions. Dataquest defines a mixed-signal IC as an IC that has both analog and digital input/output pins, a condition that requires both digital and analog functions on chip and both digital and analog interfaces externally. Mixed-signal IC categories include data converters, interface ICs, mass-storage ICs, mixed-signal ASICs, and telecommunications ICs.

Discrete

Diodes

A diode is a basic two-layer, single-junction device. It is essentially a two-pin device that offers a high impedance to current flow in one direction and a low impedance to current flow in the other. Diodes have no additional means of controlling current flow. The primary types of diodes are signal diodes, power diodes or rectifiers, Schottky barrier diodes, and zener diodes. Signal diodes are diodes with a forward current of less than 100 milliamperes (0.1 amperes).

Transistors

Transistors are three-terminal devices in which two of the terminals provide the normal current path and the third represents the controlling electrode. This control electrode allows the transistor to amplify signals (analog mode) or to operate as a current switch (digital mode). The two main types of transistors are bipolar transistors and field-effect transistors (FETs). Bipolar transistors have a base electrode that allows a small current

©1998 Dataquest

to control a larger current between the emitter and collector electrodes. The FET differs in that a voltage at the gate electrode controls current flow between the source and drain electrodes. The FET, a voltage-controlled device, requires no power at its controlling gate.

Small-signal transistors control relatively small currents (less than 1 ampere) and dissipate less than 1 watt of power. Also, they are confined to operating voltages below 100 volts. They are used as amplifiers and low-power switches in industrial and consumer electronics. Small-signal transistors show limited growth potential because of the continued integration of high-speed transistors.

Power transistors are devices that can control 1 ampere or more of current, can dissipate 1 or more watts of power, or are capable of operating with voltages exceeding 100 volts. Power transistors are used in applications such as switch-mode power supplies, power inverters, regulators, and motor controls. Power transistor applications have been dominated by bipolar devices. In the past decade, however, the power MOSFET device has become prevalent in applications involving high-speed switching. In power-switching applications, the range above 1,000 volts is still dominated by the bipolar power transistor, but power MOSFETs have become competitive in the 100-to-600-volt range. The insulated-gate-bipolar transistor (IGBT) is a recent arrival that offers the low drive current of the MOSFET with the low saturation voltage of the bipolar transistor.

Thyristors

Thyristors consist of a four-layer slice of silicon. The device is characterized by a self-latching switch effect. Once a thyristor has been triggered into conducting current, it will continue to conduct current until the main current falls to zero. Large amounts of power can be controlled with very little gate power.

The name thyristor is used in a generic sense to include silicon-controlled rectifiers (SCRs), triacs, and diacs. A modification of the SCR—the gate turnoff SCR (GTO)—can be turned off with a negative voltage applied to the gate terminal. A newer variation using MOS technology is the MOS-controlled thyristor. There are three principal thyristor market segments: consumer, commercial, and heavy industrial. Triacs are the fastest-growing part of the thyristor segment because of the demand for AC control in appliances. The microwave oven is a very large consumer of triacs in current ratings up to 40 amperes. Hair dryers are large consumers of small SCRs.

Other Discrete Devices

This category accounts for other types of products not specifically characterized in the preceding paragraphs. These devices include microwave diodes, varactor tuning diodes, and tunnel diodes.

©1998 Dataquest

Optical Semiconductors

Photosensors

Photosensors or detectors are individual optical sensing devices using photodiodes or phototransistors. In these devices, the impinging light creates a current flow. The photodiode is more linear in its light-to-current relationship than a phototransistor and switches faster than a phototransistor. The phototransistor, either a junction field-effect transistor (JFET) or bipolar device, offers the advantage of current amplification.

Phototransistors are used as sensors in facsimile and photocopier machines. Photodiodes are used in CD players and in remote control devices for VCRs and other consumer products. Photodiodes are also important in optical data communications. Consumer products and the proliferation of optical communications are fueling the significant growth for these photodiode sensors.

CCD Sensors and MOS Arrays

The two main semiconductor image sensors are MOS arrays and charge-coupled devices (CCDs). Both of these devices use photodiodes as the light sensor. The MOS array is addressed in an x-y format like a memory device. The CCD provides a serial data transfer of the analog signal. The CCD image sensor consists of a PN photodiode array, a CCD analog shift register, and an output circuit. Light enters the photodiode array generating electron-hole pairs. The photo-generated carriers (electrons) are stored within diodes of the array as signal-charge packets. When a designated voltage is applied to the shift gate, the stored charge packets are transferred to the CCD shift register, instantly and in parallel.

CCD image sensors are employed in numerous applications. Linear CCDs are used in facsimile machines, scanners, and electronic copiers. Area CCD applications include camcorders, monitoring systems, robots, and electronic still cameras.

LED Lamps and Displays

LED lamps and displays are based on the light-emitting diode. This device is a pinhead-size PN junction formed from combinations of gallium, arsenic, and phosphorus. Light emission is the result of hole-electron recombinations that take place near the junction of the p-doped and n-doped regions. As the electrons in the n region of the diode travel through the area near the junction, they recombine with a hole, releasing a photon with energy within the band of visible light. The wavelength or color of the emitted light is determined by energy released during recombination.

The most common materials used to manufacture LEDs are gallium arsenide phosphide (GaAsP), which emits light in the 650-nanometer red-light region of the visible spectrum, and gallium phosphide (GaP), which can, with appropriate doping, be made to emit light in the 565-nanometer green region. Mixing GaAsP and GaP in various substrate combinations can result in various color variations, including orange-red, amber, yellow, or bright green. Blue LEDs have been difficult to achieve but are being developed. The blue color is crucial for the construction of a full-color LED display.

 ©1998 Dataquest

Light from LEDs is proportional to current, and altering the drive current modulates the light output. The electrical requirements needed to operate an LED are current from 0.5 to 20 milliamperes and voltage from 1.6 to 2 volts.

Individual LED dice may be bonded to metal lead frames or substrates of ceramic or fiberglass-epoxy laminate to form discrete numerical modules or multidigit displays. Seven separate dice are used to form a discrete seven-segment display module—an eighth die is used for the decimal point. Each of the seven dice illuminates a segment, or bar, used to form numbers from 1 to 10 and the letters A through F.

As indicators and displays, Dataquest believes that visible LEDs have entered the maturity stage. They are found as indicating lights on every type of electronic equipment. Although they have lost significant markets to liquid crystal displays (LCDs) in numeric and x-y displays, they can still be found in applications where their monochrome, active light emission is more desirable than LCDs.

New application areas are emerging to keep LEDs a growth product. One new growth area for LEDs involves the use of linear LED array printheads. These devices can provide high resolution and high speed in laser printers, facsimile machines, and other printers where light is used to create an image that is transferred to paper. The LED printed competes with laser diodes and thermal printheads in printer applications. Another growing application is the use of high-brightness LEDs in automotive signaling and braking lights.

Optocouplers

Optocouplers or optoisolators consist of an LED separated from a photodetector by a transparent, insulating, dielectric layer and mounted in an opaque package. A current in the LED causes light radiation to travel across the dielectric material to the photodetector, which, in turn, modulates a current at the output relative to the detected light. Because the input and output circuits are separated by an electrical insulator, these devices provide signal isolation. Signal isolation is important in noisy industrial environments, in medical sensing, and in isolating power-control devices from the low-voltage control circuitry.

The coupler may be used in a linear mode, where output current will be a linear function of the input signal, or in a pulsed mode, where the device is merely pulsed on or off (to pass digital bits). A modified optocoupler is the optointerrupter, in which an open space between the LED and the photodetector allows an outside vane or slotted disk to interrupt the light, effectively detecting motion, position, or optically encoded signals. These sensors are used as data encoders in computer peripheral equipment and as position sensors or limit detectors for motor controls.

The current transfer ratio (CTR) is used to rate the efficiency of the coupler. Therefore, it is important to match the radiation wavelength of the LED to the absorption band of the detector. A considerable variety of couplers is available. Although diode couplers offer higher speed, transistor couplers (to 250 kHz) have higher sensitivity. Photo-Darlington couplers are available for high transfer ratios and increased current with speeds up to

 ©1998 Dataquest

25 kHz. The phototriac driver output coupler provides high-voltage (line-voltage) isolation protection for logic-triggering circuits.

Optocouplers are used in high-performance solid-state relays, position sensors, optical encoders, and voltage isolators for connecting logic circuits to power devices.

Laser Diodes

Semiconductor lasers are categorized according to their oscillation wavelength into the 1.55-, 1.30-, 0.85-, and 0.78-micron bands. The 1.55-micron band is the laser that is believed to have the greatest potential for use as a light source in long-distance optical communications. Currently, however, this wavelength is used only in a very few measuring instruments for optical communications. Semiconductor lasers of the 1.30-micron and 0.85-micron bands are being widely used for optical communications. The 1.30-micron band laser is used in long distance optical communications and is expected to have high growth potential. Semiconductor lasers of the 0.78-micron band are widely used in CD players, optical video disks, and laser printers. Shorter-wavelength laser diodes are starting to replace other laser types in bar-code scanners and offer the potential of increasing the storage capability of optical memories.

Other Optoelectronics

This subcategory includes solar cells, optical thermopiles, and other exotic optical semiconductor products. Photovoltaic cells, or solar cells, are used in widely divergent applications, ranging from sun-powered consumer products to self-powered terrestrial communications links, as well as in powering satellite communications. Solar cells in the consumer environment are expected to show relatively low growth because they have been largely confined to calculator applications. Growth may hinge on whether solar cell-powered portable data processing products are made available.

Insight

SEMICONDUCTORS JAPAN

Dataquest's Semiconductors Japan program provides quantitative and qualitative information on the products, markets, technologies, and companies driving the Japanese semiconductor industry. This program provides a comprehensive view of all aspects of the industry, including manufacturing and consumption by application market.

Key Business Issues

Want to learn more about Dataquest?

Please visit our Internet web site at ***www.dataquest.com***

The Semiconductors Japan program provides advice and analysis to help clients make successful business decisions. Publications include a mix of analytical articles, weekly news bulletins and event-driven faxes, focused reports, and timely market statistics published on a regular schedule throughout the year. Briefings and conferences bring clients together with analysts to share insights and opinions.

Key semiconductor issues covered throughout the year in our publications and briefings will include:

- Will Japan continue to lag behind other regions in semiconductor market growth?
- How will digitization of consumer equipment contribute to Japanese semiconductor consumption?
- Who among the users are increasing semiconductor purchase in Japan?
- Will the wafer industry benefit from SLI?
- Will the soft DRAM market continue to persist in the Japanese market?
- Will the arrival of SLI pose an opportunity or a threat to Japanese semiconductor companies?
- Will Japanese semiconductor companies lead in the race for 300 mm wafer fab construction?
- Is foundry going to be an alternative in Japanese companies' strategies?
- Will Japanese companies increase capital spending within Japan, or overseas?

Market Coverage

The program provides timely strategic viewpoints related to semiconductor production and consumption in Japan.

Product Segmentation

This program covers the following product markets:

- ASIC and standard logic
- MOS memories
- MOS microcomponents
- Analog ICs
- Discretes
- Optoelectronics

Geographic Coverage

- Japan
- Worldwide

Application Coverage

Market estimates and forecasts are provided for key applications:

- Data processing
- Communications
- Industrial
- Consumer
- Military/aerospace
- Transportation

Market Statistics

Dataquest provides the following market statistics and growth projections:

- Japanese semiconductor market share estimates
- Detailed Japanese semiconductor market forecast by product
- Electronic equipment production in Japan
- Semiconductor consumption by application in Japan
- Japanese semiconductor industry monitors:
  - Wafer fabrication facilities
  - R&D and capital spending trends
  - Strategic alliances
- Worldwide consumption forecasts by region

Perspective

Semiconductors Japan
Market Analysis

Restructuring Goes On at Japanese Semiconductor Fabs

Abstract: *In 1998, industry reorganization has emerged as a trend against the backdrop of an unprecedented downturn in the worldwide semiconductor industry. A variety of factors, including the protracted semiconductor slowdown, weakening profits, changing dynamics for product-specific markets, and system-level integration (SLI) efforts, are forcing chip makers to reconsider their businesses. In this Perspective, Dataquest reviews fab construction trends among the Japanese manufacturers based on the results of Dataquest's fall 1998 semiconductor fab survey. Please note that we are still in the process of finalizing the results of this survey on a global basis, and therefore, our final release of data may vary slightly from what is presented in this Perspective.*
By Yoshihiro Shimada

Overview of 1998 Fab Survey

Three main observations were made from the results of the 1998 fab survey of Japanese semiconductor manufacturers. They are as follows:

- There are no announced plans for building new fabs.
- DRAM fabs are being substantially reorganized.
- Overseas fabs are being substantially reorganized.

Some of these moves have already been announced by chip makers. Moreover, these results are reasonably predictable considering the current state of supply and demand and the earnings environment. However, a comparison with past low points in the market cycle indicates that more significant steps are being taken this time around.

The survey results for Japanese manufacturers are shown in Figures 1 and 2. Note that the numbers provide a comparison with the situation at the end of 1997.

San Jose, CA 95134
408-468-8600

The key points are listed below:

- Among the wafer processing capacity categories, the 50mm to 100mm segments contracted substantially, the 125mm and 150mm segments contracted slightly, and the 200mm segment rose.
- The 0.35-micron process is becoming the mainstay design rule for MOS digital.
- There are 0.25-micron fabs being launched.
- Some chip makers have 300mm fab pilot line plans, but volume production line plans are undetermined.

Figure 1
1998 Japanese Manufacturers' Wafer Processing Capacity by Wafer Size (Change over the Previous Year)

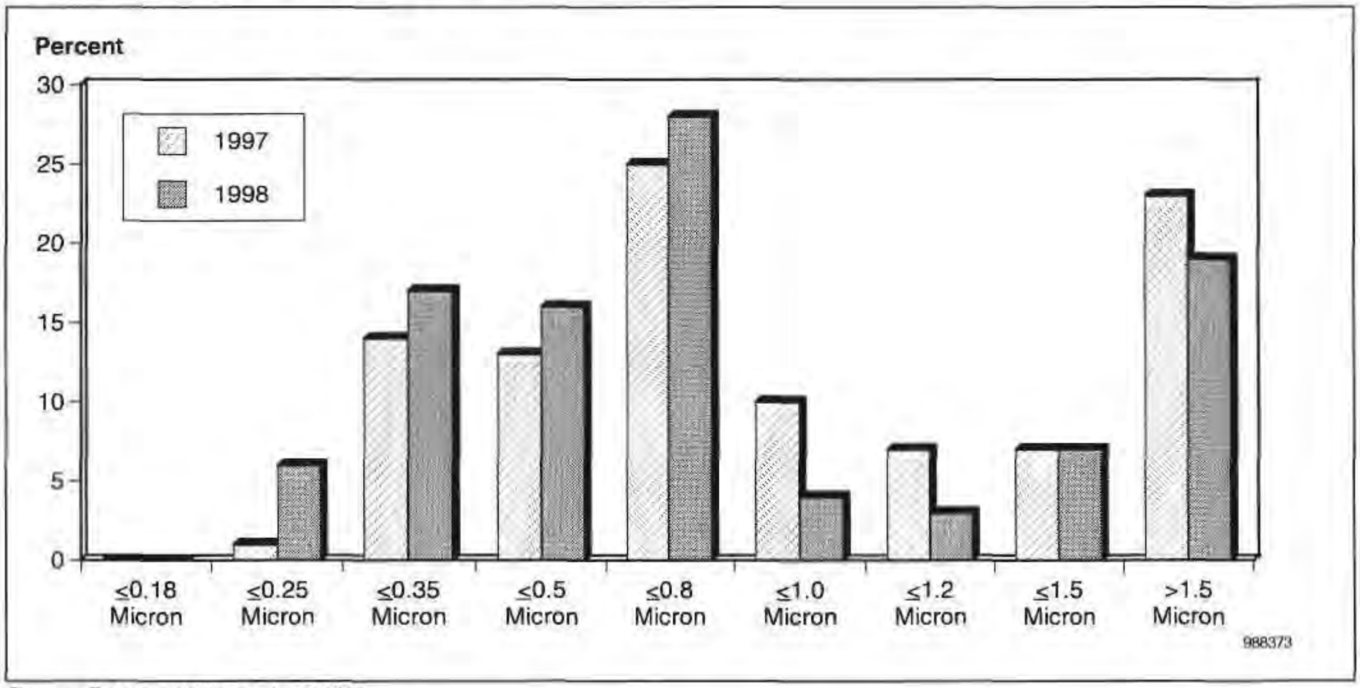
 ©1999 Dataquest

Figure 2
Japanese Manufacturers' Production Capacity by Operating Minimum Geometry (Change over the Previous Year)



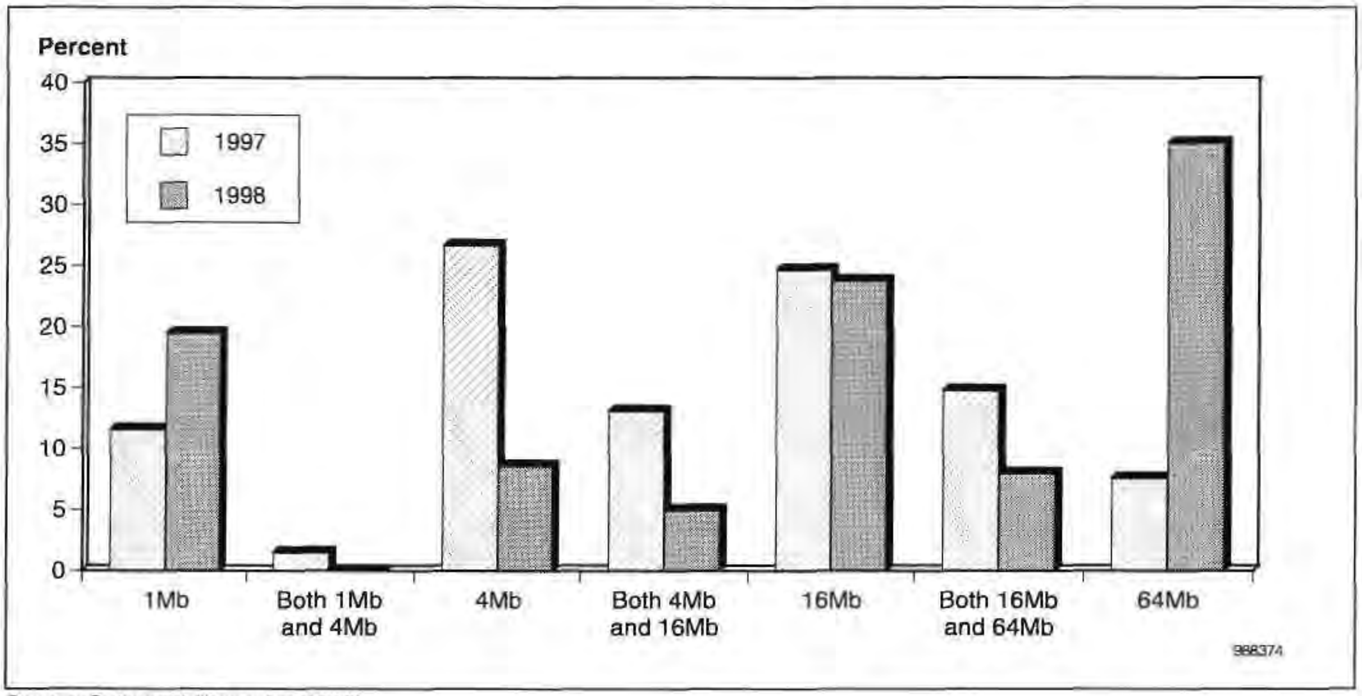
Source: Dataquest (December 1998)

Figure 3 shows the state of DRAM production capacity by memory size for Japanese chip makers. The 200mm fabs designed primarily for DRAMs began operation in 1994 and continued to be built to keep up with the sharp increases in semiconductor demand from the PC boom. Facility launches were equally harried, with only six months between the start of volume production and escalation to maximum equipment output levels. Unable to apply the brakes to this rapid expansion of wafer processing capacity, new facility launches continued even after the DRAM market conditions reversed their course from the end of 1995. However, by 1997, new fab construction had ended, and no new line launches were reported for 1998.

Chip shrink techniques, which have gained rapid acceptance by chip makers as a way of improving profitability, dramatically increase the number of devices obtained from a fixed amount of wafer processing capacity and have worked against the dissolution of excess production capacity. Even though this makes it possible to achieve production capacity expansion while delaying the construction of new 200mm fabs, Dataquest expects continued investment in 200mm fabs by the semiconductor industry as a whole; this is because investment in 64Mb-and-later-generation, high-speed DRAM facilities is being given priority, and the useful life of 200mm fabs is being extended by a move to push back the timing of a switch to 300mm fabs. The question is whether Japanese chip makers will make these investments on their own or whether they will utilize resources outside of their own operations.

 ©1999 Dataquest

Figure 3
Japanese Manufacturers' DRAM Production Capacity by Memory Size



Source: Dataquest (December 1998)

Despite the shift for MOS digital devices to 200mm fabs, 150mm fab facilities are relatively stable with support from the shift by analog 100mm and 125mm fabs. Dataquest's wafer consumption forecast expects just a slight decline in worldwide 150mm wafer consumption, and we believe that 1998 fab trends are in line with this forecast. 100mm and 125mm fabs were operating through the mid-1990s to fill analog and discrete device demand, but the transition to larger-diameter wafers began with the wafer shortages experienced during the 1994-to-1995 time period. Meanwhile, even though investments to expand fab capacity for MOS digital devices are on hold, investments in fabs to satisfy analog device requirements have continued. Specifically, these investments are aimed at responding to high-growth products such as mixed-signal ICs, power devices, and high-frequency devices, as well as to growing demand for linear ICs, which contain standard analog devices.

Trends by Product Type

Reviewing the situation by product type, it is evident that the number of DRAM-dedicated fabs has dropped sharply. Even when adding fabs that combine DRAMs with other devices, it is clear that the DRAM presence is declining. We believe this is happening for the following reasons:

- Even though volume demand is strong, chip shrink techniques enable production volume increases without expanding wafer processing capacity.

- Chip maker fab investments are being reduced by utilizing external resources such as foundries and OEMs.
- Acceleration of the chip shrink trend is making older-generation fabs outdated and unable to compete.
- There is already adequate capacity for other device types that might be used as a conversion alternative or for facility sharing.

As things currently stand, the primary focus in DRAM capacity strategies is on increasing production volumes through chip shrink techniques, and new investments are dominated by facility upgrades to accomplish this. Therefore, DRAM fab investments in 1998 are dedicated mainly to 0.18-micron design rule capabilities, moving forward with greater precision. Leading chip makers expect to have prototypes using the 0.18-micron process at the end of this year and intend to embark on volume production in 1999.

Logic fabs are also increasing design rule precision to 0.25 micron, and investments in 0.18-micron facilities are beginning to be made for system-level integration (SLI) devices. Looking at process technology line widths, logic fabs have caught up with DRAM fabs at the 0.25-micron mark. Furthermore, the facility investment burden for logic fabs is rising in order to introduce planar technology required for multilayer logic devices and process integration to deal with embedded memory and analog function elements.

This survey has confirmed the development of two distinct types of logic fabs. One is an application-specific standard products (ASSP)-oriented fab, and the other is a microcontroller (MCU)- and ASIC-oriented fab. For the former type, the main focus is on reducing costs by enhancing productivity, and for the latter type, productivity improvements are being accomplished by stabilizing yields with process integration. Considering the product technology and production technique, the expression "microcomponent core ASIC" can be applied.

These product-specific trends are creating clear distinctions among the fab construction investments of Japanese chip makers. Naturally, the restrictions on capital spending resources vary by company, and differences in earnings structures also produce differences in capital investment approaches. However, capital spending investments ultimately are guided by product strategies. Dataquest expects to see differences in the capital-to-application capital spending investment stances having a significant impact on the positioning of Japan's chip makers.

Capital Investments

Dataquest is currently in the process of conducting a survey on capital investments by chip makers, and it appears that changes in capital investment levels are linked to the fab survey results. We will report on the details in a separate document, but the gist of it is that leading chip makers are significantly reducing their investment levels.

 ©1999 Dataquest

The reductions in capital investments during 1998 are most prominent in the area of production-expansion investments primarily for DRAMs. Taking a slightly different angle, the downward trend is steepest for overseas plants (see Table 1). During the DRAM boom, chip makers moved aggressively to establish new overseas plants. However, under the current DRAM recession conditions, the impetus to secure overseas production capacity has subsided considerably as chip makers focused on improving the operating rates at domestic plants and on reducing the foreign exchange risk from yen depreciation. Also, because the chip makers are giving priority to the introduction of chip shrink techniques at domestic plants, in cases where the overseas plants are joint ventures or where production items are jointly developed, Dataquest believes that overseas plants will have considerable trouble staying competitive.

Table 1
Japanese Manufacturers' Overseas Plant Trends

Company Name	Fab Name	Date of Change	Prior to the Change	After the Change
Oki Electric	Oregon	September 1998	Back-end fab in operation	Back-end fab closed
Hitachi (joint venture with TI)	TwinStar	March 1998	16Mb DRAM	Hitachi's share sold to TI (afterward, TI sold the whole share to Micron Technology)
Hitachi	Irving	June 1998	4Mb DRAM, MCU	Fab closed
Fujitsu	Dahrum	December 1998	16Mb DRAM	Fab closed
Matsushita Electronic Industries	Matsushita Semiconductors America (MASCA)	December 1998	New 64Mb fab, suspension of 4Mb fab, continuation of 4/8-bit MCU fab	Operations halted
Mitsubishi Electric	Aachen	Early 1999	16Mb DRAM	Product types changed (embedded DRAM, SRAM, flash memory)
Mitsubishi Electric	Raleigh	March 1998	4Mb DRAM	Wafer fab stopped, packaging continued
Mitsubishi Electric	Raleigh	November 1998	Discrete assembly and test, memory module assembly	Packaging stopped (capabilities moved to Nagano packaging facility)

Source: Dataquest (December 1998)

At overseas plants where older-generation DRAM fabs are being converted to logic and analog device operations, it is becoming increasingly difficult to offer the functionality that customers demand as logic products rely more and more on advanced technologies. The value of these facilities has largely vanished as the benefits of supplying products that use existing technologies at a low cost and free of foreign exchange risk have diminished. Further, countries and regional governments that showed an active interest in attracting semiconductor plants with preferential measures during the strong

 ©1999 Dataquest

years are not wooing additional investments; this is because a larger number of plants require infrastructure upgrades, and tax revenue is down from the poor earnings performance.

Under these circumstances, there has been a string of overseas plant closures and freezes on additional investments. These appear to be appropriate business decisions for the current situation. However, a longer-term view shows a pattern of extremes in Japanese chip makers' overseas investments, with extremely aggressive investment during the good years and retreat and withdrawal strategies during the bad years. In fact, the passive posture of the Japanese chip makers in the early 1990s, following the rise in overseas plant openings in the latter half of the 1980s, can be cited as a factor in their slow start in the semiconductor boom, which materialized initially in the overseas markets. If the overseas plant strategies of Japanese chip makers are on the retreat merely as a by-product of a cutback in total capital investment levels, these companies run the same risk once again of missing future opportunities.

Dataquest's spring survey forecast a 20 percent reduction in capital investments by Japanese chip makers in 1998 compared to the previous year, but it appears that the actual rate of decline will exceed this level. This larger-than-expected decline in capital investments is a combination of large-scale cutbacks through the postponement of new fab investments and microadjustments to existing fab upgrade and production-expansion investments. The relative share of investment funds going to the packaging process is rising as new test equipment is introduced to handle the growing diversity in package types and higher device speeds. However, chip makers are working to reduce gross unit levels, the basis for determining investment amounts, by enhancing yields and thereby avoiding an excessive rise in investment costs, as has happened with the fab process.

The motivation to limit capital investment is twofold: restrictions on investment resources and a move to stem excess supply capacity. However, the real question is whether chip makers have lost a sense of direction in the industry's so-called focus on "system LSIs." Not only are chip makers unable to determine what facilities are necessary, how to best link products and technology development, and other key strategic points, but they also appear to be having trouble defining an appropriate road map for their own fab operations. This suggests that once economic conditions recover, the chip makers will simply re-start the supply capacity expansion approach to competition.

A less simplistic readying of supply capacity requires a well-reasoned capital investment strategy, which includes the following:

- A strategic narrowing of business areas based on systematic marketing
- A narrowing of production items for company fabs and the selective use of external resources
- Development of a company structure that utilizes external resources

 ©1999 Dataquest

At the same time, these strategies also involve the following risks:

- Trouble commercializing products if appropriate customers cannot be secured, even if the application-specific narrowing of products is performed in advance at the development stage through systematic marketing
- The need to develop a structure for assessing and minimizing the costs of utilizing external resources

Japanese chip makers are currently in the process of cautiously, but steadily, expanding production consignment to outside companies. However, in cases where the consignments are not for integrated production from the fab to final testing, it is necessary to develop know-how to avoid overlapping tests and understand how to utilize foundry services.

It is difficult to define clear income levels for custom logic production, which cannot assume the high yield levels of classic memory device production. Also, real operating rates are falling because of multiple-lot and mixed-lot production. Thus, facility plans must be worked out using lower yield and operating rate assumptions. This is reminiscent of the generational shift in DRAM production when facilities were allocated on the basis of low yield rates, but yields surprised everyone by rising sharply and then combined with chip shrink techniques to cause excess supply.

Although increasingly complex business management is required for SLI opportunities, given our outlook that restrictions on investment resources will continue, chip makers will be forced to make decisions from the perspective of their total semiconductor business rather than planning capital investments at the individual product or business unit level.

Dataquest Perspective

Far from the initial expectation for a recovery in the world semiconductor market in 1998, conditions worsened, and the overall market contracted, making this a year of serious challenges for chip makers. Meanwhile, the 1999 outlook foresees a return to a path of recovery, and high growth at 20 percent annual levels is expected again in 2000 and 2001. However, this growth pace is just an average for the total semiconductor market. Dataquest expects to see the market split into two segments: chip makers who achieve high growth rates and those who only receive a minor boost. There are two reasons for this departure of fortunes. From the demand side, there are signs that the market is moving from system diversity to integrated systems, and the success of chip makers enjoying the benefits of the SLI era, which hinges on system support, depends largely on whether they can secure suitable customers. On the supply side, investment strategies currently crippled with a variety of restrictions will define the course of chip makers' potential capacities.

Price stabilization is revisiting the DRAM market, beginning with PC100 specification, high-speed devices, and talk of long-term agreements (LTAs) has returned after a long interlude. Meanwhile, in 1999, leading chip makers

 ©1999 Dataquest

will prepare 0.15-micron facilities and gear themselves up for the next phase of market growth. Dataquest believes that under these circumstances, semiconductor companies' capital investments require both bold and refined judgment, which ensures that an overall balance in the business and appropriate investment timing are maintained.

Market Analysis

Silicon Wafer Market in Transition: Moderate Growth Is Expected for the Japanese Market

Abstract: *The silicon wafer market seemed to be in a stage of recovery during the first quarter of 1997. However, the market is staggering again, partly because of the sluggishness of the device market late in 1997 and partly because of reduced wafer consumption caused by the accelerated pace of chip shrinkage in DRAM production. Now, two more forces, the expected changes in regional wafer consumption patterns in the future and a delay in migration to the 300mm wafer process, are working against a market that faces significant changes and turning points. This Perspective analyzes the current state of the Japanese wafer market as well as Japanese suppliers and offers a future outlook for the market.*
By Takashi Ogawa and Clark Fuhs

World Trends in Silicon Wafer Consumption

According to Dataquest's survey, worldwide consumption of silicon wafers in 1997 increased 7 percent from the previous year to 4,014 million square inches (MSI). This is the result of some recovery seen between late 1996 and early 1997, which was partially offset by a decline that began late in the second half of 1997. At present, the market is losing the momentum that was gained from the temporary recovery. Among the major factors causing the downturn, chip shrinkage is particularly noteworthy. It was accelerated by DRAM suppliers that desperately needed to improve profitability under pressure from the market slump, resulting in a significant drop in wafer consumption.

During the 1Mb and 4Mb DRAM era, the rate of chip shrinkage between the first and final versions was estimated to be in the range of 50 to 60 percent. Since last year, however, DRAM suppliers have accelerated the pace, and 60 to 70 percent reduction has already been achieved in shrink versions of 16Mb

DRAM. For 64Mb DRAM, for which volume shipments began only last year, shrink versions have been developed over a shorter period of time by using the deep ultraviolet (DUV) technology. As a result, even under the optimistic scenario where bit growth is assumed to reach 60 to 70 percent between mid-1997 through the end of 1998, wafer consumption for DRAM production will remain almost unchanged on a quarterly basis.

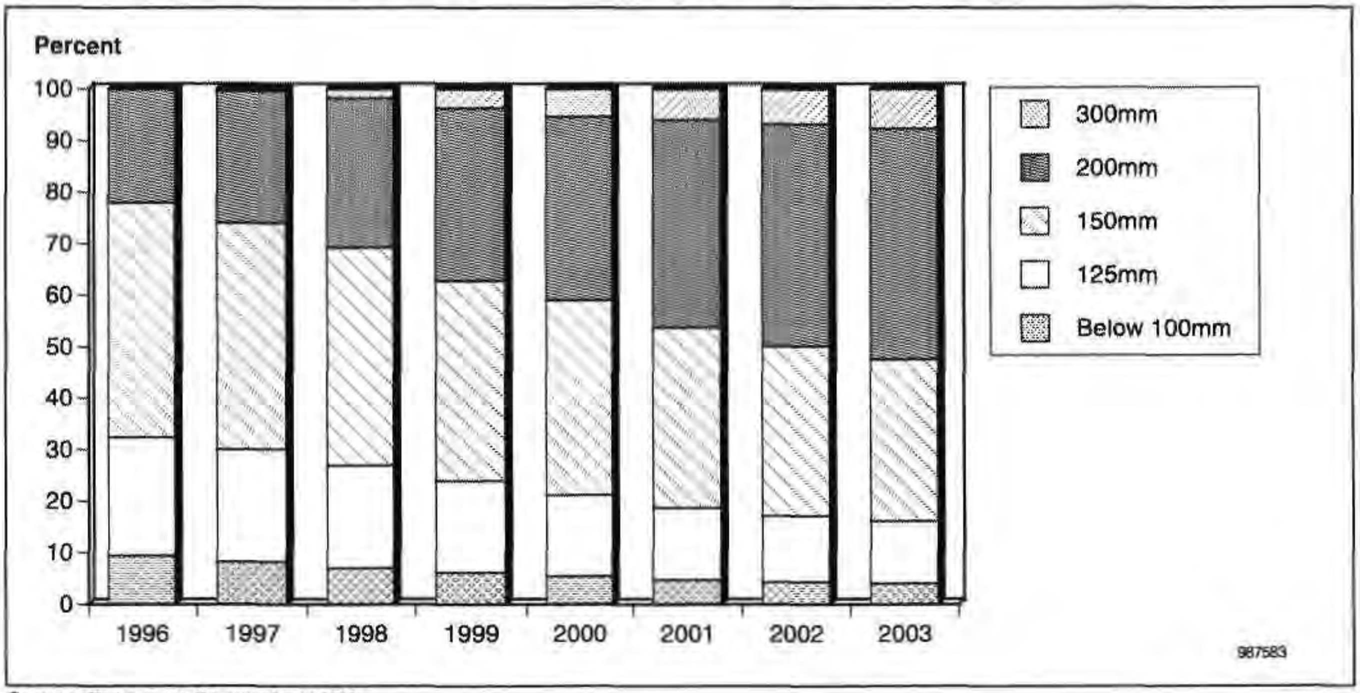
Given the effect of the rapid pace of chip shrinkage and the slack device market as a whole, wafer consumption in 1998 is expected to expand at a meager 3 percent to 4,113 MSI, according to Dataquest's July forecast. Furthermore, if device demand continues to wither beyond the current forecast, the wafer market will likely experience negative growth. It is expected to make a rebound in 1999 when the device market will show a modest recovery, but full-fledged recovery will have to wait until 2000 as the crossover of DRAM generations (on a unit basis) is completed. The market will then record two-digit growth in 2000 and 2001. Dataquest predicts that silicon wafer consumption will expand at a compound annual growth rate (CAGR) of 9 percent between 1997 and 2003, reaching 6,825 MSI in 2003.

Japanese Trends in Silicon Wafer Consumption

In 1997, silicon wafer consumption in the Japanese market grew 2 percent to 1,527 MSI, reflecting its sensitivity to DRAM market conditions. Again, the sluggish DRAM market and the accelerated pace of chip shrinkage will continue to suppress wafer consumption in 1998. Although Dataquest expects, as of June 1998, that 1998 consumption will remain unchanged from 1997's growth rate of 2 percent, silicon wafer consumption may experience negative growth, depending on an actual recovery of DRAM demand in the second half of 1998. Recovery will occur in 2000 or afterward, accompanied by the revival of the DRAM market. In 2000, wafer consumption in Japan will reach 1,887 MSI, a 12 percent increase over consumption in 1999.

One of the notable characteristics of the Japanese wafer market is a high percentage of smaller-diameter wafers (150mm or less). This is evidenced by the 1997 distribution of water consumption by diameter: 75mm wafers accounting for 0.6 percent of total consumption in the market (on a wafer-area basis), 100mm accounting for 7.7 percent, 125mm accounting for 21.8 percent, 150mm accounting for 43.9 percent, and 200mm accounting for 25.6 percent (see Figure 1). Because Japanese semiconductor manufacturers have curtailed their capital spending in reaction to the murky market conditions in the past few years, the resulting modification or delay in the planned installation of 200mm fab lines will further delay the shift from 150mm to 200mm fabs in terms of percentage share of wafer consumption. In fact, if this trend of cautious investment continues to prevail in the industry, 200mm wafers will not become the mainstay of the Japanese market until 2001—a sharp contrast to the world market, where they will take over 150mm wafers in 1998.

Figure 1
Silicon Wafer Consumption by Wafer Size in Japan, 1996 to 2003



Source: Dataquest (November 1998)

Another important trend is the rapid growth of epitaxial wafer demand for 64Mb DRAM production, which is breaking away from the historical trend, where the Japanese market typically has been a relatively small consumer of epitaxial wafers, primarily using them for discrete and bipolar devices. According to Dataquest's survey, epitaxial wafer consumption for DRAM production (including R&D) jumped from 7.2 MSI to 56 MSI in 1997. Then, after a slowdown anticipated in 1998 because of the DRAM recession, it will grow at a CAGR of 13 percent between 1997 and 2003, amounting to 475 MSI in 2003. Thus, Japan will become the second-fastest-growing market for epitaxial wafers, following the Asia/Pacific market.

In the long run, growth in total wafer consumption in the Japanese market will turn into moderate growth for two reasons: continued investment cutbacks by Japanese semiconductor companies whose business is still highly DRAM-dependent and a decreased reliance on domestic production by Japanese companies as a result of increased procurement from foreign manufacturers through alliances. Dataquest predicts that the Japanese market will record a CAGR of 7 percent between 1997 and 2003, the lowest among four regions (Europe, Asia/Pacific, the Americas, and Japan), and it will lose share in the world wafer market in terms of consumption (see Figure 2).

Figure 2
Silicon Wafer Consumption Forecast, 1996 to 2003

Japanese Silicon Wafer Manufacturers: 1997 Market Review

Table 1 summarizes the world market share of Japanese silicon wafer suppliers in 1997 (on a revenue basis), and Table 2 lists their product focus. Share distribution in the world market has remained virtually unchanged during the past decade. In the world market, Shin-Etsu Handotai Co. Ltd. has maintained the leading position with a market share of 24 to 26 percent, and the next five companies, including non-Japanese, have generally stayed within the share range between 10 percent and 12 percent. Japanese companies control a dominant share in the world market. In 1997, they held a combined share of 63.8 percent, while U.S. companies held 15.5 percent, European companies held 13.3 percent, and Asia/Pacific companies held 7.4 percent. In particular, Japanese companies nearly monopolize the Japanese market with an outstanding 90.8 percent share.

Table 2
Japanese Silicon Wafer Makers' Product Focus in 1997

Maker	DRAM	CMOS Logic Epitaxial	Power/Discrete Epitaxial
Shin-Etsu	X	Emerging	-
Sumitomo Sitix	-	X	X
Mitsubishi Materials	-	X	X
Komatsu Electronic Metals	Small	-	X
Toshiba Ceramics	X	-	X
NSC Electron	X	-	-

Note: The "X" indicates the products that each company makes.
Source: Dataquest (November 1998)

Shin-Etsu, controlling the dominant share, is a key supplier of silicon wafers to DRAM manufacturers, together with MEMC Electronic Materials Inc. (MEMC). Because Shin-Etsu gains most of its revenue from 200mm wafers in the DRAM market, it was directly hit by the slow market in 1997, which was accompanied by wafer price erosion, and its market share fell slightly (0.3 percentage points) from the previous year. Sumitomo Sitix Corporation, which recently merged with Sumitomo Metal Industries Ltd., is a major player in the epitaxial wafer market for CMOS logic applications. It is also a major supplier to Intel Corporation and maintains first place in the U.S. epitaxial market with a 22.7 percent share. The company is now boosting share in the power and discrete IC market.

Mitsubishi Material Silicon Corporation (MSIL) is another important supplier in the epitaxial wafer market for power and discrete devices. Although the market is still small, together with sales in epitaxial wafers for DRAM, MSIL registered strong growth in the Americas market in 1997, a 19.1 percent increase over the previous year, and increased its share by 1.3 percentage points. In the future, the company expects business expansion in the epitaxial wafer market for CMOS logic applications, to follow in the footsteps of Shin-Etsu. Komatsu Electronic Metals Co. Ltd. is a secondary supplier to the DRAM market and the major supplier in the power/discrete device segment. In 1997, it demonstrated healthy annual growth of 19 percent in the epitaxial

©1998 Dataquest

market but lost revenue in the polished wafer market by 13.6 percent, resulting in a 0.2 percentage point decline in its overall market share.

Toshiba Ceramics Co. Ltd. supplies epitaxial wafers for power and discrete devices and DRAM wafers, but the latter is limited to several customers, as is also the case with NSC Electron Corporation. Toshiba Ceramics now is focusing on hydrogen annealed, low-defect wafers and steadily is improving product quality in an attempt to expand its share. Finally, Showa Denko KK announced that it would withdraw from the silicon market entirely in fiscal year 1998.

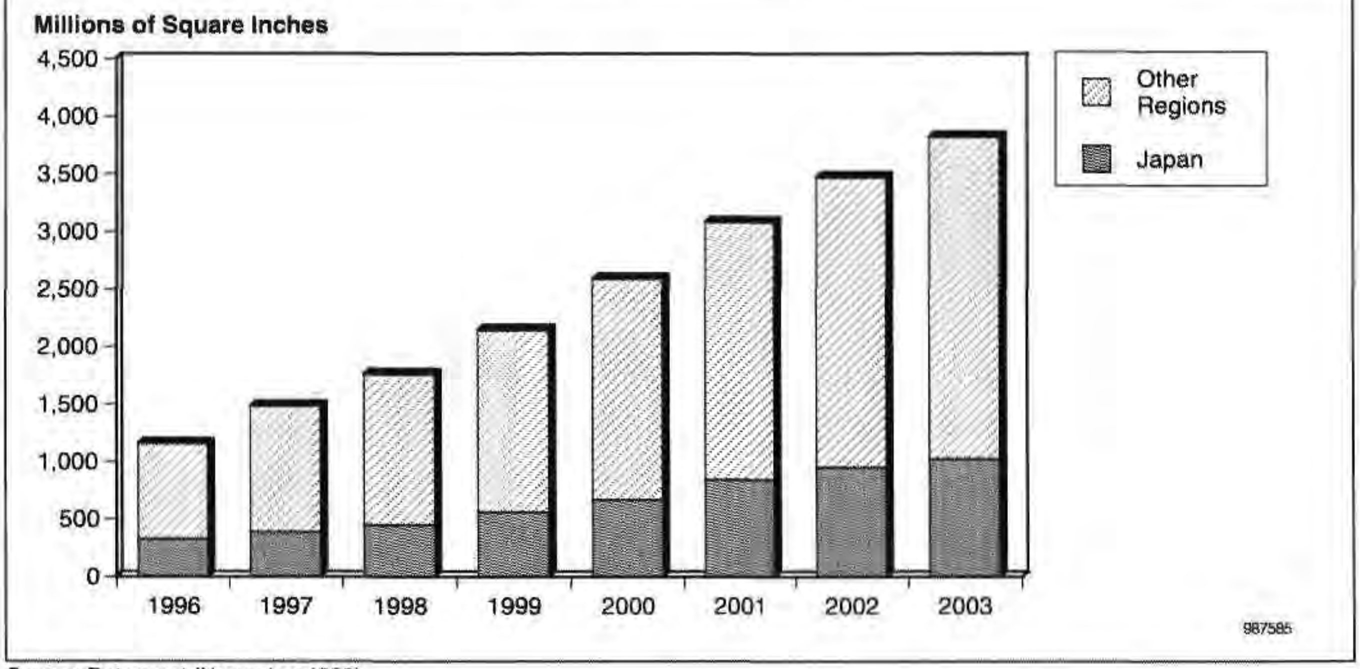
Global Trends in 200mm Wafer Consumption

In 1997, world consumption of 200mm wafers grew 26 percent to 1,485 MSI. In 1998, however, consumption inevitably will be affected by increased cases of phased-down or postponed construction of 200mm fab lines and a slowdown in consumption by the DRAM industry because of the chip shrinkage boom. In June 1998, Dataquest predicted that the 200mm wafer market would expand at a CAGR of 17 percent between 1997 and 2003, reaching 3,824 MSI in 2003 (see Figure 3). However, because the average monthly shipments during the first half of 1998 remained at around 2.6 million wafers, the short-term results may fall below the forecast. Given the many uncertainties about new fab construction plans—which are heavily dependent on the general economy, the timing of the much-awaited DRAM market recovery, and the development of shrink versions—consistent analysis and vigilant watching are essential. Dataquest expects that essentially all of the reduced levels of wafer consumption for 1998 will take place in the 200mm wafer segment.

It is also important to note that test wafer consumption is experiencing a significant decline, reflecting the maturing of production technology and the increased demand for cost reduction. In particular, consumption of 200mm test wafers in the Asia/Pacific region in 1997 decreased by around 30 MSI compared to the previous year. It is expected to decline further during the forecast period, and as a result, the test/process wafer ratio will change from 1:3 in 1998 (worldwide average) to 1:5 in 2003.

 ©1998 Dataquest

Figure 3
200mm Silicon Wafer Consumption Forecast, 1996 to 2003



Source: Dataquest (November 1998)

Japanese Trends in 200mm Wafer Consumption

In 1997, around 391 MSI of 200mm wafers were consumed in Japan, accounting for 26 percent of the world total; epitaxial wafers represented 26 percent of those (23 percent in the world market). Because demand for 200mm wafers in the Japanese market primarily comes from the DRAM industry, it will be adversely affected in the short run by the sluggish DRAM market and the increased efficiency in wafer use because of chip shrinkage. Dataquest's June forecast expected recovery in the second half of 1998 and double-digit annual growth, but the apparent delay in recovery will likely cause 200mm wafer consumption in Japan to remain flat or record negative growth compared to consumption in 1997. One exception is the demand for epitaxial wafers, which grows steadily because it is driven by demand for 64Mb DRAM production. As a result, epitaxial wafers will account for 30 percent of 200mm wafer consumption in the first half of 1998. In the long run, 200mm wafer consumption in the Japanese market will expand at a CAGR of 17.5 percent between 1997 and 2003.

300mm Wafer Trends and Fab Activity

Technological development efforts to commercialize the 300mm wafer are undertaken through two consortiums—Semiconductor Leading Edge of Technologies (SELETE) and International 300mm Initiative (I300I)—which have produced a number of achievements and deliverables. Nevertheless, semiconductor companies are forced to cut back investments in 300mm wafer production in order to weather the unfavorable business environment—a grave, but logical consequence of the persistent slump in the device market. Dataquest believes that most of the movement toward 300mm fab construction will be postponed further by another year.

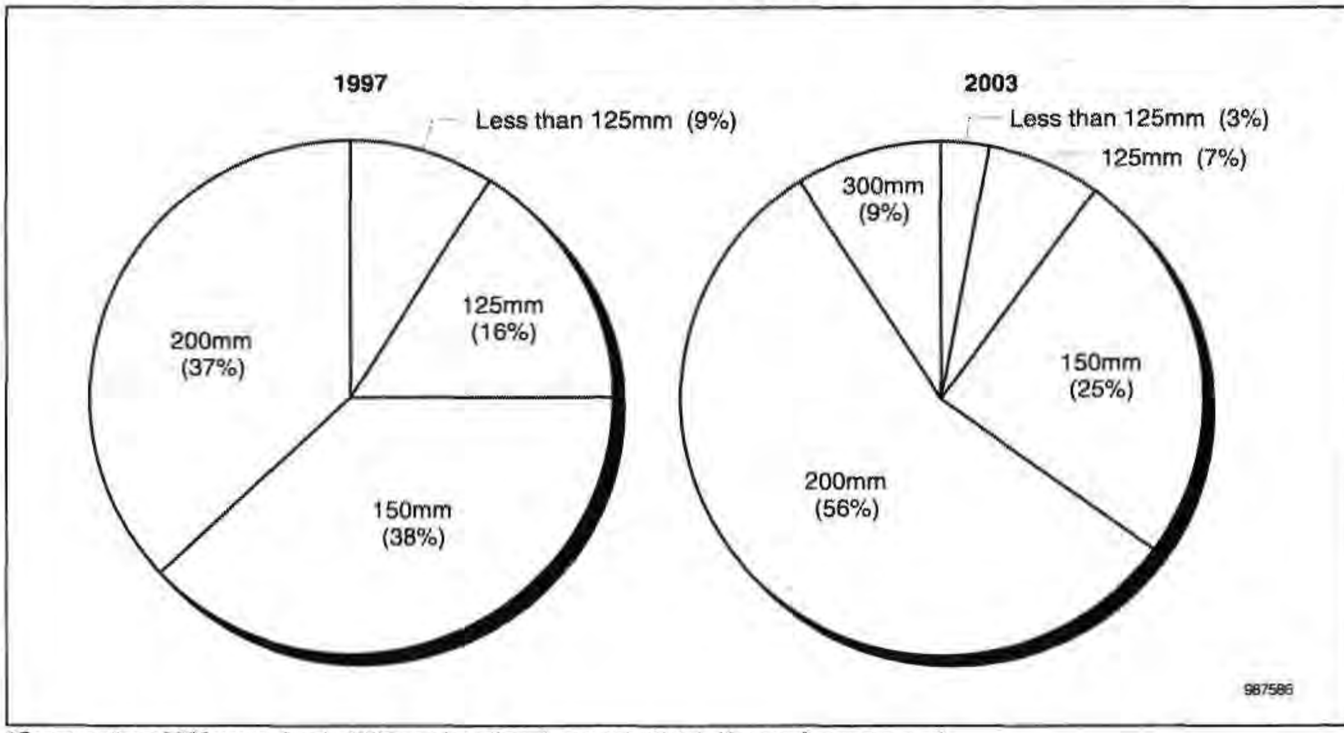
According to Dataquest's fab equipment market forecast, the share of semiconductor equipment for 300mm processes will grow to 2.4 percent in 1998 as the market for R&D and pilot production purposes emerges; it then will grow to 7.0 percent in 1999 and 9.0 percent in 2000, reaching a small peak. Then, after a temporary setback, the market for volume production will ramp up, and 300mm process equipment will boost its share to over 20 percent by 2003. It is assumed that eight to 11 pilot fab lines will be operating by the end of 2001, followed by volume production in 2002, with a substantial wafer volume ramp-up during 2004 and 2005.

In addition to the unfavorable investment climate, 300mm fab plans seem to have lost their impetus because most semiconductor manufacturers are still struggling to find the business case (viability) for the 300mm process in the changing semiconductor market environment. In particular, many Japanese semiconductor companies are striving to cultivate new market opportunities, such as system-level integration (SLI), in an attempt to become less dependent on the DRAM business; it is difficult for them to find proper positioning for the 300mm process technology in future business strategies. On the other hand, the 300mm process seems to be one possible choice for companies that have product offerings in the established monopolistic markets and that can find technical advantages from the new process. Dataquest believes that Intel, IBM, and Siemens AG will likely become early adopters of the 300mm process.

Historically, silicon wafer consumption has experienced the crossover of generations at an interval of six to seven years (on a wafer-area basis). The life cycle of 200mm wafers is expected to be much longer: probably ten to 11 years. The previous crossover occurred in 1998 when 200mm wafers took over 150mm products in terms of volume consumed. At that time, 300mm wafers accounted for less than 1 percent of total silicon wafers consumed and were mainly used for testing purposes related to the development of transportation systems (see Figure 4). The share will grow slowly to reach 9 percent in 2003, which would be almost the sixth year of the historical life cycle. This will be equivalent to 5.6 million wafers.

 ©1998 Dataquest

Figure 4
Worldwide Silicon Wafer Consumption Forecast by Wafer Size, 1997 versus 2003

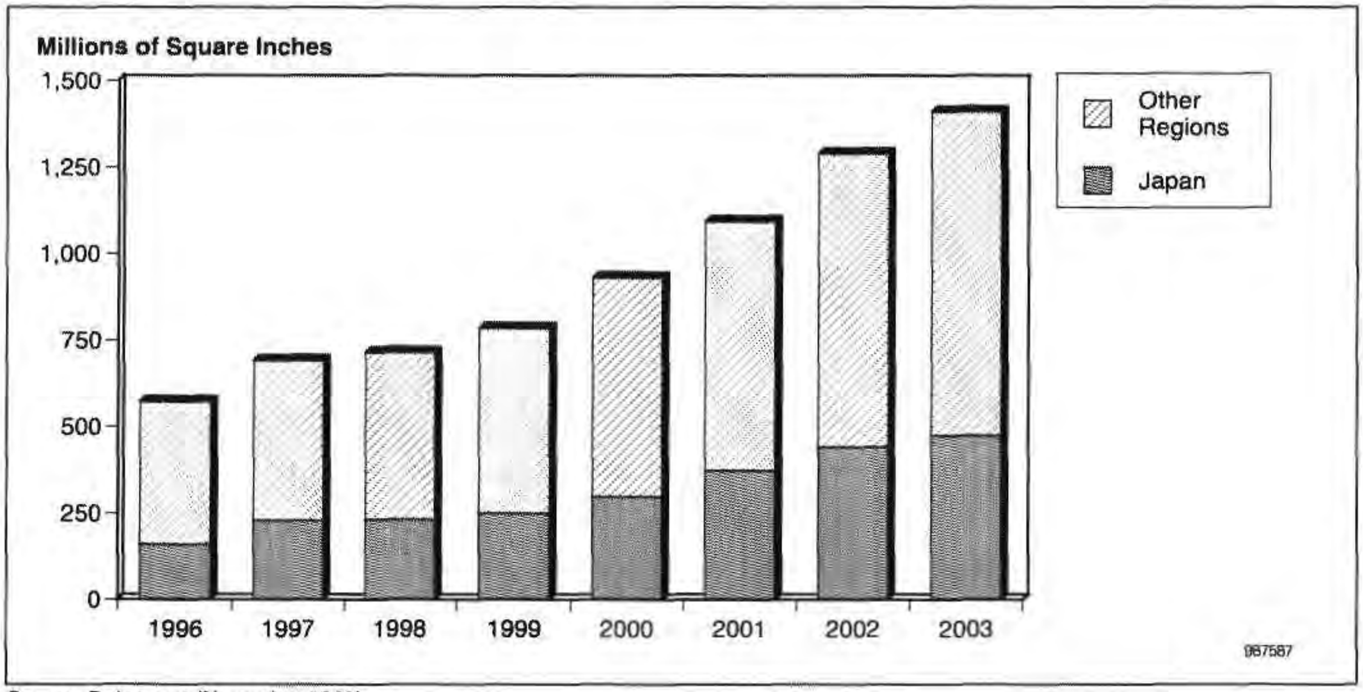


*Consumption of 300mm wafers in 1997 was less than 1 percent of total silicon wafers consumed.
Source: Dataquest (November 1998)

Epitaxial Wafer Consumption Trends

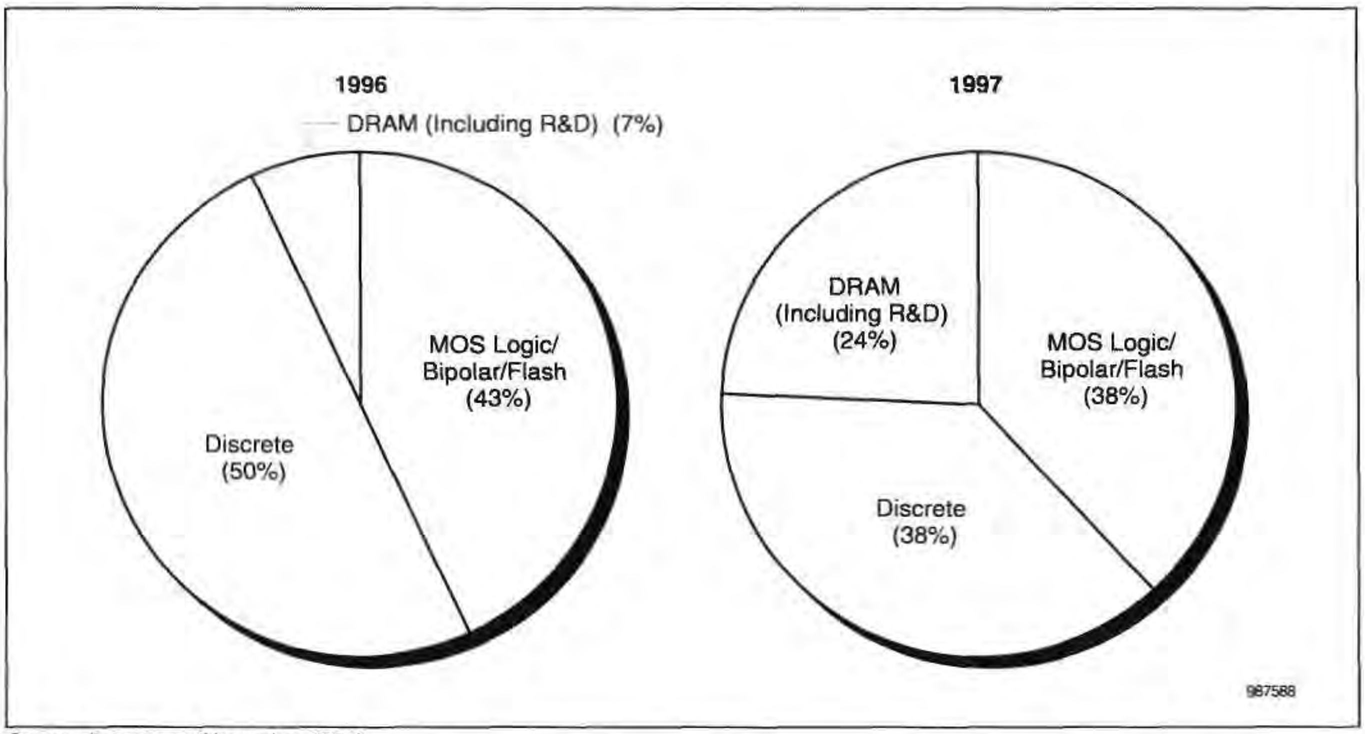
Worldwide epitaxial wafer consumption (merchandise sales only) in 1997 surged 21 percent to 693 MSI, far exceeding polished wafer consumption, which remained at a 5 percent growth rate. In particular, the Japanese market registered an impressive 42 percent growth rate to 230 MSI in 1997 (see Figure 5). In 1997, the breakdown of the world market by application was logic/bipolar/flash memory with 61.6 percent, discrete with 25.4 percent, and DRAM with 13.0 percent. (DRAM applications jumped from 3.0 percent in 1996.) The breakdown was far more conspicuous in 1997 in the Japanese market where the DRAM market still plays a major role: Logic/bipolar/flash memory represented 38.1 percent, discrete represented 37.6 percent, and DRAM represented 24.3 percent (see Figure 6).

Figure 5
Epitaxial Wafer Consumption Forecast, 1996 to 2003



Source: Dataquest (November 1998)

Figure 6
Epitaxial Wafer Consumption by Application in Japan, 1996 versus 1997



Source: Dataquest (November 1998)

Epitaxial demand for DRAM production has risen sharply since the end of 1996 because epitaxial wafers are an effective means of preventing grown-in defects, such as crystal-originated particles (COPs), on silicon wafers. These defects are known to cause a variety of device defects in 0.3-micron-or-finer processes, such as abnormal electric fields below the gate, the poor separation of features, and increased current leakage, depending on the actual position of the COPs.

Meanwhile, other factors that influence epitaxial demand have loomed over the past year. First of all, the persistent DRAM recession forces manufacturers to accelerate the development of shrink versions in a desperate attempt to reduce production costs by improving per-wafer yields. This suppresses wafer consumption while DRAM shipments increase in volume. Second, epitaxial technology was the first to receive industry attention due to its high levels of perfection and reliability. Also, the development of competing technologies—hydrogen annealed wafers and low-COP-type CZ wafers—has progressed steadily with improved performance, so that DRAM suppliers need to be cautious in their choice of wafer technology in consideration of price trends as well as technological advancement.

Nevertheless, Dataquest predicts that epitaxial wafer demand for DRAM production will grow firmly in the medium term at a CAGR of 30 percent between 1997 and 2003. Volume demand will reach 428 MSI in 2003, of which 46 percent will be consumed in Japan. This will fuel epitaxial demand, to achieve a CAGR of 13 percent during the same period, totaling 1,411 MSI in 2003. Similarly, consumption in the Japanese market will grow at an annual rate of 13 percent, bolstered by DRAM demand, and will amount to 475 MSI in 2003, of which the DRAM industry will consume a lofty 42 percent.

Dataquest Perspective

The silicon wafer market is about to experience some significant changes and turning points. The accelerated pace of process miniaturization since 1997, driven by the proliferation of DUV technology, has brought a wave of changes to the silicon wafer market. In particular, this has created a dilemma for the wafer industry because consumption does not grow side by side with increased DRAM shipments. The move is expected to prevail in the medium term, making it necessary for the industry to interpret the market trends on the basis of new criteria to reflect the future evolution of submicron processes (that is, its impact on wafer consumption). A regional consumption pattern will also change. In the past, most of the wafers produced in Japan were consumed locally to meet the gigantic appetite of the fast-growing DRAM industry. In the future, however, domestic consumption will slow down because of increased offshore production and the use of overseas foundries in the form of joint ventures, not to mention the sluggish DRAM market. As a result, domestic consumption market share will drop appreciably.

At the same time, the introduction of a larger-wafer generation will follow a new pattern. The delay in the commercialization of 300mm processes will break the historical pattern, and 200mm wafers will maintain the longest life

©1998 Dataquest

cycle among past generations since the start of product standardization by the Semiconductor Equipment and Materials Industry (SEMI). This means that the wafer industry will face difficulty in relying on its traditional strategy for market expansion, under which it has used larger wafers as a source of value add. In addition to the structural changes in factors affecting profitability, the industry is required to continue capital investment in 300mm wafers. Various moves have recently surfaced as clear signs of response to the situation—for example, the announcement that Showa Denko KK planned to pull out from the market and the merger between Sumitomo Sitix and Sumitomo Metal Industries, which was partly motivated by the need for strengthening the financial base to meet increasing R&D investment. Because wafer manufacturers are facing the same situation as that of chip makers and semiconductor equipment manufacturers, such moves are expected to intensify in order to spread investment risks and boost market share.

Regional wafer consumption trends largely reflect regional device market and production trends. In the Japanese markets that remain in a stage of moderate growth, wafer consumption seems to signify the stagnate semiconductor industry, which is still groping in the dark to find new market opportunities as alternatives to the sluggish DRAM market. Although the need to make a livelihood will likely force Japanese companies to rely on the DRAM business for the time being, there is no doubt that any new direction that they find will have important bearing on the future of the Japanese wafer market. In fact, Dataquest believes that the move for change by the semiconductor industry will not be felt directly by the wafer industry until 2003.

Semiconductors Japan

Market Analysis

Fall 1998 Forecast: Japanese Electronic Equipment Production and Semiconductor Market

Abstract: *Dataquest has brought down its forecast of the semiconductor market in Japan. Economic difficulties both in Japan and other parts of the world, including Asia/Pacific and the Americas, are hurting Japanese electronic equipment production, causing semiconductor consumption to remain below the 1997 level. Persistent oversupply is also a culprit, bringing revenue down even where unit demand is sound. From 1997 to 2002, the Japanese semiconductor market will experience only modest growth, with a 6.7 percent compound annual growth rate (CAGR). However, there will be changes and challenges in each product market, including product transitions in DRAM and an accelerated move toward system-level integration (SLI) ASIC. There are also a number of possible drivers to this semiconductor market forecast, as well as restraints, and the key for resuming growth lies in the overall recovery of Japanese electronics production in various categories, specifically leveraging on infrastructure development.*

By Yoshihiro Shimada, Motoya Ohgami, Masahiro Suzuki, and Yoshihisa Toyosaki

Overview of Electronic Equipment Production in Japan

Japan's economic slump is becoming increasingly severe, with practically no sign of a recovery. This is most starkly seen in the outlook for negative gross domestic product (GDP) growth. Although yen depreciation has improved the profitability of exports, Japan's export markets are drying up. Asian economies, a major destination for Japanese exports, are embroiled in the Asian financial crisis (AFC), and even the United States, Japan's other key trading partner, has begun to show signs of weakening since mid-1998. This economic environment has spelled trouble for Japan's electronic equipment production.

Electronic equipment production in Japan in 1997 rose by 9.7 percent against the previous year on a yen basis, but the real slowdown has taken hold since

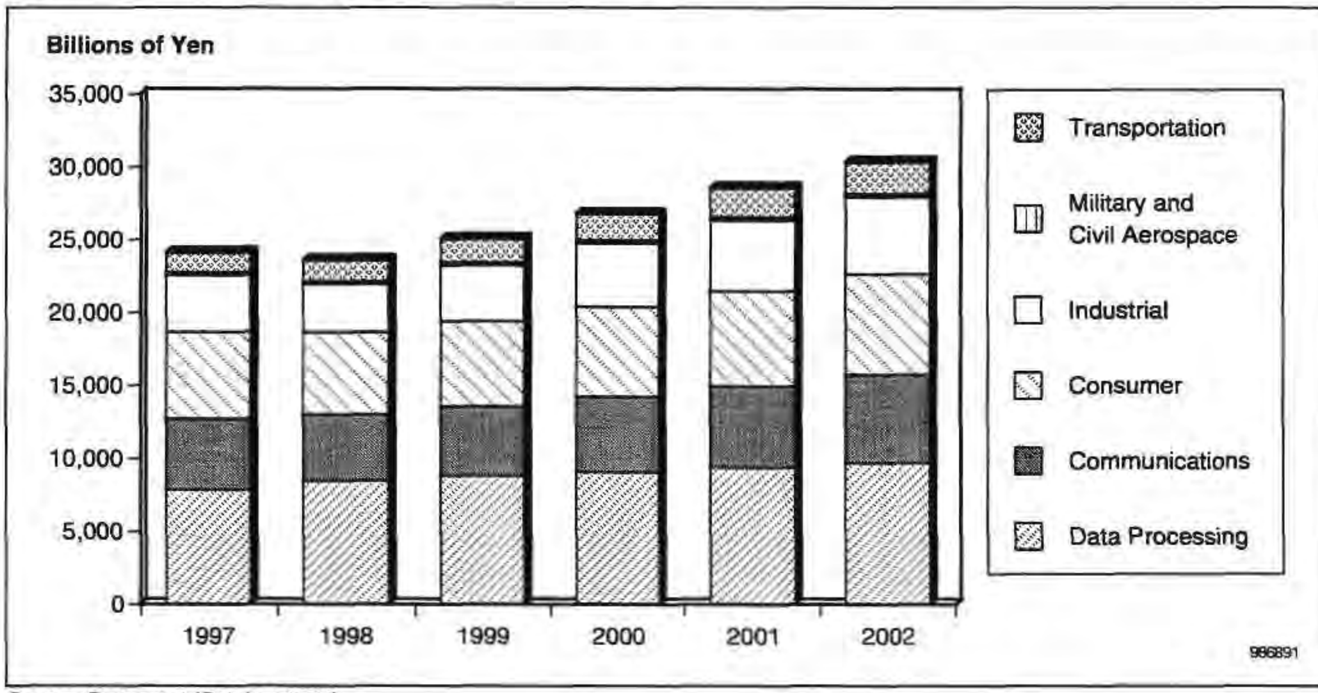
spring 1998. In our spring forecast, Dataquest estimated 3.1 percent growth in Japan's electronic equipment production for 1998. Based on the production results for the first half of 1998, which show a substantial decline in PC and other key electronic equipment production, Dataquest determined that it is necessary to adjust our outlook for 1998 downward. Dataquest expects electronic equipment production in Japan to achieve ¥23,579 billion in revenue in 1998, a 2.1 percent decline since 1997, and to maintain a compound annual growth rate (CAGR) of 4.7 percent during the 1997 to 2002 period (see Figure 1).

Figure 1
Japanese Electronic Equipment Production Forecast



Source: Dataquest (October 1998)

Slumping PC Market and EDP Equipment Production

With the release of Windows 98 delayed until July, PC shipments from January through June suffered a sharp turn for the worst, off 11.9 percent from 1997's shipments to 1.67 million units. Following the release of Windows 98, however, the market is rebounding, fueled primarily by individual demand. Hope is limited for an expansion of demand for PCs used by businesses, which account for nearly 70 percent of the domestic PC market, because of cutbacks in corporate capital spending in response to financial difficulties, including loans. At the same time, client/server systems are picking up as companies move to purchase computer systems to support the introduction of business applications such as enterprise resource planning (ERP) and supply chain management.

In the area of universal serial bus (USB)-compatible peripheral devices, designed to capitalize on the new Windows 98 USB feature, a steady stream of keyboards, mouse units, and other medium- and low-speed equipment is being marketed. Therefore, Dataquest is expecting increased demand not

 ©1998 Dataquest

only for new PCs but also for peripheral devices. With the popularity of sub-$1,000 PCs, storage devices such as CD-ROMs, DVD-ROMs, and rigid disk drives (RDDs) are faced with rather difficult price metrics. As a result, CD-ROM drives continue to be primarily available in a 40x speed mode, while 2.5-inch-and-smaller RDDs are becoming the mainstream for thin, high-capacity notebook computers. From the perspective of added value, desktop computers are offering high-speed rotation at 7,200 rpm and faster. Dataquest expects scanners and printers to continue enjoying healthy demand in the input/output (I/O) device segment in Japan.

Dataquest estimates that data processing equipment production in Japan will increase by 7.7 percent, compared to 1997 production, to ¥8,462 billion in 1998. The CAGR for the 1997 to 2002 period is set at 4.4 percent.

A Breather for Communications Electronic Equipment Production

The total number of wireless phone subscribers including those subscribing to personal handyphone systems (PHSs) has surpassed 40 million, but new subscriber growth for personal digital cellular (PDC), the primary domestic digital cellular phone service, is slowing. In contrast to the steady pace of new subscriber growth for PDC service at 700,000 to 800,000 new subscribers per month, PHS, pager, and other service contracts continue their downward slide. Replacement demand for home phone terminals has been reinvigorated by the start of number display service. Nonetheless, the number of new contracts for fixed telephone service is declining as an increasing number of users are opting for mobile phones to satisfy their telephone requirements. In November 1998, regulatory changes are planned that will allow phone service rates to be set or changed through a reporting system rather than requiring permission in advance. Dataquest expects that this will increase the variety of low-cost services offered.

Investment in communications infrastructure in 1998 is tailing off following the completion of the digitization of all telephone office switching systems by the end of 1997. While demand for LAN and WAN systems is strong, the benefits are being discounted by sharply lower hub and router prices. In fact, the Japanese market is now considered to be more price-attractive than other Asian markets—even Taiwan, where Japanese companies used to go for a deal. Dataquest believes that demand for LAN-related equipment will expand at an annual rate of around 20 percent for the next few years.

Communications electronic equipment production in Japan is expected to decrease to ¥4,559 billion in 1998, which is 6.5 percent lower than production in 1997. The CAGR for 1997 to 2002 is forecast to be 4.3 percent.

Digital Systems—A Bright Spot for Domestic Consumer Equipment Production

Japan's consumer equipment market for audiovisual equipment is rapidly being digitized. In the audio equipment area, mini-disc (MD) shipments are posting solid gains. MD functionality is no longer only a portable phenomenon and can be found as a standard capability in minicomponent systems. As a result, its growth is expanding into all sectors, including replacement demand. Meanwhile, in the video equipment market, DV-C shipments are sharply increasing. On a domestic shipment basis, DV-Cs account for 70 percent of all video camera volume, surpassing analog video cameras.

The digital still camera (DSC) market is discovering two distinct segments: a high-pixel-density version with over 1 million pixels and an economy version. With more than 30 companies participating in this market, excessive competition is a concern. Demand is also expanding in overseas markets for application as a simple image input device for Internet home page creation. However, this opportunity is being challenged by the expense of DSC compared to the recent emergence of flatbed-style scanners, which are selling in the ¥20,000 range. DVD player revenue growth is expected to exceed 100 percent in 1998, compared to 1997, but shipment volumes are still small. The conditions for further expansion of this market are in place as consumer prices for a stationary system are down to around ¥30,000, and DVD software offerings are being enhanced.

Domestic production in existing TV and VCR markets improved in 1998, spurred by the Nagano Olympics and World Cup Soccer, major sporting events that had a positive effect on the sales of wide-screen TVs. Upcoming opportunities in this market include receiver equipment for earth-based wave digital broadcasts and broadcasting satellite (BS) digital broadcasts scheduled to begin in 2000. Given these developments, Dataquest expects continued growth in demand for wide-screen TVs with high-image quality and multiple functions. In contrast, Dataquest expects negative growth for air conditioners, refrigerators, other consumer appliances, and VCRs.

Dataquest estimates that the value of consumer equipment production in Japan will be ¥5,624 billion in 1998, a 5.3 percent decrease from 1997 production. The CAGR is forecast to be 3.1 percent from 1997 to 2002.

Trends for Other Electronic Equipment Production in Japan

With the worsening economic situation, capital investments in manufacturing have substantially dropped off. Facility operating rates are also lower, and temporary operation halts have been introduced in some cases. The production of production-related and machining equipment is down across the board for the first half of 1998, with negative annual growth of 20 percent or more. Meanwhile, the necessity of monitoring equipment and other security applications in the safety and security alarm markets is expected to grow. For all industrial electronic equipment, Dataquest expects a 1998 production value of ¥3,316 billion, a 15.0 percent decline from 1997 production. A CAGR of 6.3 percent is forecast for the 1997 to 2002 period.

Although the number of new vehicles registered in Japan's domestic car market recorded a double-digit decline from 1997 in the first half of 1998, sales of car navigation sets continued posting steady growth. This market received a boost from the start of the Vehicle Information and Communication System (VICS) transportation information service, and currently more than 600,000 car navigation systems with VICS functionality have been shipped. There are also plans for evolving this system into an all-around information service with more sophisticated capabilities than

 ©1998 Dataquest

Intelligent Transport Systems (ITS). The value of transportation electronic equipment production in Japan is expected to be ¥1,428 billion in 1998, a 7.9 percent increase from 1997 production. The CAGR from 1997 to 2002 is forecast to be 10.4 percent.

The 1998 Semiconductor Market Disappoints

In a forecast update issued in July, Dataquest put forth a scenario of 1.4 percent growth in the 1998 worldwide market, compared to the same market in 1997. However, the market has continued to lose ground, and there is little doubt that even this scenario is no longer attainable. The following points can be cited as causes of this market's decline:

- Continuing downward slide in DRAM prices—Chip shrinking and other efforts to secure supplier-side profits are backfiring on the elimination of oversupply.
- Growing AFC impact—The AFC has spread on a worldwide scale and is causing an economic slowdown in the United States and other regions.
- Oversupply is spreading to the entire semiconductor market—Market conditions began weakening for microcomponents and logic devices late last year, and this trend has extended to analog and discrete devices. Foundry demand is also rapidly declining.
- Oversupply of electronic equipment—Production adjustments are starting for electronic equipment, and either demand for semiconductor volume is temporarily falling, or the pace of growth is slowing.

Eliminating Excess Supply Capacity

When setting forecasts for the semiconductor market, Dataquest formulates a supply/demand scenario and uses this as the basis for analyzing semiconductor consumption trends. The scenario adopted for this market forecast is outlined as follows:

- Shortages of PC100-specification DRAMs are already occurring, and facility investment cutbacks, factory closings, and other efforts to adjust supply capacity for the entire DRAM segment have started. In light of these circumstances, Dataquest believes that the DRAM supply/demand will balance in mid- to late-2000.
- A restoration of the supply/demand balance for the overall semiconductor market is expected to occur approximately one to two quarters after the DRAM supply/demand balance recovers.
- As a result, there will be a slight shortage in the semiconductor market in 2000, and market conditions will recover. The positive market conditions will continue through 2001, and this will prompt a reinstatement of capital investment.
- Supply capacity will expand because of the increasing capital investments, and another excess supply situation will occur in 2002. Affected by a mild worsening of market conditions, the peak in market

 ©1998 Dataquest

growth rates is expected to occur in 2001. Furthermore, negative growth is only expected for the DRAM segment. The rest of the semiconductor market will continue growing.

The main culprit behind the semiconductor market slump since the end of 1995 has been excess supply capacity. Since 1997, however, the market sentiment has shifted, and slowing demand has emerged as the key factor dragging the market. The phase during which adjustments of supply capacity had a significant impact on semiconductor market trends is approaching an end, and the primary question is whether demand can continue expanding. This is the scenario on which the current Dataquest forecast is based. Accordingly, in 1998, Dataquest expects a 5.9 percent decline for worldwide market growth and a 15.8 percent decline for Japan's market growth, compared to 1997. The main points of this forecast are as follows:

- 1998
  - The worldwide semiconductor market will again post negative growth (see Figure 2).
  - The DRAM market, following three consecutive years of negative growth, will contract to one-third of the historical peak reached in 1995.
  - The "non-DRAM" category, which previously managed to experience positive growth despite negative growth in the overall market, will also record negative growth this year.
  - The Japanese market, affected by yen depreciation, is turning in the weakest results and will be surpassed by the Asia/Pacific market (see Figure 3).
  - The only region likely to record positive growth in 1998, compared to 1997, is the European market.
- 1999 and later
  - The worldwide market in 1999 will begin to recover with double-digit growth.
  - Growth rates will be highest in the Americas and lowest in Japan. As a result, the Japanese market will be surpassed by Europe and will become the smallest of the four regional markets.
  - The supply/demand balance is expected to improve in 1999, and positive market conditions will be enjoyed in 2000 and 2001.
  - A mild adjustment period will occur in 2002 with DRAM revenue falling to negative growth and overall semiconductor market growth slowing to the single-digit level.

Drivers and Restraints

Dataquest's market forecasts are based on the "most likely scenario," as described previously. However, actual market trends will change depending on the manner in which various factors move, either upward or downward. The main elements that could affect market trends for the current forecast are the following:

- Drivers
  - Short-term (1998 to 1999)
    - Improvement in domestic economic trends (personal consumption trends and capital investment)
    - Early recovery of the Asian economies
    - Future Olympic demand and progress in audiovisual-related infrastructure projects
    - Stabilization of DRAM prices
  - Long-term (2000 to 2002)
    - Recovery in the domestic economy
    - Progress in infrastructure projects that link the digital consumer, communications, and data processing segments, and related increases in domestic electronic equipment production
- Restraints
  - Short-term (1998 to 1999)
    - Continuing economic weakness in the Asian and Japanese economies
    - Sluggish replacement demand as the level of mobile communications equipment dissemination rises
    - DRAM price stabilization limiting the pace of megabyte demand expansion
  - Long-term (2000 to 2002)
    - Delays in information communications infrastructure development
    - Falling prices because of intensified competition in system-level integration (SLI)

The forecast for growth of electronic equipment production in Japan is the lowest of the four regions. Likewise, the 6.7 percent dollar-based CAGR for Japan's semiconductor market for the 1997 to 2002 period is also the weakest (see Figure 4). Although from past experience Dataquest knows that growth in Japan's semiconductor market is accelerated during periods of yen strength, Dataquest's market forecast is based on a constant exchange rate in future years (see Figure 5).

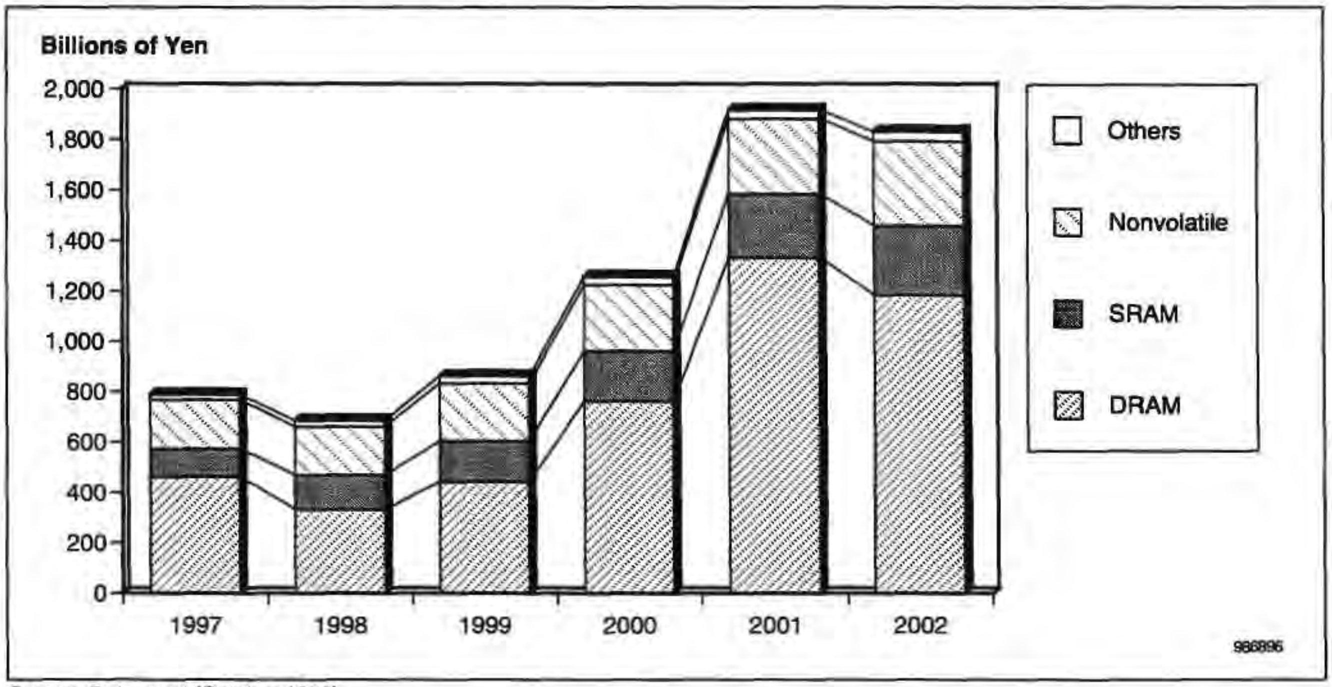
MOS Memory Market in Japan

Dataquest expects the MOS memory market in Japan to decline 13 percent (22.8 percent on a U.S. dollar basis) in 1998, compared to 1997 (see Figure 6). This represents a hefty downward adjustment of 20.0 points from the spring forecast. The primary factor behind this forecast revision is the rapid pace of DRAM price deterioration, which has been much faster than originally thought because of excess supply capacity, a similar pattern to what is happening in the worldwide MOS memory market. In the spring forecast, Dataquest stated that the activities of Korean manufacturers in 1998 would significantly affect DRAM prices and that plummeting 16Mb DRAM prices would also affect 64Mb DRAM prices. In fact, these worries have become a reality over the course of this year. Shipments of 16Mb DRAMs by Korean manufacturers in the first half of 1998 at levels far exceeding demand triggered a downward price slide for not only 16Mb DRAMs but also 64Mb DRAMs. In the 1998 MOS market, static RAM (SRAM) and other MOS memory devices will compensate for the negative DRAM factor.

Figure 6
Japanese MOS Memory Market Forecast



Source: Dataquest (October 1998)

From 1999 onward, Dataquest again expects the MOS memory market in Japan to follow the worldwide market trend, in which the DRAM and nonvolatile memory segments return to positive growth while solid SRAM performance continues. A full-scale expansion of the market will not happen until 2000, and this phase will peak in 2001 with a drop back to negative growth in 2002. The outlook also follows the worldwide market cycle. Dataquest believes that the dip in 2002 will occur when the colossal DRAM market takes a downturn from the negative effect of a generational transition from 64Mb to 256Mb memory devices. Japan's MOS memory market CAGR

 ©1998 Dataquest

for the 1997 to 2002 period is forecast to be 18.3 percent, a 2.9-point upward revision from the spring forecast's projected CAGR.

DRAM Market in Japan

On a product basis, Dataquest is forecasting a 28.2 percent decline in Japan's DRAM market in 1998 (36.3 percent on a U.S. dollar basis) compared to 1997. This is a sizable downward adjustment of our spring forecast. Just as in worldwide market forecasts, the dramatic reductions in DRAM prices at a pace way beyond original expectations are forcing lower forecasts. Even though DRAM-makers have taken steps to reduce capital investment plans, they also have adopted a strategy of maintaining shipment volumes at a certain level through the introduction of reduced-size chip technology and OEM procurement from Taiwanese manufacturers, while keeping capital investment budgets to a minimum. Moreover, DRAM-makers already have sufficient production capacity with existing 16Mb DRAM facilities, and it is this product area (16Mb DRAMs) that can be blamed for the DRAM price slide.

However, Dataquest sees the shift in PC DRAM demand from the 66-MHz type to the 100-MHz type picking up speed in the latter half of 1998 and believes that this will require more advanced production facilities. In 1999 and thereafter, DRAM-makers will need 0.2-micron-level production facilities to keep up with high-speed DRAM demand. Capital investments in 1998 and 1999 will be vital for maintaining production capacities based on such advanced facilities at a certain level. The implementation of finer process technology is moving forward at a faster pace than it did previously. Dataquest expects this trend to continue, and therefore, Dataquest foresees DRAM-makers having to shoulder an even heavier capital investment burden.

Dataquest's positive growth forecast for 1999 is based on an assumption that production capacity using advanced facilities will be introduced in balance with demand. Dataquest expects the DRAM market in Japan to enter a phase of full recovery in 2000, with a peak reached in 2001. Thereafter, in 2002, the market will be revisited by negative growth. Dataquest forecasts a CAGR of 20.6 percent for the 1997 to 2002 period.

Nonvolatile Memory Market in Japan

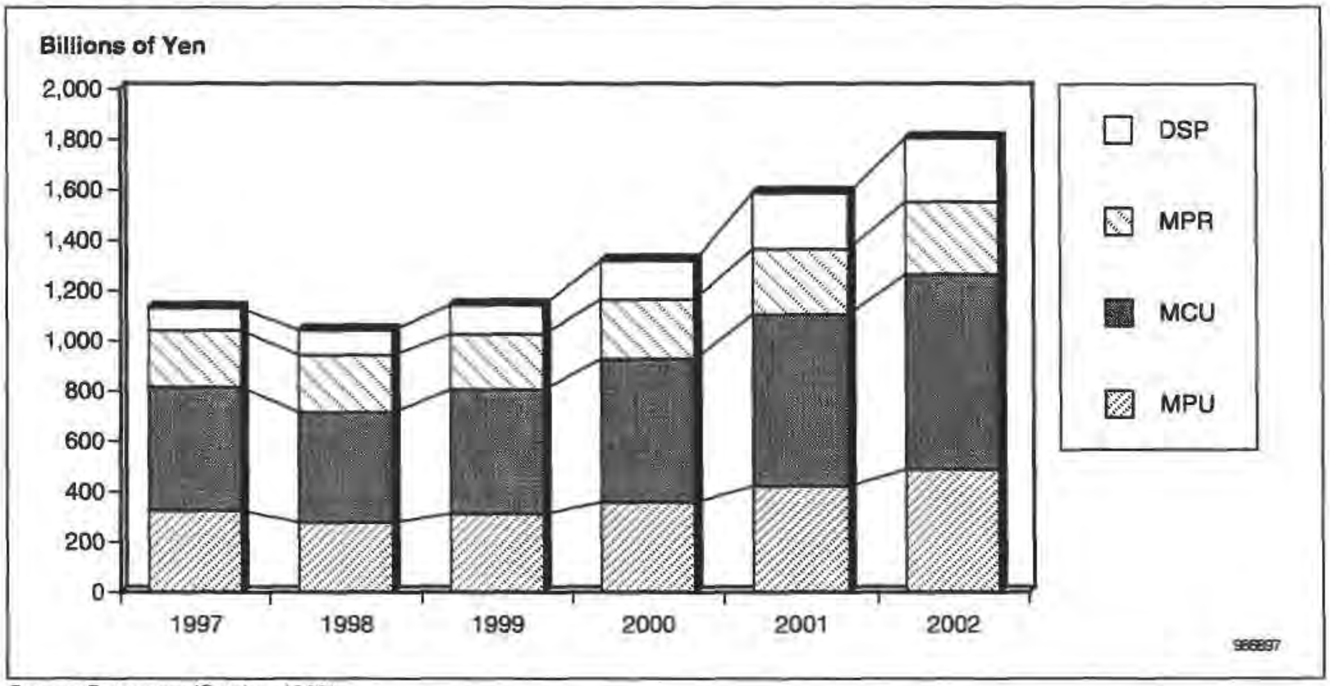
Dataquest's forecast for the nonvolatile memory market in Japan is a 1.5 percent decline (12.5 percent on a U.S. dollar basis) in 1998 compared to 1997. This represents a 1.8-point downward adjustment from the spring forecast. Dataquest's decision to lower the forecast was prompted by a change in the flash memory outlook from positive growth to slight negative growth. Over the next few years leading up to 2002, Dataquest expects that flash memory and EEPROM will turn in positive-growth performances, but it is worth emphasizing that the real driver in the nonvolatile memory market is flash memory. Dataquest is sticking to its view that the EEPROM market will shrink and the mask ROM market will be flat.

Portable equipment such as mobile phones is the primary application fueling growth in the flash memory market. Japan's semiconductor makers, in particular, rely heavily on mobile phones. In contrast, U.S. semiconductor makers depend on the communications equipment application. While the flash memory market currently is led by NOR-type devices, Japan's top semiconductor makers are making a move into the large-capacity flash memory arena in 1998. The main application for large-capacity flash memory is DSCs; however, this market is still rather small. The success of developing new market opportunities will be the primary determining factor for flash memory market expansion.

MOS Microcomponent Market in Japan

Dataquest has revised its 1998 forecast for the MOS microcomponent market substantially downward, compared to the previous forecast, to a 7.9 percent decline (18.2 percent on a U.S. dollar basis) since 1997. During the 1997 to 2002 period, a CAGR of 9.8 percent is expected (see Figure 7). Dataquest expects Japan's MPU market to record negative growth in 1998 because of weak demand in the domestic PC market and sliding MPU prices. Meanwhile, the microcontroller (MCU) segment, which accounts for the largest share of Japan's microcomponent market, is still posting higher shipment volumes, but revenue growth is being diluted by the decline in product prices. Feeling the effect of the disorder in the Asian economies caused by the AFC, Japanese makers' shipments of low-bit MCUs to the Asian market are experiencing even tougher circumstances than those of Asian competitors. Another factor hampering market growth is the stringent cost reduction demands of Asian system manufacturers.

Figure 7
Japanese MOS Microcomponent Market Forecast



Source: Dataquest (October 1998)

Looking at MCU market trends by product type, although the range of applications for 4-bit products has greatly broadened, this market entered a mature phase in 1997 from a growth perspective, and prices are falling. Revenue performance for 4-bit products is taking the brunt of slowing demand for portable game machines, a major market driver until last year. Meanwhile, Dataquest expects stable growth opportunities for 8-bit products, with the upper-layer compatibility shift from 4-bit products and growing demand for more complicated system control.

Although there is a possibility of 16-bit products experiencing a slight decline from the correlation between existing application shipments and unit prices, the first half of 1998 recorded high annual growth, benefiting primarily from strong demand for air conditioners caused by the strange weather. In other areas, as well, including VCRs, RDDs, telephones, digital mobile phones, CD-ROMs, printers, DSCs, automotive equipment, analog camcorders, and pachinko game machines, shipments are posting steady gains. On the technology front, a shift from mask ROM to flash technology is taking place, and the added value that this technology can deliver is expected to win 8-bit application business.

The main applications for 32-bit-and-higher MCUs, including 64-bit MCUs, are DSCs, DV-Cs, DVD players (including ROM), car navigation systems, next-generation home game machines, printers, digital mobile phones, and smart cards. Dataquest expects that demand for lower-power consumption features and cost reduction in the digital mobile phone category will drive a transition from 16-bit MCUs to higher-bit MCUs. Sharply higher growth is expected in the higher-bit MCU market, primarily in applications such as digital consumer equipment and mobile communications equipment, shored up by requirements for systems with sophisticated digital signal processing and advances in SLI technology. From 1999 onward, DVD player demand is expected to rise dramatically, mainly in the U.S. market, and Dataquest expects that this will also contribute to growth for higher-bit MCU products.

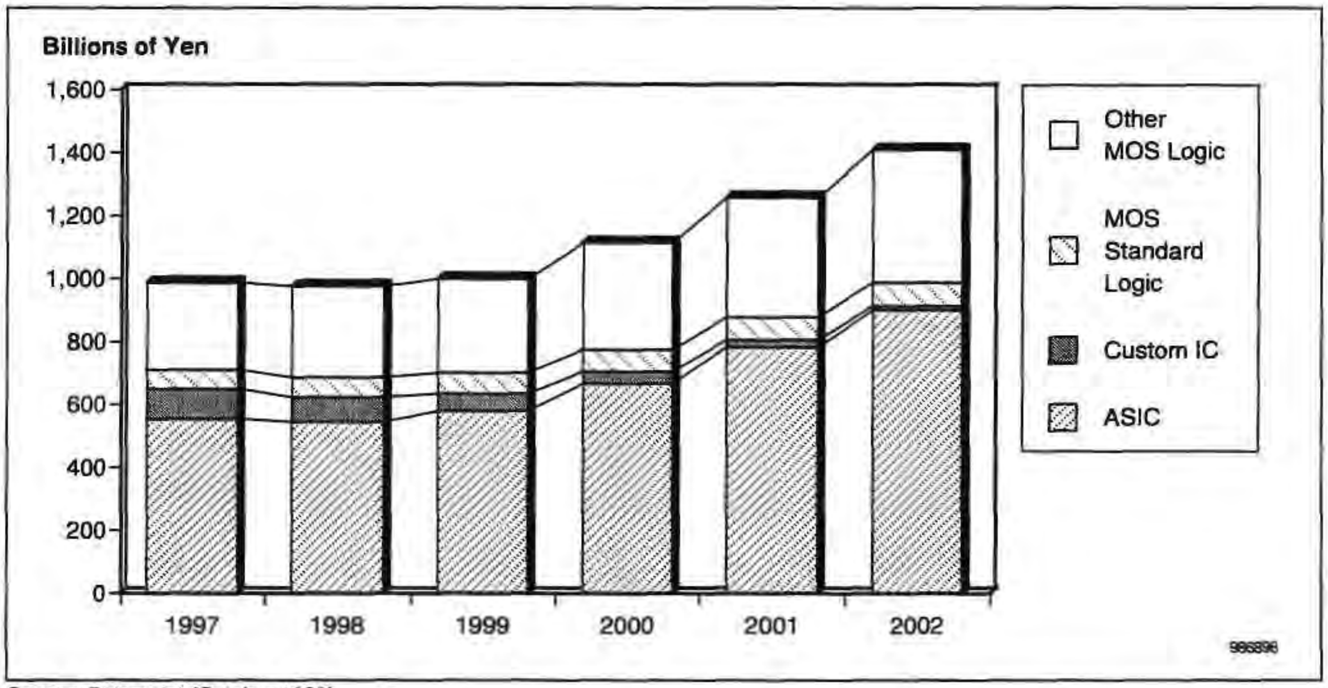
Demand for flash MCUs is showing steady growth in 1998. Applications driving the 8-bit, 16-bit, and 32-bit flash MCU market are memory cards, CD-ROMs, DVD-ROMs, RDDs, and automotive equipment. Also, Dataquest expects that custom LSIs, which combine an embedded ARM core with a flash core, will open up entirely new opportunities in the portable game machine market. Digital signal processors (DSPs) are finding demand in inverter-control and servo-control application areas, in addition to the existing market for mobile communications equipment.

MOS Digital Logic Market in Japan

Dataquest's forecast for the MOS digital logic market in Japan is a 1.2 percent (12.2 percent on a U.S. dollar basis) decline in 1998 compared to 1997. A CAGR of 7.4 percent is forecast for the 1997 to 2002 period (see Figure 8).

 ©1998 Dataquest

Figure 8
Japanese MOS Logic Market Forecast



Source: Dataquest (October 1998)

Japanese chipmakers excel in the gate array segment of the ASIC market and have shown impressive growth while Americas chipmakers have vanished from the top of the rankings for this segment. Essentially, while the Americas chipmakers are strategically focused on the SLI business and are staging a withdrawal from the gate array market, the Japanese chipmakers are stepping up to the plate in this segment and are winning orders from markets around the world that have been left open. Dataquest believes that this trend will continue.

The programmable logic device (PLD) market in Japan still has not demonstrated the expansion taking place in the Americas market. This is primarily because of internal system customer requirements that a stable supply of gate arrays and extensive support be provided. Chipmakers in Japan and the Americas are clearly operating in different business environments. In Japan, chipmakers are part of a vertically integrated organization that is dedicated to generating profits as a whole. This contrasts starkly with the situation in the Americas, where companies are divided into independent entities or independent business groups and have a mandate to return profitable results. The approach of Japanese chipmakers to the ASIC business is escalating the weakness of the market in Japan. A similar trend is observed across the full spectrum of logic products.

Although today ASIC and application-specific standard product (ASSP) devices incorporate nearly all of the functions offered by standard logic devices, Dataquest still anticipates demand for logic devices that satisfy special applications such as one-gate CMOS, ultrahigh-speed CMOS, and low-amplitude signal logic. Dataquest also believes that strong future demand exists for LCD drivers, grouped in the "other logic" category, from the proliferation of portable systems with built-in LCD panels and flat panel display (FPD)-related products.

Dataquest Perspective

When the semiconductor market fell short of previous-year results in 1996, there was a pervasive recognition that this was the first negative growth in a decade. At the same time, while acknowledging that the market was in an adjustment phase, expectations were that once the adjustment was completed, the market would recover to a growth trajectory again. What has happened instead is that market conditions have not improved and are heading for a second dip in results. The DRAM market has contracted back to the level it was at before its last burst of growth, and joining this is negative growth for all other non-DRAM semiconductor products. The CAGR for the 1997 to 2002 period for the worldwide market is forecast to be 11.5 percent, indicating a long-term trend during which the semiconductor market will enjoy double-digit, stable growth, but not at the feverish pace of past years.

The semiconductor industry in Japan is in the process of transitioning supply capacity from DRAMs to other products as a response to the sharp cycles in market conditions characteristic of the DRAM segment. In fact, logic product offerings have been bolstered with each DRAM downturn. However, recent trends clearly underline the ineffectiveness of this approach for dealing with future market circumstances.

It is apparent from the domestic market's slip into the position of being the smallest of the four regional markets worldwide that Japanese chipmakers must make every effort to strengthen their approach to overseas markets. In doing so, the Japanese market cannot be the model for conceiving business strategies. This effort must be firmly rooted in applications and customer trends enjoying success in these overseas markets. From this perspective, Dataquest believes that the limits have been reached in the conventional approach, which treats the Asia/Pacific market as merely a site for the offshore operations of Japanese electronic equipment makers and puts this region in the same category as semiconductor business in Japan.

From a perspective of product evolution, the importance of SLI and other system-oriented products is growing. Success in this field requires further integration of product functions and manufacturing processes. The prolonged weakening of market conditions is increasing the losses incurred by Japan's semiconductor industry as a whole and thereby is limiting the resources available for expanding the scale of operations. However, Japan's chipmakers should consider the process of building an infrastructure to support system products as an opportunity to implement much-needed efficiencies. Dataquest sees growth in alliances and intellectual property business in the product design and development field. Meanwhile, foundry business is gaining force in the manufacturing area. Finally, for sales and customer support, alliances are being formed to ensure the proper response to application trends in regions throughout the world, and distributors with a global presence are accelerating their activities.

©1998 Dataquest

In a situation where mild semiconductor market growth is expected for the next few years, the focus has returned to the demand side. Given this current market outlook, Dataquest believes that the future evolution of the semiconductor industry hinges on the extent to which efficient resource use can be accomplished in all aspects of the semiconductor business.

Technology Analysis

CSP: Next-Generation High-Density Packaging Technology

Abstract: *Low-cost chip scale package (CSP) technology has entered a full-growth stage as the package for system-level integration (SLI) ASICs and memory, including flash memories and static RAMs (SRAMs) in the 0.25- to 0.35-micron arena. A major driver is the increased demand for more compact and lighter systems by mobile communications equipment and digital consumer equipment, which form fast-growing markets. This Perspective analyzes CSP technology, which holds the key to the successful implementation of device miniaturization.*
By Yoshihisa Toyosaki

Evolution of High-Density Mounting Packaging Technology

With the rapid growth of the information and communications equipment markets, such as personal digital assistants (PDAs), digital cellular phones, mobile computing devices, and subnotebook PCs, and with the swift expansion of digital consumer equipment markets, including digital video camcorders (DV-Cs), digital still cameras (DSCs), and portable digital video disk (DVD) players, packaging technology for high-density mounting is becoming a technological and commercial focal point. For IC packaging, leading-edge technologies such as chip scale package (CSP) and ball grid array (BGA) have been accepted by a number of applications at a faster pace than previously forecast. In the near future, flip chip (FC), direct chip attach (DCA), and known good die (KGD) are expected to follow suit as emerging technologies.

These leading-edge IC packaging technologies—as well as printed circuit boards (PCBs) accommodating multiple chips that represent buildup substrates, such as surface laminate circuits (SLCs)—are being widely used in a range of volume applications that demand system miniaturization, and new materials appear to be expanding into sizable markets. There are various issues to be addressed, however. First, buildup substrate suppliers continue

to be limited in number, keeping board costs at lofty levels. Also, the reliability of the materials for IC packaging still needs to be improved. Finally, there are differences in CSP package standards between the United States and Japan.

What Is CSP?

CSP is highly compact IC packaging, which almost equates to a die area. Many CSPs use terminals of a dense area array type on their rear side. CSP is considered to be the same as BGA, but it is not. CSP occupies a smaller area on the PCB (to reduce cost) and helps implement a variety of mobile applications. Also, its ability to reduce the IC package size leads to the improvement of electrical performance. Its market potential is being carefully examined by system manufacturers.

At present, volume markets using CSP are divided into digital consumer equipment, including DV-Cs and portable DVD players, and communications equipment, including digital cellular phones and pagers. Other promising markets are hard disk drives (HDDs), PC cards including modem cards, PDAs, DSCs, and portable audio equipment. These application markets are demanding system size and cost reduction, which can also be satisfied by CSP. These systems have relatively small pin counts (176 or fewer, as of 1998), and many of them are restricted in package height in addition to width and depth. At present, the CSP with the smallest form factor is primarily used to accommodate memories such as flash, static RAM (SRAM), and Rambus DRAM (RDRAM). These devices are relatively large in chip size with 50 or fewer pins, making them highly suitable for the package that is slightly larger than the die.

There are various obstacles to a wider market acceptance of CSP. One of them is establishing a small package with a narrow terminal pitch width. This increases the initial packaging cost, which is an important element of digital consumer equipment, and limits wiring patterns on the PCB. More precisely, to avoid "pin-out" in the area array type package with a narrow terminal pitch, a highly dense PCB needs to be used to secure a certain degree of freedom in the wiring pattern. Partly because the PCB industry must invest in costly equipment to meet the density requirements at a low cost for major applications, the cost issue related to CSP equipment is primarily governed by the PCB cost. As a result, Dataquest believes that an industrywide use of "true" CSP will take some more time.

Nevertheless, the industry must address package miniaturization requirements demanded by system manufacturers, which entails the development of an optimum solution to meet a specific cost target. The solution should include low-profile/thin quad flat package (L/TQFP) and BGA. In due course, the industry is expected to improve the ability to provide a matured technological infrastructure and will offer CSP with higher pin counts, which increasingly will be consumed by volume applications. In fact, system-level integration (SLI) ASICs in CSP are adopted in many DV-Cs, where buildup substrates consisting of an average of six to eight layers are used in PCBs.

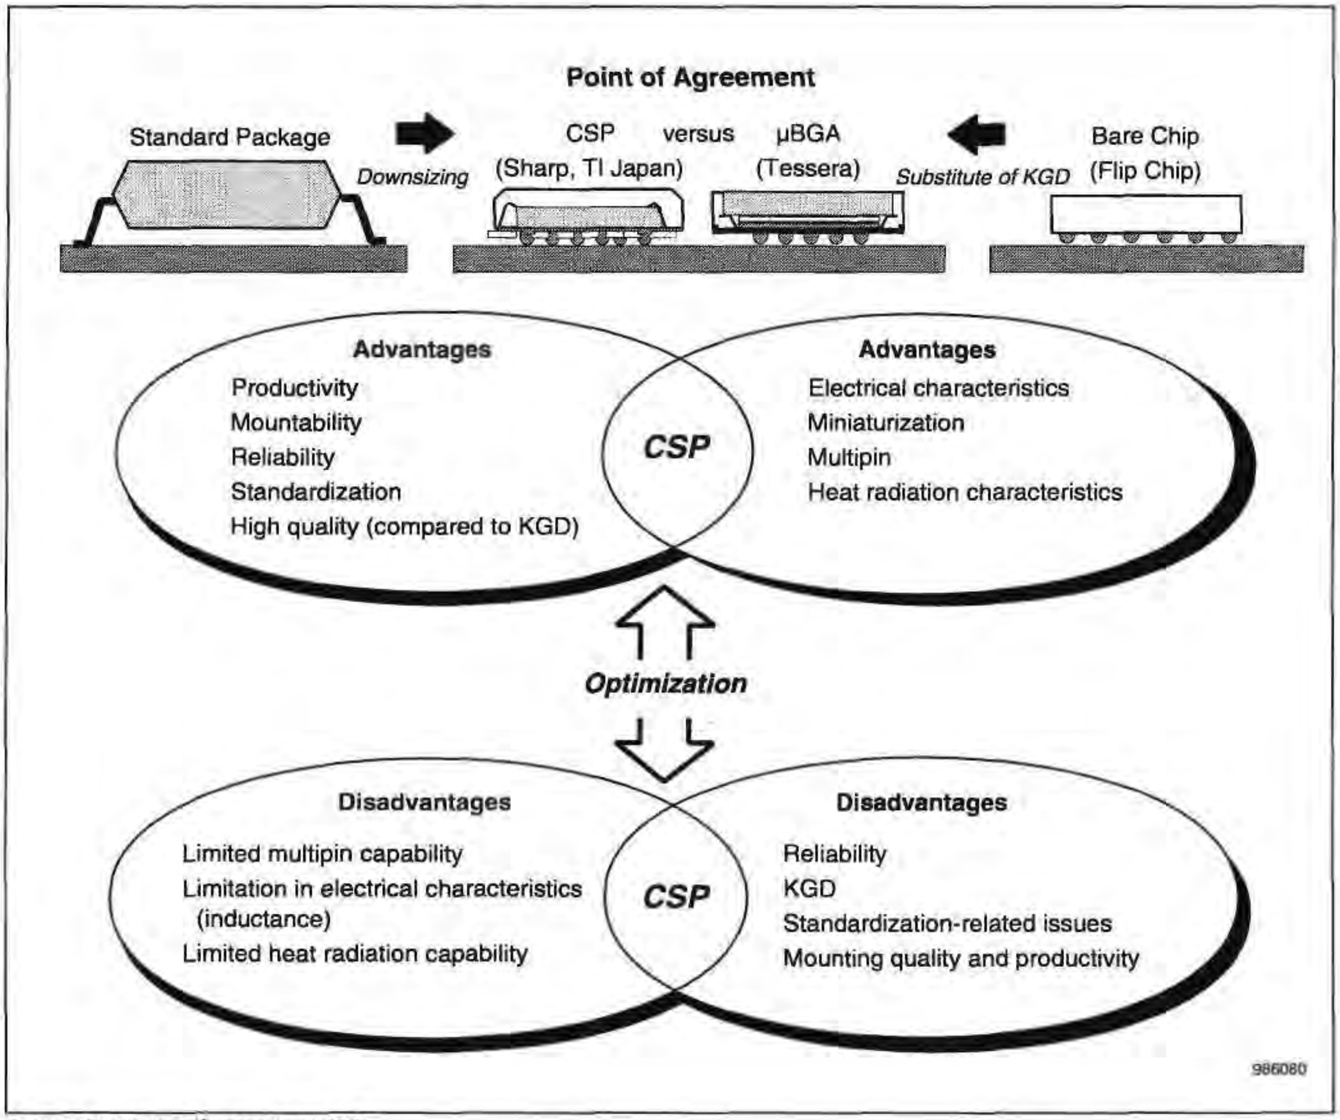
Devices most suitable for CSP are those having a very large area of logic circuits compared to pin counts, namely "core-limited design," where an inner core is limited. This type of circuit design requires a relatively large die area to accommodate balls in the interconnection area, so that the ball terminal pitch can approach a standard grid arrangement. As for applications, CSP is optimum for those that must mount low-pin-count devices on a very small and highly dense PCB. These applications usually use 176 or fewer pin packages. For digital cellular phone and DV-C manufacturers, size and weight reduction of system products are of supreme importance; it is justifiable for them to use very costly SLC boards. In fact, SLC boards permit CSP to be used in the area array layout. In contrast, CSP is not suitable for computing or transmission/telecommunications applications that require high-pin-count packages.

The full-featured CSP, which increasingly is used for memory devices, is ready for volume production in 1998. This serves as the buildup of the technological infrastructure and will spur demand. At this point, chip makers and their subcontractors will provide "true" CSP technology. CSP technologies implemented by Sharp and Texas Instruments Japan are not technological breakthroughs, but they will build on top of proven technologies; their main goal is to minimize cost and risk. Technological advancement will occur in the reduction of ball pitch to less than 1.27mm, namely 1.0mm and 0.8mm. IC package size will continue to shrink until the chip itself becomes a limiting factor, because the improved infrastructure for PCB production and assembly will enable a smaller terminal pitch (the 0.5mm pitch used in DV-C, for example).

Current Status of CSP

Currently available chip packages are mostly shrink versions of existing packages—the results of gradual efforts. A typical example is seen in modified plastic BGA (PBGA) and L/TQFP versions with a 1.27mm or smaller ball pitch. CSP, having the same or a similar pin count, is smaller and lighter than these modified versions. In this sense, CSP can be defined as a low-cost, low-pin-count solution. The industry defines CSP as a package that does not exceed 120 percent of the chip area. The development of CSP was started around 1990, and a large number of semiconductor suppliers are currently working with diverse structures in their R&D efforts. From the density point of view, CSP is positioned midway between existing standard packages and FC, with technical issues to be cleared accordingly (see Figure 1). Given the industrywide trend toward increasingly high-density mounting, CSP is expected to provide a feasible solution for a wide range of applications; however, it is difficult to forecast when exactly it will win which share of which market.

Figure 1
Advantages and Disadvantages of CSP



Source: Dataquest (September 1998)

CSP is undoubtedly a focal point of the PCB industry. Overall, the volume market for true CSP will be a bit slower than expected because of the immature technological infrastructure. Meanwhile, CSP technology capable of satisfying diverse applications will enable package miniaturization at the lowest cost. The CSP-enabled package size will be free from chip size limitation and can be reduced to address a wide range of terminal counts, required by system manufacturers according to a ball pitch allowed by wiring patterns on a PC. Regardless of the package type and name, the industry's goal is to supply small packages in volume and at low cost, as required by system companies.

Major Features and Advantages of CSP

The proliferation of CSP is driven by size and cost. In particular, applications subject to strict limitations in terms of size and weight will find the solution highly attractive. As the continued miniaturization of devices ends up in bare chips—the minimum practicable package size is no package—CSP will be compared to bare chips and KGD in addition to existing packages. CSP implementation methods commercially adopted in the industry are basically divided into chip-on-board (COB)—derived from wire bonding technology—and FC-on-board (FCOB)—derived from FC technology.

In terms of size, CSP is much smaller than standard packages and is larger than bare chips. A major advantage of package miniaturization, in addition to its space-saving, is its reduction of the accumulation of electricity and heat. CSP is a surface-mounting package and is mainly of area array type. As a result, its terminal pitch is more narrow than that of current BGA packages and wider than that of FC.

Figure 2 shows CSP structures developed by leading vendors. A few of them have already implemented CSP for ASICs and other devices. As for CSP used in the SLI ASIC business, Dataquest believes that the Sharp/Texas Instruments Japan type (a tape type that can be implemented at low cost by using existing equipment) and the Matsushita/Kyocera type (alumina ceramic) will become the mainstay for mobile communications equipment and digital consumer equipment with low system operation frequency. At present, other technologies still have yet to reach a volume production stage. Commercialization depends on several factors, including cost, technical feasibility, and infrastructure development.

In fact, applications suitable for CSP vary with each technology. For instance, the area array type is suitable for applications with a relatively high pin count (50 pins or more) designed by ASIC vendors because of a large terminal pitch. Table 1 compares specifications of the packaging technologies. Compared to bare chips (including KGD), CSP has the advantages that are usually available in packages. In terms of external appearance and terminal shape, CSP is a standard contact device, and it can help simplify the subsequent mounting of parts in the following respects:

- Ability to standardize sockets for cost reduction and simplified testing
- Ability to simplify PCB design regardless of chip design change or generation shift (silicon respin) by offering the same package solution (for bare chip, PCB design modification is often required)
- Ability to allow any semiconductor suppliers to reduce the mounting cost, as demanded by system companies, by standardizing packages' external appearance and terminal shape

It should be noted that system companies that adopted CSP at an earlier time intend to use it as a differentiating factor and to provide their own solutions before standards are established.

Figure 2
CSP Structures of Leading Manufacturers

Package Type	Sectional View	Manufacturer
Tape Type (TCP Base)		Intel, AMD, Hitachi, Samsung, Sony, LG Semicon, Hyundai (Tessera, Shinko, Amkor-Anam, Mitsui High-Tech)

CSP Technology and Competitive Analysis

Diverse CSP technologies that are under development are all categorized by chip scale and include area array and peripheral packages. These technologies use substrates, flex inserters, wafer-level reallocation, and overmolding for interconnections to the PCB. Table 2 lists selected CSP technologies currently owned by vendors. Table 3 ranks currently offered CSP packages according to their estimated volume production costs. Note that the list ranks the packages that are similar to low-cost LQFP, which is already commercialized with a sufficient technological infrastructure. Sandia National Laboratories' technology is not included because it is closer to reallocated FC than to CSP.

Table 2
CSP Technologies under Development

Manufacturer	Terminal Structure	Interconnection/Substrate
Tessera	A	Tape inserter, TAB bonding, solder balls
TI MicroStar	A	Tape inserter, wire bonding, solder balls
Matsushita Electric/Electronics	A	Mounting of flip chip to ceramic LGA, underfill
Motorola SLICC	A	Mounting of flip chip to laminated substrate, underfill
NEC	A	Tape inserter, thermo-compression bonding, solder balls
Mitsubishi Electric	A	Reallocation to solder pads, transfer molding, ball bonding to pads
Sandia National Laboratories	A	Reallocation of polyimide to gold or solder balls
GE	A	Flex bonding to Si and bump formation using bear holes, development of HDI
Hitachi Densen	A	Derivative of leadframe technology arranging metal posts in perimeter, overmolding
IBM	A	Flip chip bonding to ceramic mini-BGA with cap, eutectic crystal solder balls
Nitto Denko	A	Tape inserter, thermo-compression bonding, solder balls
Toshiba	A	Flip chip bonding to ceramic LGA, underfill
Sharp	A	Wire bonding to flex substrate, molding
Hitachi Densen	P	Leadframe by small J lead, overmolding
ChipScale	P	Wafer reallocation to silicon post, expoxi-resin encapsulation to active face
Rohm	P	Flip TCP, resin sealing of die front side
Fujitsu	P	Die-size leadframe LOC, formation of LGA by one side overmolding
LG Semicon	P	Small leadframe, formation of LGA by overmolding
ShellCase	P	Sealing of Si between two glass plates, metallization of end contact

A = Array terminal layout
P = Peripheral terminal layout

Table 3
Current State of CSP Packaging Development and Volume Production

Manufacturer	Volume Production Cost	Maturity Level	Advantage/Disadvantage
Matsushita Electric/Electronics	Low	Commercialized	Flip chip (SBB), ceramic substrate (mainly for captive users)
NEC	Low	Using two systems of sample level	Advantages/disadvantages vary with methods. The NEC system is similar to the one in Figure 1.
Fujitsu	Low	Prototype	TSOP's derivative technology
Kyocera	Low	Commercialized	Land-type ceramic substrate/PCB (supplied to semiconductor suppliers, SBB technology applied for partial connection)
Hitachi Densen (P)	Low	Commercialized	QFP's derivative technology
Nitto Denko	Medium to low (future)	Commercialized	Additional cost because of bold bonding on tape
Motorola SLICC	Medium	Sample level	Flip chip, for PowerPC
Mitsubishi Electric	Medium	Development level	Cost increase because of multistage process
Hitachi Densen (A)	Medium	Development level	Cost increase because of multistage "post" leadframe, no standard substrate assembly
Tessera	High to medium (future)	Partially commercialized	Equity participation by Amkor-Anam and a few licensing agreements have accelerated CSP development and capital investment; this is expected to result in cost reduction in the near future.
GE	High	Development level	Scrap cost increase because of the initial die mounting process
IBM	High	Development level	Flip chip, ceramic substrate
Toshiba	High	Development level	Flip chip, ceramic substrate

SBB = Stud bump bonding technology
P = Peripheral structure
A = Array structure
Source: Dataquest (September 1998)

Major factors affecting the CSP cost are the substrate cost, assembly techniques (FC and wire bonding technology, for example), the number of process steps, and yield. On the other hand, the price is ultimately governed by the level of market penetration. No technology can achieve the lowest possible cost unless it follows learning curves determined by very large volume production. Dataquest sees that any CSP technology involves a certain risk until official standards are established to depict a "technological winner."

 ©1998 Dataquest

An Analysis of Alternative Technologies

The introduction of CSP technology is hindered by interindustrial barriers that increase the initial cost. To meet short-term design requirements for cost and size, LSI Logic and other vendors propose the small form factor package (SFP)—mini-BGA—technology as a temporary substitute for CSP. This solution includes LQFP and BGA with a small terminal pitch. Table 4 compares existing products using these alternative technologies. It should be noted that the size difference between each IC package and the chip varies greatly among them. For instance, the large core-limited design allows a more efficient use of the package, so that the name "chip scale package" is not appropriate.

Table 4
Comparison of Existing Packages and Mini-BGA

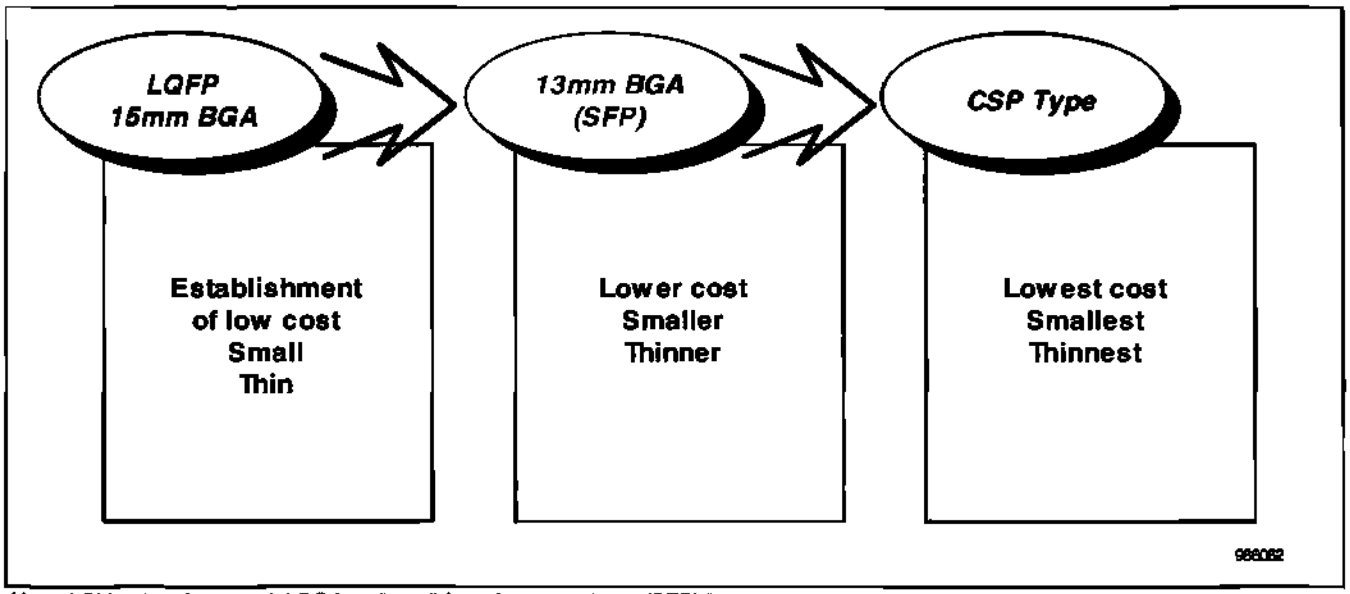
Package Item	LQFP	PBGA	1mm BGA/SFP
Package Total Width	7mm to 28mm	23mm to 35mm	15mm
Package's Relative Size (Compared to Chip Size)	2.5 to 28 times	3.7 to 25 times	3 to 10 times
Height	1.0mm to 1.4mm	2.3mm	1.6mm
Package's Relative Cost in 1997 (Compared to PQFP)	1.2 times	1.5 times	1.5 times
Terminal Width	0.4mm to 0.5mm	1.27mm to 1.8mm	1mm to 0.8mm
Pin Count	44 to 208	169 to 456	100 to 176

Source: Dataquest (September 1998)

Because the package size is primarily governed by size requirements for the system and PCB, it is more appropriate to standardize the package size relative to an available area on the PCB rather than the chip area. In the future, as the CSP cost declines and capabilities related to PCB production and assembly improve, the high-density, area array package will be promoted. The possible evolution of these technologies is analyzed by taking the example of LSI Logic: how the company will implement SFP technology for the 100-to-200-pin markets (see Figure 3).

 ©1998 Dataquest

Figure 3
SFP to CSP Road Map at LSI Logic



Note: LSI Logic refers to mini-BGA as "small form factor package (SFP)."
Source: Dataquest (September 1998)

Not all of the currently available CSP-alternative technologies, such as COB, FCOB, chip-on-flex (COF), and LQFP, are suitable for the ASIC market. They basically consist of many bare chip technologies and several types of packages. Many ASIC suppliers have not weighed bare chip sales, because there are pros and cons on the use of the bare chip. The bare chip can be less costly than packaged devices if all the tests are eliminated; however, it must sacrifice many of the advantages offered by the package solution, while suffering the following drawbacks:

- Testing—Testing techniques on the bare chip still have to be matured.
- Standardization—Chip design changes or the commercialization of a new-generation chip often lead to various changes in external appearance and pad shape. Unless a standard package to absorb such changes is used, the PCB needs to be reconfigured and then tested.
- Risk and reliability related to handling—Without physical protection provided by the package, the bare chip can be damaged by various causes, including corrosion and a mechanical or physical shock. Also, the production process to mount bare chips to systems, similar to a semiconductor assembly line, is required.
- Exchange of chips (rework)—The exchange of chips is more difficult for the bare chip than for CSP.

Barriers to Commercial Implementation of CSP

Major obstacles to the commercial implementation of CSP are an immature technological infrastructure and high equipment costs. The major technical issue facing CSP is how to maintain the terminal pitch and array required to

©1998 Dataquest

implement cost-effective interconnection patterns at a PCB level. The infrastructure refers to the technological capabilities of the PCB industry in supporting assembly and testing operations. In particular, infrastructure development should address the following areas:

- Standard lead and package shapes to support compatibility
- Test socket connection
- Testing process
- Standard tapes and reels
- Assemblies handling equipment
- Visual aid systems for assembly
- Assembly process and thermal distribution, including adequate soldering materials and their geometries

These areas require extensive development efforts, and the use of a standard BGA is considered to be the first step toward the development of CSP.

Also, the total system cost poses a major challenge. Following the learning curve for volume production, the CSP package cost will fall to a very low level because small amounts of materials are used and existing assembly techniques can be used with some modifications. On the other hand, the PCB cost as the basis of the above technologies, particularly Tessera's BGA, is much higher than the cost of standard PCBs.

Figure 4 lists routing issues related to small-pitch, area array packages. As shown in this figure, the escape route is established in one layer, representing the worst case. In a small 7 x 7 array, the maximum number of traces escaping between two balls in the array is three. Generally, the required routing density is proportional to the number of ball rows; the routing issue becomes more serious as the array becomes larger. In practice, the required routing density is secured by using a multilayer PCB. Basic rules related to the PCB are governed by the terminal pitch of the package array, the number of balls, and the size of the capture pads. The PCB's cost impacts vary with markets and are generally determined by PCB size and the number of CSP devices mounted on it.

Dataquest Perspective

In the conventional ASIC process development, each manufacturer has established its basic process and packaging technology that are then incorporated into products. Also, in many cases, the memory process, such as DRAM, has been adapted to the ASIC process as a technology driver. Historically, Japanese semiconductor companies have developed products on the basis of "the supply-side logic" and have palmed them off to system companies. This reflects that the product development process lacks the marketing concept—efforts to grasp and serve market needs. In recent years, Americas ASIC suppliers seem to have established a clear competitive edge over Japanese competitors. The difference comes from not only a technology gap in the basic process and packaging but also the lack of market analysis and marketing strategy to address users' needs on the Japanese side.

Because the ASIC industry has already entered the SLI ASIC age, where large-scale LSI development efforts are required, it has become imperative for ASIC suppliers to respond effectively to the needs of application users. Future challenges for establishing the product concept of SLI ASIC include optimizing application requirements by semiconductor technologies, including packaging, process, libraries, and IP core. Dataquest believes that CSP will be one of the critical factors for success.

Semiconductors Japan

Market Analysis

A Comparative Analysis of Wafer Fab Equipment Markets in 1997: The Japanese Market Was Down 23 Percent

Abstract: *In 1997, the worldwide wafer fab equipment market declined 7 percent from the year before to $20.2 billion. The regional breakdown showed mixed results, however. While the Americas and Taiwan maintained double-digit growth, Europe, Japan, and Asia/Pacific (excluding Taiwan) recorded negative growth. From the first quarter through the third quarter, leading-edge equipment, led by excimer laser and equipment used for MPU and logic production, expanded and bolstered growth of the entire market. In the fourth quarter, however, a lingering slump in the DRAM market put a drag on market growth because of capacity expansion, resulting in negative growth on an annual basis.*
By Takashi Ogawa

1997 World Market Trends

In 1997, the wafer fab equipment market recorded negative growth for the first time since 1992 with a 7 percent decrease from 1996. Of $20.2 billion, the Americas accounted for $6.7 billion and maintained a double-digit growth of 15 percent. In contrast, the Japanese market decreased by 23 percent (to $5 billion), Asia/Pacific decreased by 7 percent (to $6 billion), and Europe decreased by 15 percent (to $2.4 billion). Within the Asia/Pacific market, Korea plunged 37 percent (to $1.9 billion), whereas Taiwan expanded 30 percent (to $3.3 billion). The polarized results between regions as well as individual markets (see Figure 1) seem to reflect their semiconductor product mix. Japan and Korea, which are heavily dependent on DRAM, showed sharp declines, while the Americas maintained firm growth, fueled by the expansion of the MPU, ASIC, and logic markets. Taiwan benefited from the booming foundry business, which was increasing capacity.

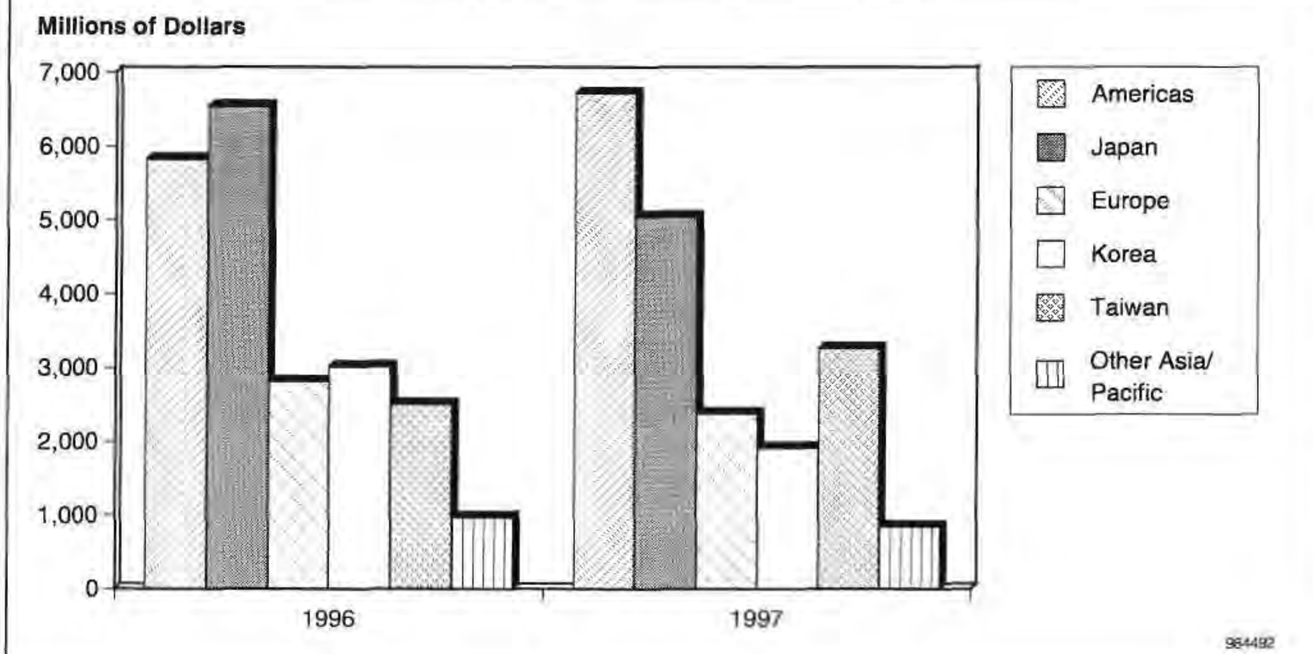
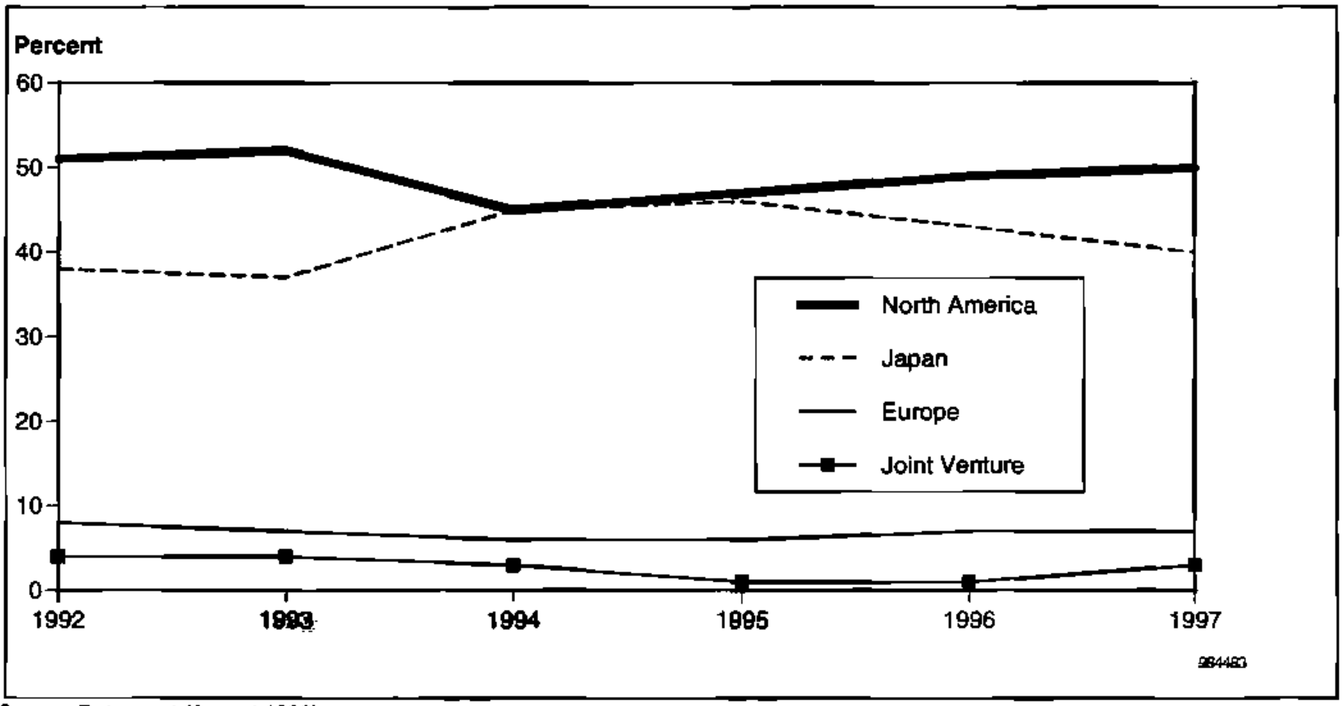
Figure 1
Wafer Fab Equipment Market Trends by Region



Source: Dataquest (August 1998)

The market breakdown by segment also showed mixed results. Major winners were leading-edge equipment markets, including excimer steppers, chemical mechanical polishing (CMP), rapid thermal processing (RTP), and high-density plasma chemical vapor deposition (CVD). On the other hand, the segments relying on capacity expansion, such as auto wet stations and diffusion equipment, suffered a defeat. By ownership, North American companies increased their share to 50 percent, widening a lead over Japanese competitors, whose share declined to 40 percent. This shift was mainly because U.S. companies had a stronger lead in the logic-oriented technologies, which grew relative to the DRAM-oriented equipment segments. Also, the Japanese companies were weaker than average in 1997. European companies maintained their share of 7 percent with their strength in the lithography segment (see Figure 2).

Figure 2
Recent Trends in Wafer Fab Equipment Market Share by Ownership



Source: Dataquest (August 1998)

1997 Japanese Market Trends

After Korea, in terms of losses, the Japanese fab equipment market suffered a major decline of 23 percent. Notably, as shown in Table 1, all of the categories recorded double-digit negative growth. Resist processing equipment plummeted 44 percent to $256 million, ion implantation equipment was down 41 percent to $202 million, and RTP and diffusion equipment declined 29 percent to $208 million. The major downturns reflect the direct impact of curtailed capital spending by Japanese semiconductor companies because of the sluggish DRAM market. As a result, the Japanese market's world share dropped from 30 percent in 1996 to 25 percent, a sharp contrast to the Americas market, which increased its share from 27 percent to 33 percent.

Table 1
Breakdown of Wafer Fab Equipment Market in 1997

Equipment	Japan's Revenue ($M)	Worldwide Revenue ($M)	Japan's Market Share (%)	Japan's Growth Rate (%)
Lithography	1,058.5	3,904.2	27	-14
Resist Processing	255.5	1,205.9	21	-44
Etching, Cleaning, and Planarization	1,285.4	5,194.8	25	-23
Deposition	1,186.1	4,551.5	26	-21
RTP and Diffusion	207.7	805.9	26	-29
Ion Implantation	202.3	912.2	22	-41
Process Control	570.7	2,212.9	26	-14
Manufacturing and Control	196.1	1,056.1	19	-28
Others	84.2	327.6	26	-21
Total	**5,046.5**	**20,171.0**	**25**	**-23**

Source: Dataquest (August 1998)

The breakdown by ownership reveals a similar pattern. Japanese companies lost revenue by 13 percent to $7.9 billion, compared to moderate performances of North American companies (down 1 percent) and European companies (up 1 percent). Of Japanese companies' total revenue, lithography equipment accounted for 31 percent, and resist processing accounted for 11 percent, indicating a continued dominance of exposure technology in terms of revenue. In contrast, North American companies, which are strong in the MPU and logic (including ASIC) markets, earned 59 percent of the revenue from equipment related to interconnection technology, such as etching, cleaning, and planarization and deposition.

The following sections analyze major trends, reflecting the Japanese fab equipment market and manufacturers by the type of equipment.

Steppers

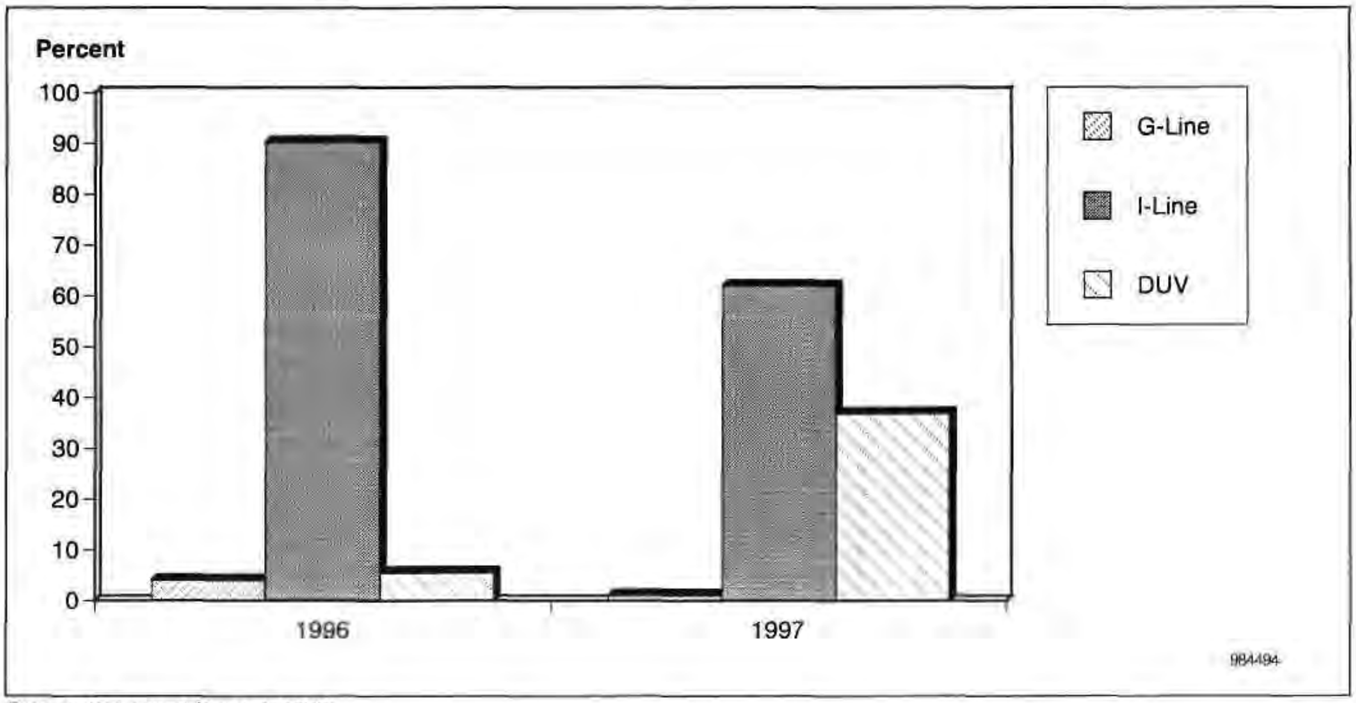
Steppers form a major element of wafer fab equipment investment. In 1997, the world stepper market remained almost flat from the previous year, totaling $3.6 billion. The Japanese market dropped 16 percent to $938 million. Notably, while shipment revenue (on a dollar basis) maintained more or less the previous year's level, unit shipments declined from 1,321 to 1,043. This reflects the fact that the shipment of conventional i-line steppers declined significantly because of cutbacks in capital spending for capacity expansion, whereas sales of higher-priced krypton-fluoride (KrF) excimer laser steppers grew considerably because of the commercial rollout of 0.25-micron technology. Dataquest's survey indicates that unit shipments of excimer steppers surged from about 8 percent in 1996 to 30 percent in 1997.

The breakdown by region and technology indicates that the Americas and European markets previously held high shares of deep ultraviolet (DUV) stepper shipments, but in 1997, unit shipments to the Japanese and Korean

 ©1998 Dataquest

markets grew rapidly as 0.25-micron technology was introduced to 64Mb DRAM production (Figure 3). The increased use of excimer steppers for volume production has affected each vendor's share as well; while no significant change was seen in unit shipment ranking, companies that dominated the excimer stepper segment on a revenue basis increased their shares. Following Nikon Corporation, which maintained first place with a 43 percent share in 1997 (47 percent in 1996), ASM Lithography Holding N.V. advanced to second place by expanding its share from 20 percent to 25 percent and replaced Canon Inc., whose share dropped from 25 percent to 23 percent. In the second-tier group, Silicon Valley Group Inc. raised its share from 4 percent to 7 percent.

Figure 3
Recent Trends in Stepper Shipments to the Japanese Market by Technology (Units)



Source: Dataquest (August 1998)

Auto Wet Stations

The world auto wet station market totaled $954 million in 1997, an 18 percent decrease from the previous year. The highest rates of decline were seen in Europe (down 43 percent) and Korea (down 25 percent). The Japanese market also experienced a 17 percent decrease, totaling $247 million. All of these regions were adversely affected by a major setback in capacity expansion investment, particularly in the DRAM area.

The market shares by company underwent some reshuffling. While Dainippon Screen Corporation continued to hold the leading position with a 20 percent share, Sugai Corporation advanced from fourth to second place (13.3 percent), and Tokyo Electron Ltd. fell from second to third place (12.6 percent), followed by Kaijo Corp. (from fifth to fourth) and STEAG

 ©1998 Dataquest

MicroTech Inc. Japanese companies command a combined share of around 70 percent of the market. Interestingly, different companies have established dominant positions in different regions. Dainippon takes a lead in the Americas, Japan, and Korea; Kaijo takes a lead in Taiwan; Tokyo Electron takes a lead in other countries in Asia/Pacific; and STEAG MicroTech takes a lead in Europe. While there is no global winner, Sugai and Sankyo Engineering Company Ltd. are moving toward a merger, and the new company is expected to emulate Dainippon's 1997 market share. Much more consolidation is expected in the market.

Resist Processing

The resist processing market was by no means immune to the sluggish capital spending triggered by the DRAM recession. As a result, the worldwide resist processing market declined 28 percent in 1997 to $1.2 billion. The momentum of the equipment for DUV lithography, market-driven by the proliferation of excimer steppers, was dwarfed by a major decline in the conventional equipment segment. The Korean market was hit hardest, and value shipments decreased 45 percent to $105 million, followed by the Japanese market, which dropped 44 percent to $256 million. Again, high dependency on the DRAM business was a determinant factor.

As for vendor ranking, Tokyo Electron dominated the market (59 percent share), followed by SVG (15 percent) and Dainippon (13 percent). Fairchild Technologies GmbH was the only company reporting high growth (50 percent increase over the previous year) and advanced to fifth place by winning a 4 percent share. Its significantly increased presence in the Korean market served as a major impetus for this.

The DUV equipment market is expected to grow consistently with expansion of the excimer stepper market. Vendors are vying for higher performance by focusing on several areas: the controllability of atmosphere inside equipment by means of chemical filters and increased durability of the filters, accurate temperature control in the oven, and the reduction of footprint for the 300mm wafer process.

Dry Etching

In 1997, the worldwide dry etching market declined 13 percent from the previous year to $3.0 billion. Segment-wise, the low-density plasma etching equipment market was down 26 percent to $1.6 billion, while the high-density segment reported an impressive 9 percent increase to $1.4 billion. High-density plasma etching equipment has gained popularity with the pervasiveness of the 0.25-micron process, on account of profile characteristics accompanying the pattern's high-aspect ratio, selectivity, and adaptability to pattern shape. It has now reached a market size similar to that of low-density plasma etching equipment.

Regionally, the high-density plasma etching markets in the Americas and Taiwan recorded high growth, 62 percent and 61 percent over the previous year, respectively, whereas the Japanese market plunged 17 percent to $333 million. As for each company's share in the high-density plasma etching markets, Applied Materials Inc. boosted revenue by 208 percent to hold a 27 percent share and get closer to the leader, Lam Research Corporation (43 percent). Hitachi Ltd. came in third. Applied Materials increased sales in the Americas, European, and Japanese markets.

Chemical Mechanical Polishing

Compared to the dreary condition of the wafer fab equipment market, which recorded a 7 percent decline, the worldwide CMP market grew 75 percent in 1997 to $518 million. In addition to the traditional strongholds in the Americas and Europe, the CMP market underwent rapid expansion in Asia/Pacific, particularly in Taiwan (up 352 percent) and Korea (up 303 percent). In all of the regions, CMP technology expanded its applications from the production of leading-edge logic devices to DRAMs. The Japanese market grew 56 percent to $134 million. As a result, regional shares changed to 41 percent for the Americas, 26 percent for Japan, 10 percent for Europe, and 23 percent for Asia/Pacific, with the Japanese and Asia/Pacific markets ahead of the European market.

In terms of system configuration, integrated CMP equipment that incorporates post-cleaning equipment has expanded its market, a 227 percent increase over 1996, to total $179 million and a 35 percent share. In particular, the Japanese market accounted for 53 percent of the entire segment.

Each company's share showed notable changes as well. IPEC/Planar managed to hold the No. 1 position, although its share dropped to 26 percent, and Ebara Corporation came in second by boosting its share to 22 percent. Applied Materials also gained a 15 percent share and followed SpeedFam Corporation, which was in third place (21.5 percent). Japanese companies together registered a considerable gain from 36 percent to 49 percent. With more Japanese companies (for example, Mitsubishi Materials Corporation, Tokyo Seimitsu Co. Ltd., and Sony Corporation) looking for market share, coupled with expanded applications (such as shallow trench isolation and the dual damascene process), the market should become more competitive.

Chemical Vapor Deposition

In 1997, the worldwide vertical- and horizontal-tube CVD system market totaled $603 million, down 24 percent from a year ago. Two markets recorded healthy growth: the Americas with 22 percent and Taiwan with 18 percent. On the other hand, the Korean and European markets declined sharply, with 64 percent and 47 percent, respectively. Similarly, the Japanese market recorded a negative growth of 25 percent, totaling $190 million. The regional disparity clearly reflects the different conditions of individual device markets.

The distinctive patterns in different segments are more pronounced in the nontube CVD system market. Low-pressure CVD (LPCVD) and

 ©1998 Dataquest

atmospheric/subatmospheric CVD (APCVD/SACVD) maintained the same revenue levels as the previous year, as bolstered by the first growth of the markets in Taiwan, the Americas, and Europe. In these markets, primary film demand comes from logic-oriented products such as blanket tungsten and gap-fill dielectric depositions. The worldwide nontube CVD market grew 6 percent to $610 million, and the worldwide APCVD/SACVD market was up 1 percent to reach $657 million. In contrast, the Japanese market recorded double-digit negative growth in the both segments—the nontube CVD market totaling $180 million, and the APCVD/SACVD market totaling $138 million—as these markets depended on the DRAM-sensitive films of tungsten silicide and higher-temperature deposited dielectric materials.

In the plasma CVD market, the low-density segment reported a 13 percent decline to $609 million, while the high-density segment recorded an outstanding gain of 88 percent, totaling $202 million. Strong market expansion was seen across the regions: The Americas grew 77 percent, Europe grew 144 percent, and Asia/Pacific grew 144 percent. The Japanese market also grew 10 percent to $12 million.

In the future, further market expansion is expected in the 0.25-micron-and-finer processes where high-density plasma CVD systems expand applications such as dielectric layers below metal films and trench isolation, in addition to the formation of dielectric layers between metal films. Leading the high-density plasma CVD market is Novellus Systems Inc., which managed to maintain first place with a 49 percent share, closely followed by Applied Materials, which increased revenue by 246 percent to gain a 48 percent share. Thus, the market is almost equally divided between the two vendors.

Silicon Epitaxial Reactors

The worldwide silicon epitaxial reactor market recorded a 25 percent growth in 1996 that was driven by DRAM demand; this turned into a negative growth of 13 percent in 1997, totaling $226 million. While it grew somewhat in the first half of 1997, it seemed to cool down in the second half. A major cause was the delay or cutback in the expansion of 200mm wafer production capacities by silicon wafer manufacturers because of the sluggish DRAM market and the lackluster outlook for wafer demand as a result of accelerated chip shrinkage. The falloff from investment in power/discrete capacity was another major cause. Regionally, the Japanese market recorded a 20 percent growth ($99 million), while other regions suffered declines: the Americas by 26 percent ($79 million), Europe by 26 percent ($39 million), and Asia/Pacific by 50 percent ($9 million). This reflects the continuous efforts of Japanese companies to explore the DRAM market as design rules fall below 0.3 micron.

In the world of 0.3-micron-or-finer linewidth, it is well known that crystal defects such as crystal-originated particles (COPs) impede yield in DRAM production. DRAM suppliers take varied approaches, which primarily reflect the maturity and economics of their processes. At present, most Japanese companies address the issue by using epitaxial wafers. At the same time, some continue to use CZ wafers (wafers created using the Czochralski

 ©1998 Dataquest

Method), adopt hydrogen-annealed wafers (Hi wafers), or consider low-COP CZ wafers.

In terms of share by company, Applied Materials continued to lead the market by holding a 57 percent share, followed by ASM International N.V. (24 percent), whose position also did not change. In third place, however, Concept Systems Design was replaced by Moore Epitaxial Inc. with a 12 percent share.

Rapid Thermal Processing

In 1997, the worldwide RTP equipment market grew strongly at 49 percent and reached $273 million. Double-digit growth was recorded in all of the regions except Europe. The Americas market was up 60 percent (totaling $106 million), Japan was up 69 percent ($69 million), and Asia/Pacific was up 69 percent ($71 million), while Europe was down 19 percent ($28 million). Entering the 0.25-micron age that requires ever finer and thinner devices, precise temperature control in the thermal treatment process becomes increasingly critical, and RTP finds new applications in ion implantation and annealing of source drains, silicide formation, and the formation of gate oxide films.

In terms of vendor ranking, Applied Materials, in first place, recorded a 139 percent increase in revenue to $162 million and gained a 59 percent share. While the company boosted sales in all of the regions, major contributions came from the Japanese market, where its sales skyrocketed by 1,640 percent over the previous year and its share grew to 58 percent. As a result, Dainippon slid from the top position in 1996, and its share plummeted to 17 percent in Japan. In the worldwide market, STEAG AST Elektronik maintained second place with a share of 18 percent. AG Associates came in fourth with a 15 percent share. Future technological challenges in the market include uniform temperature control, the improvement in temperature reproducibility because of variation in wafers' emissivity, and the improvement in the maintainability and reduction of running costs associated with the use of 300mm wafers. Various vendors are establishing volume production capabilities.

Ion Implantation

The ion implanter market is one of the markets primarily governed by individual device market trends and new fab construction. In 1997, the worldwide ion implanter market declined 18 percent to $912 million. Regionally, the Americas and Taiwan reported double-digit growth, whereas other regions suffered negative growth in double digits. Looking at individual segments, high-current ion implanters used in the source drain process and medium-current ion implanters used in the field threshold voltage control process recorded negative growth of 27 percent and 23 percent, respectively, to reflect new fab investment cutbacks by most companies, except for those in the Americas and Taiwan. On the other hand, the high-energy ion implanter market (used for the formation of barrier

 ©1998 Dataquest

layers and retrograde wells) recorded a 12 percent growth. A regional breakdown, however, unveils mixed results. While the DRAM-dependent Japanese and Korean markets declined 8 percent and 47 percent, respectively, the Americas and European markets reported appreciable growth of 59 percent and 31 percent, respectively, because they rely on logic processes where high-energy ion implantation expands applications. Overall, the Japanese market declined in all of the segments, resulting in a 41 percent decrease and $202 million.

Share by company has remained unchanged for the top three vendors: Eaton Corporation (45 percent), Varian Associates Inc. (30 percent), and Applied Materials (13 percent). However, because Varian acquired the ion implanter division of Genus Incorporated and vendors are introducing products with wider applications, market reshuffling is expected among the segments.

CD-SEM

In 1997, the worldwide critical dimension scanning electron microscope (CD-SEM) market decreased 1 percent to $327 million. Again, a regional breakdown shows polarized results. Two markets recorded strong growth: the Americas (up 21 percent) and Taiwan (up 46 percent). Two markets suffered declines: Korea (down 50 percent) and Japan (down 16 percent and totaling $79 million). The wafer testing and inspection systems industry went through major consolidations between 1996 and 1997, including the merger of KLA Instrument with Tencor Instrument and the market entry of Applied Materials. These moves have already affected market share. Hitachi continued to dominate the 1997 market with a 60 percent share, followed by KLA-Tencor Corporation (18 percent) and Applied Materials (13 percent). In the future, performance improvement efforts will focus on measurement accuracy and reproducibility at low acceleration voltage and on higher throughput. Recently, the need has arisen to implement defect analysis capabilities and evaluation capabilities in the form of data processing utilities through a graphical execution manager (GEM) interface.

Manufacturing Automation and Control

This year, Dataquest newly defined a segment in the factory automation equipment market, called semiconductor manufacturing automation and control (SMAC), for a full-scale market study. The SMAC market is further divided into automation software systems covering system integration and similar functions, transport and storage automation covering wafer handling and transportation, lithography management systems, transition environmental control systems such as standard mechanical interface (SMIF), and process environmental control systems such as cluster tool platforms.

Generally, the SMAC market is expected to be directly affected by fab investment, which was clearly seen in 1997. The entire market showed a slight increase of 2 percent to $1,209 million. Regionally, three markets showed firm growth: The Americas grew 10 percent, Europe grew 36 percent, and Taiwan grew 19 percent. The Korean and Japanese markets, on the other

 ©1998 Dataquest

hand, declined 22 percent and 23 percent, respectively. Again, the market contrasts are evidence of the impacts of major cutbacks in DRAM-related capital spending on some markets. However, in the Japanese market, to which total shipments in 1997 amounted to $237 million, the transition and process environmental control segments registered positive growth, albeit a small size, and systems adaptive to the next-generation production environment, including SMIF and cluster tool platforms, showed some signs of market expansion.

In terms of share by company, Japanese and North American manufacturers dominate the market, controlling 30 percent and 64 percent, respectively. North American companies hold high shares in Taiwan, other Asia/Pacific countries, and Europe, in addition to their home ground. On the other hand, Japanese companies take the lead in the Japanese and Korean markets. In the 1997 market share ranking, PRI Automation came first with a 15 percent share, followed by Daifuku Company Ltd. (14 percent), Asyst Technologies Inc., and Digital Equipment Corporation. Among the Japanese companies, Shinko Electric Company Ltd. ranked sixth (6 percent).

Equipment Vendor Ranking

Table 2 lists the top ten semiconductor equipment manufacturers in 1997. Clearly, Japanese companies decreased their revenue, whereas U.S. companies recorded firm growth. While no change is seen in the top three, KLA-Tencor ranked fourth because of the merger, and Canon fell from fifth to seventh place because of slow sales in the stepper market. In contrast, ASML maintained sixth position by gaining share in the excimer stepper market and boosting revenue by 21 percent. SVG was also driven by increased revenue from excimer steppers and achieved ninth place. On the other hand, Dainippon stepped down from seventh to tenth place because of the slump in the resist processing and auto wet station markets.

Table 2
Semiconductor Equipment Vendor Ranking

1996 Rank	1997 Rank	Vendor	1996 Revenue ($M)	1997 Revenue ($M)	1997 Growth (%)	1996 Market Share	1997 Market Share
1	1	Applied Materials	3,350.5	3,669.3	9.5	15.9	18.7
2	2	Tokyo Electron	2,591.2	2,145.1	-17.2	12.3	10.9
3	3	Nikon	1,721.2	1,565.2	-9.1	8.2	8.0
-	4	KLA-Tencor	-	1,027.2	-	-	5.2
4	5	Lam Research	1,091.9	915.6	-16.1	5.2	4.7
6	6	ASML	726.0	875.9	20.6	3.5	4.5
5	7	Canon	956.0	862	-9.8	4.5	4.4
8	8	Hitachi	631.9	609.2	-3.6	3.0	3.1
10	9	SVG	551.2	560.6	1.7	2.6	2.9
7	10	Dainippon	648.1	500.8	-22.7	3.1	2.6

Source: Dataquest (August 1998)

The wave of consolidation in 1997—including the mergers, acquisition of divisions, and alliances—seems to have subsided in 1998. Nevertheless, Sugai and Sankyo Engineering plan to merge for the sake of survival in the auto wet station market to form a new company, SES, and Varian has announced the acquisition of the ion implanter division of Genus. Thus, market reorganization is expected to continue through mergers or acquisitions, and market share in various segments will change accordingly.

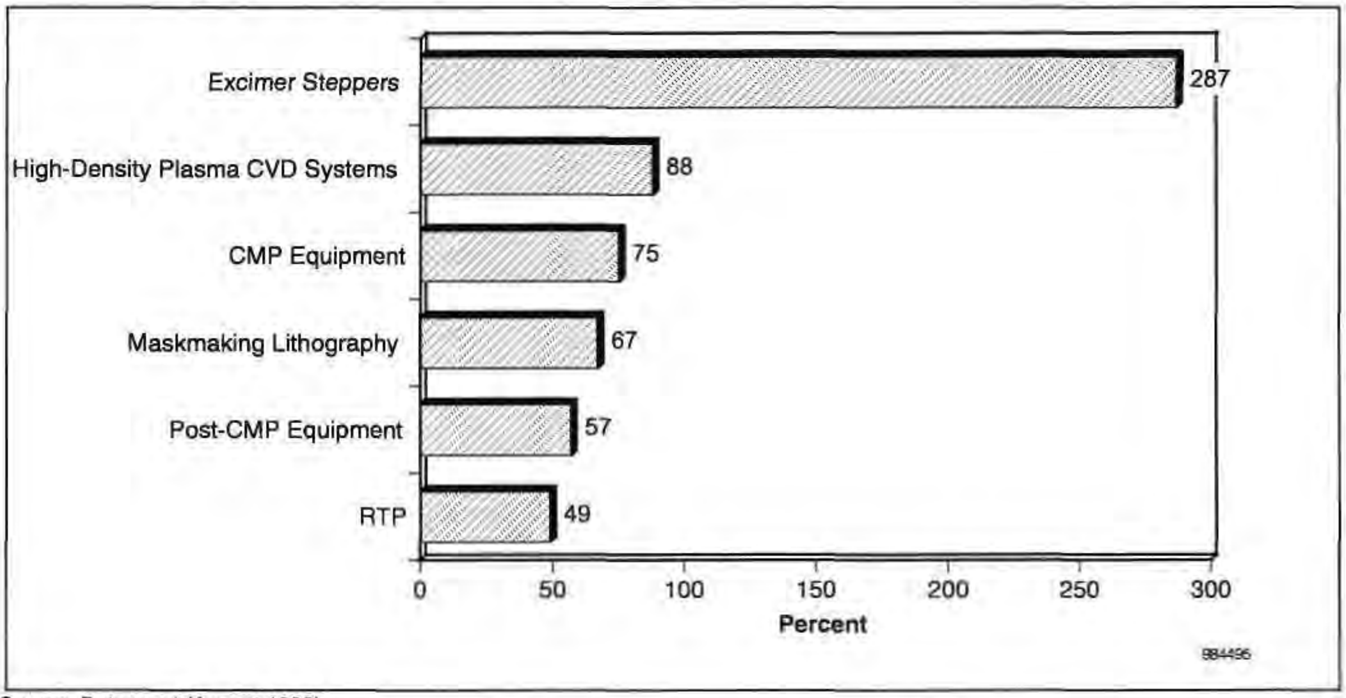
Dataquest Perspective

The 1997 fab equipment market trends can be summarized in several ways. Generally, the Japanese and Korean markets contracted dramatically as they relied heavily on DRAM investment, and, therefore, equipment companies selling their products primarily in these two markets suffered significant revenue loss. In contrast, the Americas market, whose lifeblood lies in logic (including ASICs) and MPUs, and Taiwan, where foundry investment is rampant, enjoyed expansion, and equipment manufacturers holding share in these markets recorded healthy growth. Thus, the fab equipment market in 1997 was directly linked to the local characteristics of device production, which resulted in a notable regional gap.

Parallel to the widening regional disparity, technology-driven market expansion continues, as seen in 1996. Figure 4 lists segments that recorded high growth in 1997. While the fab equipment market recorded a negative growth of 7 percent, several segments related to 0.25-micron and later process technologies, led by excimer steppers, grew strongly. While the entire market is expected to remain sluggish for another year or two, these high-end segments that hold the key to the commercialization of leading-edge process technology—particularly, sputtering equipment that forms copper interconnections (seed layers) and the formation of electroplated films—will follow a path of solid growth.

©1998 Dataquest

Figure 4
Fast-Growing Segments in 1997 (Worldwide)



Source: Dataquest (August 1998)

In the future, regional equipment market trends will further be differentiated according to the development of leading-edge technology and according to their local device markets and growth patterns. At present, Japanese semiconductor companies are struggling to pursue and nurture high-value-added businesses, such as system-level integration (SLI). In the short run, however, they still have to depend upon DRAM. Dataquest predicts that the DRAM market will make a sufficient recovery after the end of 1999, allowing suppliers to resume full-scale capacity expansion. In the meantime, the Japanese wafer fab equipment market will have to rely on leading-edge equipment such as excimer steppers, CMP, RTP, and high-density plasma CVD as market drivers.

Semiconductors Japan
Market Analysis

Time to Think about the Marketability of 128Mb DRAM

Abstract: *Traditionally, DRAM has quadrupled its integration level. In 1998, however, the grand tradition has been broken with the introduction of 128Mb DRAM. The industry considered the development of 32Mb DRAM in 1996 to be a bridge between 16Mb and 64Mb DRAM, although the 32Mb DRAM failed to materialize as marketable, generic DRAM. Likewise, many view the newly rolled-out 128Mb as a short-lived stopgap between 64Mb and 256Mb DRAM. Whether the quadrupling pattern will continue to dominate or the industry will undergo a paradigm shift in DRAM evolution where the doubling becomes the norm is a critical issue for both DRAM users and suppliers in their product development. This Perspective analyzes 128Mb DRAM from the marketability point of view and examines differentiating factors for 64Mb, 128Mb, and 256Mb DRAM with opportunities for market segmentation.*

By Masahiro Suzuki

Market Forecast for 128Mb DRAM

In 1998, the DRAM market is in transition from 16Mb to 64Mb, the demand for which has yet to ramp up. However, some leading Japanese and Korean DRAM vendors have unveiled the start of volume production of 128Mb products, which is to take place at the end of this year, and other companies seem to be following suit. To add complexity or choice, some Japanese and Korean suppliers have announced commercial shipments of 256Mb DRAM, starting in early 1999. If these plans proceed according to schedule, 64Mb will become the mainstay in the 1998 DRAM market, and three generations of leading-edge DRAM—64Mb, 128Mb, and 256Mb—will coexist in 1999.

In making forecasts for various device markets, Dataquest refers to past trends and demand forecasts for electronics. In our extensive database, however, there is no comparable case like this one—three generations of leading-edge devices competing in the same market. It is therefore important

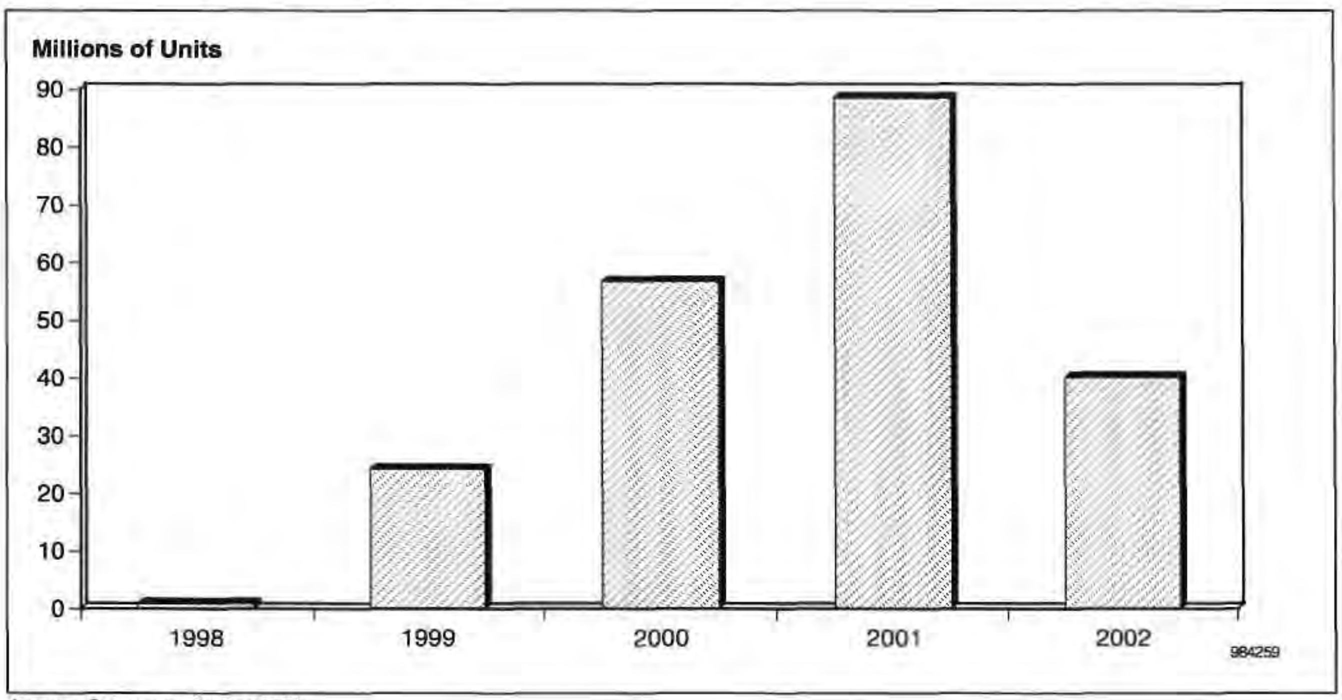
to analyze the 128Mb DRAM market in our May 1998 forecast by focusing on the demand-side, system vendors and their products.

Figure 1 shows unit shipment forecasts for 128Mb DRAM between 1998 and 2002. Note that the 1998 shipments are rather limited, around 900,000, as the forerunners are expected to start up volume production in the third quarter of 1998. To encapsulate the 128Mb chip in the 400-mill package required by DRAM users, semiconductor companies must use the leading-edge production process of 0.23-micron or finer, the capacity of which will inevitably be limited in 1998.

In 1999, other leading vendors will enter the market, and unit shipments will grow steadily. The market is expected to peak in 2001 and then plummet in 2002 to one-half the level of 2001, under the assumption that volume production of the 256Mb version will start to trigger the bit price crossover with 64Mb in that year. Some believe that 128Mb will be further short-lived as volume production of 256Mb ramps up earlier than expected. However, if this happens and 256Mb starts to replace 128Mb at an earlier time, suppliers will face price erosion of the leading-edge device, which will make it difficult for them to reap major investment and secure sufficient profitability for the DRAM business.

Figure 1
Total 128Mb Unit Demand



Source: Dataquest (July 1998)

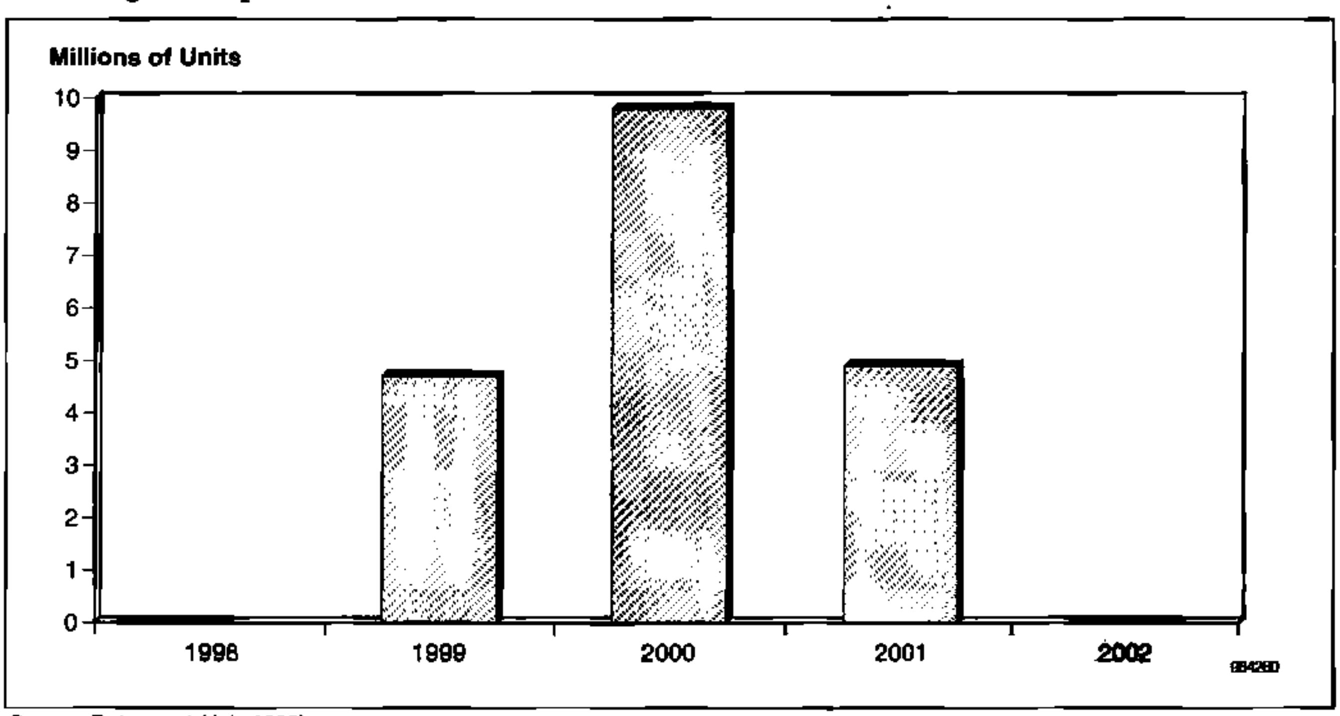
Demand Forecast for 128Mb DRAM

Major target applications for 128Mb DRAM include midrange computers, workstations, PC servers, and high-end notebook PCs. Generally, high-end computers require a larger main memory, which consumes DRAMs of larger capacity, resulting in a higher price premium. On the other hand, semiconductor companies are focusing their efforts on the development of 128Mb synchronous DRAMs (SDRAMs). Generally, when SDRAMs are packaged in a buffer-type dual inline memory module (DIMM), the number of slots available on the motherboard is limited to eight. Thus, supercomputers and mainframes, which require a very large main memory, tend to use extended data out (EDO)-type DRAMs rather than SDRAMs by maximizing performance through the interleave approach.

Midrange Computers

Midrange computers are classified as one class above workstations and thus have relatively large main memory requirements. 128Mb DRAMs will be an attractive choice for low-end machines with a smaller memory size, but they will soon be replaced with 256Mb DRAMs according to the price decline. As a result, 128Mb DRAM demand in the midrange market will reach its peak level in 2000 (see Figure 2).

Figure 2
Midrange Computers: 128Mb Unit Demand



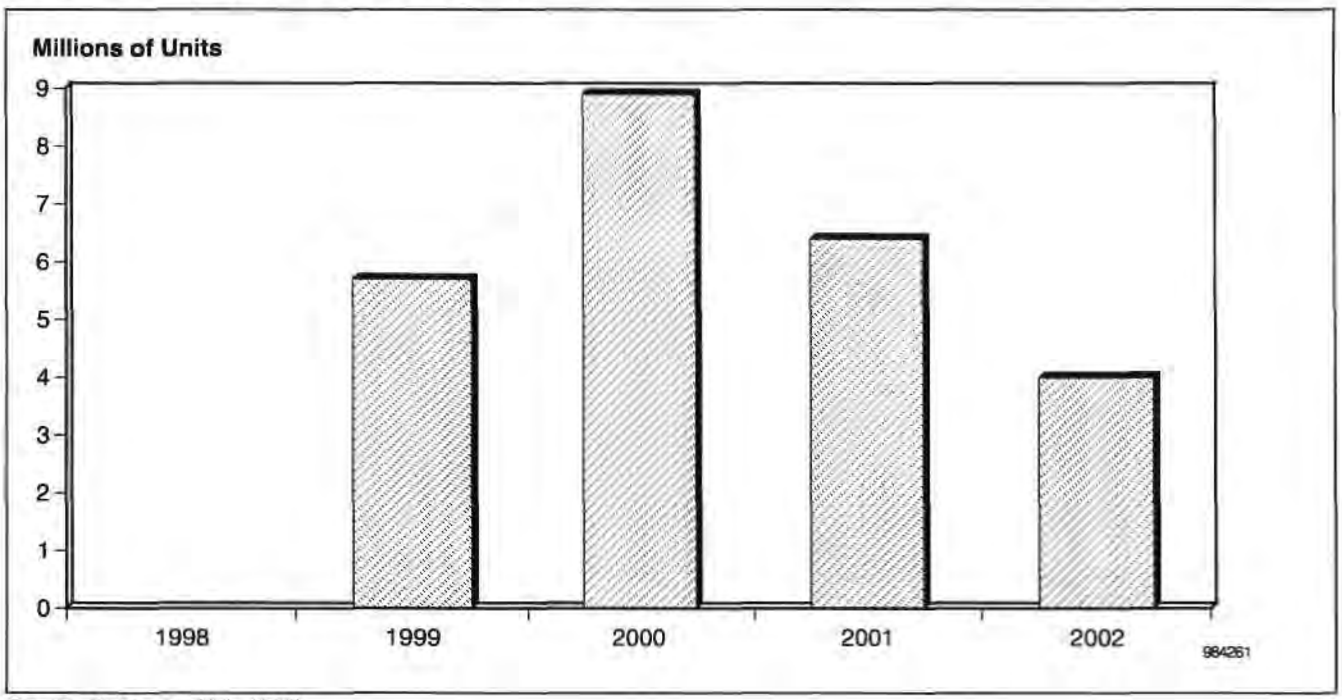
Source: Dataquest (July 1998)

Workstations

This is the segment where replacement of 128Mb by 256Mb is not certain. When the market is divided into three parts—high-end, midlevel, and low-end—the replacement process will be sure to occur in the high-end segment. On the other hand, in midlevel and low-end machines, it will be conditional to the 256Mb price, which must decline to a level triggering the crossover. Furthermore, the low-end segment should be preceded by the proliferation of 128Mb products as their bit price becomes closer to that of 64Mb products.

Interestingly, high-end workstations account for less than 1 percent of the total annual unit shipments, whereas low-end machines represent more than 70 percent. This means that unless the 256Mb price falls significantly, the rate of replacement is not likely to accelerate. In the low-end segment, the 256Mb nonbuffered DIMM will be mainly used for cost saving. In contrast, high-end machines with large memory will demand the buffer DIMM version. The main memory size of 1GB seems to be a threshold. Dataquest predicts that demand for 128Mb DRAM in the workstation market will peak in 2000 and then will gradually be replaced by 256Mb DRAM with a declining price (see Figure 3).

Figure 3
Workstations: 128Mb Unit Demand

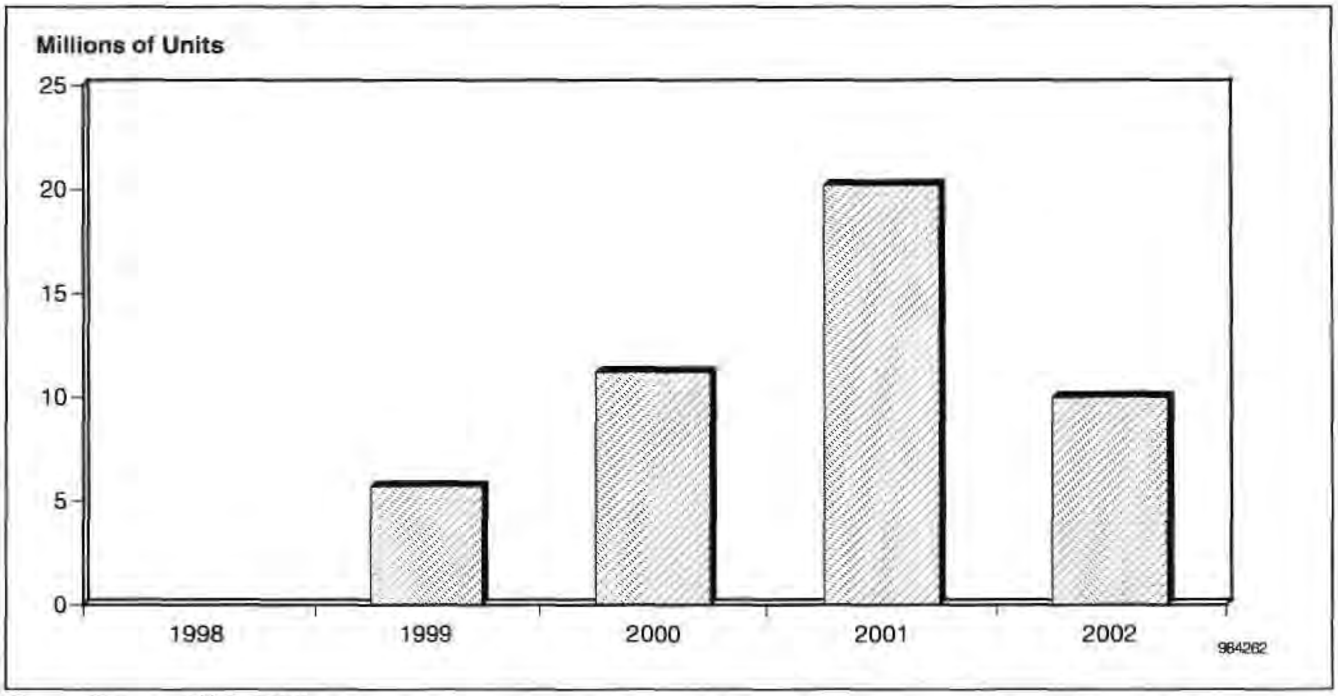


Source: Dataquest (July 1998)

PC Servers

As also seen in the low-end workstation segment, PC servers will become a major application market for 128Mb DRAM that can replace 64Mb DRAM if a parity is reached for the bit price. Between 1998 and 1999, unit demand for 128Mb will expand so much that it will prompt DRAM suppliers to launch strategic pricing for market share. Again, PC servers will opt for the nonbuffered DIMM type. Market demand for 128Mb will reach the highest level in 2001 (see Figure 4), during which time 128Mb will still keep price competitiveness against 256Mb on a bit-price basis.

Figure 4
PC Servers: 128Mb Unit Demand



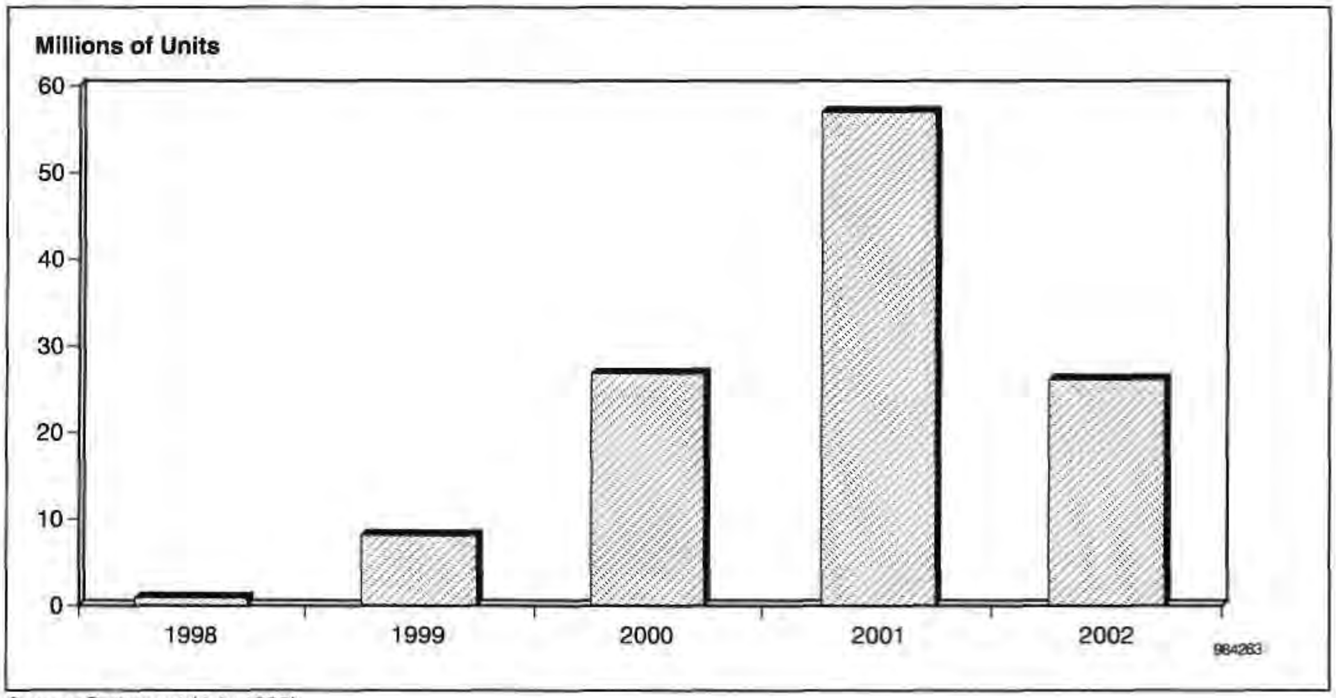
Source: Dataquest (July 1998)

Notebook PCs

The seemingly relentless drive for a thin form factor makes the packing of parts into less space an increasingly critical issue. The use of 64Mb DRAMs in high-end notebook PCs in early 1997 is evidence that vendors can afford to select costly, large-capacity DRAMs if main memory is to be expanded. The 64MB main memory will increasingly become a standard feature of 1998 models with the release of Windows 98. 128Mb DRAMs will be able to easily configure a thin 64Mb module by allowing four units to be mounted on the single side of the small-outline DIMM (SODIMM). Dataquest believes that high-end models will start to incorporate 128Mb DRAMs in the second half of 1998. The 128Mb price is expected to enter a downward path in 1999, pushing the pervasiveness of notebook PCs. Demand in the notebook PC market will reach its peak in 2001 (see Figure 5).

 ©1998 Dataquest

Figure 5
Notebook PCs: 128Mb Unit Demand



Source: Dataquest (July 1998)

As demand forecast for 128Mb DRAM in four major target applications indicates, actual market acceptance is governed by price levels and the timing of model changes in each segment. Another factor is the generation shift from 64Mb to 256Mb, which is expected to occur in 2002. Once the bit price crossover takes place between 64Mb and 256Mb products, it will entail accelerated replacement of 128Mb DRAM by 256Mb DRAM. Table 1 lists 128Mb DRAM shipment schedules of eight leading DRAM suppliers in Japan and Korea.

Table 1
128Mb DRAM Shipment Schedules of Leading Suppliers in Japan and Korea

	Hitachi	NEC	Samsung	Toshiba	Hyundai	LG Semicon	Mitsubishi	Fujitsu
Samples	Q1/98	Apr 98	Q2/98	Q3/98	Q3/98	Q3/98	Q4/98	H1/99
Volume Production	Q2/98	Aug 98	Q3/98	Q4/98	Q4/98	Q4/98	Q1/99	H1/99

Source: Dataquest (July 1998)

Dataquest Perspective

In 1998, the previous hype about 128Mb DRAM is beginning to subside among leading Japanese and Korean DRAM suppliers, as they can afford less and less R&D expenditure. At present, the highest priority is given to the development of a 64Mb shrink chip, for which leading-edge fabrication processes are starting up at an accelerated pace. The next priorities will be

 ©1998 Dataquest

the 64Mb version that is adaptive to column address strobe (CAS) Latency 2 for PC100, which will take up much time toward the end of 1998, and the next-generation high-speed DRAM in 1999. Future development points to cost reduction, high speed, and large capacity. In particular, the first two areas are already subject to intensive competition. Under these situations, 128Mb DRAM, which is doomed to serve as a stopgap between 64Mb and 256Mb, inevitably lags behind in the R&D priority list.

128Mb DRAMs come in two types: the stack type to integrate two 64Mb chips into one package and the single-chip type. The stack type, already marketed by a Japanese manufacturer, is more costly than the single-chip version. Also, the use of two chips doubles input capacitance, which results in larger dynamic power loss because of charge/discharge with the switching operation, making it unsuitable for notebook PCs. Korean suppliers, originally working on the stack type, are now focusing on the single-chip version. Dataquest believes that the single chip will become the mainstay in the 128Mb segment.

Because there is a limited number of Japanese and Korean DRAM suppliers who can start volume production in 1998, the forerunners will be able to maintain leadership in the 128Mb pricing. The use in PC servers is spurred when the bit price of 128Mb becomes 1.5 to two times that of 64Mb. Dataquest expects that the total shipments of 128Mb DRAMs will reach 24.2 million units in 1999, which translates to a moderate number of 2 million per month. Thus, the initial target is set for midrange computers, workstations, PC servers, and notebook PCs; the market can be sufficiently served by the three forerunners. However, as shown in Table 1, more entrants are expected, and oversupply is highly likely in 1999.

In conclusion, the general impact of 128Mb products on the entire DRAM market can be described by two possible scenarios:

- Scenario 1: When the bit price of 128Mb DRAM constantly exceeds that of 64Mb DRAM, target markets for 64Mb, 128Mb, and 256Mb become highly distinctive: 128Mb for midrange computers, workstations, PC servers, and notebook PCs; and 64Mb for supercomputers, mainframes, and PCs. Then, once 256Mb DRAM is introduced, migration will start from the high-end segments. In this case, DRAM suppliers, particularly the three forerunners, will be able to reap profits from the business.
- Scenario 2: Generally, the semiconductor business relies on volume production for profitability. However, unless semiconductor companies listed in Table 1 discipline themselves in curtailing their output, a supply glut is hard to avoid, and price erosion will follow. The question is how far the price will decline. As the bit price of 128Mb becomes closer to that of 64Mb, desktop PC manufacturers will be enticed to use it, which will push the 64Mb price downward to trigger the price decline cycle between the two products. In this case, manufacturers having volume production capabilities of both 64Mb and 128Mb on the 0.23-micron-or-finer process will be able to have a cost advantage in 128Mb fabrication, if the production yield is more or less the same for the two products. In other words, 128Mb DRAM will be a lucrative product for companies that have

a competitive edge in leading-edge process technology. On the other hand, those without it will have to suffer a blow.

Dataquest believes that the significance of 128Mb DRAM is found not only in the fact that it breaks from the traditional quadrupling but that this device will determine the profitability of DRAM suppliers entangled in persistent excess capacity.

Perspective

Semiconductors Japan
Market Analysis

A Changing Landscape for the Japanese Foundry Business

Abstract: *This Perspective analyzes foundry business trends for Japanese semiconductor companies on the basis of Dataquest's latest foundry shipments survey results. The prolonged recession of the Japanese semiconductor market increases the capital investment burden, and alliances are needed to build the ability to produce system LSIs—the wave of the future. In the changing environment, foundry business plays a much different, increasingly active role in the industry. Foundry business is gaining new meaning for Japanese semiconductor manufacturers, which are becoming foundry users themselves rather than foundry providers as in the past.*
By Yoshihiro Shimada

Start of Dataquest's Official Foundry Survey

Dataquest has been tracking semiconductor companies' brand shipment revenue trends in the annual market share survey. In 1997, we added a new item, foundry shipments and purchase, covering gross revenue from foundry business, as well as users and technology trends. Since foundry demand is continuously on the rise, the new survey focus is designed to shed light on this demand from the foundry company's perspectives and analyze the overall impact of foundry business on the semiconductor industry.

Most Japanese semiconductor companies have their own fabs and are generally referred to as integrated device manufacturers (IDMs). Japanese IDMs characteristically ramped new fabs producing the most advanced DRAMs, and as new fabs with more advanced technology are built, the old fabs are converted to produce other devices, including MOS logic, MOS microcomponents, and later, even analog. This has been regarded as the most efficient method of fab utilization and has actually been the most typical method. This traditional conversion cycle, however, has been changing recently. Instead of converting DRAM fabs to production of other

408-468-8600

devices, companies are required to build new fabs with logic capabilities. The change is partially driven by the notable success of dedicated foundry providers led by Taiwan Semiconductor Manufacturing Company (TSMC), together with the high profitability they have demonstrated.

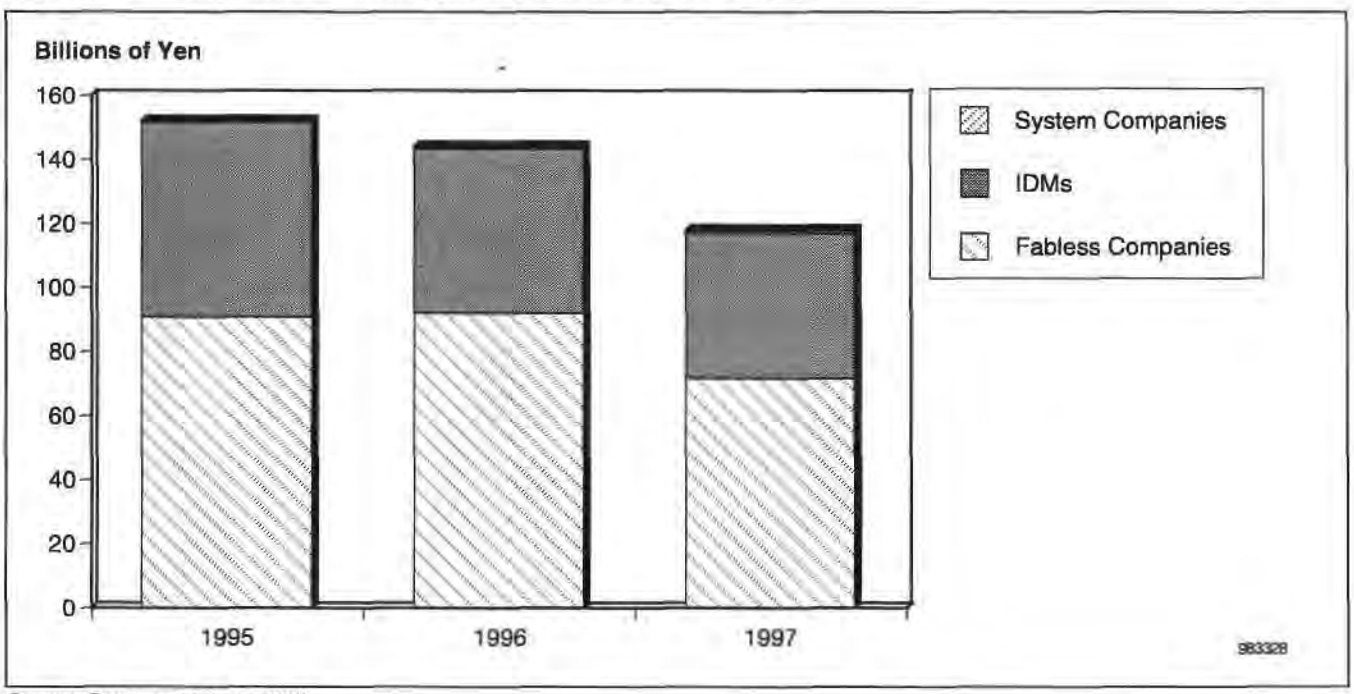
Foundry production as referred to throughout this Perspective includes the OEM production observed among Japanese and Korean companies.

Declining Foundry Shipments from Japan

In the 1997 semiconductor brand shipments ranking, Japanese companies again lost share in the worldwide market. At the same time, their total foundry shipments declined while the worldwide foundry market was expanding (see Figure 1). This makes a sharp contrast to the increasing commitment by Japanese semiconductor companies to foundry business. To put it simply, their decision came long after that of their competitors, especially dedicated foundry providers in Taiwan, who established technical leadership and developed close relationships with U.S. fabless companies.

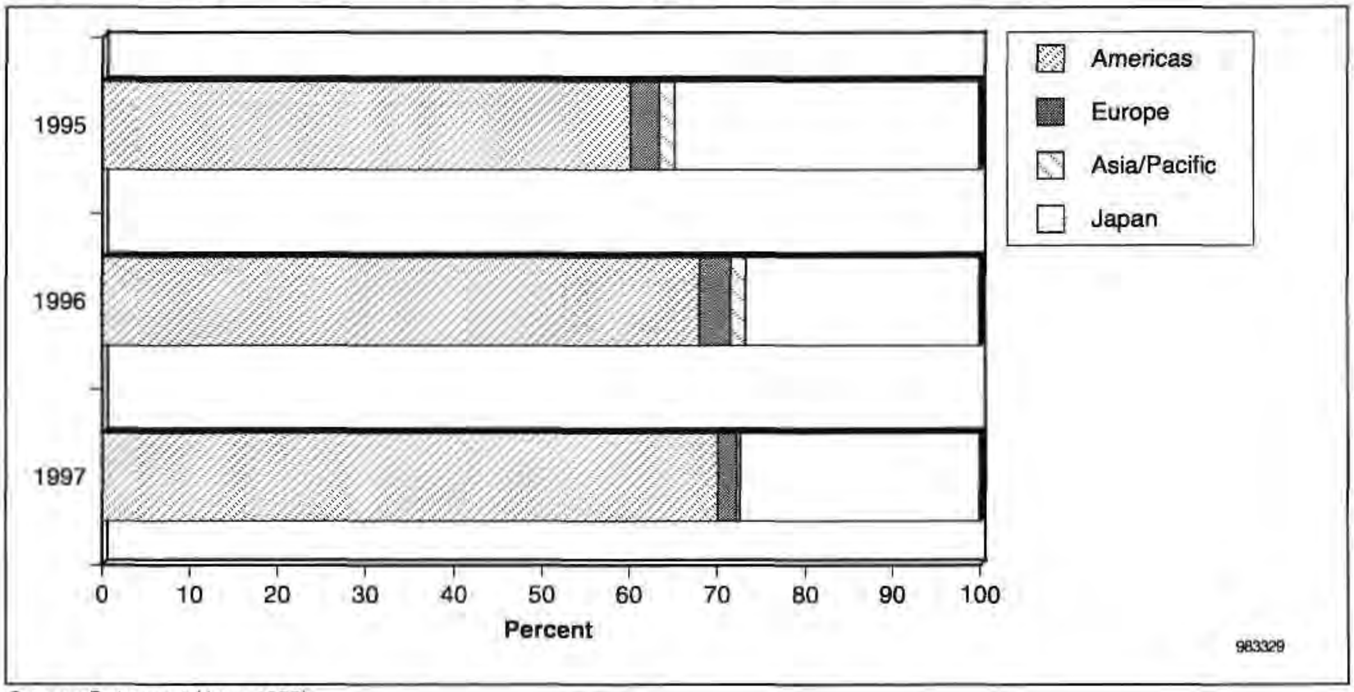
A major destination of foundry shipments by Japanese companies is the Americas market, which accounts for 70 percent of the total (see Figure 2). While the share of the Americas region has been on the rise since 1995, the absolute figure shows slight declines. This reduction in shipments comes mainly from reduced foundry business with U.S. fabless companies. At the same time, the value of shipments to the Japanese market has been declining, which reflects not only sluggish foundry contracts among Japanese companies, but also a decline in domestic delivery to foreign foundry users.

Figure 1
Japanese Companies' Foundry Shipments by User Type



Source: Dataquest (June 1998)

Figure 2
Japanese Companies' Foundry Shipments by Destination



Source: Dataquest (June 1998)

The downward trends are clearly evident in an analysis of revenue by product. The market share of logic and microcomponents, which accounts for a major portion of foundry shipments to Americas fabless companies, has dropped significantly compared to two years ago (see Figure 3). Instead, flash memory foundry has increased, with shipments from Japanese companies such as Sharp Electronics Corporation and SANYO Electric Company Ltd. to U.S. partners.

Technology trends are visible in the change in share by wafer size, down for 150mm and up for 200mm (see Figure 4). The major reasons for these changes include the following, given that 200mm fabs:

- Account for a large chunk of excess capacity because they were built during the previous boom
- Need to be operated to their capacity to vie effectively for the increasingly competitive foundry business
- Are more advanced than their 150mm counterparts in terms of design rule

The third point is substantiated by the fact that 0.5-to-0.8-micron processes using 150mm wafers lost share, while 0.5-micron or finer processes, which can be translated to 200mm fab technology, have gained sharply (see Figure 5). Finally, products with one to two metal layers lost share, while three-layer designs grew to 17 percent of the total in 1997. No contract has been won for four or more layers (see Figure 6).

These technology trends suggest that Japanese foundries are focusing on higher capacity utilization for 200mm fabs, while they still have to establish capabilities to support U.S. fabless companies.

Source: Dataquest (June 1998)

Foundry Orders on the Rise

Showing a clear contrast to declining foundry shipments, foundry orders by Japanese companies have been increasing steadily, although their worldwide share is still fairly small. While Japanese IDMs have not yet utilized their DRAM capacity fully, their logic fabs are not meeting customer demand, either in volume capacity or in technological capability. Rather than converting memory fabs to logic, which requires additional capital spending, Japanese IDMs are trying to leverage the low production cost of dedicated foundry providers. Alliances and foundry deals involving Japanese companies can be classified into the following models.

Evolution from Joint Development to Foundry Production

Primary examples are Sharp, producing flash memory for Intel Corporation, and Hitachi Ltd. and Mitsubishi Corporation, which share development and production efforts for their own brands of flash products. The intent is to reduce the R&D burdens on circuit design, process technology development, and product planning, while optimizing a production system where partners are responsible for production resources that they can provide with a comparative advantage.

Generally, the manufacture of a product developed by a partner leaves a foundry (an OEM) with relatively little value added. Still, the foundry provider can benefit by gaining experience with a product that it would be difficult to develop or market on its own, not to mention the infusion of new technology, which may enable it to develop proprietary products. This type of partnership can be mutually beneficial as long as each partner has a key technology to license. By sharing the development process from the outset, the production process can be made more reliable. At the same time, it allows the partners to maximize flexibility and efficiency in marketing their own products.

Capacity Supplementation

Traditionally, Japanese companies have seen foundry contracts as a means of using their excess capacities and keeping fabs highly utilized. In particular, when companies are hit by recession just as fabs invested in during a booming market come on line, foundry use is considered to be the "last resort" to avoid idling capacities. Companies often accept orders that are far below the ordinary break-even point for brand shipments.

Foundry deals in the form of such capacity supplementation are typically limited to a specific period, especially in the case of an IDM, that is, until the IDM's own fab is ready for start-up. In the case of an OEM deal, foundry production may be a temporary relief for the customer until it has the ability to develop and manufacture its own products. On the other hand, the OEM may rely on the foundry deal as a strategic instrument that effectively prevents the manufacturer from making inroads into the market.

At present, Japanese companies that order foundry production to supplement their capacities are primarily doing so in the DRAM field, such as Hitachi/LG Semicon, Fujitsu/TSMC, and Toshiba/Winbond Electronics.

The Hitachi/LG Semicon deal is unique in that the two companies—major players in the DRAM market with their own established brands—have entered an alliance in the form of a joint production arrangement. Hitachi also maintains a long-term relationship with Texas Instruments Inc. and operates diverse DRAM processes. This framework allows Hitachi to disperse burdens and risks related to product development and manufacture, but at the same time, Hitachi has presumably been loaded with the management of those diversified masks and processes. For LG Semicon Co. Ltd., the alliance is intended to ensure a jump-start of its new business thrust by leveraging technology and production capacities.

The other two deals differ from that of Hitachi and LG Semicon. TSMC and Winbond Electronics Corporation do not intend the first step of entering the DRAM market for foundries. The decision by TSMC to start a DRAM foundry with Fujitsu seems to represent a point of confluence for TSMC's strategy to establish "0.35-micron and beyond DRAM cell" technology, which was included in its technology road map. On the other hand, Fujitsu intends to disperse risks related to capital spending. These two companies' strategies match, which has led to their foundry deal. The Toshiba/Winbond alliance, which follows a similar pattern to the TSMC case, is characterized as part of their broader partnership, including LCDs.

Strategic Alliance

The Toshiba/Motorola alliance has served as a model for a constructive relationship between Japanese and U.S. semiconductor industries facing much-publicized trade friction. This broad-based, long-term (seven-year) relationship embraced a number of models and paved the way for a myriad of subsequent alliances. Among these were joint product development initiatives uniting the strengths of the partners, committed assistance in increased access to the Japanese market, wafer fab production at a joint venture (for instance, Tohoku Semiconductor), and factory-based collaboration in production efforts.

Nevertheless, the relationship seems to have matured to a stage requiring redefinition as the Japanese semiconductor market is losing its attractiveness in the global context and semiconductor production in the country is waning in terms of comparative advantage. The Hitachi/TI alliance faces a similar situation. Under the long-term relationship, the two companies chose a U.S. joint venture rather than a foundry contract. However, the joint venture was discontinued this March. In this sense, foundry is becoming a less desirable option for IDMs, which have traditionally used it as part of a strategic alliance. Foundry business itself increasingly makes sense on the basis of its flexible, low-cost production.

Evolution from Joint Production

Mitsubishi Electric Corporation has established Powerchip Semiconductor Corporation with UMAX Group of Taiwan to reduce financial burdens from capital spending, use the Taiwan semiconductor industry and its increasingly credible resources, and explore a new DRAM user (since UMAX is a PC motherboard manufacturer). The deal includes a new attempt to reduce the workload for marketing efforts through the joint venture, as opposed to the traditional approach that foundries are solely responsible for production. Powerchip is authorized to ship its own products in excess of a certain production level under its own brand. If this happens, shipments to Mitsubishi Electric will be on a partial foundry basis that goes beyond the traditional, narrow definition.

The Powerchip case relied on UMAX's high expectations for profits from the booming DRAM business as well as Mitsubishi's expectation of securing users for its products. In this sense, this type of alliance cannot be positioned as a general model. Nevertheless, it certainly suggests one of the feasible directions for the industry, which is seeking a way to reduce capital investment requirements by leveraging the technological prowess of each company.

This categorization seems to depict, among other things, the versatile roles of Taiwan companies. Backed by rich financial resources, they have successfully developed semiconductor production into the broad relationships shown here. Japanese PC manufacturers have accelerated procurement from Taiwan companies on an OEM basis since the mid-1990s. The viability of these complementary roles is based on the fact that semiconductor companies in the two countries are both primarily vertically integrated electronics manufacturers. This long-term relationship seems to lay the foundation for diverse alliances in semiconductor production and can serve as the core of a strategy.

Dataquest Perspective

Japanese semiconductor companies largely assume foundry business to be less than profitable, which clearly reflects the "opportunistic" nature of the Japanese foundry business model. Foundry business is forced to assume this less-than-exalted position for several reasons. First, obsolete fabs, rather than leading-edge ones, are used for foundry. Second, the primary purpose of foundry production lies in maximizing utilization. Finally, foundry production is considered a part of complementary or diverse alliances between IDMs. However, with the emergence of TSMC, which has proven the high profitability of the dedicated foundry business, Japanese companies are looking for opportunities to improve the profitability of their own foundry contracts. Many are expecting foundry deals to fill a growing gap between demand and supply capacity stemming from the prolonged recession of the semiconductor market. However, this expectation is no longer feasible, as evidenced by declining foundry revenue. Clearly, the tide has turned. The foundry market continues to establish itself by offering lucrative opportunities for specialized manufacturers. It cannot be viewed as the last resort for IDMs to replenish idling capacities.

Dr. Morris Chang of TSMC, in his recent speech at Dataquest's Semiconductor Conference 98, stated, "It is not correct to think of foundry as a manufacturing issue. Rather, foundry is a service business, and without that notion, you cannot be successful in the business." Foundry service as a reliable and viable business becomes feasible only when there is no need for

 ©1998 Dataquest

the manufacturer to adjust a process conflict with its own products, which strongly suggests the need for the specialized company.

For dedicated foundry providers, Japanese semiconductor companies can be primary customers because of their broad product lines and business structure, which require ever-growing capital spending. The benefits they offer, that is, elimination of the need for capital investment, including broad process development and optimization toward volume production, are highly attractive for Japanese companies. Not many Japanese companies, however, have a clear, corporatewide foundry strategy; only a handful of them are prepared to deploy foundry business by keeping the optimum balance with brand businesses. What Japanese companies need is to establish core competence in the semiconductor business, which entails a redefinition of "strategic domains" in many cases. Dataquest believes that it is increasingly becoming a critical management issue for Japanese companies to utilize foundry providers (especially Taiwanese companies) effectively as an integral part of the redefinition process.

Semiconductors Japan

Dataquest Predicts

Spring 1998 Forecast: Japanese Electronic Equipment Production and Semiconductor Market

Abstract: *Dataquest's spring forecast shows downward adjustments for electronic equipment production and the semiconductor market in Japan and worldwide, reflecting a clear slowdown in the electronics industry following the end of the PC boom. In the long run, however, growth of the industry will continue, along with expansion of the semiconductor market. When will we see the market bottom out from the present recession, and in what form will this occur? In particular, will the DRAM market reach its bottom this year? Will system LSI become the key to market recovery? With a focus on Japan, this Perspective analyzes electronics production and semiconductor consumption trends up to 2002, on the basis of Dataquest's latest forecast. Unless otherwise specified, world market data is indicated in U.S. dollars, and Japan market data is in yen (exchange rates: ¥121.10/$1.00 in 1997 and ¥129.73/$1.00 from 1998 through 2002).*

By Yoshihiro Shimada, Motoya Ohgami, Masahiro Suzuki, and Yoshihisa Toyosaki

Electronic Equipment Production in Japan

The Japanese economy in 1997, after a temporary surge in domestic demand prior to the consumption tax hike in April, was beleaguered by turmoil in the financial system, a decline in consumer expenditure, and a slowdown in capital spending, which was amplified by the Asian financial crisis toward the year-end. Against the backlash, electronic equipment production showed stronger growth than expected, 7.8 percent over 1996, reaching ¥23,715 billion. Cellular phones contributed greatly as fueled by a series of price cuts and the shift in demand from personal handy phone (PHS) models. Electronic data processing (EDP) equipment also outgrew the forecast, despite a slowdown in domestic PC shipments, and consumer equipment added some momentum that came from video game systems and digital equipment.

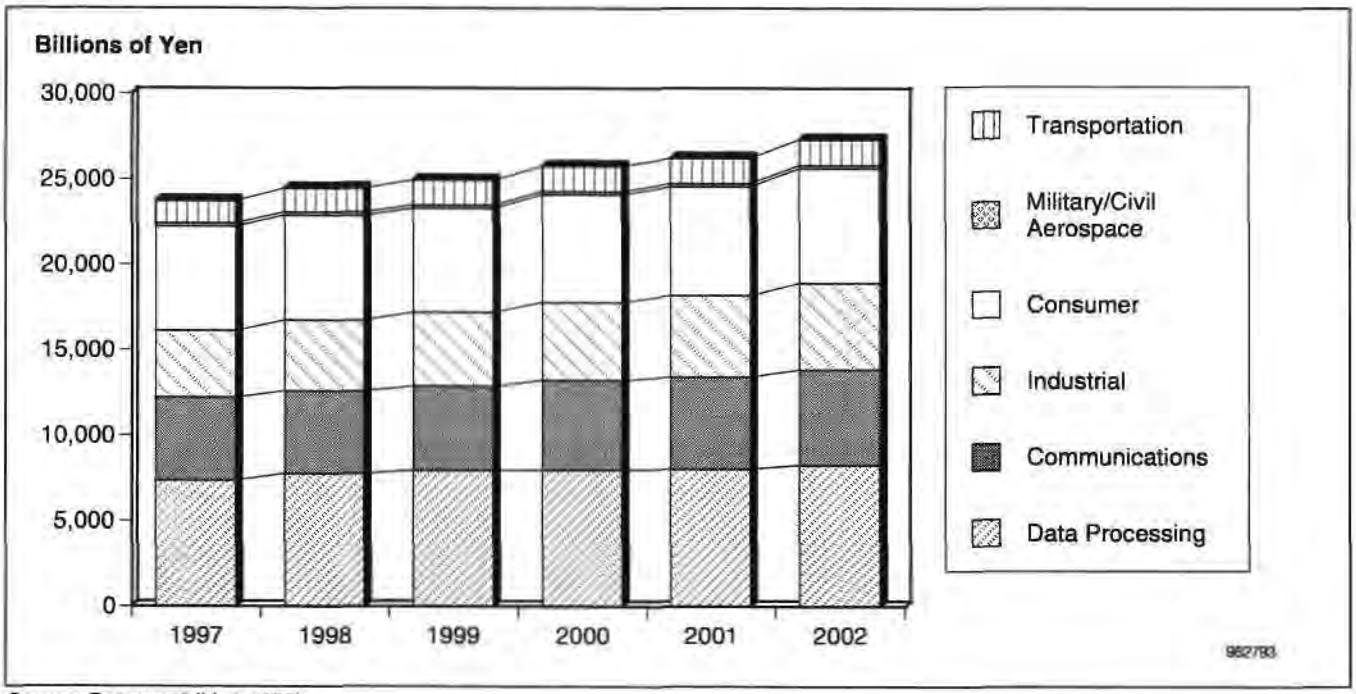
Dataquest
Program: Semiconductors Japan
Product Code: SEMI-JA-DP-9805
Publication Date: June 8, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

In 1998, communications equipment will no longer serve as a major impetus, as the cellular phone market reaches a high level of penetration and digitization of backbone networks completes its first round. Thus, Dataquest predicts that electronic equipment production in Japan will grow at a moderate 3.1 percent to ¥24,459 billion, down 1.5 percentage points from the fall forecast. Similarly, the compound annual growth rate (CAGR) between 1997 and 2002 will settle at 2.8 percent (see Figure 1).

Future growth opportunities must come from a surge in PC demand stimulated by introduction of low-cost models, and increased implementations of plug-and-play interfaces such as Universal Serial Bus (USB) and Institute of Electrical and Electronics Engineers (IEEE) 1394. While Windows 98 will not have much impact on the PC market, evolution of PCs to a new platform for WebTV and other media-mix services will hold the key to growth of demand for personal equipment.

The following section provides a detailed analysis of electronic equipment production in Japan, by major segment.

Figure 1
Japanese Electronic Equipment Production Forecast



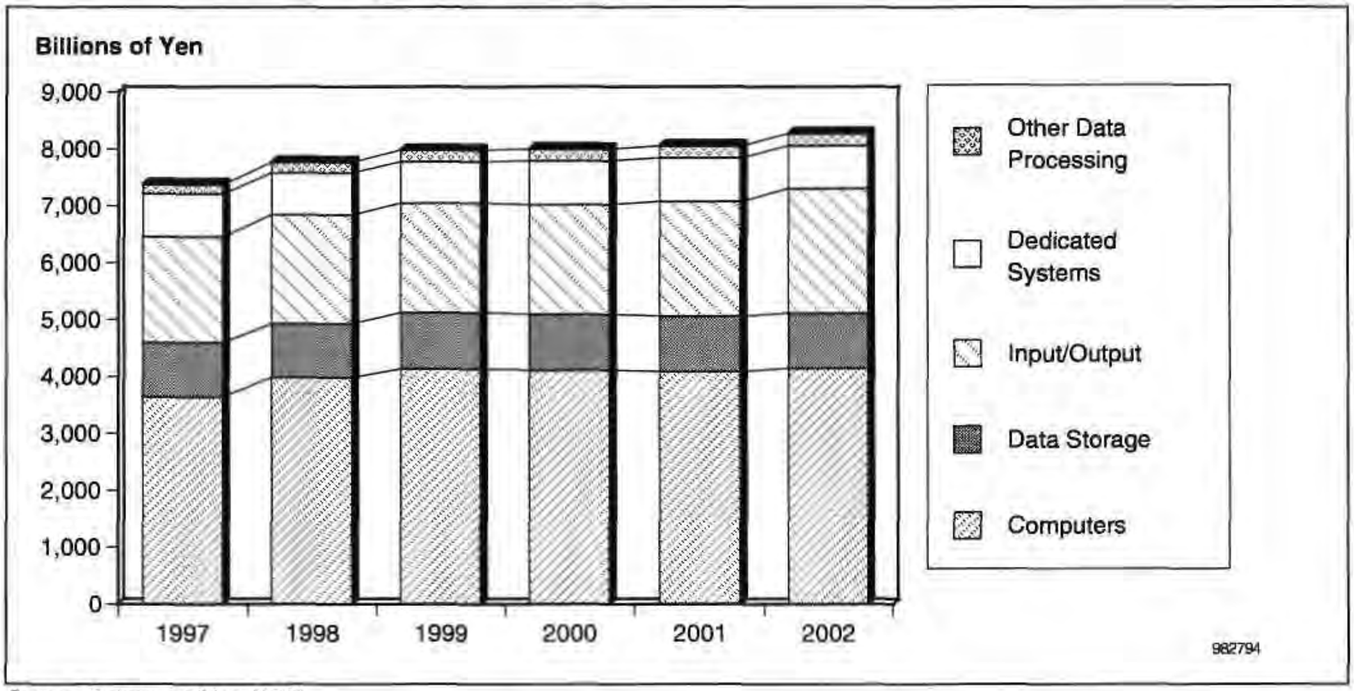
Source: Dataquest (May 1998)

EDP Equipment

In 1997, EDP equipment production in Japan soared 8.3 percent to ¥7,380 billion (see Figure 2). While PC shipments to the domestic market slowed down to less than 5 percent on a unit basis, the price decline spurred the purchase of peripherals such as printers and display units. Also, storage devices led by high-speed optical disk drives, for example, 32x CD-ROM drives and DVD-ROM drives, enjoyed strong growth. The segment is expected to drive the market in the forecast range.

 ©1998 Dataquest

Figure 2
Japanese Data Processing Production Forecast



Source: Dataquest (May 1998)

IT investment will continue to be a major driver in 1998 while Japanese financial institutions are exposed to global competition as a result of the "Big Bang," which urges them to strengthen information systems. Therefore, more than compensating for the general economic slump, computers will drive EDP equipment production, growing 5.3 percent in 1998 with a CAGR of 2.3 percent during the next five years. Gradual recovery of the Japanese economy will continue to fuel EDP equipment production after 1998, which should exceed ¥8 trillion in 2001.

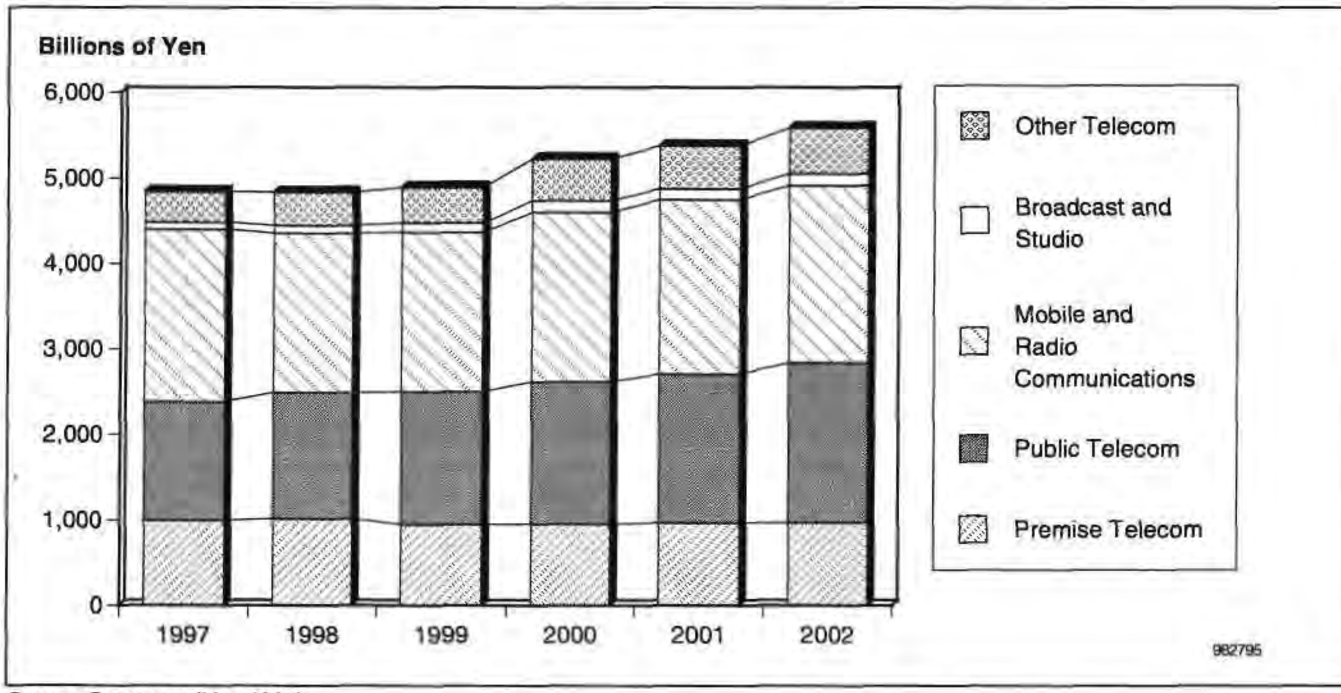
Communications Equipment

Communications equipment production in 1997 jumped 19.8 percent to ¥4,844 billion (see Figure 3). A prime driver was mobile communications equipment; subscribers grew much faster than expected, recording a net increase of 10 million in 1997. While PHS production decelerated at 7 million units, the market is expected to expand as its focus shifts from personal to office use.

Nevertheless, the penetration of mobile phones combining PHS and cellular phones has surpassed 50 percent, and continuation of previous high growth will become inevitably difficult. Meanwhile, digitization of infrastructure facilities by Nippon Telegraph and Telephone (NTT) was completed by the end of 1997. These factors will consequently put a brake on communications equipment production, which will turn into negative growth of 0.2 percent. On the other hand, network equipment, including LANs, will experience healthy growth at a CAGR of 15 percent or above. All in all, communications equipment production will grow at a CAGR of 2.9 percent between 1997 and 2002.

 ©1998 Dataquest

Figure 3
Japanese Communications Equipment Production Forecast



Source: Dataquest (May 1998)

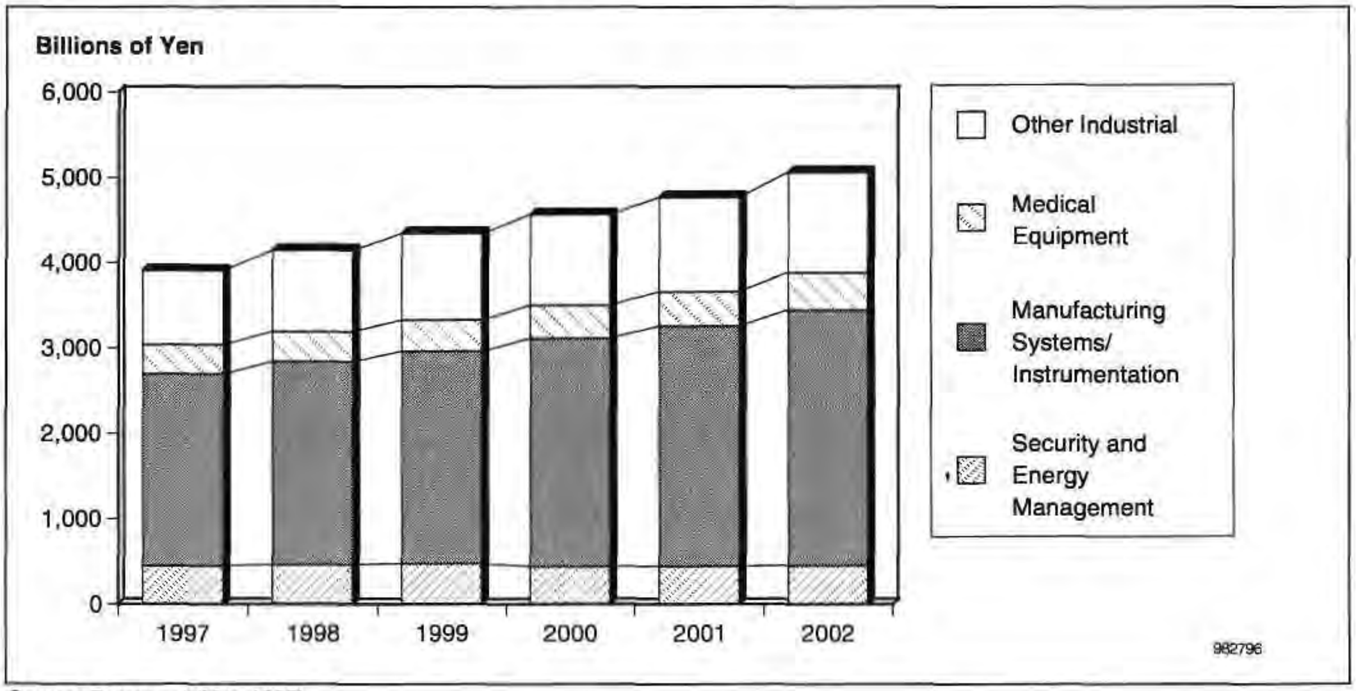
Industrial Equipment

Industrial equipment production in 1997 was up 7.2 percent, totaling ¥3,908 billion (see Figure 4). Of the total, manufacturing systems and instruments recorded the highest growth rate of 14.9 percent. As the wave of relocation of production sites to Asia/Pacific countries subsides, the focal point of the market will shift to computerization and sophistication for value addition and further automation. In particular, medical equipment will show strong growth, with increasing demand for advanced systems to meet the needs of the aging society, resulting in the CAGR of 5.2 percent between 1997 and 2002. Overall, Dataquest predicts a CAGR of 5.3 percent, the highest among the six segments.

Consumer Equipment

Consumer equipment production recorded a 1.3 percent increase in 1997, reaching ¥6,098 billion (see Figure 5). In the video equipment segment, where TVs and VCRs sold in the domestic market are mostly made overseas, it was the replacement demand for wide-screen TVs produced at domestic sites that contributed greatly. In the digital consumer equipment market, digital video cameras (DV-Cs) recorded notable growth, and unit shipments up to the end of 1997 were estimated at slightly below 1 million. The DV-C will become pervasive quickly, driven by price declines and improved availability of key components. Similarly, digital still cameras (DSCs) will ramp up rapidly as they can be easily connected to PCs or TVs via a flash memory card or IEEE 1394 interface. On the other hand, commercialization of digital TVs will have to wait until after 2000 as infrastructure construction has been delayed.

Figure 4
Japanese Industrial Equipment Production Forecast



Source: Dataquest (May 1998)

The current recession will hit household appliance production directly, leading to negative growth in 1998. Video game systems will continue to be a fierce battlefield for a 32-bit hegemony, but production will remain mostly unchanged in 1998, until the next-generation products are introduced in 1999. Dataquest predicts that consumer equipment production as a whole will grow at a CAGR of 1.9 percent between 1997 and 2002.

Japanese Semiconductor Market

In 1997, the Japanese semiconductor market recorded negative growth on a dollar basis, becoming the only market to shrink among the four world regions. Although the yen depreciation diluted the dollar-based figure, the fact remains that the Japanese market is the weakest of the four regions. While electronic equipment production grew faster than previously forecast, semiconductor consumption was sluggish. This indicates that a major source of growth in electronics production came from the segments with little semiconductor content. Also, PC shipment lost momentum in Japan, exerting negative impact on consumption of a variety of semiconductor products, including memory, microprocessors (MPUs), and logic.

The Japanese semiconductor market in 1998 will grow at 9.8 percent (2.5 percent on a dollar basis), down from the fall forecast (see Figure 6). While this reflects the anticipated slowdown in electronic equipment production and the hovering market conditions for DRAMs, a recovery is expected in the second half, leading to double-digit growth. Nevertheless, the CAGR

 ©1998 Dataquest

between 1997 and 2002 will be the lowest among the four regions, at 12.4 percent (10.9 percent on a dollar basis).

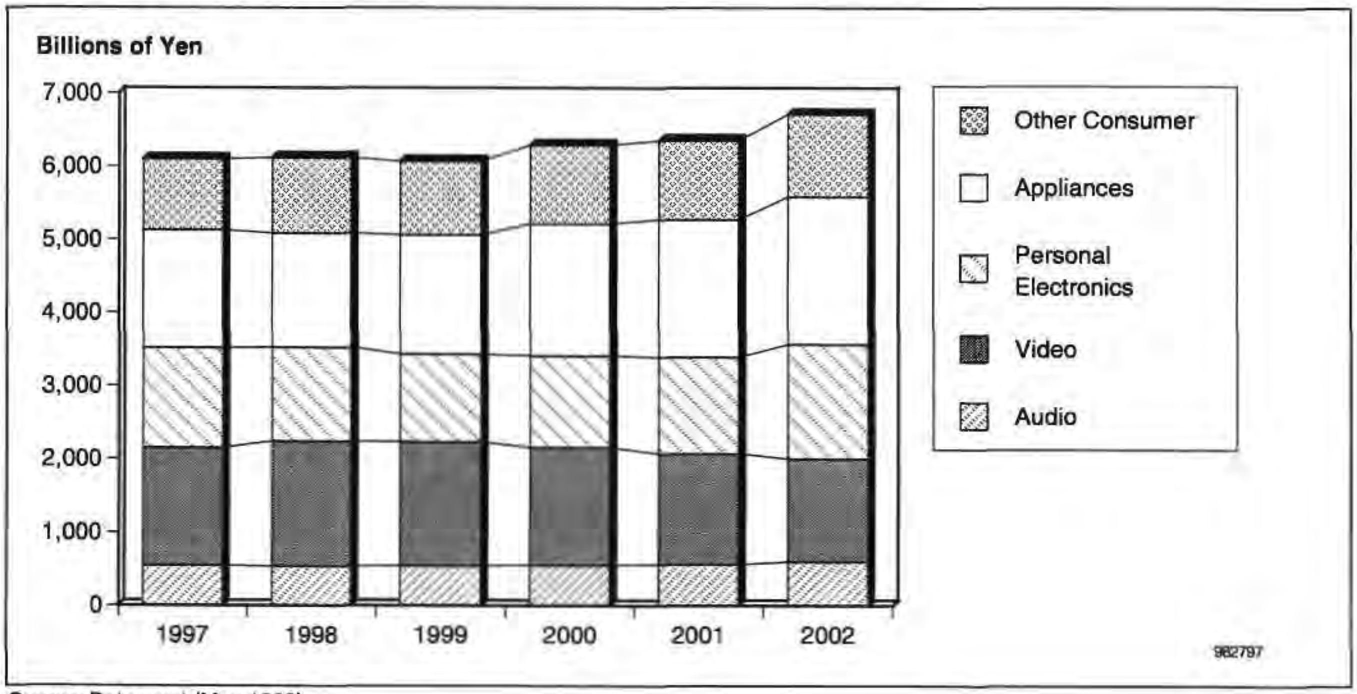
The following section analyzes the future outlook for the Japanese semiconductor market by device.

MOS Memory

In 1997, the Japanese MOS memory market suffered a 14.5 percent decline (23.1 percent on a dollar basis) (see Figure 7). Dataquest predicts that the 1998 market will grow 7.0 percent (a 0.1 percent decrease on a dollar basis), which represents a downward adjustment of 6 percentage points compared to the fall forecast. Again, DRAM price decline because of supply glut is the major culprit. While increased 16Mb production by U.S. companies triggered the price fall in 1997, the aggressive moves of Korean suppliers will dictate DRAM prices. At present, 16Mb prices continue to fall below $3 on the spot market, which pulls 64Mb prices downward.

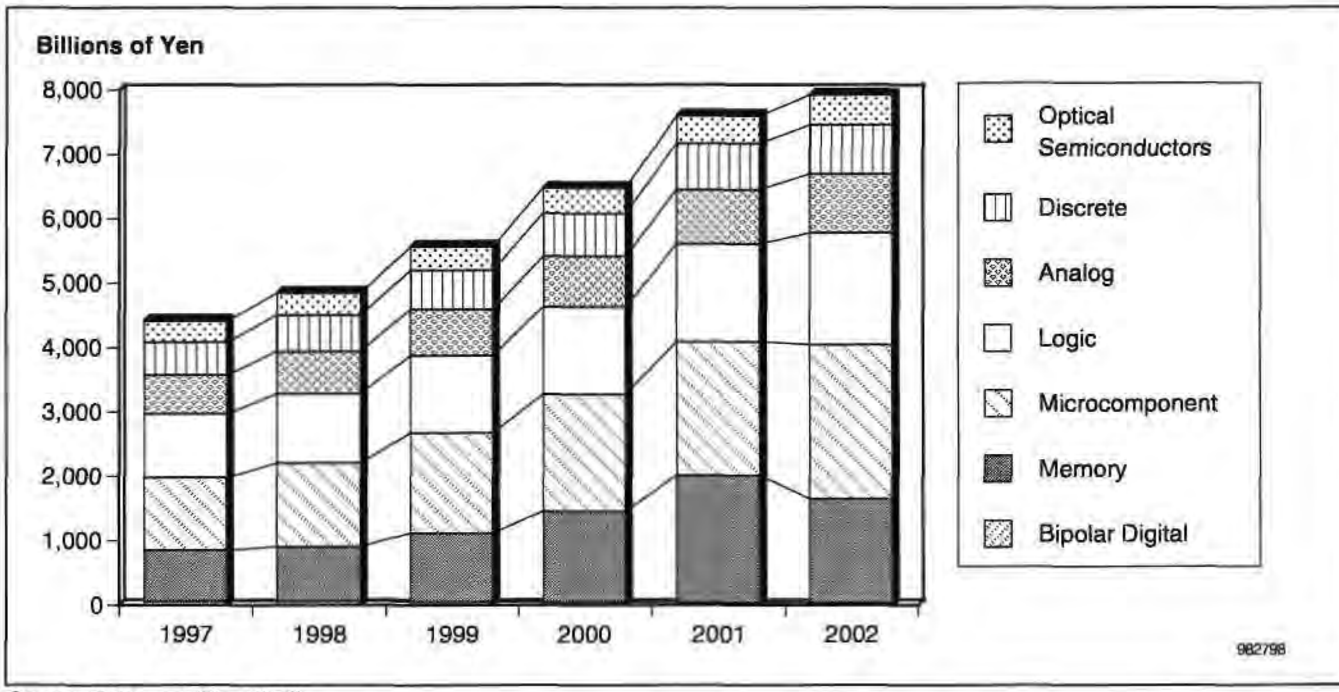
The Japanese MOS memory market in 1998 will be driven by SRAM, EEPROM, and flash memory. In particular, after 1999, the DRAM market will expand at an accelerated pace, while SRAM and nonvolatile memory markets will maintain healthy growth. In 2002, however, the DRAM market will experience negative growth as the generation crossover from 64Mb to 256Mb occurs. Dataquest predicts that the market's CAGR between 1997 and 2002 will be 15.4 percent (13.8 percent on a dollar basis).

Figure 5
Japanese Consumer Equipment Production Forecast



Source: Dataquest (May 1998)

Figure 6
Japanese Semiconductor Consumption Forecast



Source: Dataquest (May 1998)

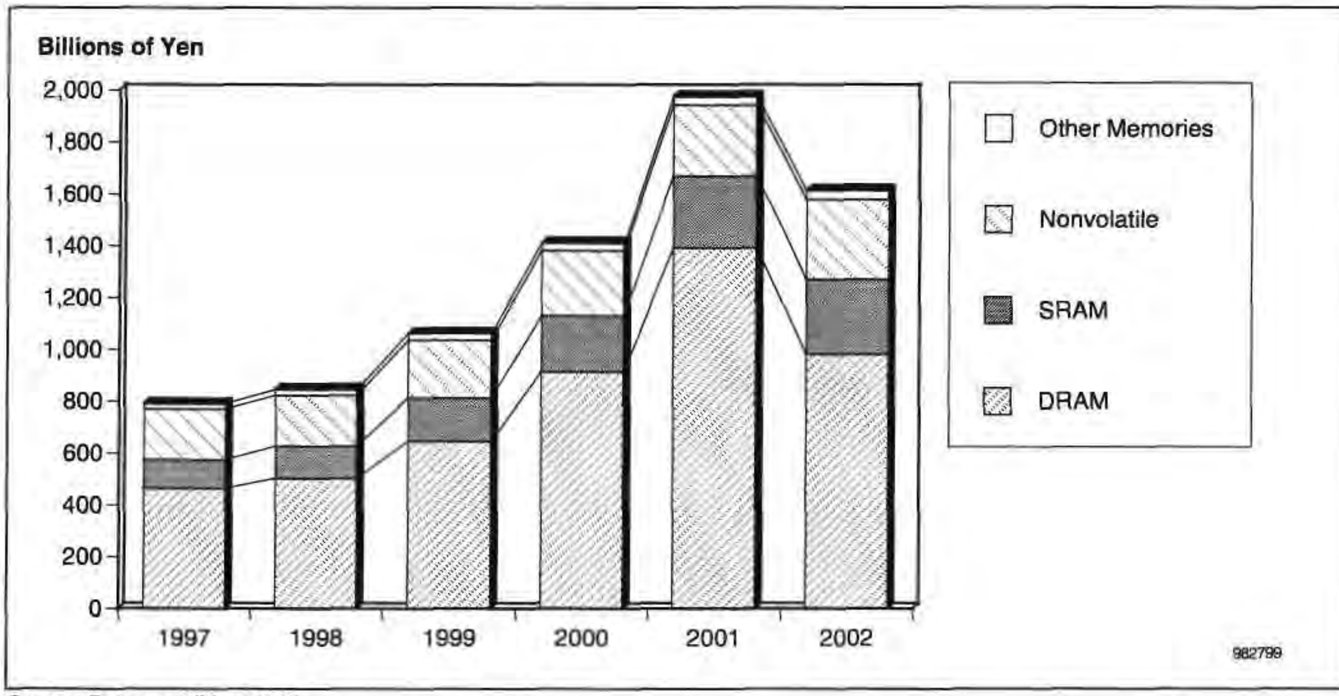
While the fall forecast assumed that DRAM companies would curtail capital spending in 1998, they are currently moving to minimize the rate of investment cutbacks where possible. In particular, Korean companies are considering maintaining capital spending as close as possible to the 1997 level (on a won basis), despite the DRAM recession and the pain from the AFC. Dataquest pointed out in the fall forecast that a major reduction of 64Mb-production capacity would be required to regain revenue growth in 1998. However, DRAM companies are not reducing capital spending as much as expected, which necessitated the downward adjustment of the DRAM market growth forecast.

In 1998, a major event in the DRAM market will be a full-blown shift from extended data out (EDO) to synchronous DRAM (SDRAM). During the first half of 1998, 100-MHz SDRAMs for PC100 will keep a price premium against 66-MHz versions, which will significantly narrow in the second half as DRAM companies roll out 0.25-micron fab lines. After 1999, the Japanese DRAM market will be driven by better-managed capacity expansion by DRAM suppliers, recording a CAGR of 16.1 percent (14.6 percent on a dollar basis) between 1997 and 2002.

The Japanese nonvolatile memory market will be up slightly 0.3 percent (6.3 percent down on a dollar basis) in 1998 because of double-digit declines in EPROM and mask ROM, which will more than offset the 20 percent growth of EEPROM and flash segments. The CAGR between 1997 and 2002 will be 9.6 percent, as the market will be driven by EEPROM and flash memory.

 ©1998 Dataquest

Figure 7
Japanese Memory Consumption Forecast



Source: Dataquest (May 1998)

The Japanese flash memory market recorded negative growth of 9.8 percent in 1997, but it is expected to resume growth in 1998. Major applications include mobile communications equipment, led by cellular phones as well as IC cards. In particular, smart phones are expected to ramp up early in Europe, becoming an important consumer of flash memory. This is expected to a have a positive impact on the Japanese mobile communications and flash memory market.

In the MOS memory market, Japanese semiconductor companies still strive to become less dependent on DRAM business. Large suppliers will increasingly shift their strategic focus to flash memory. The 1997 flash market saw price declines in 8Mb-or-less products. Dataquest expects that the move will spread to 16Mb-or-larger segments in 1998 and after.

MOS Microcomponents

The Japanese MOS microcomponent market will expand 15.2 percent (7.5 percent on a dollar basis) in 1998 (see Figure 8). The CAGR between 1997 and 2002 will be 16.2 percent (14.6 percent on a dollar basis) with firm growth expected for each year.

The Japanese MPU market in 1998 will fail to meet the previously forecast level because of the slowdown in the PC market. The market should grow at 12.6 percent (5.1 percent on a dollar basis). The market will see a wider variety of products besides Intel's X86 families (Pentium with MMX technology, PentiumPro, and MMX Pentium II). Products will include non-Intel, high-speed MPUs, MPUs for low-cost PCs, and MPUs designed for

 ©1998 Dataquest

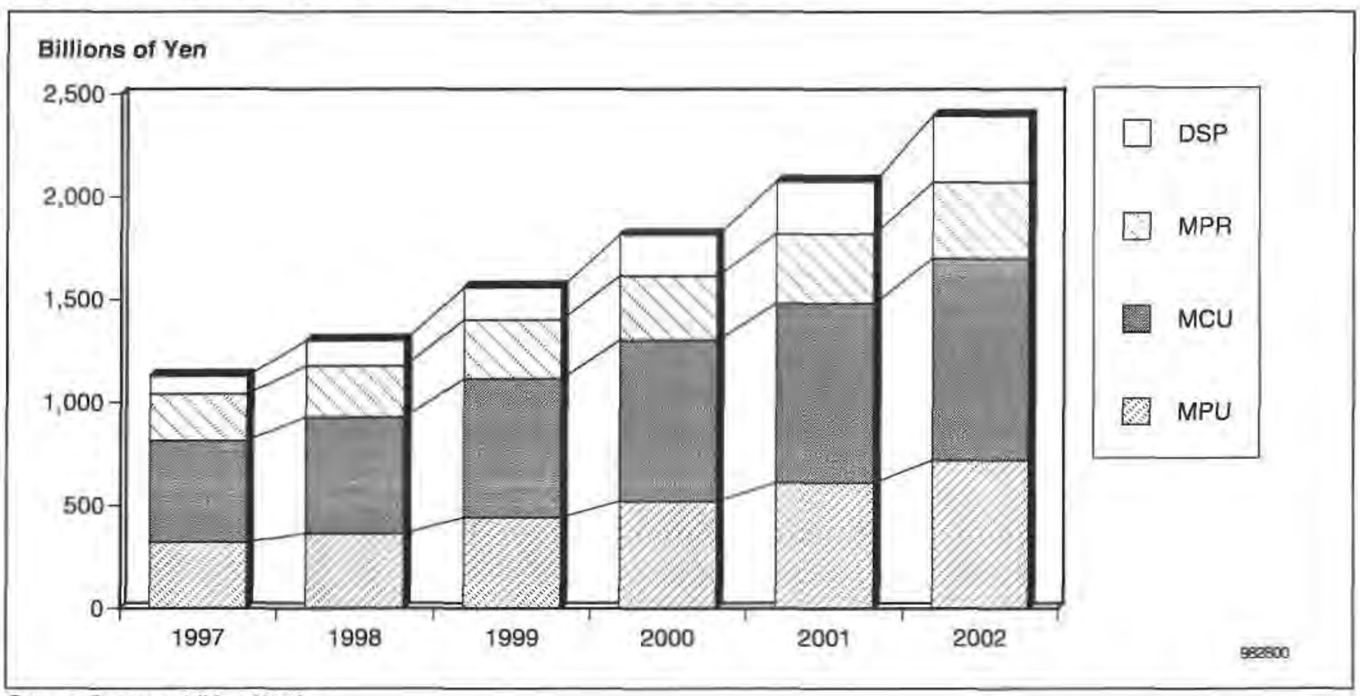
portable applications, including mobile computing (embedded MIPS, SH, Strong ARM), for example, Tillamook, Mobile Pentium II, and Windows CE2.0.

Microcontrollers (MCUs), the largest of the Japanese microcomponent segments, are expected to surge 15.1 percent (7.4 percent on a dollar basis) in 1998. They are incorporated into a variety of electronic equipment. Low-bit versions are embedded into household appliances for system control purposes, many of which are implemented on a 4-bit or 8-bit basis. Japanese companies still hold a dominant share in the 4-bit segment.

Four-bit MCUs are used in diverse products ranging from toys to analog cordless telephones, and companies are still exploring new applications. Nevertheless, the market size will grow only moderately, partly because of the weakening demand from portable game systems, which have been a major driver, and partly because of increased migration to 8-bit products. In particular, revenue growth will be minimal because of low prices, although unit growth may continue.

On the other hand, the 8-bit MCU market will enjoy strong growth as a result of upgrading from 4-bit applications and the need to address the increasing complexity of system control. Development of MCUs embedding flash-memory technology is under way, and the competition has heated up among U.S., European, and Japanese companies for market share.

Figure 8
Japanese Microcomponent Consumption Forecast



Source: Dataquest (May 1998)

In 1997, 8-bit MCUs were used in most electronic equipment, including the following range of products:

- Video and audio equipment
- Computer-related equipment, including keyboards and display units
- Communications equipment, including analog cordless telephones and digital portable telephones
- Antilock braking systems (ABSs)
- *Pachinko* game systems
- Household appliances

Applications expected to emerge in 1998 and afterward include smart cards, minidisc (MD) players, USB controllers (8-bit basis), and MCUs incorporating Infrared Data Association (IrDA) communications features. Encouraged by potential demand for contact/noncontact IC cards, semiconductor companies will opt for alliances to consolidate technological resources and vie for industrial standards. Finally, MCUs integrating ferroelectric memory technology will be introduced to the noncontact IC card market to invigorate the 8-bit MCU market.

Sixteen-bit MCUs, on the other hand, will be increasingly used for digital processing applications, particularly digital cellular phones, PHS phones, hard disk drives (HDDs), and CD-ROM drives. Applications expected in 1998 and afterward include DVD, fixed and on-board audio MD players, and DV-C. Again, flash memory technology will be increasingly incorporated to address system requirements in terms of flexibility, and semiconductor companies will focus on enhancement of their offerings.

As for 32-bit and 64-bit MCUs, system-level integration (SLI) based on ASIC technology will become the mainstay. Promising applications that will be developed after 1998 by using a leading-edge process and an embedded MPU include vehicle information and communication system (VICS)-based car navigation systems incorporating DVD-ROM drives, next-generation home/portable video game systems, and set-top boxes (STBs). Sixteen-, 32-, and 64-bit MCUs will enjoy strong growth next to 8-bit products, driven by price declines resulting from SLI, the emergence of digital consumer equipment, and digitization of systems. Dataquest expects solid profitability.

In 1997, rapid growth was seen in the flash MCU market. Major applications include memory cards for video game systems, CD-ROM drives, and HDDs, spurring consumption of 8- and 16-bit MCUs. As for multibit, embedded MPU (MCU) architectures, ARM will be rapidly accepted in 1998 and afterward. Diverse architectures offered by vendors (MIPS, M Core, SH, SPARC, PowerPC, and X86) will be optimized for different applications according to their SLI strategy.

In 1998, the Japanese microperipherals (MPR) market is expected to grow 9.6 percent over the previous year (2.3 percent on a dollar basis). A variety of PC peripherals based on PC98 standards will become pervasive, and different application-specific standard product (ASSP) segments (chipset, USB, IEEE 1394, and MPACT1/2) will grow in relation to different applications.

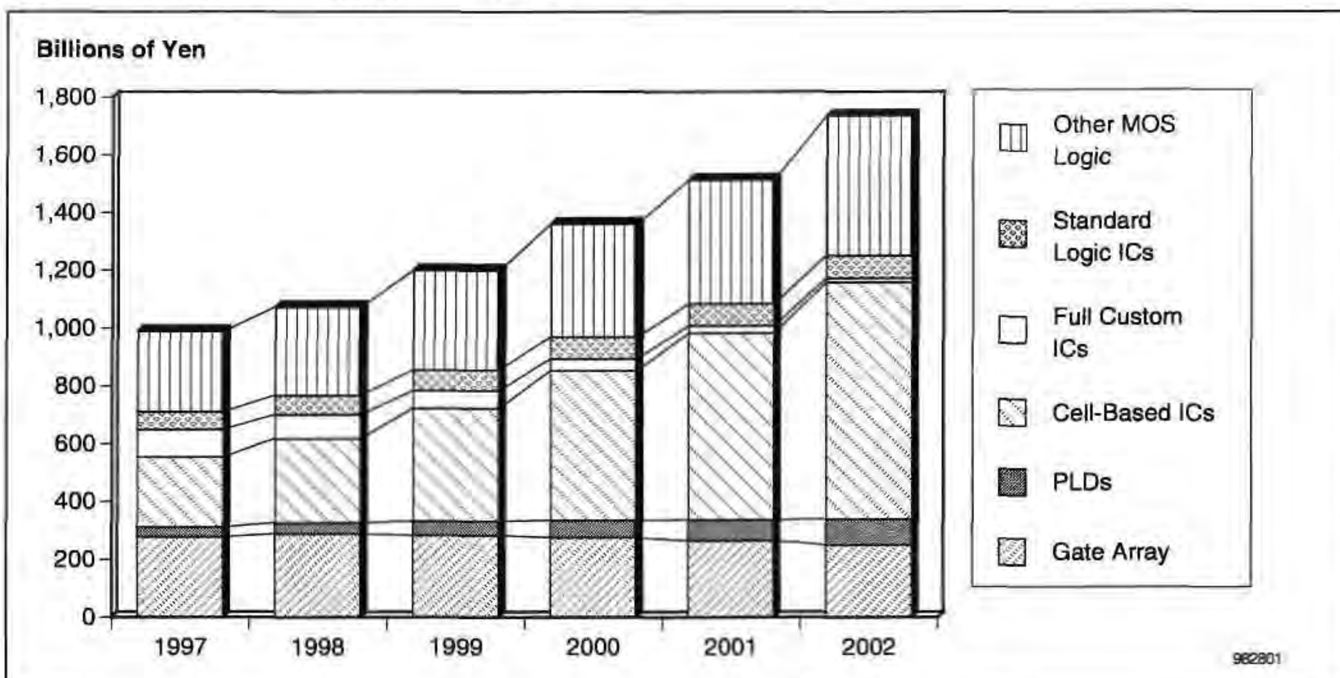
The Japanese digital signal processor (DSP) market will continue strong growth of 39.8 percent (30.5 percent on a dollar basis) in 1998. With the increasingly shortened development cycle for system products, DSPs and media processors will undoubtedly become core technologies as they offer flexibility in development of digital consumer equipment with the ability to reconfigure themselves by replacing middleware/microcode. By 2002, 0.18-to-0.12 micron processes will be commercialized. As a result, the DSP market will grow strongly at a CAGR of 29.7 percent (27.9 percent on a dollar basis) between 1997 and 2002.

Finally, embedded DSPs are increasingly incorporated into servo controllers for CD and MD players as well as codec processing for cellular phones. Generic DSPs including media processors are primarily used in high-speed analog modems (56Kbps) for PCs and sound source processing. New applications emerging in 1998 and afterward include digital cellular phones, which use a single chip integrating a 16/32 bit MCU and DSP, HDD controllers containing DSP/MCU and DRAM for buffer memory, and high-speed disk drives such as DVD-ROM/RAM, incorporating partial response maximum likelihood (PRML) technology and DSP.

Logic/ASICs

In 1998, the Japanese total logic market will grow 8.7 percent (1.5 percent on a dollar basis). The total ASIC market will expand 11.8 percent (4.3 percent on a dollar basis) (see Figure 9).

Figure 9
Japanese Logic Consumption Forecast



Source: Dataquest (May 1998)

In 1997, high-performance systems, as seen in digital consumer equipment, were implemented to incorporate multiple, large-scale circuits by using intellectual property (IP) core and leading electronic design automation (EDA) tools. We also saw a rapid increase in volume production of ASSPs and SLI ASIC products in single-chip implementation by using a highly integrated ASIC process and SLI technologies. A future challenge lies in reducing the cycle time for system development to minimize turnaround time (TAT) and R&D investment, reduce development-related risks, and support early LSI implementation.

Traditionally, the "core-limited design" issue, derived from large-scale internal cores, was a major obstacle in designing ASICs. Recently, however, as the ASIC process reached submicron levels, the shrink ratio of the internal core has been improved. This, in turn, has resulted in an increase in the "I/O pad-limited design," where I/O pads set the limit rather than cores. Also, flexibility in ASIC design to result in small-lot production adversely affects the profitability of business.

Many leading ASIC vendors in the Americas region started to de-emphasize gate array business by 1997. This move is favorable for the programmable logic device (PLD) market and accelerates the collapse of the U.S. gate array market. Technically, PLDs have already integrated 250,000 to 500,000 gates on a commercial basis by using process technology based on 0.25-micron, five-layer interconnect, and shallow trench structure. Dataquest believes that 1 million gates will be integrated by using a 0.18-micron process technology by 2000.

In 1998, the Japanese PLD market will show a strong growth of 15.6 percent (7.9 percent on a dollar basis). In Japan, the gate array business still dominates because of high captive demand. Nevertheless, as SLI will lead ASIC business in the future, the Japanese PLD market will grow to an appreciable size compared to the Americas market. Dataquest expects that the market will register the second-highest growth rate, following cell-based ICs (CBICs), with a CAGR of 21.3 percent between 1997 and 2002.

The Japanese CBIC market (including mixed signal) will grow 20.7 percent (12.7 percent on a dollar basis) in 1998. The ramp-up of 0.35- to 0.25-micron process manufacturing and the increasing need for design optimization in various applications have been driving the market for CBICs, which are regarded as the key infrastructure factor in SLI technologies such as embedded MPUs/DSPs, IP core, embedded memories, and mixed-signal designs. At the same time, the establishment of CBIC technology has caused the custom IC market to shrink rapidly, resulting in the negative CAGR of 15.2 percent (20.8 percent on a dollar basis) between 1997 and 2002.

At present, standard logic features such as small-scale integration (SSI), middle-scale integration (MSI), and large-scale integration (LSI) are mostly incorporated into ASICs, but demand for standard logic still exists in the area of super high-speed CMOS- or BiCMOS-based standard logic, such as CMOS-based one-gate logic products and wide bus products. Thus, the Japanese standard logic market will continue to grow steadily at a CAGR of 5.1 percent (3.7 percent on a dollar basis).

Finally, LCD drivers classified as other MOS logic will be driven by increased market acceptance of LCD-equipped systems as well as exploration of new application markets. As a result, the Japanese market's CAGR will be 11.8 percent (10.3 percent on a dollar basis) during the five-year period.

In 1998, ASIC suppliers announced a number of next-generation 0.18-micron processes, and some of them in Japan and the United States started volume production. Also development efforts are under way to commercialize a "unified process" that represents a "dream process integration." Dataquest believes that portable applications in the Japanese market will contribute to technological progress in the areas of ultralow operating voltage below 1.0V, embedded flash memory, mixed-signal designs, and high-density packages such as chip-scale packaging (CSP) and direct chip attach (DCA), thereby driving the SLI ASIC market.

Other Devices

The outlook for analog, discrete, and opto markets has been adjusted downward from the previous forecast. It should be noted that the analog market was partially affected by reclassification of linear array and mixed signal ASICs (although small in size) into total ASICs.

Dataquest sees that strong demand growth for analog ICs in the past few years has caused the industry to hold unduly high expectations. With the rapid progress of system diversification, accompanied by LSI implementations over several generations, demand for analog ICs and discrete devices experiences a momentum surge. Nevertheless, expansion of mixed-signal analog IC markets will ultimately lead to CBICs absorbing analog functions, so that suppliers tend to overestimate long-term demand by extrapolating the recent high-growth trends. Also, sluggish electronics production causes demand for generic analog devices to slow down.

In the first quarter of 1998, suppliers do not seem to be accelerating analog capacity, partly because of heavy constraints on investment resources. If supply capacity expands abruptly, prices will plummet to result in unit growth without revenue growth. Given this cap for capacity expansion, Dataquest believes that it is difficult for the Japanese analog market to continue double-digit growth.

Dataquest Perspective

After the rapid progress of production site relocation to the Asia/Pacific countries, electronic equipment production in Japan has increasingly depended on the domestic market by building high-value-added production capacities. Given the economic slump and curtailed personal spending in response to the gloomy outlook, digital consumer equipment incorporating advanced technologies fails to create a market opportunity, despite its great potential. Thus, strong growth of electronics production hinges highly on whether the ongoing attempt to reinvigorate domestic consumption can spur demand for new digital consumer equipment and personal information equipment.

©1998 Dataquest

The slack state of electronic equipment production is directly reflected in softened semiconductor demand. At present, Japanese semiconductor companies sell about 50 percent of their products to the domestic market, even though Japan is expected to show the weakest growth trends in the forecast range years. If slow growth persists, overseas strategies cannot help being affected seriously. If the foreign exchange rate does not change significantly, and manufacturers opt to site production capacities near their markets, the increasing weight of overseas markets will cause Japanese companies to boost overseas production. Manufacturers lacking distribution channels other than Japan and the Asia/Pacific region will not be able to survive under the traditional strategy. This may create a dramatic change in the industrial landscape, including semiconductor equipment and materials.

The industry seems to expect a paradigm based on a new market driver: the development of digital consumer equipment by offering SLI-based solutions. Before that, it must answer a question raised in relation to the development of 300mm wafer fabs: "Will there be a market large enough to absorb the explosive growth of supply capacity?" Unless the industry finds an answer, it cannot rely on the domestic market as it has in the past. While Japanese companies have to streamline their business from nontechnological perspectives, such as the introduction of supply chain management, they may have to redefine their global operations and business structure. Dataquest believes that the industry's future lies in its ability to determine whether the redefined business structure serves the overall interest of maintaining business efficiency and whether it can adapt to the change derived from the redefinition process.

Perspective

Semiconductors Japan
Market Analysis

The Present and Future of the Japanese Semiconductor Equipment Industry

Abstract: *The Japanese semiconductor device industry thrived on its DRAM business, but it is now being threatened by the Korean and Taiwanese competitors. The prosperity of the device industry led to the eminence of the wafer fab equipment industry. Today, Japanese equipment suppliers share the world market equally with U.S. competitors, with different industry structures that reflect the characteristics of the device industries of the two countries. This Perspective discusses the position of the Japanese wafer fab equipment industry on the basis of the two clearly distinguishable semiconductor markets and discusses opportunities and issues facing the industry.*
By Takashi Ogawa

The Japanese Semiconductor Equipment Industry Is Prosperous

According to Dataquest's survey, the world wafer fab equipment market in 1996 reached $21.68 billion, of which Japanese companies earned $8.75 billion and held a 40 percent share. Figure 1 shows the total semiconductor revenue of Japanese companies between 1982 and 1996, together with revenue from DRAM and wafer fab equipment. During that period, Japanese companies' semiconductor revenue recorded a compound annual growth rate (CAGR) of 17.4 percent. As is already widely known, Japanese companies earn a higher percentage of their semiconductor revenue from DRAM sales (the DRAM ratio) than U.S. companies. In 1996, the average DRAM ratio among U.S. chipmakers was 7 percent, while that of Japanese companies was a lofty 23 percent. This is closely associated with the development history of the Japanese device industry, which is equated with the DRAM business that has recorded such phenomenal success.

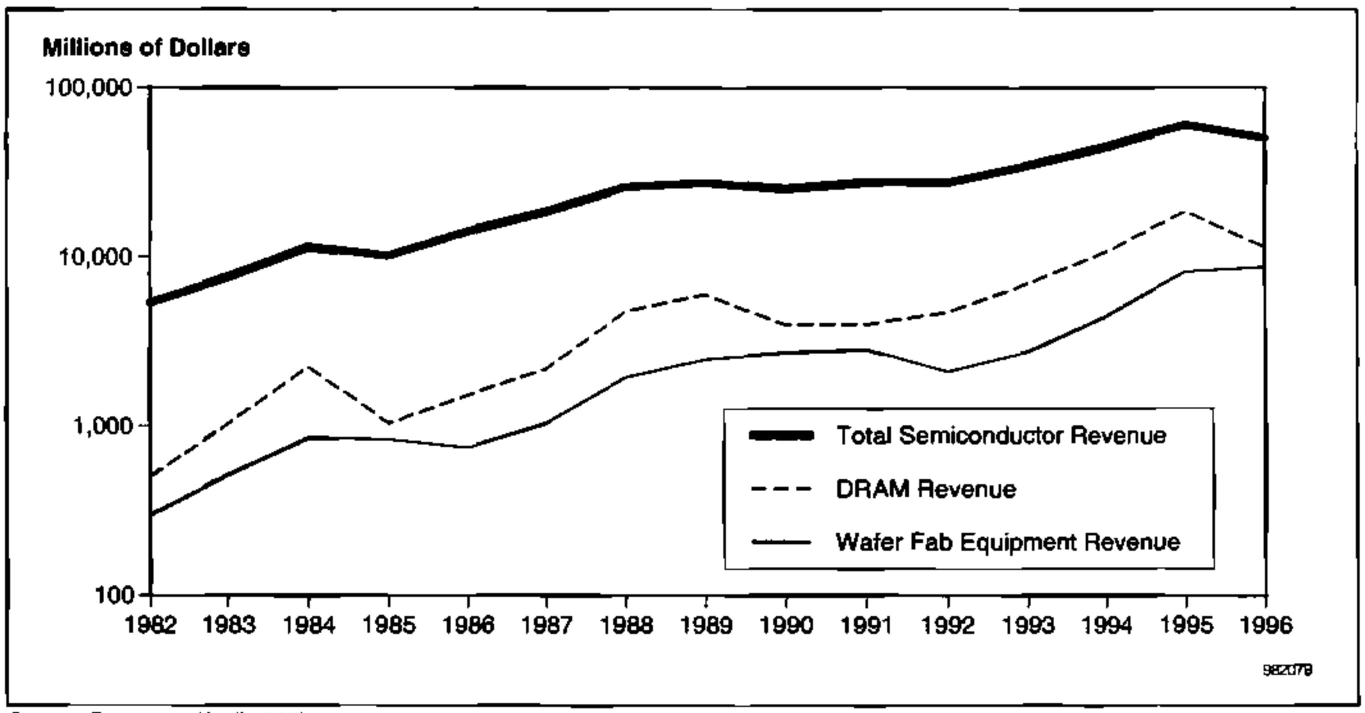
Between 1982 and 1996, the Japanese DRAM industry maintained strong growth at a CAGR of 25 percent. The growth path virtually synchronized with growth in sales of wafer fab equipment supplied by Japanese companies, which grew 30 times from $298 million to $8.75 billion during the period, at a CAGR of 27 percent. Semiconductor manufacturing technologies share common ground with device process technologies, so the emergence of a new process technology or the enhancement of existing technology spurs the birth of new production technology and equipment. Adoption of the new technology then leads to the emergence of a market.

Analyzing the history of semiconductor device development reveals a complementary relationship between wafer fab equipment technologies and device process technologies; both served to support the remarkable growth of the semiconductor industry. In other words, the device market and the equipment market have been evolving in closely related patterns that reflect their specific characteristics.

Figure 1
Changes in Japanese Companies' Semiconductor and Wafer Fab Equipment Revenue, 1982 to 1996



Source: Dataquest (April 1998)

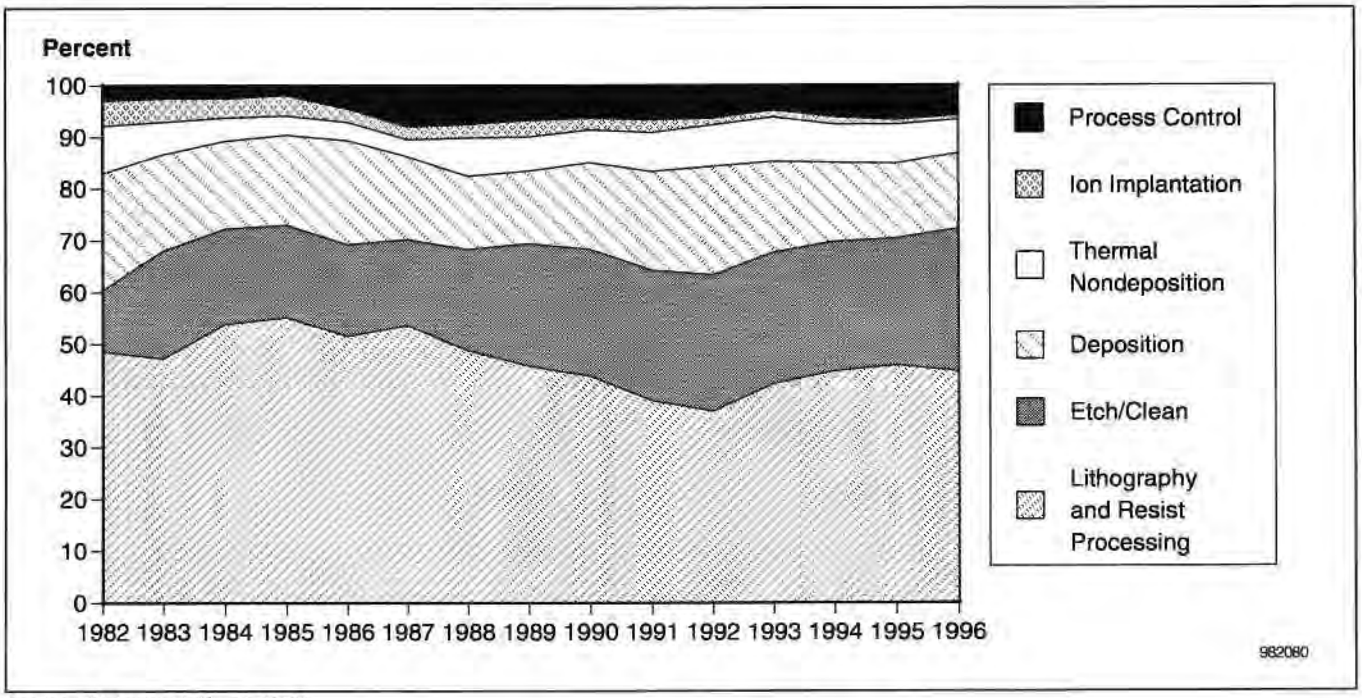
Why Is the Japanese Wafer Fab Equipment Market the Way It Is?

In Japan, semiconductor production technology has evolved in close association with development of DRAM process technology. In the 1970s, Japan, under a near-national consensus to develop the semiconductor industry as a strategic sector, established several consortia, such as the VLSI Technology Research Association, which aimed to develop key process technologies. The industry used these projects to build a technological

 ©1998 Dataquest

infrastructure in key areas such as exposure, deposition, and wafer fabrication. In the development process, a number of semiconductor equipment makers worked together with device makers. As they entered the nascent market, industrial leaders such as Nikon Corporation, Canon Inc., Kokusai Electric Co. Ltd., and Ulvac Japan Ltd. prepared themselves for success. More important, certain characteristics emerged and cemented the market. Figure 2 shows a breakdown of wafer fab equipment revenue by Japanese companies between 1982 and 1996 by segment.

Figure 2
Changes in Japanese Companies' Wafer Fab Equipment Revenue, by Segment, 1982 to 1996



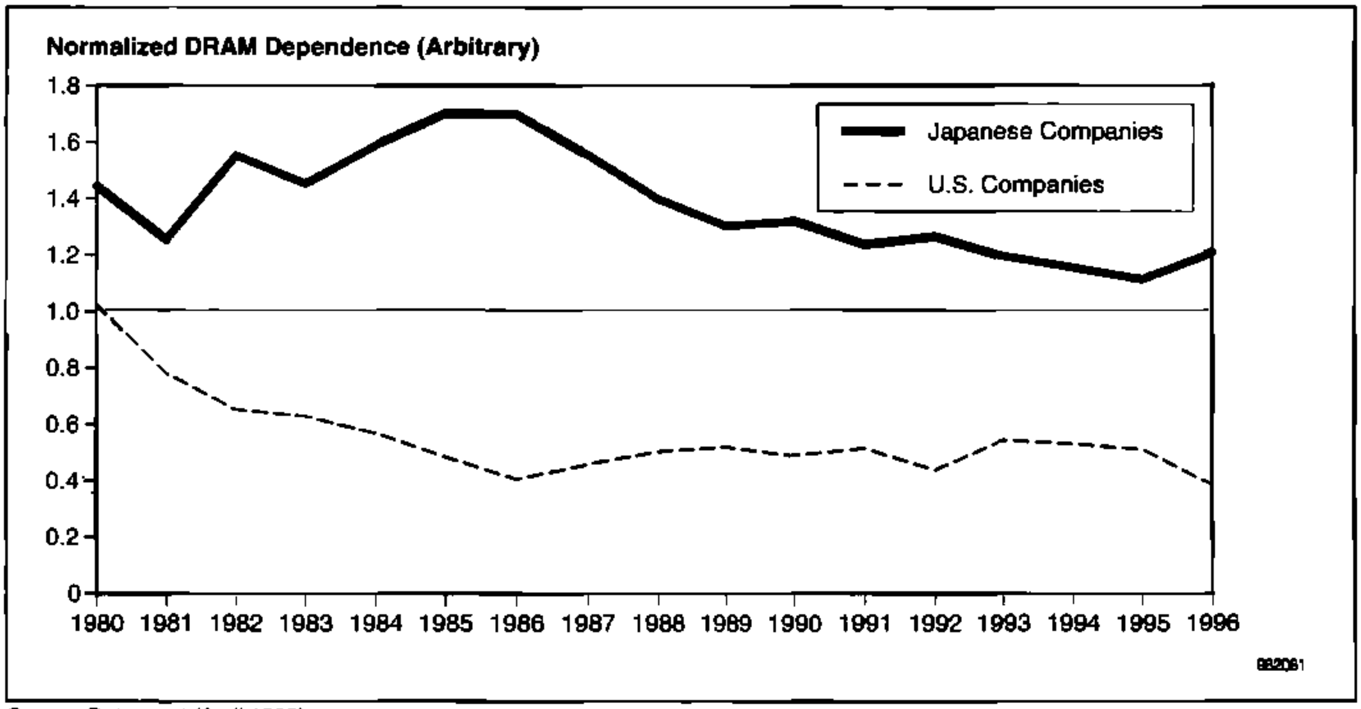
Source: Dataquest (April 1998)

Lithography and resist processing equipment has consistently held a very high share, around 45 percent, except for some turmoil during downward phases of the silicon cycles. Of the DRAM process technologies, lithography equipment, led by steppers and developers, constitutes a critical element. To survive in the highly competitive and volatile DRAM market, manufacturers must keep up with a relentless cost-cutting race, boosting integration levels through chip shrinkage, adoption of increasingly fine design rules, and increasing the number of die from each wafer. Japanese semiconductor manufacturers, armed with superb production technologies, centered on lithography. Through joint development initiatives and quality control practices, they gained share in the worldwide DRAM market until the 1980s. Explosive device market growth has, in turn, spurred the equipment market. Japanese makers virtually monopolized the lithography and resist processing equipment market. This was during the time when the market was highly skewed toward lithography, and the resist processing segment was born.

 ©1998 Dataquest

Figure 3 shows normalized DRAM dependence in semiconductor revenue. "Normalized" means that the worldwide average of DRAM dependence is standardized as 1.0. After 1986, Japanese companies gradually decreased their dependence on DRAM; however, their ratio remains at 1.2, higher than the worldwide standard of 1.0. Meanwhile, Japanese equipment makers, which have grown under the umbrella of the device makers, are pursuing global business deployment strategies, including targeting Korean chipmakers, but the market structure originally shaped by the DRAM industry during the dawn of the market has shown little change.

Figure 3
Changes in Normalized DRAM Dependence in Semiconductor Revenue, 1980 to 1996

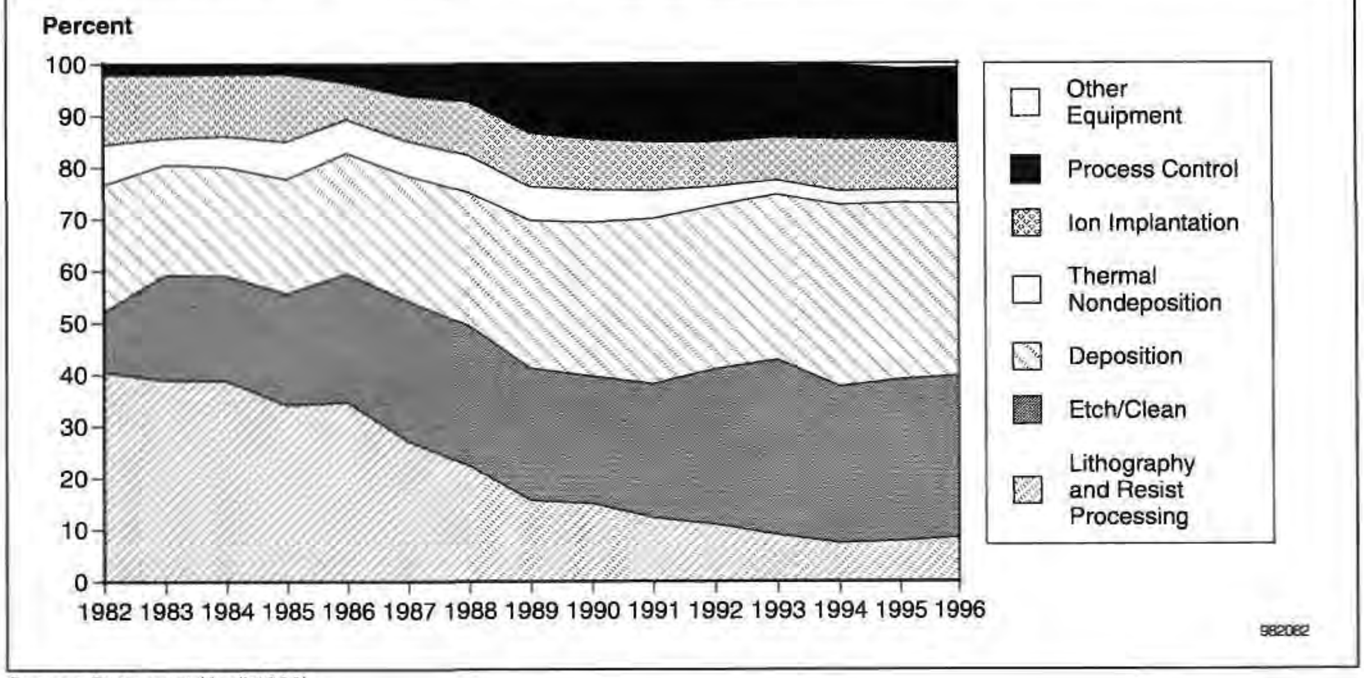


Source: Dataquest (April 1998)

The U.S. Wafer Fab Equipment Industry

The wafer fab equipment market in the United States has also shown distinctive characteristics. In 1996, the wafer fab equipment revenue of U.S. companies totaled $9.73 billion. The world market was more or less divided between U.S. companies and Japanese companies. The U.S. market's CAGR from 1982 through 1996 was 21 percent, about in parity with the Japanese market. Figure 4 shows a breakdown of revenue for U.S. equipment manufacturers between 1982 and 1996 by segment, which reveals a noticeable change. In 1982, lithography and resist processing equipment accounted for about 40 percent of the U.S. equipment market. The share dropped sharply, to 8.5 percent, in 1996. In contrast, the share of the deposition and etch/clean segments grew steadily, from 24.4 percent to 33.3 percent and from 11.7 percent to 31.2 percent, respectively, during the period. In 1996, the combined share of the two segments amounted to 65 percent. Clearly, the U.S. equipment market transformed itself from a structure centered on lithography and resist processing to one centered on deposition and etch/clean during this period. Again, this structural change reflects the evolution of the U.S. device industry.

Figure 4
Changes in U.S. Companies' Wafer Fab Equipment Revenue by Segment, 1982 to 1996



Source: Dataquest (April 1998)

In the U.S. semiconductor industry, DRAM served as a starting point and springboard for prosperity. Before 1980, U.S. semiconductor companies wielded the power in the DRAM market. According to a Dataquest survey, they controlled more than 40 percent of the market before 1980. At that time, they relied on domestic suppliers for wafer fab equipment, including lithography and other key technologies. In fact, the stepper market was dominated by U.S. companies until the mid-1980s, including such companies as GCA, Perkin-Elmer Corporation, and American Semiconductor Equipment Technology, with a combined share exceeding 50 percent. Thus, the U.S. fab process equipment market was originally dominated by lithography and resist processing segments. However, U.S. companies faced aggressive competition and lost share to Japanese DRAM manufacturers. At the same time that the market landscape changed, Nikon and Canon made inroads into the stepper market, and U.S. companies were driven out or lost substantial share.

Intel Corporation, which withdrew from the DRAM market, established new turf, the microprocessor market. Following this bellwether, the U.S. semiconductor industry successfully converted its structure to microcontroller (MCU) and application-specific IC (ASIC) production. In the process, it adopted the consortium approach seen in Japan in the 1970s; the SEMATECH consortium was born in 1987. This initiative focused originally

 ©1998 Dataquest

on developing device processes, but this was later replaced by efforts to strengthen semiconductor manufacturing technology.

It is important to understand what the strategic shift in the U.S. semiconductor device industry has meant for the equipment industry. Although DRAMs demand state-of-the-art lithography technologies and have acted as a technology driver for device miniaturization, production of ASICs and MPUs calls for technology to form multiple layers for interconnection, including metallization and formation of contact holes. This entails refinement of deposition, etching, and planarization technologies. The United States maintained an advanced technological base in this field, particularly within the military and aerospace industries, and semiconductor equipment companies capitalized on this and expanded their share of these segments through vigorous R&D efforts.

Comparing of Figure 4 with Figure 3 shows that, as DRAM dependence dropped, starting in the early 1980s, U.S. market share from the lithography and resist processing segment declined as well, in contrast to the rise in share of the deposition and etch/clean segments. In 1996, these two segments held a combined share of more than 60 percent. Clearly, the U.S. semiconductor equipment market has completed a structural transformation, moving from the original market focus in response to the changing device market.

Another Strategic Shift?

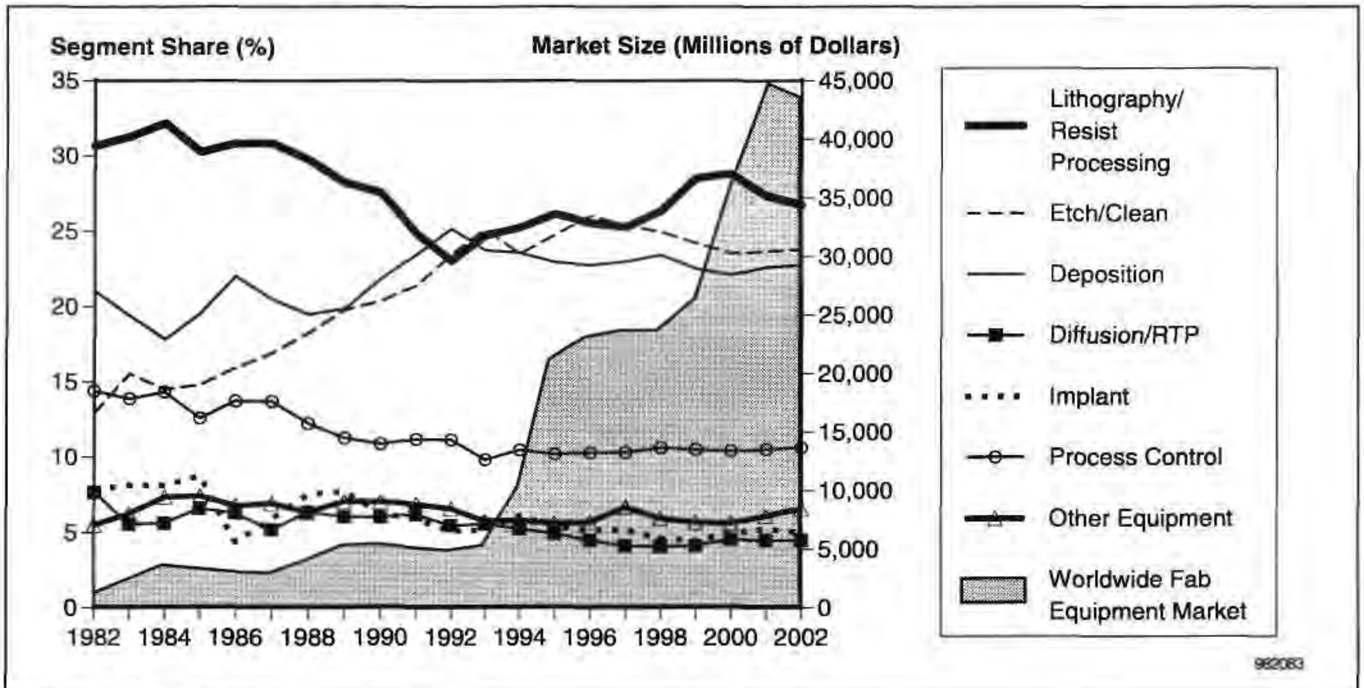
It is reasonable to ask how the semiconductor device market will evolve to understand how the equipment market will evolve. Dataquest predicts that the world semiconductor market will grow at a CAGR of 16 percent between 1996 and 2001, reaching $300 billion in 2001. The DRAM market's CAGR will be 19 percent for the same period, and in 1999, it will achieve major growth, reaching $620 billion in 2001. The DRAM market's share of the total semiconductor market will grow slowly in the next few years and will ramp up in 1999. As a result, DRAM market share is expected to go from 14 percent in 1997 to 16 percent in 1998, to 19 percent in 1999, and to 25 percent in 2000. How will this trend be reflected in the fab process equipment market? Figure 5 summarizes the changes in the world equipment market size and in the percentage breakdown by segment between 1982 and 2002. In short, the semiconductor equipment market is expected to expand at a CAGR of 12 percent up to 2002, when the total market will reach $43 billion. The change in segment composition reveals the following two trends:

- Lithography/resist processing segment will take an increasing share because of the shift to deep-UV laser-based technologies.
- Three markets, lithography/resist processing, deposition, and etch/clean, will polarize.

Year 1 for excimer technology at volume production levels was clearly 1997. According to the results of Dataquest's preliminary surveys, the excimer equipment market in 1997 grew at 240 percent over the previous year. As 0.25-micron or finer processes are adopted for ASICs as well as for DRAMs, deep-UV equipment will become a driver for expansion of the lithography and resist processing equipment market. Because the unit price of the krypton-fluoride (KrF) excimer equipment is higher than that of traditional i-line products (about 70 percent higher at present), the deep-UV segment will gain share, with deep-UV applications expanding after 1998. Therefore, in the lithography and resist processing equipment market, in which Japanese companies have been showing dominance, the ability to gain share in the excimer market will hold the key to success. In fact, the landscape is already changing with the emergence of ASM Lithography.

The lithography and resist processing segment's share eroded gradually from the late 1980s through the early 1990s, while the deposition and etch/clean segments expanded share. In the future, the three segments will divide the market nearly equally. In other words, the deposition and etch/clean market size will increase to approach that of the lithography/resist processing market. Also, new technologies , including the use of such new materials as copper in interconnection and the addition of metal layers, will make deposition and etching technologies more prominent in the ASIC market. Moreover, in DRAM technology, which has traditionally been driven by lithography, mainstream technologies for ASIC/MCU production such as chemical mechanical polishing (CMP) are increasingly being adopted for stack-structured 64Mb and higher devices using 0.25-micron design rules. Again, the deposition and etch/clean segments will be critical in the equipment market.

Figure 5
Trends in the Wafer Fab Equipment Market and in Segment Share, 1982 to 2002

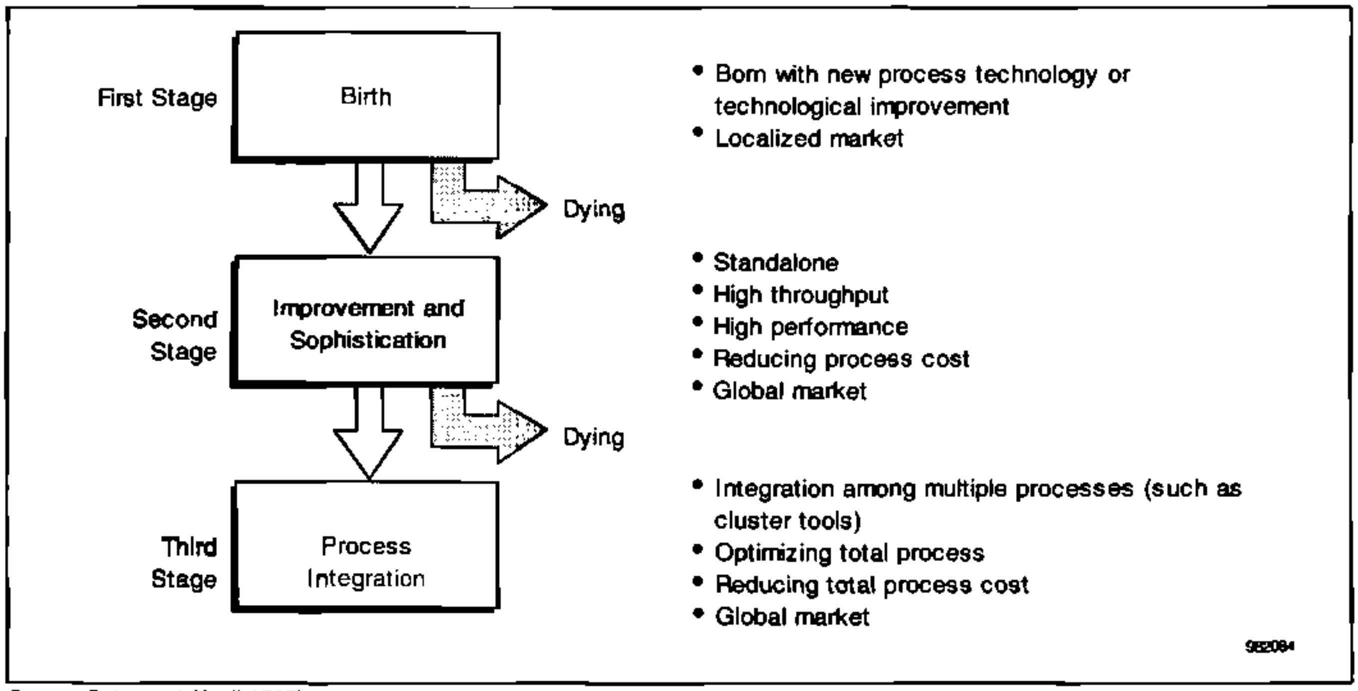


Source: Dataquest (April 1998)

Moving to Process Integration

In addition to market changes, wafer fab equipment is about to enter a new era. Figure 6 shows a conceptual view of the evolution of wafer fab equipment. As discussed earlier, most equipment has been developed for a particular semiconductor process technology. As a new process technology comes on stream, it is incorporated into equipment that will be marketed widely later. At this first stage, the market is still localized; that is, the technology is used by a handful of manufacturers, or the market is limited to a specific country or industrial area.

Figure 6
Development of Semiconductor Manufacturing Equipment



Source: Dataquest (April 1998)

Eventually, the process technology and its advantages become widely recognized, and the equipment is widely accepted, expanding the market. At this level, the market becomes global and attracts new customers. Competition increases, and equipment manufacturers are busy developing variants that extract maximum performance by improving throughput and yield and by reducing process costs, as well as enhancing the original process technology. Now the market is at the second level. Most equipment that incorporates field-proven process technology and has entered the world market is considered to be in this stage.

What's next, then? In the next stage, multiple processes are integrated and a new development concept pursues maximum performance. More precisely, cluster tools and other equipment will be adopted to integrate various process steps, and equipment manufacturers will be required to help optimize performance, including costs. This concept has already been proposed by a U.S. manufacturer. At this stage, equipment vendors must

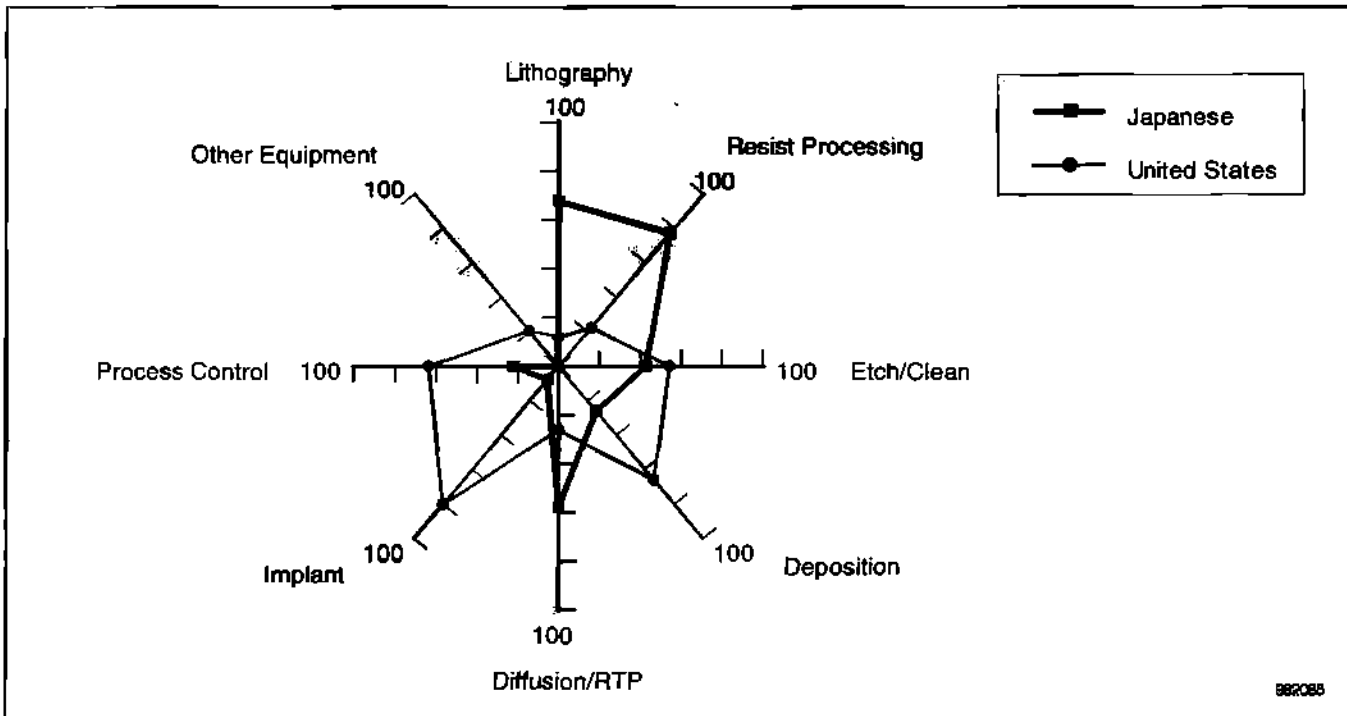
 ©1998 Dataquest

provide know-how related to process conditions, in addition to upgrading hardware technology, such as improving the reliability of existing equipment. In fact, the ability to provide such expertise will increasingly become a key factor in the success of semiconductor equipment makers, which will be required to address "software aspects" of market needs—they will need to cover the entire semiconductor production process.

Dataquest Perspective

Figure 7 shows the share of Japanese and U.S. companies in the semiconductor equipment market by segment. As noted earlier, Japanese companies dominate the lithography and resist processing segment, which has been nurtured in the DRAM market, but they are weak in other segments of the market, except for diffusion and rapid thermal processing (RTP). If market share reflects strength, including technological and management capabilities, then the lopsided share structure of the Japanese wafer fab equipment industry suggests unbalanced allocation of abilities and resources.

Figure 7
Comparison of Wafer Fab Equipment Market Share of Japanese and U.S. Companies by Segment, 1996



Source: Dataquest (April 1998)

A similar pattern is found in the diffusion/RTP segment, in which Japanese companies hold a high share of traditional diffusion equipment. They are being overwhelmed by U.S. companies in the RTP area, which is considered to be essential in advanced control of the thermal process. Given the technological significance and market potential of the deposition and

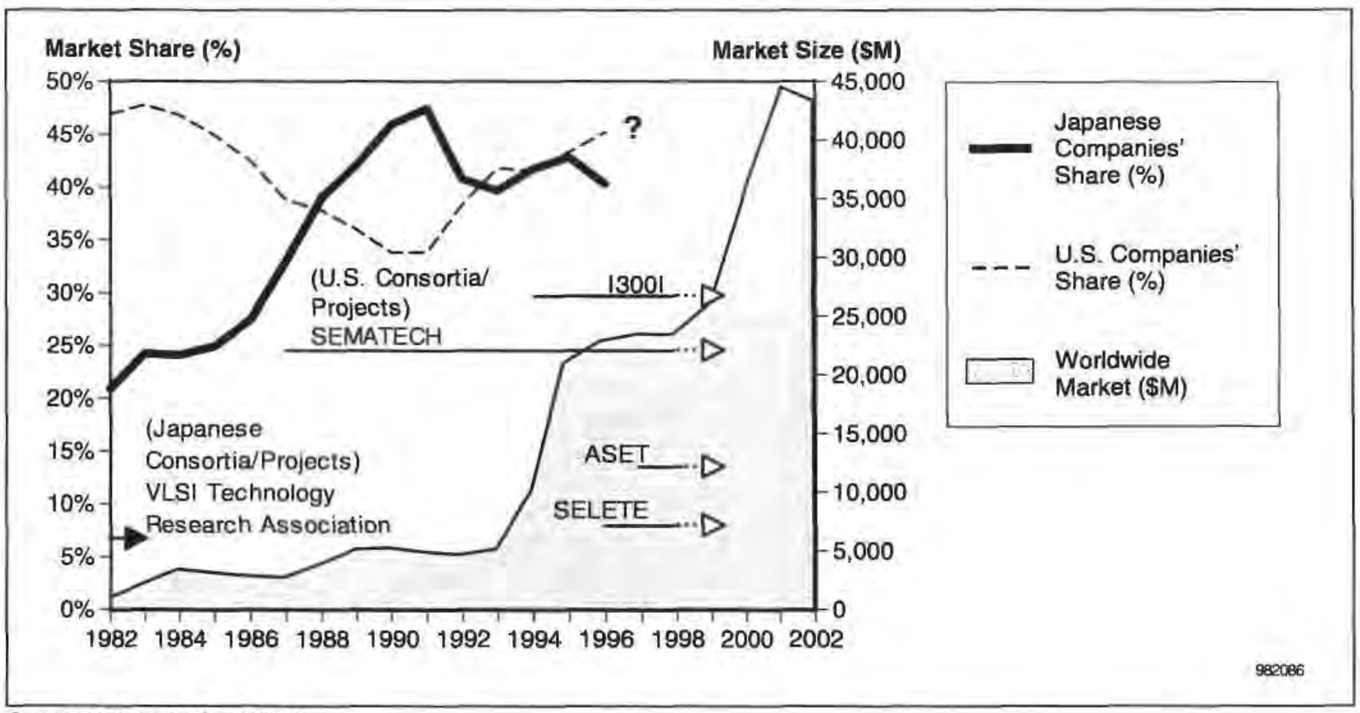
 ©1998 Dataquest

etch/clean segments, the Japanese wafer fab equipment industry needs to refocus on these areas. At the same time, the irreversible move toward process integration will require a broad range of technical capabilities and know-how in a variety of segments. The prosperity of the Japanese wafer fab equipment industry will hinge on its ability to foster companies or consortia that can offer such capabilities, including cost reduction.

It is very important for semiconductor equipment vendors and device makers to work together in developing new process technologies, which lead to new equipment and market opportunities. In retrospect, national projects and consortia have been the most effective means of producing results for the wafer fab equipment industries in both Japan and the United States.

Figure 8 shows the changes in market share of Japanese and U.S. wafer fab equipment companies and the progress of joint development projects in the two countries. Market share positions reversed five to six years after the start of a joint development project in either country. These projects have developed tangible technologies that have helped strengthen the equipment industries and have produced measurable results. In fact, the enhancement of key technologies has proven to play a critical role in periods when a major technology change occurs.

Figure 8
Semiconductor Technology Development, Wafer Fab Equipment Market Size and Share, 1982 to 2002



Source: Dataquest (April 1998)

Today, the industry is in the midst of technology change as various novel technologies, including deep UV and 300mm wafer processing, are about to enter a commercial stage. It is a technology change that will significantly alter the market's structure, and the winners of the race will become the next-generation market leaders. The Japanese wafer fab equipment industry is aware of the imminent change and seems to be determined to meet the challenge by initiating joint development projects—Semiconductor Leading-Edge Technology (SELETE) and Association of Super-Advanced Electronics Technologies (ASET). Dataquest believes that the time has come for Japanese equipment companies to make concerted efforts to refine and enhance key technologies by setting aside their own interests, just as they did in the 1970s—which remains the best course of action to ensure the industry's growth.

Semiconductors Japan

Market Analysis

Analyzing the 1998 DRAM Market

Abstract: *The DRAM market has been plagued by oversupply since 1996, and there are no clear signs of its moving toward a balance. The persistent glut has been squeezing profits for DRAM suppliers, who must relentlessly restructure their DRAM business. Predicting the timing of the market recovery has become urgent. This Perspective analyzes the 1998 DRAM market, focusing on synchronous DRAMs, which are expected to become central in the market. The DRAM shipment and demand data used in this Perspective is based on Dataquest's DRAM supply/ demand quarterly statistics survey in December 1997.*
By Masahiro Suzuki

The General Outlook for the DRAM Market in 1998

The 1998 Japanese DRAM market will be characterized by three distinct trends: increased 64Mb production, 16Mb production cutbacks led by Japanese companies, and rapidly growing share of synchronous DRAMs (SDRAMs).

First, 1998 will be a year of a generation shift from 16Mb to 64Mb. Volume production of 64Mb, led by Samsung Electronics Company Ltd. and NEC Corporation, is steadily on the rise, with other leading suppliers having started commercial production from the second half of 1997. As of February 1998, both 16Mb and 64Mb products were in oversupply, except for 100-MHz, 64Mb SDRAMs, of which a slight shortage is being felt. Dataquest estimates that DRAM demand measured by total bits will reach about 7.5 billion megabytes in 1998, while total supply will amount to 7.7 billion megabytes, resulting in a sufficiency ratio (supply/demand ratio) of around 102. Dataquest believes that, even if DRAM suppliers curtail capital spending significantly, the glut will prevail in 1998.

Dataquest
Program: Semiconductors Japan
Product Code: SEMI-JA-DP-9803
Publication Date: March 30, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Information Resource Center
Gartner Group / Dataquest

Meanwhile, 1998 will see another major shift, an accelerated technology shift from EDO DRAMs to SDRAMs. SDRAM emerged in the third quarter of 1997, when it was rapidly adopted in 16Mb products. Nevertheless, development of 64Mb SDRAMs, particularly PC-100 versions, is somewhat behind schedule. PC-100-enabled and 100-MHz versions will therefore be in slightly tight supply during the first and second quarters. A stable supply of PC-100 versions can be expected in the third quarter of 1998.

DRAM Demand in 1998

The total DRAM demand forecast for 1998, about 7.5 billion megabytes, translates to 3,760 million 16Mb DRAMs, representing a 56 percent increase over 1997. The major driver continues to be PCs, with shipments expected to surge 16.7 percent in 1998, reaching 98.4 million units. At the same time, the average system memory size of PCs will grow to 56.3MB (including the aftermarket). Two factors are important here: The market environment will still work against DRAM prices, which are unlikely to rise rapidly in 1998, and the release of Windows 98 and NT 5.0 will prompt a further increase in system memory size.

Meanwhile, the use of SDRAMs on PCs has accelerated since the third quarter of 1997, and SDRAMs are increasingly outpacing EDO DRAMs in share of design wins. This trend is expected to continue throughout this year. It should be noted that the adoption of SDRAMs for notebook PCs is a bit slower than for desktops, mainly because current SDRAMs consume more power than EDO products. In fact, SDRAMs consume much less power than LCD backlighting and mechanical components, but notebook suppliers continue to use power-saving versions of SDRAMs. DRAM companies are apparently being slow to develop low-power 64Mb SDRAMs.

DRAM Demand Outlook by Integration Level

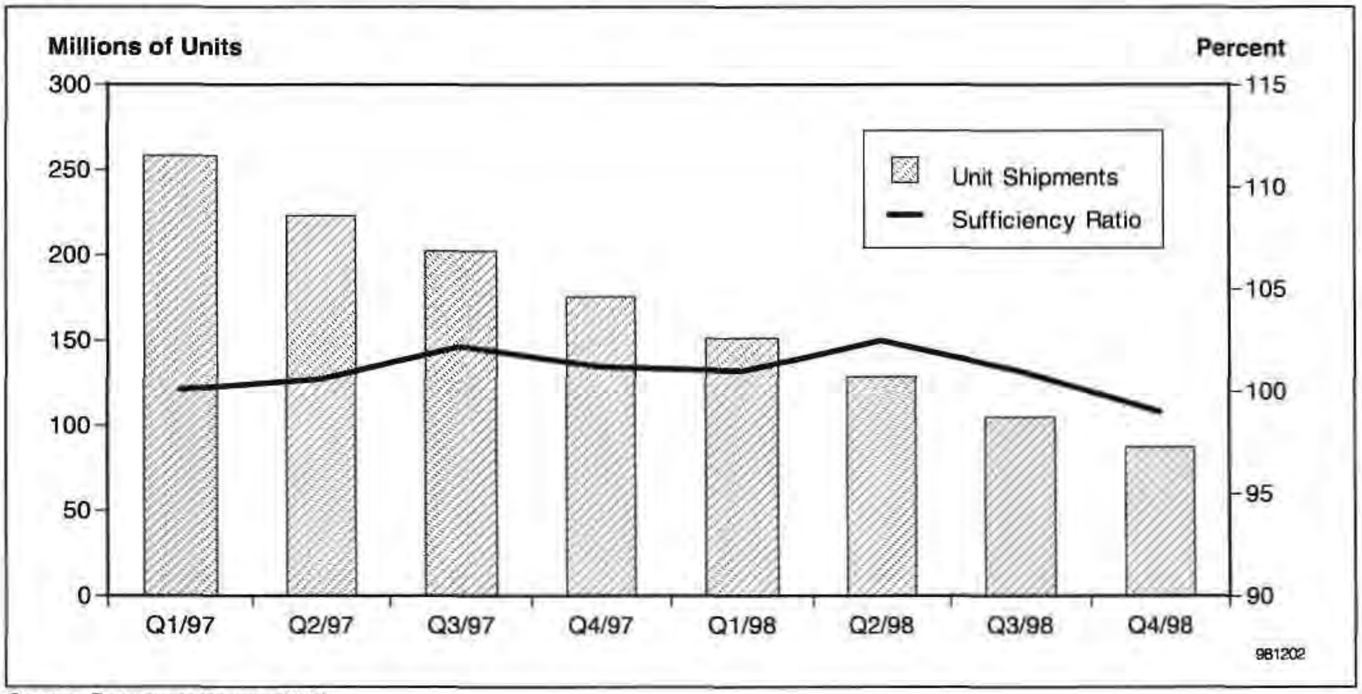
Figures 1, 2, and 3 show Dataquest's worldwide supply and demand forecast for 4Mb, 16Mb, and 64Mb DRAMs, respectively. Note that a sufficiency ratio of over 100 represents a market glut.

4Mb DRAM

Major systems consuming 4Mb DRAMs include PCs, rigid disk drives (RDDs), printers, facsimile machines, network routers, set-top boxes, and video game systems. Note that total consumption has entered a declining trend. One exception is 4Mb, which is now replacing 1Mb in RDDs. Similarly, the supply of 4Mb DRAMs is on the decline, as shown in Figure 1; unit shipments in 1998 are expected to plunge 45 percent to 472 million from 859 million in 1997. The shipment forecast data for leading manufacturers indicates that most of them will proceed with production cutbacks throughout 1998. In particular, leading suppliers have already switched to order production. The sufficiency ratio will be at about 100 throughout 1998, meaning that the market will be near balance this year. One variant scenario would be further acceleration of production cutbacks by major suppliers, which would spur second-tier companies to boost their production.

©1998 Dataquest

Figure 1
Supply/Demand Forecast for 4Mb DRAMs



Source: Dataquest (March 1998)

16Mb DRAM

Major application markets for 16Mb DRAMs, in addition to PCs, include printers, network routers, DVD players, set-top boxes, and video game systems. Of these, laser printers are the largest consumer. Supply was on the rise in 1997 but flattening in 1998 (see Figure 2). Total shipments of 16Mb DRAMs in 1998 will reach 2,128 million, a 10 percent increase from 1,982 million in 1997.

Analysis of shipment trends by individual manufacturers indicates that leading Japanese and Korean suppliers have already launched production cutbacks. Leading DRAM companies have changed the plans made in mid-1997 and now plan to make the actual cutbacks one or two quarters earlier, to the third or fourth quarter of 1997. However, second-tier companies will generally increase their production throughout 1998, which reflects their delay in developing 64Mb products. Depending on price trends, they may boost 4Mb production while curtailing 16Mb output.

Conspicuous 16Mb DRAM players in the 1998 market are Micron Technology Inc., Texas Instruments Inc., Siemens AG, and Nan Ya Technology Corporation. All of them plan to continue to expand production in 1998. Micron has announced plans to boost 16Mb production while it has the ability to expand 64Mb production. Micron's annual 16Mb shipments reached 224 million units in 1997, ranked second in the world next to the 244 million units shipped by Samsung Electronics. Micron plans a further increase to 416 million units in 1998. Nevertheless, Dataquest believes that Micron will cut back 16Mb capacity and ramp up 64Mb production once

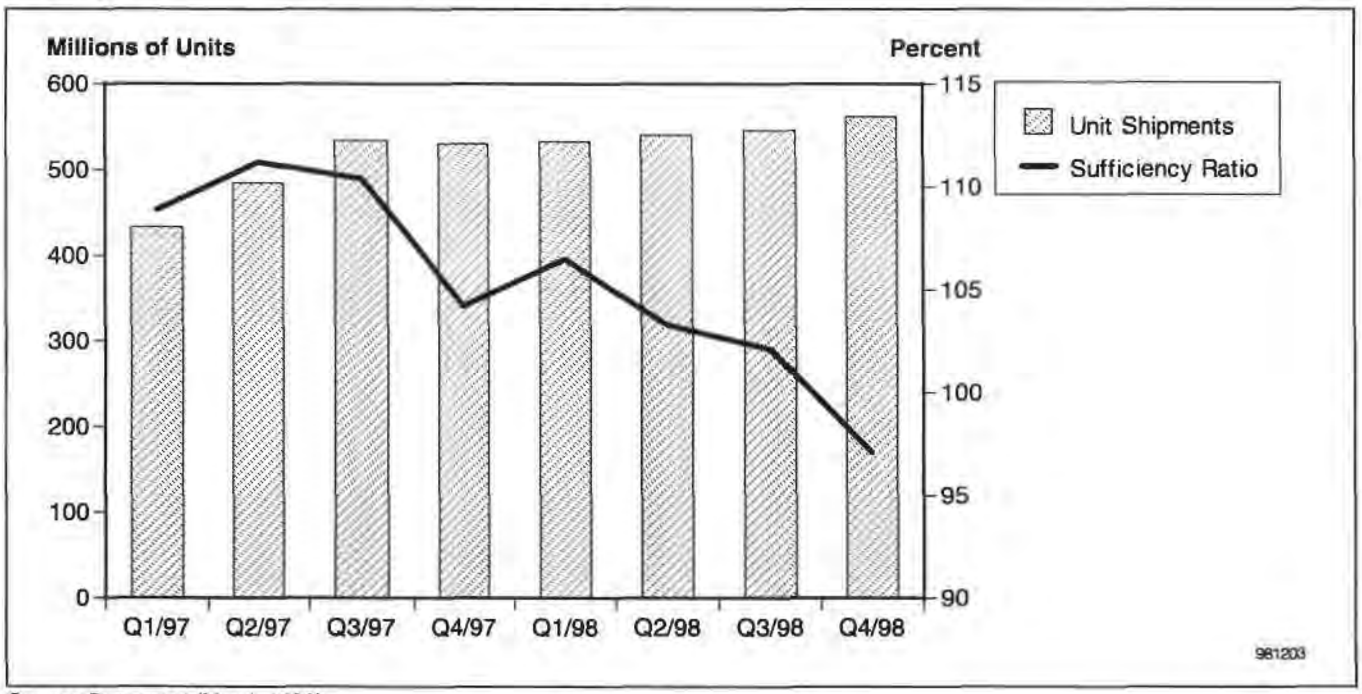
©1998 Dataquest

64Mb DRAMs begin proliferating in desktop PCs. In that case, the total supply in 1998 might be reduced from 2,128 million.

TI follows Micron in a major production expansion plan. The company's 16Mb shipments in 1997 totaled 205 million units, ranked No. 3, next to Micron, and it is expected to churn out 278 million units in 1998. However, Siemens and Nan Ya, although they plan to increase production, will ship a combined total of 243 million units in 1998, far below TI's shipments. Thus, Micron and TI will have major clout in the 16Mb market in 1998.

As shown in Figure 2, the oversupply will remain pervasive in the 1998 market if these companies act on their plans to increase production, which will compensate for the production cutbacks planned by other companies. One note of caution—a temporary shortage is possible if so many suppliers cut back production so quickly. More important, Micron's move needs to be watched because it plays a key role in the group intending to boost production. The company may adjust the production ratio between 16Mb and 64Mb according to 64Mb demand. By doing so, it would be a decisive factor in supply and demand trends in 1998.

Figure 2
Supply/Demand Forecast for 16Mb DRAMs



Source: Dataquest (March 1998)

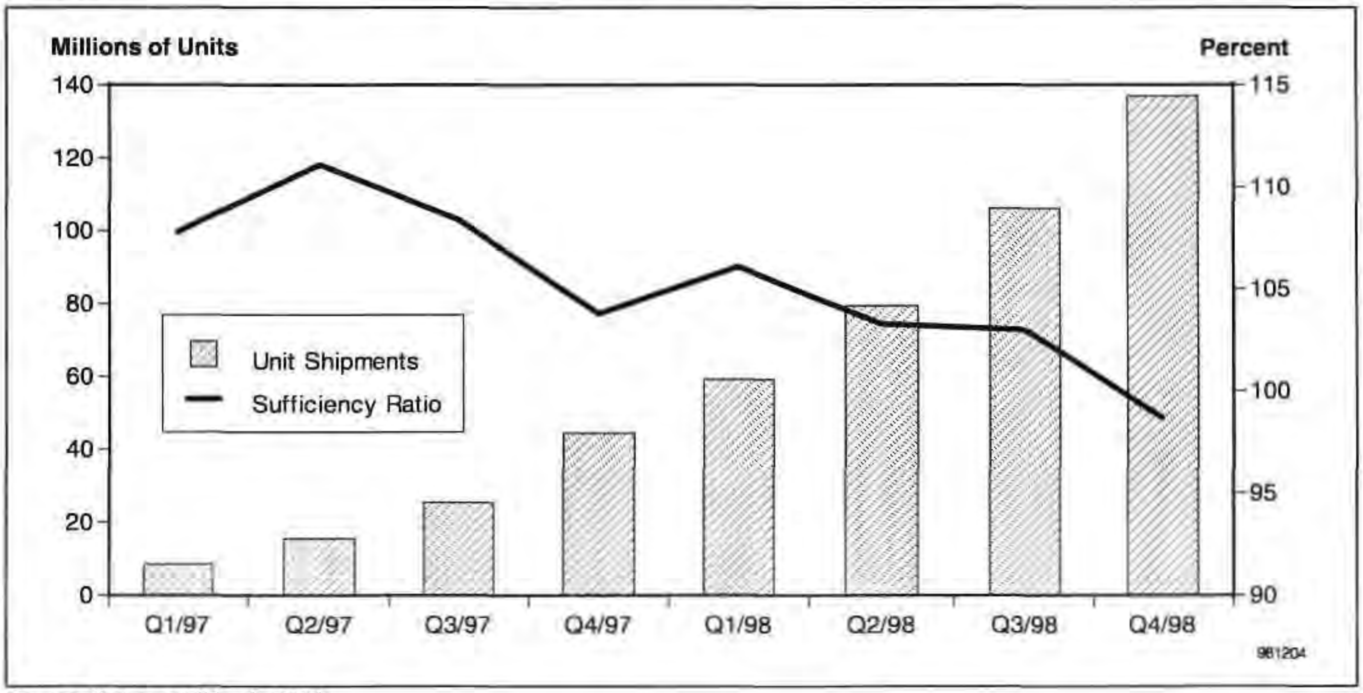
64Mb DRAM

Again, PCs and other higher-end computers are a major consumer of 64Mb DRAMs. In fact, computer main memory seems to be the only application requiring 8MB capacity in the memory device. In addition to PCs, workstations, with a relatively short product cycle, are fast adopting high-integration DRAMs. In 1997, major demand came from workstations in the first half and from some notebook PCs in the second half.

In 1998, 64Mb DRAMs will make inroads into desktop PCs to replace 16Mb products. As shown in Figure 3, 64Mb production will ramp up steadily, and oversupply will be seen in 1998. Korean and Japanese DRAM suppliers have been forced since 1996 to curtail capacity expansions in the wake of the recession. However, Dataquest believes that their cutbacks alone will not lead to the long-awaited balance unless other DRAM companies follow suit by substantially reducing capital spending.

Samsung Electronics shipped an estimated 32 million units in 1997 and will ship 79 million units in 1998. NEC followed Samsung with 21 million units in 1997 and 63 million units in 1998. Micron, however, in 1997 produced 2.8 million units and plans production of 10 million units this year, although the company will likely adjust its plans when 64Mb demand ramps up.

Figure 3
Supply/Demand Forecast for 64Mb DRAMs



Source: Dataquest (March 1998)

Shipment Trends and Forecast by DRAM Type

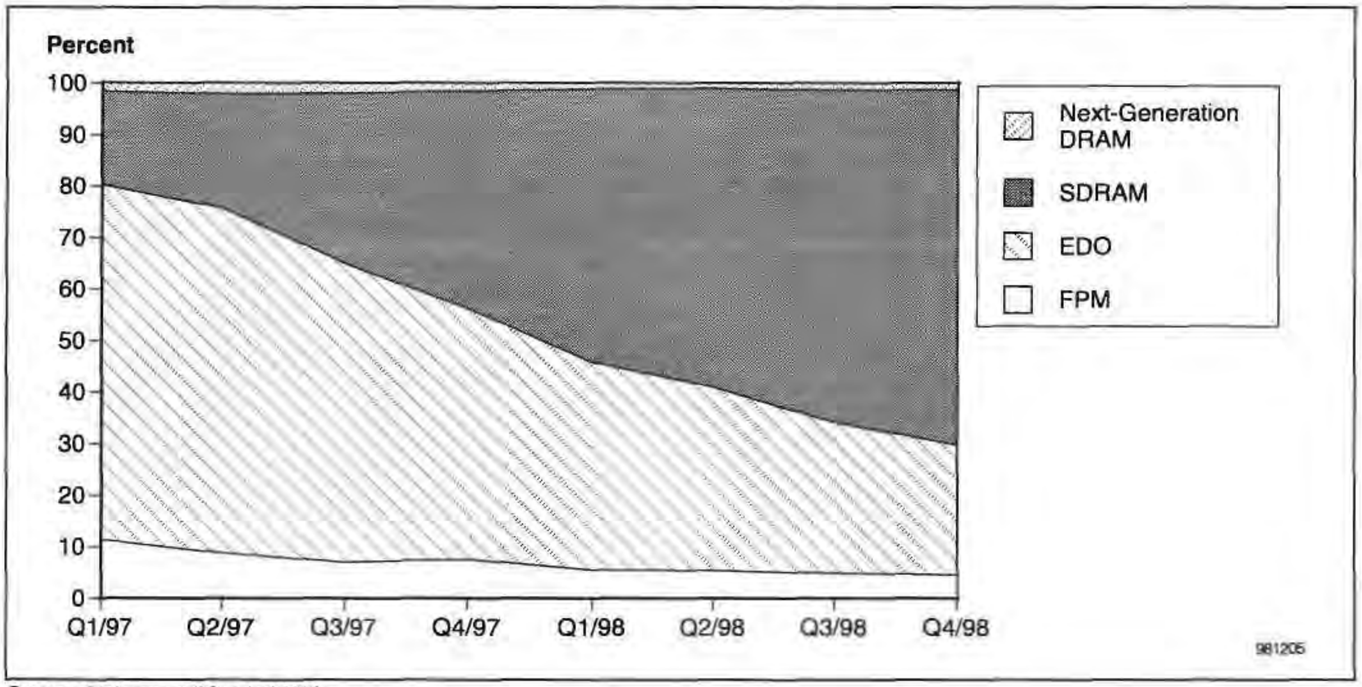
Figures 4 and 5 show shipment trends and the forecast for 16Mb and 64Mb DRAMs, respectively. (The category "next-generation DRAM" refers to Rambus DRAMs, or RDRAMs).

For 16Mb, the shift to SDRAMs has accelerated since the third quarter of 1997. In 1997, Intel released the 430TX and the 440LX for supporting SDRAMs. The increase in SDRAM shipments coincided with Intel's release of the 440LX in the third quarter. Nevertheless, it is well known that replacement of EDO with 66-MHz SDRAM does not improve the performance of the memory system. Thus, the increasing use of SDRAMs

 ©1998 Dataquest

seems to reflect the intention of systems companies to gain know-how about use of the future mainstream device by adopting early. SDRAM shows little difference in price over EDO DRAMs, and using it as a replacement early reduces the kinds of products that require inventory control as early as possible.

Figure 4
Breakdown of 16Mb DRAM Shipments by Device Type



Source: Dataquest (March 1998)

Figure 5 shows that the shift to 64Mb SDRAMs will speed up during the first quarter of 1998. A major driving force is Intel's 440BX, a chipset supporting 100-MHz SDRAMs slated for release in the first quarter. At present, 64Mb SDRAMs are primarily 66 MHz, and 100-MHz versions are available from only a few vendors. For SDRAMs to operate at a system clock speed of 100 MHz on PC motherboards, they must operate at 100 MHz as they are mounted on the dual in-line memory module (DIMM), which is equivalent to a speed of 125 MHz for an SDRAM device alone. (Note that 100-MHz SDRAMs are usually used at the system clock frequency of 66 MHz.) Volume production of 125-MHz SDRAMs requires a 0.25-micron type of process technology.

Dataquest Perspective

The Japanese DRAM market in 1998 will be still characterized by oversupply, judging by analysis of total bid-based supply and demand as well as of supply capacities of DRAM suppliers and their likely changes. One exception is 125-MHz 64Mb products, which may face some shortages, accompanied by price premiums. The 125-MHz versions will be required for the 440BX, which operates at a clock frequency of 100 MHz, as well as for 350-MHz

Pentium II or later MPUs. If volume production of these MPUs is substantially delayed, DRAM suppliers will focus on building up 0.25-micron process capacities, and a shortage of the 125-MHz products will become less likely.

Many development challenges are waiting for DRAM companies. In addition to the traditional race for higher integration, they are expected to commercialize high-speed SDRAMs, low-power SDRAMs, and next-generation DRAMs, including RDRAMs, double-data-rate (DDR) DRAMs, and SLDRAMs. In particular, next-generation products, for which specifications have still not been finalized (except for RDRAMs), have a long way to go. Dataquest believes that the most important challenge for DRAM makers is to identify which device type will become mainstream and to allocate their resources effectively to allow timely introduction of suitable products to the market.

The Impact of the Asian Financial Crisis on Japanese Semiconductor Companies

Abstract: *The impact of the Asian financial crisis is beginning to be felt on a wider basis. The loss in GDP in the areas hit by the crisis has started to affect local demand for goods, including electronics, affecting both exports to those countries and local production. This Perspective analyses the impact of the crisis on Japanese electronic equipment production and Japanese semiconductor suppliers and offers possible scenarios.*
By Yoshihiro Shimada

The Asian Financial Crisis

The arrival of the Asian financial crisis in 1997 shook Asia/Pacific countries, including Thailand, Korea, Indonesia, Malaysia, Philippines, Singapore, and Hong Kong. The crisis is a financial phenomenon, but its widespread impact is beginning to be felt in the overall economies of those countries.

In Korea, as in Japan in the early 1990s, production of low-end model shifted to Association of Southeast Asian Nations (ASEAN) countries because of their lower costs, and the domestic production remaining in Korea showed a profile similar to domestic production in Japan. The yen depreciation that preceded the Asian financial crisis, however, strengthened Japanese exports of consumer equipment, and production of that equipment in Korea was adversely affected. Semiconductors had already become a major contributor to nationwide exports in Korea, but weak pricing over the past two years or so has hurt Korean exports and the country's foreign exchange reserves. At the same time, rapid expansion of DRAM production capacity required vast capital spending, but most manufacturing equipment and manufacturing materials had to be imported. This is one of the most serious impacts of the Asian financial crisis for Korean semiconductor companies.

Dataquest
Program: Semiconductors Japan
Product Code: SEMI-JA-DP-9802
Publication Date: March 9, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

In countries such as Singapore, Malaysia, Thailand, and Indonesia, the production shift from Japan, the United States, and Europe has contributed to a rapid growth in electronic equipment production. Because products have been exported back to those advanced countries, as well as to other regional markets, the economies of those countries have benefited, on the whole. This scheme, however, made those countries heavily dependent on imports as more manufacturing equipment and materials were required, making them vulnerable to the effects of the financial crisis.

Hong Kong, too, has been exposed to the Asian financial crisis, and a financial blow has been unavoidable. In Hong Kong, a large portion of imported semiconductors are re-exported to other parts of the mainland China, and the impact of the crisis must be measured in relation to equipment production sites supported by imported semiconductors. The Chinese government has been making every effort to maintain the value of renminbi, but if the currency should be hit directly by the Asian financial crisis, the impact could be felt throughout the whole Asia/Pacific region.

Taiwan has seen only a minimum impact and has proven its excellence in managing industries and finance. Major industries such as PCs, peripherals, and semiconductors are still growing fast in Taiwan, and Dataquest expects Taiwan to remain comparatively unaffected by the Asian financial crisis.

As the Asian financial crisis's adverse impact widens, Japanese export of industrial equipment is starting to show a decrease. Asia/Pacific countries have been forced to scale down utilization of production sites for equipment to be marketed within Asia/Pacific, and Japanese companies have been no exception.

Impact of the Crisis on Japanese Electronics Production in Asia/Pacific

Dataquest is conducting in the first quarter of 1998 a detailed survey of 1997 semiconductor revenue. The final results are scheduled to be released in the second quarter of 1998, but a preliminary look at Japanese companies has already shown that 1997 revenue has been influenced by the crisis. It should be noted, however, that a discrepancy between company plans and actual revenue in Asia/Pacific does not necessarily come from the Asian financial crisis alone —some equipment had been plunged into a painful correction when oversupply followed a period of robust production.

In the first half of 1997, consumer equipment production in Asia/Pacific on the whole saw recovery from an extended slump that started in mid-1995. There were doubts about PC peripherals' continued production growth, but an adjustment phase had not started yet.

By mid-1997, the winds of change had started to blow. Video CD players, which had enjoyed a sudden increase in production because of a rapid rise in demand from mainland China, began to show sluggishness, and production plummeted. CD players, portable audio equipment, rigid disk drives, and CD-ROMs also saw a decrease in production.

So far in 1998, there has been no clear sign that production levels of this equipment are recovering, and semiconductor orders for those applications continue to be slow.

The Impact on Japanese Semiconductor Companies

The impact of the Asian financial crisis on semiconductor companies is not necessarily negative. The following factors need to be considered:

- Demand side
  - Negative—Reduction in orders from Asia/Pacific users
  - Negative—Price pressure from users
  - Positive—Increase in orders because of improved competitiveness of electronic equipment manufactured in Asia/Pacific
- Supply side
  - Negative—Asia/Pacific semiconductor companies' drive to export
  - Positive—Improvement in short-term semiconductor supply and demand because of production constraints stemming from difficulties in importing materials
  - Positive—Improvement in long-term supply and demand because of limited capital spending by Asia/Pacific semiconductor companies

In this analysis, Dataquest attempts to estimate the impact of the Asian financial crisis on Japanese companies' revenue, using metrics such as revenue by country and semiconductor revenue share of local users in Asia/Pacific.

Naturally, actual problems that semiconductor vendors face will be affected also by the application involved and, eventually, each user. This analysis, however, attempts to show trends in the impact of the crisis on semiconductor orders. Dataquest classifies Asia/Pacific into the following five countries or areas: Korea, Taiwan, China/Hong Kong, Singapore, and Rest of Asia/Pacific (ROA). In this analysis, it is assumed that the higher the revenue in Korea, Singapore, and ROA and the higher the ratio of local users, the higher the risks in semiconductor orders.

Although there has been industry input into these estimates, this analysis is not based on a rigorous survey, and therefore Dataquest chooses to avoid using specific company names. Metrics have, however, been estimated based on each company's characteristics as perceived by Dataquest. The companies analyzed are the top 11 Japanese companies included in the ranking of the top 30 worldwide Asia/Pacific companies: NEC Corporation, Toshiba Corporation, Hitachi Ltd., Fujitsu Ltd., Mitsubishi Corporation, Matsushita Electric Industrial Co. Ltd., SANYO Electric Company Ltd., Sharp Electronics Corporation, Sony Corporation, Sanken Electric Company Ltd., and Rohm Company Ltd.

 ©1998 Dataquest

These 11 Japanese companies combined hold a 33 percent share of the revenue of the top 30 companies in Asia/Pacific (see Table 1), and their sales into Korea, Singapore, and ROA together account for 60 percent of their total revenue in Asia/Pacific (see Figure 1). In Korea, most of the sales come from business with local users, while in Singapore and ROA, the major portion of their revenue comes from Japanese users or Americas and European users. Among those 11 companies, consumer applications-oriented companies tend to show higher dependence on local users, but they also benefit from their internal user divisions' Asia/Pacific production sites. For those 11 Japanese companies combined, 55 percent of the revenue comes from local users in Asia/Pacific (see Figure 2).

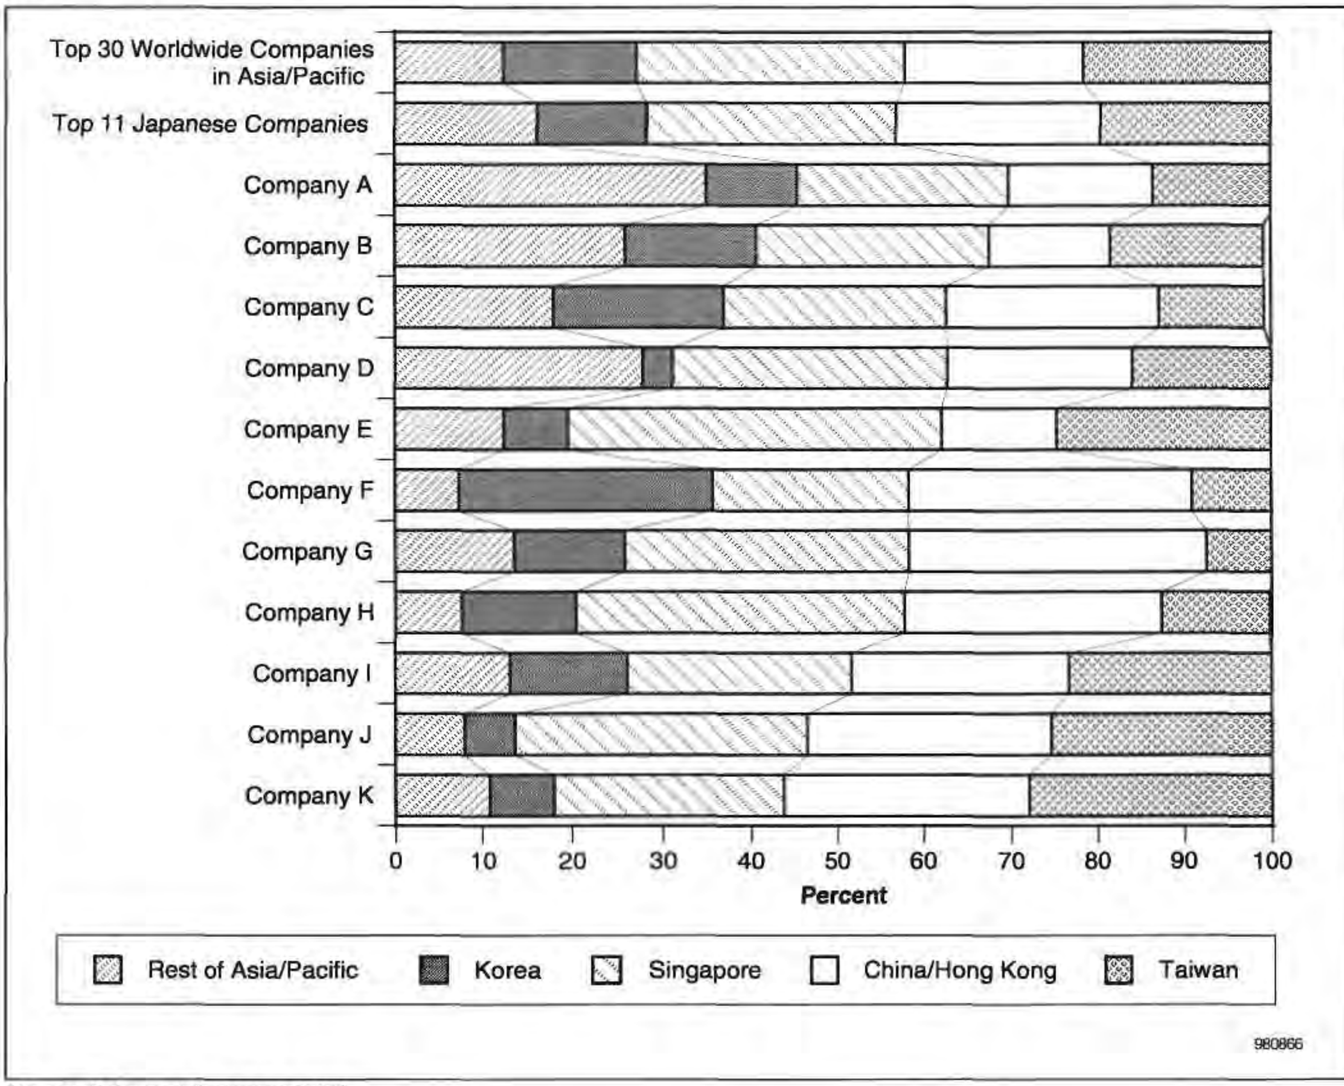
Figure 3 shows the results of estimating the risks that Japanese companies face in semiconductor orders because of the crisis. The first risk scenario is for Korea, Singapore, and ROA combined, and the second risk scenario is for Korea and ROA only. There are some companies whose sales to local users are significantly high but whose risks from the Asian financial crisis are small. Those companies' users are associated with either Japanese, Americas, or European electronics vendors. DRAM companies show similar trends. On the other hand, there are companies whose risks may be high not only because of the Asian financial crisis but also because of sluggishness in certain application markets worldwide. Japanese companies' semiconductor sales in Asia/Pacific are generally characterized by high dependence on Japanese users.

Table 1
Revenue of Selected Japanese Semiconductor Companies in Asia/Pacific, 1996 (Millions of Dollars)

1996 Rank	Company	1996 Revenue	Percentage of Top 30 Companies' Revenue
3	Toshiba	1,804	7.3
7	NEC	1,283	5.2
9	Hitachi	1,169	4.7
11	SANYO	913	3.7
13	Mitsubishi	729	3.0
15	Matsushita	500	2.0
16	Fujitsu	476	1.9
17	Rohm	471	1.9
20	Sharp	406	1.6
23	Sony	286	1.2
29	Sanken	215	0.9
	Top 11 Japanese Companies	**8,252**	**33.4**
	Top 30 Worldwide Companies in Asia/Pacific	**24,699**	**100.0**

Source: Dataquest (February 1998)

Figure 1
Japanese Companies' Sales into Major Countries in Asia/Pacific

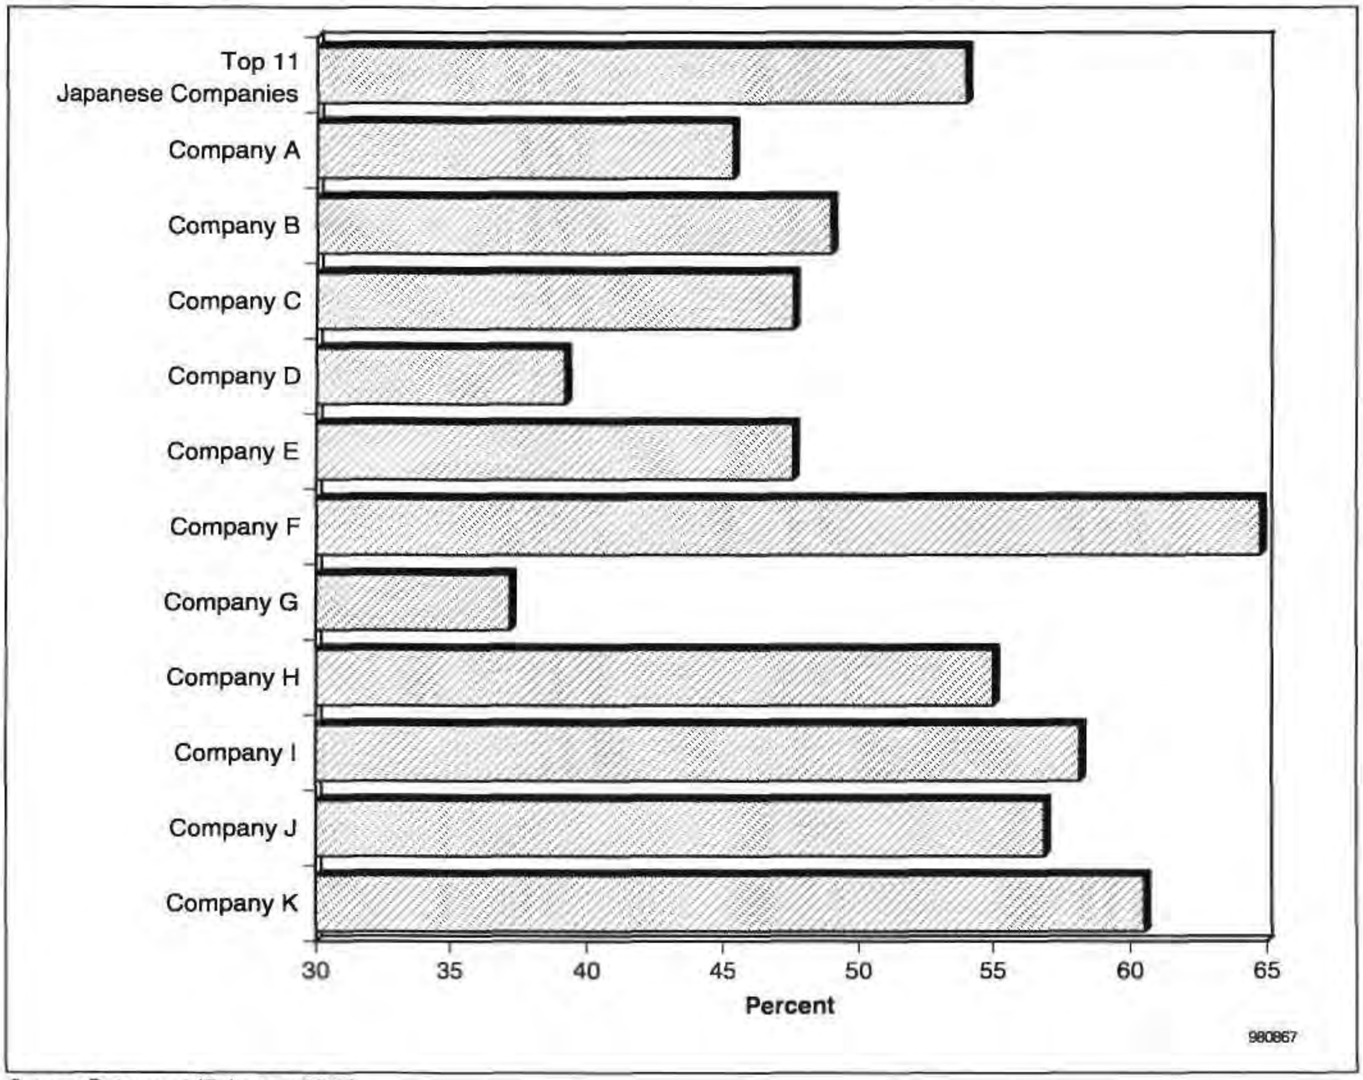


Source: Dataquest (February 1998)

One trend shown in this estimate of risk is that the element of risk added by the Asian financial crisis increases as the total revenue in the crisis-hit areas increases, but at a certain point, the crisis-based risk saturates. This again reflects low dependency on purely local users.

True, semiconductor orders from Asia/Pacific had started to decline even in 1997, and companies with a stronger emphasis on the Korean market were exposed to direct and immediate losses in orders. Dataquest has not heard of any Japanese companies officially attributing lower sales forecasts in Asia/Pacific solely to the Asian financial crisis.

Figure 2
Japanese Companies' Sales to Local Users



Source: Dataquest (February 1998)

This analysis has focused on semiconductor orders and revenue, and manufacturing issues have intentionally been put aside. There has been no immediate change to Japanese companies' wafer fab plans in Asia/Pacific. Test and assembly, or back-end, operations also remain unaffected, because most of the materials are still imported from Japan and the only visible change would come from labor costs.

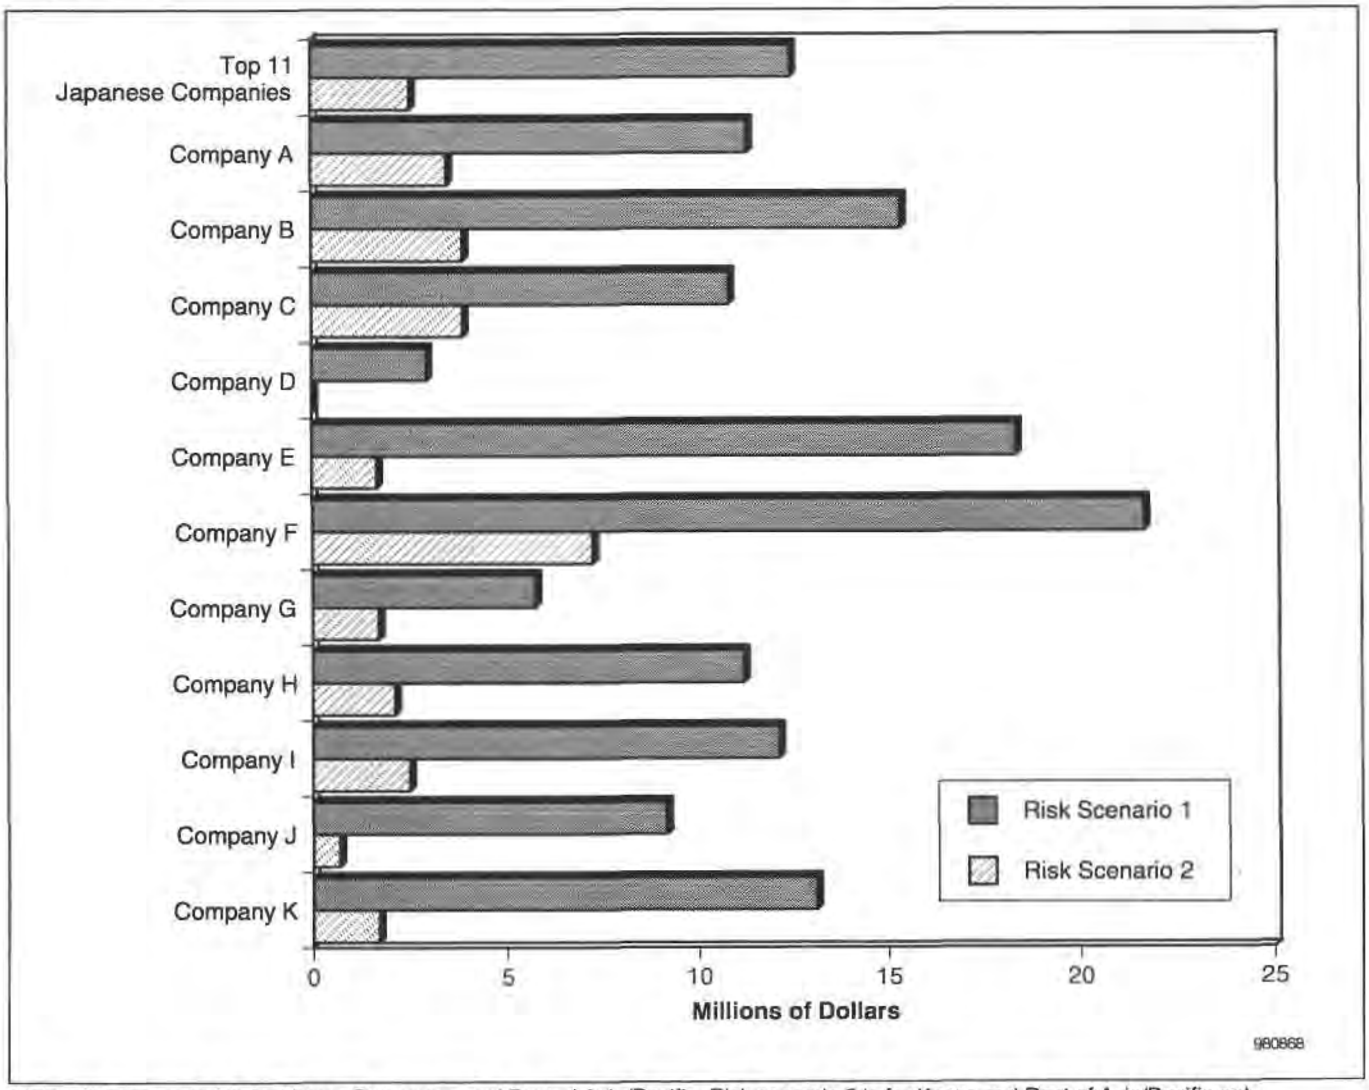
Figure 3
Impact of the Asian Financial Crisis Japanese Companies' Sales into Major Countries in Asia/Pacific



Note: Risk scenario 1 is for Korea, Singapore, and Rest of Asia/Pacific; Risk scenario 2 is for Korea and Rest of Asia/Pacific only.
Source: Dataquest (February 1998)

Possible Scenarios

The future impact of the Asian financial crisis should be measured and analyzed from several aspects, including time frame, origin of demand (whether domestic or export) for application equipment, production of equipment in Asia/Pacific or in other parts of the world, high-end models versus low-end models, availability of semiconductor materials and manufacturing equipment, and semiconductor capital spending.

In the short term, confusion in orders is unavoidable as suppliers and users try to reach new terms of trade incorporating lower exchange rates for local currencies. Local users are putting pressure on local semiconductor sales

 ©1998 Dataquest

offices to decrease prices, while prices of imported devices now translate into higher value in local currencies.

In the mid- to long term, after new terms of trade have been settled on, Asia/Pacific countries will see changes in their basic economic structures in terms of electronic product categories as Japanese electronics companies rearrange production sites to take advantage of lower costs. Lower exchange rates will also encourage foreign companies to acquire local companies, and the increase in direct investment will contribute to re-establishing and renewing manufacturing facilities in the region.

In terms of demand for electronics manufactured in Asia/Pacific, domestic demand-oriented production will suffer an immediate and direct loss while export demand remains strong. Because overall demand for electronics in Americas and Europe seems to remain firm, the key factor here would be demand in Japan and China.

Lower exchange rates for local currencies will improve the export competitiveness of electronics produced in Asia/Pacific countries, but this could happen at the expense of production in other parts of the world. There is a possibility that some electronics equipment could see lower prices in export markets, and that may increase demand for those products. Whether electronics production in Asia/Pacific increases or decreases affects industrial equipment companies in Japan, because they have benefited from the Japanese electronics companies' production shift, which brought manufacturing equipment to those new sites. One other factor to be considered in electronics manufacturing is the possible shift in product class—in the past few years, ASEAN countries have shifted to middle-range products from low-end models, while China, with its low labor costs, took up production of low-end products. Depreciation of currencies in the ASEAN countries could enable them to resume production of low-end models, especially when they are motivated to increase exports to acquire foreign currency reserves.

Industrial equipment and manufacturing equipment are the areas hit hard by the Asian financial crisis because local companies find imported equipment too expensive. Along with the impact on the purchase of imported materials, this may motivate Asia/Pacific countries to secure industry autonomy.

Dataquest Perspective

The Asian financial crisis in its early stages was a set of financial phenomena. It should be noted that in countries whose gross domestic product (GDP) was not already damaged, economic fundamentals were not necessarily ailing, but the impact of the crisis is already being felt in various industries both inside and outside Asia/Pacific.

It should also be noted that, in Japan, the bursting of the bubble economy several years ago and the yen appreciation that followed continue to drag the Japanese economy down. If the effects of the crisis are managed poorly, there

 ©1998 Dataquest

could be similar aftereffects in Asia/Pacific countries; if better managed, those countries' economies and industries could become more efficient.

One important factor that this Perspective has not covered is the impact of the Asian financial crisis on semiconductor production by Asia/Pacific companies and Japanese semiconductor companies' reactions to it. Although there is a general expectation in semiconductor industry circles that the crisis will bring the supply and demand into equilibrium sooner than predicted, the actual effects are yet to be seen. If the Asian financial crisis proves to provide an effective adjustment period, electronics industries may find it an opportunity instead.

Perspective

Semiconductors Japan
Market Analysis

A First Look at 1997 Semiconductor Market Share from the Japanese Perspective

Abstract: *Dataquest has conducted phase one of the annual market share survey for the worldwide top 20 and regional top 10 semiconductor company rankings. This Perspective analyzes the Japanese ranking trends observed in the 1997 survey, trends related to Japanese companies in foreign markets, and the top 10 topics of conversation in the semiconductor industry, from the Japanese perspective.*
By Yoshihiro Shimada

Scope of Survey

Dataquest's annual 1997 market share survey was conducted in November and early December 1997, and the results were published in an earlier Perspective ("Intel, NEC, and Motorola Remain atop the Worldwide Semiconductor Market," SCND-WW-DP-9706, January 1998). We limited our information request to total worldwide semiconductor revenue plus revenue in four regions. We structured the survey to capture the top 20 worldwide plus the top 10 in each region. We did not survey every company worldwide, which explains why the published tables do not have a market total or "other companies" category. Also, we did not survey at detailed product levels.

The Top 10 in the Japanese Market

In the 1997 spring forecast, the Japanese market was expected to show clear signs of recovery by growing at an annual rate of more than 10 percent. By the time Dataquest started work on the fall forecast, this initial expectation had started to look too optimistic. The fall forecasts states that the Japanese

Dataquest
Program: Semiconductors Japan

San Jose, CA 95134
408-468-8600

market will grow annually only 9.5 percent on a yen basis, and 1.0 percent on a dollar basis. As mentioned, total market trends will be analyzed in the detailed survey to come, but the qualitative information obtained in this semiconductor revenue survey suggests deteriorating revenue trends, basically because of weak pricing of products such as DRAM and application-specific ICs (ASICs). Production of application equipment showed a slowdown in some areas, such as PCs, peripherals, and consumer equipment. Putting aside the shift of demand from PHS to cellular phones, mobile communications, on the whole, was the only area in which the industry outpaced initial forecasts that predicted weak or negative growth.

In such a market, the top 10 rankings of semiconductor shipments into Japan changed little during 1997 (see Table 1). Hitachi Ltd. suffered a major loss in revenue because of its high ratio of DRAM to total semiconductor revenue, but managed to maintain its No. 2 position. The only change in ranking was between Intel Corporation and Mitsubishi Corporation. Mitsubishi, with the second-highest DRAM ratio of major Japanese companies, recorded a contraction, while Intel's revenue continued to grow, even though Japanese PC markets turned sluggish in the second half of the year.

Japanese Companies in Foreign Markets

Table 2 shows Japanese companies in the worldwide top 20 ranking. NEC Corporation leads Japanese companies at No. 2 in the worldwide rankings. Hitachi's revenue exceeded Toshiba Corporation's in 1996, but its lead did not last long. Other than that, because revenue changes were comparatively small for most companies, the rankings among Japanese companies did not change much.

Table 1
Revenue of Top 10 Companies Worldwide from Shipments of Semiconductors to Japan (Millions of U.S. Dollars)

1996 Rank	1997 Rank	Company	1996 Revenue	1997 Revenue	Growth (%) 1996-1997
1	1	NEC	5,756	5,830	1.3
2	2	Hitachi	4,252	3,749	-11.8
3	3	Toshiba	3,838	3,562	-7.2
4	4	Fujitsu	2,645	2,912	10.1
5	5	Matsushita	2,268	2,340	3.2
7	6	Intel	2,028	2,211	9.0
6	7	Mitsubishi	2,147	2,101	-2.1
8	8	Texas Instruments	1,634	1,640	0.4
9	9	Sharp	1,561	1,511	-3.2

19	20	Sharp	2,124	2,059	-3.1

Source: Dataquest (January 1998)

In the Americas region, three Japanese companies were listed among the top 10. NEC, with flat growth, gave way to Texas Instruments Inc. to become No. 4, while Toshiba and Hitachi switched places. In a market in which weak DRAM pricing eroded revenue, Japanese companies as well as Korean companies suffered two-digit reductions in total semiconductor revenue.

In the European market, only two Japanese companies made their way into top 10, NEC and Fujitsu. NEC maintained its No. 8 position, while Fujitsu jumped into No. 9.

In the Asia/Pacific region, three Japanese companies, again, appeared in the top 10 ranking. In this region, Toshiba has traditionally been strong, but it gave way to Texas Instruments and became No. 4. NEC, with comparatively strong growth of 7.9 percent over 1996, maintained its No. 7 position. The third Japanese company was SANYO, which has also had advantages in the Asia/Pacific region. SANYO's historical strength has been in consumer applications, and it was a beneficiary of the recovery in consumer equipment production in this region. None of these three Japanese companies' revenue showed any significant or immediate impact of Asia's financial crisis for 1997.

Starting in January 1998, Dataquest will conduct a detailed survey of all semiconductor companies' 1997 product revenue plus memory unit shipments and microprocessor (MPU), microcontroller (MCU), and digital signal processor (DSP) unit shipments. We will release that detailed information during the second quarter of 1998. Those detailed results will provide information on companies that enjoyed product successes in 1997 that are not listed in this document's tables.

The 10 Most Popular Topics in 1997 from the Japanese Perspective

Dataquest has put together a list of the top 10 news in the 1997 semiconductor industry from the perspective of the Japanese semiconductor

 ©1998 Dataquest

industry, based on interviews with Dataquest's contacts in the industry, as well as from various Dataquest analysts' input.

Table 3 lists 10 ubiquitous topics of industry conversation. The top three topics, characteristically, centered around DRAMs. DRAM consumption was expected to resume a recovery path, but the actual trends betrayed this expectation. Although the shift from 16Mb to 64Mb started to make substantial progress and overall bit demand was more than steady, the delay in the shift from extended data out (EDO) to synchronous DRAM (SDRAM), weak pricing trends, and the PC slowdown in Japan and Asia/Pacific brought revenue growth down.

Micron Technology Inc. became the third most frequent topic. Micron Technology increased production and shipments of 16Mb DRAM while Japanese and Korean companies were seeking ways to stabilize the supply/demand balance. Its production trends and pricing and the profit Micron secured in 1997 revealed a totally new strategy in the DRAM business. True, Micron has been known for its unique strategy, but the fact that the company has finally become the top producer of 16Mb DRAM was a shock to many in industry circles—especially Japanese industry circles.

PC shipment trends were the fourth most frequent topic of discussion. In 1997, the Japanese PC market started to show sluggishness, and peripherals such as CD-ROMs finally started to show signs of production constraint. There is some indication that 1997 PC market trends can be characterized by language—in two-byte language regions such as Japan and Asia/Pacific, PC shipment growth weakened. This stems from the fact that, with PC penetration becoming high, additional demand for PCs lies in the growth of networking. In two-byte language areas, where English is not necessarily spoken as a native language, access to cyberspace is limited while Web sites in the native language may appear to be less attractive than those in English, especially those with American origins. Needless to say, the turbulence in Asian economies is playing a role, too.

Table 3
The 10 Ubiquitous Topics, from a Japanese Perspective

Rank	Topic
1	Contraction in the DRAM market for the second consecutive year
2	Continued fall of DRAM prices
3	Micron Technology's production increase and marketing strategy
4	Winds of change in the regional PC markets
5	Sluggishness in equipment production and semiconductor consumption in Asia/Pacific
6	Construction of quarter-micron fabs
7	Increase in flash memory market players
8	Visibility of Taiwanese manufacturers in the DRAM business
9	Disappointment in worldwide semiconductor consumption growth
10	Continued sound growth in mobile communications applications

Source: Dataquest (January 1998)

 ©1998 Dataquest

The Asian financial crisis ranked fifth as a topic. In 1997, the real impact was yet to come and influenced Japan very little. Japanese equipment companies with production sites in Asia/Pacific maintained their levels of production, especially in cases where products were destined to be shipped out of the region. Currently, the strongest interest lies in assessing the magnitude of the impact of the crisis on Korean semiconductor companies' capital spending. A major impact is anticipated, however, on various aspects of electronics industry in 1998.

The construction of quarter-micron fabs and their production starts is one of the few positive topics. Contrary to the initial expectation of improvements in profits, quarter-micron fab output was immediately exposed to harsh pricing competition, both in memories and in logic areas.

Flash memories drew interest as a substitute for DRAM in filling fabs as the fast-growing digital still camera market diversified the applications. MCUs with flash memory have also started to show strong growth. With prices lower than originally planned, flash MCUs are finding their markets quickly.

Ranked eighth is Taiwanese companies' penetration into the DRAM market. Over several generations, the winners in the DRAM business have shifted first from American companies to Japanese companies, then to Korean companies. Now the focus of interest is the question of whether Taiwanese companies will become the next leaders in the DRAM market. Taiwanese companies have already started to produce 64Mb DRAMs to seriously penetrate into the DRAM market, which they initially planned to with 16Mb. Whether their product and technology transfers with foreign partners can contribute to the success of Taiwanese companies is yet to be determined.

Ninth on the list is the disappointment in worldwide semiconductor market growth. The industry expected 1997 to be the year of recovery, but the signs of recovery ended up being very modest. In fact, it became the year when applications that had driven the semiconductor market for the past several years failed to bring about strong demand. Although Dataquest's fall forecast was lower than the spring forecast, actual market trends toward the end of the year suggest even further reductions in growth rates.

Last comes a topic in the communications. While the emphasis of the worldwide semiconductor market is shifting from standalone PCs to communications-related applications such as networks and mobile phones, the Japanese electronics industry is still dwelling on PCs and peripherals. Network-related equipment is yet to come into focus, but mobile phones have come to be recognized as one driver of semiconductor demand. In fact, at the beginning of the year, a slowdown in the production of mobile phones was expected, especially for PHS. It is true that PHS subscriptions suffered contraction in the last few months of 1997, but cellular phones remained steady.

Outside the top 10 are other topics, including:

- Applications: Windows 97/98, CD-ROM production, Windows CE machines, and cyberpets

- Semiconductors: SDRAM, embedded memories, Pentium MMX and Pentium II, clone chips, media processors, and analog ICs
- Manufacturing: fab construction trends, Korean companies' capital spending, and 300mm fab technology and construction

A pleasant surprise was seen among analog companies. As electronic equipment production rose on a worldwide basis, it was only natural for demand for analog ICs to grow steadily. But this is an area in which capital spending and engineering staffing have been underestimated, and the actual growth in demand for analog took companies by surprise. Lack of capital spending brought tight supply, even allocation in some cases, as well as constraint in product development because of the lack of analog engineers. This is expected to continue for some years, but the industry is trying to evaluate the actual demand that remains for independent analog devices, as opposed to analog functions incorporated into system-level integration (SLI) ASICs.

Topics of 300mm fab technology kept conversation going throughout the year and will continue to in the coming several years. The collaboration agreement between the International 300mm Wafer Initiative (I300I) and SELETE groups is expected to bring efficiency into the scheme through global standardization, but actual technology development and fab construction are dependent on each company. Semiconductor companies must face issues such as the cost comparison between 300mm and 200mm technologies, technology and equipment development, the long-term semiconductor supply/demand outlook, and semiconductor companies' product development.

Dataquest Perspective

The results of Dataquest's 1997 market share survey show a sharp contrast between strengthening American and European vendors and weakening Japanese and Korean companies.

This, however, does not result solely from a difference in their emphasis on DRAM but also from a difference in their successful systems-oriented marketing and product development. Even among major Japanese and Korean companies, there are companies that have managed to minimize the negative impact of the DRAM price drops by expanding nonmemory MOS digital products, such as microcomponents and logic. Even in DRAM, which has long been considered a typical commodity product category, a systems orientation can be seen, including development of SDRAM and certain companies' marketing efforts focused on PC companies and memory module companies.

The 1997 Japanese market share results, as well as the top 10 topics of interest to the semiconductor industry from a Japanese perspective, seem to pose one question: Has the Japanese semiconductor industry really become global, selective, and diversified? In 1998, systems-oriented product

Chapter 1
Executive Summary

Scope of This Report

This Market Trends report analyzes the following trends in Japan from 1997 through 2002:

- Electronic equipment production market trends
- Semiconductor market trends
- Semiconductor companies' capital spending trends

Chapter 1 sets the stage for the analysis in this booklet. Chapter 2 discusses electronic equipment production trends, focusing on four major categories: electronic data processing (EDP), communications, industrial, and consumer. Chapter 3 covers the overall semiconductor market trends in Japan, analyzing 1997 market share results and forecasting the market for five years to come. Chapters 4 through 7 discuss detailed product market trends for MOS memories; MOS microcomponents; MOS logic; and analog, discrete, and optical semiconductors, respectively. Those chapters also cover 1997 market share results and forecast market trends for 1998 through 2002. Chapter 8 sheds light on the Japanese semiconductor industry, focusing on the capital spending trends of the Japan-based semiconductor companies during 1997 and 1998.

Research Methodology and Definitions

This Market Trends report follows standard Dataquest market share and forecasting methodologies, but several points may need to be noted.

Numbers are expressed in Japanese yen to make the analysis of time series trends free from fluctuations in the yen/dollar exchange rate. Where necessary, numbers on a dollar basis are mentioned, using the exchange rates shown in Table 1-1.

Table 1-1
Yen-per-Dollar Exchange Rate, 1992 to 1998

Year	Yen (¥)
1992	126.45
1993	111.20
1994	101.81
1995	93.90
1996	108.81
1997	121.10
Preliminary 1998	129.73

Source: Dataquest (August 1998)

©1998 Dataquest

The preliminary 1998 exchange rate estimate incorporated in this report uses actual exchange rates through December 1997 and assumes that the December rate applies to all future months. For the years 1999 through 2002, the preliminary 1998 exchange rate is assumed to apply.

Dataquest has made some minor changes to the product definitions in the 1997 market share survey and analysis and is considering a major shift to a new set of definitions in the future; these future changes will be in conjunction with those made in 1997, aiming at the best analysis of system-oriented market trends.

The following are the changes that have been made:

- The hybrid ICs category has been erased from 1997 revenue. Revenue from the shipment of hybrid ICs is counted on the basis of component chips produced by the same vendor in the product categories that those chips belong to, such as analog and discrete. 1996 revenue remains as it was.
- Linear array revenue has been moved from analog to ASIC in 1997 revenue, while 1996 revenue remains the same. Mixed-signal ASIC revenue has also been moved from analog to ASIC, both in 1996 and 1997 revenue. As a result of those changes, analog and ASIC revenue in 1996 is different from previously published numbers for vendors of those products. Also, as a result, the ASIC category is now called "Total ASIC," and what was formerly called "MOS Digital Logic" is now called "Total Logic."

These changes do not appear explicitly in this book, because it describes top-line trends for each product category, but for any comparison of 1997 trends—as well as future trends—with the past trends, including 1996 and before, these changes may need to be noted in some cases.

Major points discussed in this document include the following:

- Japanese electronics production is forecast to grow 3.0 percent in 1998, and the compound annual growth rate (CAGR) for the coming five years will be 2.8 percent. These growth rates have been brought down from the level previously forecast, and Japan still needs to identify strong drivers of electronics production.
- The Japanese semiconductor market is forecast to grow 9.8 percent in 1998, and the CAGR for the coming five years will be 12.4 percent. In a downside scenario, however, 1998 growth could go down to 1.5 percent. The lack of a strong electronics driver is affecting semiconductor consumption in Japan, and the prolonged oversupply in various semiconductor products is affecting pricing trends negatively.
- Japanese semiconductor companies' capital spending in 1998 will see a major drop from the previous year. Reduction in spending is mostly seen in memories, and Japanese companies are placing more emphasis on preparing supply capacity for advanced logic products to serve SLI markets.

- The Japanese semiconductor market is forecast to grow at the slowest pace among the four regional markets worldwide. Along with prolonged weakness in the DRAM market and the acceleration of the SLI move, the changes in regional market size and application trends will force domestic vendors to restructure their operation toward improved support of global customers. Whether digital consumer applications can revive the Japanese market, and whether it is the Japanese vendors or overseas vendors that benefit from emerging applications, depend on each company's efforts to restructure semiconductor operation and transform from commodity vendor to system-level integrator.

Project Analyst: Yoshihiro Shimada

Contributors: Motoya Ohgami, Masahiro Suzuki, Yoshihisa Toyosaki, and Hiroyuki Shimizu

Chapter 2
Japanese Electronic Equipment Production Trends

The Japanese economy in 1997, after a temporary surge in domestic demand prior to the consumption tax hike in April, was beleaguered by turmoil in the financial system, a decline in consumer expenditure, and a slowdown in capital spending. The economic hardship was amplified by the Asian financial crisis (AFC) toward the year-end.

In 1997, against all the backlash in the Japanese economy and in Asia/ Pacific, electronic equipment production showed stronger growth than expected: 7.8 percent over 1996, reaching ¥23,715 billion (see Tables 2-1 and 2-2). Cellular phones contributed greatly, fueled by a series of price cuts and the shift in demand from personal handy phone (PHS) models. EDP equipment also outgrew the forecast, despite a slowdown in domestic PC shipments, and consumer equipment added some momentum that came from video game systems and digital equipment.

In 1998, communications equipment will no longer serve as a major impetus, as the cellular phone market reaches a high level of penetration and the digitization of backbone networks completes its first round. Thus, Dataquest predicts that electronic equipment production in Japan will grow a moderate 3.0 percent to ¥24,425 billion, down 1.6 percentage points from the fall forecast. Similarly, the CAGR between 1997 and 2002 will settle at 2.8 percent.

Future growth opportunities must come from a surge in PC demand stimulated by the introduction of low-cost models and increased implementations of plug-and-play interfaces, such as universal serial bus (USB) and Institute of Electrical and Electronics Engineers (IEEE) 1394. While Windows 98 will not have much of an impact on the PC market, the evolution of PCs to a new platform for WebTV and other media-mix services will hold the key to growth in demand for personal equipment.

The following section provides a detailed analysis of electronic equipment production in Japan for the four major categories, namely, EDP, communications, industrial, and consumer.

EDP Equipment

In 1997, EDP equipment production in Japan soared 8.3 percent to ¥7,380 billion. While PC shipments to the domestic market slowed down to less than 5 percent growth on a unit basis, the price decline spurred the purchase of peripherals such as printers and display units. Also, storage devices led by high-speed optical disk drives—32x CD-ROM drives and DVD-ROM drives, for example—enjoyed strong growth. This segment is expected to drive the market during the forecast period.

IT investment will continue to be a major driver in 1998 while Japanese financial institutions are exposed to global competition as a result of the "Big Bang," which urges them to strengthen information systems. Therefore, more than compensating for the general economic slump, computers will drive EDP equipment production, growing 5.1 percent in 1998 with a CAGR of 2.3 percent during the next five years. The gradual recovery of the Japanese economy will continue to fuel EDP equipment production after 1998, which should exceed ¥8 trillion in 2001.

Communications Equipment

Communications equipment production in 1997 jumped 19.8 percent to ¥4,844 billion. A prime driver was mobile communications equipment; subscribers grew much faster than expected, recording a net increase of 10 million in 1997. While PHS production decelerated at 7 million units, the market is expected to expand as its focus shifts from personal to office use.

Nevertheless, the penetration of mobile phones combining PHS and cellular phones has surpassed 50 percent, and the continuation of the previous high growth will become inevitably difficult. Meanwhile, the digitization of infrastructure facilities by Nippon Telegraph and Telephone Corporation (NTT) was completed by the end of 1997. These factors will consequently put a brake on communications equipment production, turning into a negative growth of 0.3 percent. On the other hand, network equipment, including LANs, will experience healthy growth at a CAGR of 15 percent or above. All in all, communications equipment production will grow at a CAGR of 2.9 percent between 1997 and 2002.

Industrial Equipment

Industrial equipment production in 1997 was up 7.2 percent, totaling ¥3,908 billion. Of the total, manufacturing systems and instruments recorded the highest growth rate, with 14.9 percent. As the wave of production site relocation to Asia/Pacific countries subsides, the focal point of the market will shift to computerization and sophistication for adding value and further automation. In particular, medical equipment will exhibit strong growth, with the increasing demand for advanced systems to meet the needs of an aging society, resulting in a CAGR of 5.2 percent between 1997 and 2002. Overall, Dataquest predicts a CAGR of 5.3 percent, the highest among the six segments: data processing, communications, industrial, consumer, military/civil aerospace, and transportation.

Consumer Equipment

Consumer equipment production recorded a 1.3 percent increase in 1997, reaching ¥6,098 billion. In the video equipment segment, where TVs and VCRs sold in the domestic market are mostly made overseas, the replacement demand for wide-screen TVs produced at domestic sites contributed greatly. In the digital consumer equipment market, digital video cameras (DV-Cs) recorded notable growth, and unit shipments up to the end of 1997 were estimated at slightly below 1 million. The DV-C quickly will become pervasive, driven by price declines and the improved availability of key components. Similarly, digital still cameras (DSCs) will ramp up rapidly because they can be easily connected to PCs or TVs via a flash memory card or IEEE 1394 interface. On the other hand, the commercialization of digital TVs will have to wait until after 2000 because infrastructure construction has been delayed.

The current recession will hit household appliance production directly, leading to negative growth in 1998. Video game systems will continue to be a fierce battlefield for a 32-bit hegemony, but production will remain mostly unchanged in 1998, until the next-generation products are introduced in 1999. Dataquest predicts that consumer equipment production as a whole will grow at a CAGR of 1.9 percent between 1997 and 2002.

 ©1998 Dataquest

Chapter 3
Overall Japanese Semiconductor Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese semiconductor market recorded a growth rate of 5.7 percent over the previous year on a yen basis, which was the only negative growth rate on a dollar basis among the four regional markets in the world. As discussed in the previous chapter, the production of electronics equipment in 1997 grew faster than what was forecast, but this growth was not directly translated into faster growth in semiconductor consumption. The difference in trends was caused by two factors: An increase in electronics production took place in categories with lower semiconductor contents, such as industrial equipment, and the price erosion of semiconductor devices betrayed the increase on a unit basis. Also, PC shipments lost momentum in Japan, exerting a negative impact on the consumption of a variety of semiconductor products, including memories, microprocessors (MPUs), and logic.

As a result, the Japanese semiconductor market has become less than one-fourth of the worldwide market for the first time since 1980. It is still the second-largest regional market following the Americas, but both European and Asia/Pacific markets are close behind. In fact, there were months within 1997 when the Japanese semiconductor market fell behind those two markets.

Affecting this is the sluggishness in the domestic market as well as the fast growth in other regions, especially in the Americas and Europe. Semiconductor procurement to support Japanese electronics companies' Asian production sites has moved to each site or to international purchasing offices (IPOs) outside of Japan, and the yen depreciation observed in 1997 did not reverse the trend.

Ranking Trends

The Japanese semiconductor market is characteristically led by domestic vendors, but their market share has been on a constant decline. In 1997, non-Japanese companies together had 26.4 percent of the Japanese market, and Americas companies alone had a more than 20 percent share, while Asia/Pacific companies lost share because of the weak DRAM market. European companies hold a meager 1.5 percent share but are increasing visibility by focusing on selected product areas for the target applications of digital consumer and automotive. Needless to say, the decline of the Japanese companies' combined market share was largely caused by the DRAM price fall, but it should be noted that non-Japanese companies no longer need strong side support in penetrating the Japanese market. Successful non-Japanese companies have come to enjoy close ties with Japanese system companies with their expertise in system-oriented devices in the areas of microcomponents, logic, and analog.

NEC Corporation continued to lead the Japanese market in 1997 (see Table 3-1). While many other major domestic vendors suffered from sluggishness in various product areas, NEC managed to secure positive growth in all of the major product areas except for memories—ranging from microcomponent, logic, analog, discrete, and optical—on a yen basis. Dataquest estimates that utilization at NEC's fabs remained higher than at those of most other Japanese vendors, helping it to maintain a comparatively healthy income profile. Toshiba Corporation and Hitachi Ltd. switched places in 1997. While Toshiba became the beneficiary of design wins in the digital consumer, mobile communications, and mass storage applications, Hitachi could not fully enjoy the fruit from the increased number of design wins for its proprietary architecture microcomponent product lines. Fujitsu Ltd. and Matsushita Electronics Corporation remained at the same positions of No. 4 and No. 5, respectively. Fujitsu increased market share, with contributions from digital consumer and mass storage applications. Matsushita Electronics also benefited from those two application areas, having system manufacturing companies inside the corporate group. Although PC shipments slowed, Intel Corporation still enjoyed a sound growth of over 20 percent and became No. 6, replacing Mitsubishi Electric Corporation.

Among the non-Japanese companies that gained market share in 1997, LSI Logic Corporation, Analog Devices Inc., Macronix International Company Ltd., and Lucent Technologies stand out with their high growth rates. The growth of LSI Logic was a result of the design wins of its SLI ASIC product line in digital consumer applications, while Lucent took advantage of its communications expertise. Analog Devices was a beneficiary of healthy analog market trends, and Macronix benefited from the mask ROM business, from which Japanese companies are exiting.

Forecast through 2002

The Japanese semiconductor market in 1998 will grow at 9.8 percent (2.5 percent on a dollar basis), down from the fall forecast (see Tables 3-2 and 3-3). This reflects the anticipated slowdown in electronic equipment production and the hovering market conditions for DRAMs, and it also exemplifies the expectation for a recovery in the second half. Underlying assumptions include a mild DRAM price decline, the small direct impact of AFC, and the firming up of the PC market with the introduction of Windows 98. With this growth, however, the Japanese market will lose its share in the worldwide market, while the other three regional markets will gain share.

The CAGR between 1997 and 2002 is forecast to be 12.4 percent, or 10.9 percent on a dollar basis, which is the lowest among the four regions, making the Japanese market the smallest, with a 20 percent share in the worldwide market. With the electronics production CAGR at 2.8 percent, this slow increase in semiconductor consumption is unavoidable, but the long-term trends will pose a major challenge to Japanese vendors.

After Dataquest put together the spring forecast and announced the results in April, several major changes in the electronics industry and semiconductor market have been observed. In view of those factors, Dataquest has added another scenario to the forecast, a downside of the trends described earlier.

In this scenario, worldwide electronics production, which was forecast to show 6.9 percent annual growth in 1997, is assumed at 4.4 percent, or slightly above. Affecting this scenario is the slowdown in unit production in several electronics categories, which have suffered oversupply and reduced unit demand caused by the AFC as well as downturn in the factory average selling price for various electronic equipment.

On the other hand, price erosion in the semiconductor market accelerated, not only in DRAMs but also in various product categories, including flash memory, MPUs, and ASIC; this gloomy wave has come to affect analog and discrete devices that have enjoyed healthy markets even after MOS digital products fell victim to the oversupply-ridden market.

Incorporating these factors, the new scenario sees the worldwide semiconductor market growth this year decreasing to 1.4 percent, a sharp drop from the 8.2 percent scenario in the spring forecast. In Japan, this scenario can be translated into a growth of 1.5 percent, as opposed to the 9.8 percent growth discussed above. A detailed scenario will be illustrated in Dataquest's fall forecast.

Challenge to the Vendors

Once, the Japanese semiconductor vendors grew to enjoy the largest market share in the worldwide market by focusing on two factors: DRAM and consumer applications in the domestic market. The sales into the domestic market represented over 80 percent of Japanese vendors' worldwide revenue in the 1980s, but in 1997, this decreased to 56 percent. As discussed in the long-term forecast, however, the Japanese application markets are not likely to offer major drivers for semiconductor consumption growth.

With this demand-side outlook, vendors that have focused on the Japanese market are facing two major challenges:

- Emphasize and strengthen application-oriented marketing to identify growth segments
- Increase support capability for overseas customers

In fact, not only the consumption of semiconductors, but also the system design, has begun to show signs of overseas shift. This shift is inevitable when the localization of the system is required to best serve local markets, but another factor that is prompting this shift in design capability is the realization of limitations in engineering resources, not only within Japan but on a worldwide basis as well.

 ©1998 Dataquest

At the same time, with the DRAM market forecast to remain at around 15 percent of total semiconductors, Japanese companies need to accelerate the shift of business focus on other product areas. Already, the realization of SLI trends has prompted Japanese companies to initiate the restructuring of their businesses in all aspects of semiconductor operations, ranging from customer support and product design to process development and manufacturing capital spending. This "SLI Shift" also requires marketing power reinforcement.

With reduced profits because of weak pricing trends, major players in the Japanese market face the challenge of making all those changes with minimal resources. It is not sufficient to assume that Japanese semiconductor vendors can automatically benefit from the digital consumer just because the development and production of digital consumer equipment are taking place in the backyard. The efforts to best capture the SLI trends and reform the semiconductor operation will enable them to enjoy a reasonable share and profits in the semiconductor business.

Chapter 4
Japanese MOS Memory Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese MOS memory market recorded negative growth of 14.5 percent over the previous year. On a dollar basis, the decline reached 23.1 percent, worse than that of the world market, which registered an 18.6 percent decrease. The major factor for the MOS memory decline was the relentless erosion of DRAM prices, which hit the Japanese market hard, and Japanese companies relying on the domestic market were severely damaged. As a result, the world share of the Japanese market declined slightly, from 22.3 percent in 1996 to 21.1 percent in 1997.

A breakdown of the 1997 Japanese market by device indicates major slumps in the DRAM and static RAM (SRAM) segments, which shrunk by 15.6 percent and 17.8 percent, respectively. While the two devices grew in unit shipments, price declines caused the overall market decline on a value basis. In particular, the DRAM market has been suffering a supply glut and is still experiencing a seemingly unstoppable price erosion. The sluggish DRAM market affected SRAM prices that continued to plummet. The nonvolatile memory market was not immune to the dreary market conditions, recording a 12.2 percent decrease in 1997. Clearly, the entire memory market is satiated with excess supply capacities. Even flash memory, one of the few big hopes in the market, reported a negative growth of 9.8 percent on a value basis, although unit shipments grew strongly, as bolstered by cellular phone demand. In the 1997 flash memory market, prices of 8Mb-or-smaller products dropped sharply, to bring the entire market down. In 1998, as Japanese companies are expected to shift part of their production capacity to flash-with-view to reduce dependency on DRAMs, 16Mb flash will likely be a target for another round of price decline.

Ranking Trends

In the 1997 Japanese MOS memory market, NEC ranked first with a 16.4 percent share (see Tables 4-1 through 4-4). The company managed to keep revenue downturns at a single-digit level (7.7 percent) among leading semiconductor companies that heavily rely on the DRAM business. Hitachi held second place, just as it did in 1996, even though it reported a 14.8 percent decline. Fujitsu was the only company in the top five that recorded an increase (8.6 percent); it advanced from fifth to third place. The major contributing factor was the strong growth of 16Mb flash sales, up 53.7 percent from 1996. In contrast, Toshiba fell from third to fifth place as its revenue from flash memory declined 75.7 percent.

MOS Memory Forecast through 2002

Dataquest predicts that the 1998 market will grow 7.0 percent (an 0.1 percent decrease on a dollar basis), which represents a downward adjustment of 6 percentage points compared to the fall forecast (see Tables 4-5 and 4-6). Again, DRAM price decline because of supply glut is the major culprit. While increased 16Mb production by U.S. companies triggered the price fall in 1997, the aggressive moves of Korean suppliers will dictate DRAM prices. At present, 16Mb prices continue to fall below $3 on the spot market, which pulls 64Mb prices downward.

The Japanese MOS memory market in 1998 will be driven by SRAM, EEPROM, and flash memory. In particular, after 1999, the DRAM market will expand at an accelerated pace, while the SRAM and nonvolatile memory markets will maintain healthy growth. In 2002, however, the DRAM market will experience negative growth as the generation crossover from 64Mb to 256Mb occurs. Dataquest predicts that the market's CAGR between 1997 and 2002 will be 15.4 percent (13.8 percent on a dollar basis).

While the fall forecast assumed that DRAM companies would curtail capital spending in 1998, these companies are currently moving to minimize the rate of investment cutbacks where possible. In particular, Korean companies are considering maintaining capital spending as close as possible to the 1997 level (on a won basis), despite the DRAM recession and pain from the AFC. Dataquest pointed out in the fall forecast that a major reduction of 64Mb production capacity would be required to regain revenue growth in 1998. However, DRAM companies are not reducing capital spending as much as expected, which necessitated the downward adjustment of the DRAM market growth forecast.

In 1998, a major event in the DRAM market will be a full-blown shift from extended data out (EDO) to synchronous DRAM (SDRAM). During the first half of 1998, 100-MHz SDRAMs for PC100 will keep a price premium against the 66-MHz versions, which will significantly narrow in the second half of 1998 as DRAM companies roll out 0.25-micron fab lines. After 1999, the Japanese DRAM market will be driven by better-managed capacity expansion by DRAM suppliers, recording a CAGR of 16.1 percent (14.6 percent on a dollar basis) between 1997 and 2002.

The Japanese nonvolatile memory market will be up slightly 0.3 percent (6.3 percent down on a dollar basis) in 1998 because of double-digit declines in EPROM and mask ROM, which will more than offset the 20 percent growth of the EEPROM and flash segments. The CAGR between 1997 and 2002 will be 9.6 percent, as the market will be driven by EEPROM and flash memory.

The Japanese flash memory market recorded negative growth of 9.8 percent in 1997, but it is expected to resume growth in 1998. Major applications include mobile communications equipment, led by cellular phones, as well as IC cards. In particular, smart phones are expected to ramp up early in Europe, becoming an important consumer of flash memory. This is expected to have a positive impact on the Japanese mobile communications and flash memory markets.

Source: Dataquest (August 1998)

In the MOS memory market, Japanese semiconductor companies still strive to become less dependent on DRAM business. Large suppliers will increasingly shift their strategic focus to flash memory. The 1997 flash market saw price declines in 8Mb-or-less products. Dataquest expects that the move will spread to the 16Mb-or-larger segments in 1998 and after.

Challenge to the Vendors

To analyze the current state of memory vendors, they should be divided according to their DRAM dependency. This analysis focuses on DRAM-dependent companies. At present, DRAM vendors continue to be beleaguered by serious oversupply conditions with a deteriorating profitability that shows no signs of improvement. Cutthroat competition among vendors accelerates the race for next-generation process technology and higher integration, requiring them to engage in an endurance contest to keep high capital spending. As a result, three generations of leading-edge devices—64Mb, 128Mb, and 256Mb—will coexist in 1999.

Up until 1995, the rapid advance of process technology drove the commercial development of smaller DRAM chips by applying a linear shrink approach. At present, however, cost reduction becomes a primary reason for shrinking the chip size, while the same processing technology is applied. This means that the present supply glut is a combination of excess capacities—as the aftermath of the previous capital spending spree—and an increased number of chips taken from each wafer because of the advance of shrink technology.

Needless to say, the DRAM supply capacity must be cut down drastically to bring the market back to parity. However, a reduction of production capacity would be a hard blow to Korean companies and some U.S. manufacturers that heavily depend upon the DRAM business. Compared to them, Japanese DRAM vendors are less dependent and have alternative products to offer. It is thus a reasonable option for them to convert DRAM capacities to other devices on a continuous basis. Although the large-scale production shift will adversely affect prices of other products, such as flash, it makes better sense than desperately insisting on DRAM production under the present no-win situation. While reducing DRAM capacities, even on a temporary basis, it is desirable for them to continue R&D efforts on finer process technology. Because the DRAM market is increasingly driven by higher integration and faster speeds, vendors that lead in design rules are beginning to enjoy early profits. Dataquest predicts that the current oversupply condition will continue until the end of 1999. Vendors should cut down their own DRAM capacities in consideration of capital spending by the end of the century, allowing them to establish leading-edge process technology.

Chapter 5
Japanese MOS Microcomponent Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese microcomponent market saw a sound 18.1 percent growth over the previous year (6.1 percent on a dollar basis). The major source of the increase was in the MPU and microcontroller (MCU) markets, both of which recorded two-digit growth rates.

PCs drove the MPU market, and the introduction of clone MPUs compatible with Pentium MMX helped the formation of the low-end PC and subnote PC markets. MCUs were boosted by the expansion of digital consumer equipment production, mobile communications equipment, and mass storage devices. In the emerging markets, such as the digital consumer and next-generation markets, ECU/euro areas consumed value-added 32-bit MCUs, which contributed to MCU vendors' profits. The Japanese digital signal processing (DSP) market shows a trend different from other regional markets because of Japanese application markets and the Japanese vendors' strategic technology. Notably, in mobile communications and in mass storage, Japanese system manufacturers tend to use semiconductor products developed by internal semiconductor divisions. This tendency has limited the penetration of foreign-made DSPs into the equipment and has created Japanese proprietary trends.

Ranking Trends

Intel increased its share to 22.8 percent, securing the No. 1 position in the Japanese MOS microcomponent market, as well as in other regional markets in 1997 (see Tables 5-1 through 5-5).

Following Intel was NEC, which led the worldwide MCU market as the No. 2 vendor, with a wide MCU product offering ranging from 4-bit to 64-bit. Its growth came mainly from 8-bit, proprietary 32-bit with proprietary architecture, and 64-bit million of instructions per second (MIPS) MCUs.

Ranked No. 3 was Hitachi, which lost market share in 1997 in spite of two-digit growth. Its growth in the previous year was boosted by 32-bit MCUs and MPUs used in video game applications. As its share in that application lowered in 1997, it penetrated into other applications, such as mass storage devices, but it could not make up the loss in other applications fast enough.

Toshiba, ranked No. 4, also grew in two digits, helped by mass storage and mobile communications applications. Fujitsu, with the contribution of 16-bit MCUs in mobile communications and 32-bit MCUs in storage and digital VCR applications, grew at an astonishing 49 percent, to be ranked at No. 5, surpassing Mitsubishi Electric. Mitsubishi Electric has traditionally been strong in VCR applications, and its revenue grew at a sound 13 percent, helped by 16-bit MCUs in storage applications and 32-bit proprietary MCUs with embedded DRAM for digital VCRs.

MOS Microcomponent Forecast through 2002

The Japanese MOS microcomponent market will expand 15.2 percent (7.5 percent on a dollar basis) in 1998. The CAGR between 1997 and 2002 will be 16.2 percent (14.6 percent on a dollar basis), with firm growth expected for each year (see Tables 5-6 and 5-7).

The Japanese MPU market in 1998 will fail to meet the previous forecast level because of the slowdown in the PC market. The market should grow at 12.6 percent (5.1 percent on a dollar basis). The market will see a wider variety of products besides Intel's X86 families (Pentium with MMX technology, Pentium Pro, and MMX Pentium II). Products will include non-Intel, high-speed MPUs; MPUs for low-cost PCs; and MPUs designed for portable applications, including mobile computing (embedded MIPS, SH, and StrongARM)—for example, Tillamook, Mobile Pentium II, and Windows CE2.0.

MCUs, the largest of the Japanese microcomponent segments, are expected to surge 15.1 percent (7.4 percent on a dollar basis) in 1998. They are incorporated into a variety of electronic equipment. Low-bit versions are embedded into household appliances for system control purposes, many of which are implemented on a 4-bit or 8-bit basis. Japanese companies still hold a dominant share in the 4-bit segment.

Four-bit MCUs are used in diverse products, ranging from toys to analog cordless telephones, and companies are still exploring new applications. Nevertheless, the market size will grow only moderately, partly because of the weakening demand from portable game systems, which have been a major driver, and partly because of the increased migration to 8-bit products. In particular, revenue growth will be minimal because of low prices, although unit growth may continue.

On the other hand, the 8-bit MCU market will enjoy strong growth as a result of upgrading from 4-bit applications and the need to address the increasing complexity of system control. The development of MCUs embedding flash memory technology is under way, and the competition has heated up among U.S., European, and Japanese companies for market share.

In 1997, 8-bit MCUs were used in most electronic equipment, including the following range of products:

- Video and audio equipment
- Computer-related equipment, including keyboards and display units
- Communications equipment, including analog cordless telephones and digital portable telephones
- Antilock braking systems (ABSs)
- Pachinko game systems
- Household appliances

Applications expected to emerge in 1998 and afterward include: smart cards, minidisc (MD) players, USB controllers (8-bit basis), and MCUs incorporating Infrared Data Association (IrDA) communications features. Encouraged by potential demand for contact/noncontact IC cards, semiconductor companies will opt for alliances to consolidate technological resources and vie for industrial standards. Finally, MCUs integrating ferroelectric memory technology will be introduced to the noncontact IC card market to invigorate the 8-bit MCU market.

Sixteen-bit MCUs, on the other hand, will be increasingly used for digital processing applications, particularly digital cellular phones, PHSs, hard disk drives (HDDs), and CD-ROM drives. Applications expected in 1998 and afterward include DVD, fixed and on-board audio MD players, and DV-C. Again, flash memory technology will be increasingly incorporated to address system requirements in terms of flexibility, and semiconductor companies will focus on enhancing their offerings.

As for 32-bit and 64-bit MCUs, SLI based on ASIC technology will become the mainstay. Promising applications that will be developed after 1998 by using a leading-edge process and an embedded MPU include: vehicle information and communication system (VICS)-based car navigation systems incorporating DVD-ROM drives, next-generation home/portable video game systems, and set-top boxes (STBs). Sixteen-, 32-, and 64-bit MCUs will enjoy strong growth next to 8-bit products, driven by price declines resulting from SLI, the emergence of digital consumer equipment, and the digitization of systems. Dataquest expects solid profitability.

In 1997, rapid growth was seen in the flash MCU market. Major applications include memory cards for video game systems, CD-ROM drives, and HDDs, spurring consumption of 8- and 16-bit MCUs. As for multibit, embedded MPU (MCU) architectures, ARM will be rapidly accepted in 1998 and afterward. Diverse architectures offered by vendors (MIPS, M Core, SH, SPARC, PowerPC, and X86) will be optimized for different applications according to their SLI strategy.

In 1998, the Japanese microperipheral (MPR) market is expected to grow 9.6 percent over the previous year (2.3 percent on a dollar basis). A variety of PC peripherals based on PC98 standards will become pervasive, and different application-specific standard product (ASSP) segments (chipset, USB, IEEE 1394, and MPACT1/2) will grow in relation to different applications.

The Japanese DSP market will continue a strong growth of 39.8 percent (30.5 percent on a dollar basis) in 1998. With the increasingly shortened development cycle for system products, DSPs and media processors will undoubtedly become core technologies because they offer flexibility in the development of digital consumer equipment with the ability to reconfigure themselves by replacing middleware/microcode. By 2002, 0.18- to 0.12-micron processes will be commercialized. As a result, the DSP market will grow strongly at a CAGR of 29.7 percent (27.9 percent on a dollar basis) between 1997 and 2002.

Finally, embedded DSPs are increasingly incorporated into servo controllers for CD and MD players as well as codec processing for cellular phones. Generic DSPs, including media processors, are primarily used in high-speed analog modems (56-Kbps) for PCs and sound source processing. New applications emerging in 1998 and afterward include digital cellular phones, which use a single chip integrating a 16/32-bit MCU and DSP; HDD controllers containing DSP/MCU and DRAM for buffer memory; and high-speed disk drives such as DVD-ROM/RAM, incorporating partial response maximum likelihood (PRML) technology and DSP.

Challenge to the Vendors

In order to meet technology requirements from a wide range of applications, 32-bit MPUs with embedded RISC have been rapidly expanding their market since 1996. Major applications include mobile equipment, such as cellular phones and personal digital assistants (PDAs); digital video systems, such as digital camcorders (DVC) and digital still cameras; and systems that require real-time graphical processing, such as in-car navigation and video game machines.

It is difficult to accomplish the real-time processing of large volumes of data such as graphic and/or sound in multimedia systems without high-performance MPUs. DSPs are one solution, but they could increase the number of large-scale integrators (LSIs), which poses a threat to overall system cost and/or size. This can be solved with an embedded RISC MPU solution with multimedia processing by middleware, which enables system makers to save cost and circuit board space.

User needs for graphical user interface (GUI) increases in MPU-driven systems and for high-performance embedded MPUs will be growing, expanding demand for embedded MPUs with advanced SLI ASIC technology, such as MIPS, ARM, SH, SPARC, V853(E), M32R/D, and Shark.

Complex-instruction-set computing (CISC) MPUs that can be represented by x86 architecture have expanded their market mainly in PC applications. Currently, this segment of the market is served with products that are developed and manufactured with 0.25-micron process technology, aiming at production efficiency, cost competitiveness, and high performance, such as high frequency and low-power dissipation. System makers can take advantage of existing resources such as development technology and environment.

Thus, progress in SLI ASIC technology, electronic design automation (EDA) technology, and the development of high-performance 32-bit and 64-bit RISC embedded MPUs and 32-bit CISC MPUs are enabling system companies to develop new systems and subsystems, enjoying benefits in specification optimization, shortening turnaround time, and lowering system cost.

In the microcomponent market, SLI has arrived. No longer are system designers using standalone microcomponents such as MPU, MCU, and DSP; rather, they are increasing their dependency on SLI LSIs. This trend has made the choice, alliance, and development of architecture ever more important in meeting requirements in applications.

These trends are also making the border obscure between ASIC and microcomponent, forcing microcomponent vendors to incorporate various factors, such as supply support, technology support, development environment, and future marketability, when planning microcomponent business for processor architecture. This planning should include the understanding of system technologies so that the architecture can best support system memory, cost management, system size optimization, power, and noise management.

Achieving those technology targets alone cannot bring success in the MPU/MCU or DSP business. Microcomponent vendors will be required to focus more on factors such as technology support, risk evaluation, marketability and launch timing, business opportunity evaluation, and cost of ownership (COO) evaluation. Also included is marketing power, which previously may not have been a strength, especially for Japanese microcomponent vendors. Dataquest believes that those factors are the key to choosing processors in optimizing systems.

Chapter 6

Japanese Total Logic Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese total logic market grew at 16.2 percent over the previous year (4.4 percent on a dollar basis), while the total ASIC market showed a solid growth of 15.7 percent, driven by cell-based ICs (CBICs), including mixed-signal ASICs. This sound growth in total ASICs is supported by the SLI market expansion, where CBIC technology is the key for developing ASIC and ASSP products that can meet competitive cost targets.

The Japanese ASIC market has followed its own trends, and 1997 was no exception. The worldwide ASIC market saw the following three changes:

- LSI Logic slipped from No. 2 to No. 4 in the total ASIC market.
- IBM and Lucent moved up to No. 2 and No. 3, respectively.
- Programmable logic device (PLD) makers made it to the top 10, but Xilinx Incorporated gave way to Altera Corporation, which has become the top PLD vendor.

These worldwide trends are clearly seen in the Americas market; however, in 1997, Japanese ASIC vendors were not affected. In Japan, where ASIC market growth depends on limited applications in digital consumer equipment and mobile communications, these trends can hardly be observed.

Japanese vendors in the ASIC market are very unique in that they continue to grow in the gate array market, where Americas companies are disappearing from top rankings. Americas companies are choosing to de-emphasize gate arrays so that they can focus on SLI business, while Japanese vendors are filling the void in the market, resulting in their positive growth in gate array revenue in 1997.

In the longer run, however, this trend will turn out to be a burden rather than a market opportunity, because Japanese companies will have to allocate their resources in process technology development, library development, designing power, and profitability to this low-growth segment of the ASIC market.

The PLD market in Japan has not grown to be a major segment as it is in the Americas market. A major cause of this is the persistent demand among system makers for gate array products in supply and in technology support. Japanese ASIC companies are at the same time vertically integrated companies, where overall corporate-level profit comes before profits in product segments such as semiconductors, while at Americas companies, profit maximization as well as the independence of each business unit is clearly defined.

As a result, in an effort to meet domestic customer requirements, small to medium-size designs, which could be optimized with PLDs, are still developed with gate arrays, limiting the growth of the PLD market. Gradually, however, this inefficient design practice is being improved in areas such as communications infrastructure systems, which helped the PLD market in Japan in 1998 to show a sound growth of 15.6 percent over the previous year.

Ranking Trends

As the determinant factor in the total logic market, ASICs played a key role in ranking trends (see Tables 6-1 through 6-5). In the 1997 Japanese ASIC market, NEC ranked No. 1, capturing one-quarter of the market. NEC is actually the worldwide leader in ASICs, having strength in a wide range of applications, including industrial, communications, consumer, and data processing. In the Japanese market, it was the consumer area that contributed to NEC's two-digit growth.

Following NEC was Fujitsu, also with a more than 20 percent market share, which it increased by revenue growth in digital consumer and communications applications. The third company in Japan was Hitachi, which grew in the number of designs, leveraging on its SLI strategy based on SH architecture, but was not free from the competitive pricing trends. LSI Logic ranked at No. 4, growing an overwhelming 64.6 percent over the previous year. LSI Logic leads the SLI trends, and in Japan, its growth comes from successes in ASSP and ASIC business in digital consumer applications, as well as custom LSI for video game machines based on a MIPS architecture embedded MPU core. Ranked as No. 5, Toshiba dropped one notch, recording a negative two-digit growth—the only negative growth among the top 10 Japanese companies.

Total Logic Forecast through 2002

In 1998, the Japanese total logic market will grow 8.7 percent (1.5 percent on a dollar basis). The total ASIC market will expand 11.8 percent, or 4.3 percent on a dollar basis (see Tables 6-6 and 6-7).

In 1997, high-performance systems, as seen in digital consumer equipment, were implemented to incorporate multiple, large-scale circuits by using intellectual property (IP) core and leading EDA tools. We also saw a rapid increase in the volume production of ASSPs and SLI ASIC products in single-chip implementation by using a highly integrated ASIC process and SLI technologies. A future challenge lies in reducing the cycle time for system development to minimize turnaround time and R&D investment, reduce development-related risks, and support early LSI implementation.

Traditionally, the "core-limited design" issue, derived from large-scale internal cores, was a major obstacle in designing ASICs. Recently, however, as the ASIC process reached submicron levels, the shrink ratio of the internal core has been improved. This, in turn, has resulted in an increase in the "input/output (I/O) pad-limited design," where I/O pads set the limit rather than cores. Also, flexibility in the ASIC design, resulting in small-lot production, adversely affects the profitability of business.

Source: Dataquest (August 1998)

By 1997, many leading ASIC vendors in the Americas region had started to de-emphasize the gate array business. This move is favorable for the PLD market and is accelerating the collapse of the U.S. gate array market. Technically, PLDs have already integrated 250,000 to 500,000 gates on a commercial basis by using process technology based on 0.25-micron, five-layer interconnect and shallow trench structure. Dataquest believes that 1 million gates will be integrated by using an 0.18-micron process technology by 2000.

In 1998, the Japanese PLD market will show a strong growth of 15.6 percent (7.9 percent on a dollar basis). In Japan, the gate array business still dominates because of high captive demand. Nevertheless, because SLI will lead ASIC business in the future, the Japanese PLD market will grow to an appreciable size compared to the Americas market. Dataquest expects that the market will register the second-highest growth rate, following CBICs, with a CAGR of 21.3 percent between 1997 and 2002.

The Japanese CBIC market (including mixed-signal) will grow 20.7 percent (12.7 percent on a dollar basis) in 1998. The ramp-up of 0.35-to-0.25-micron process manufacturing and the increasing need for design optimization in various applications have been driving the market for CBICs, which are regarded as the key infrastructure factors in SLI technologies such as embedded MPUs/DSPs, IP core, embedded memories, and mixed-signal designs. At the same time, the establishment of CBIC technology has caused the custom IC market to shrink rapidly, resulting in a negative CAGR of 31.0 percent (31.9 percent on a dollar basis) between 1997 and 2002.

Among other logic products, standard logic features such as small-scale integration (SSI), middle-scale integration (MSI), and LSI are mostly incorporated into ASICs, but demand for standard logic still exists in the area of super-high-speed CMOS- or BiCMOS-based standard logic, such as CMOS-based one-gate logic products and wide bus products. Thus, the Japanese standard logic market will continue to grow steadily at a CAGR of 5.1 percent (3.7 percent on a dollar basis).

Finally, LCD drivers will be driven by increased market acceptance of LCD-equipped systems as well as by the exploration of new application markets. As a result, the Japanese market's CAGR for the "Total other MOS Logic" category is expected to be 11.8 percent (10.3 percent on a dollar basis) during the five-year period.

In 1998, ASIC suppliers announced a number of next-generation 0.18-micron processes, and some of them in Japan and the United States started volume production. Also, development efforts are under way to commercialize a "unified process" that represents a "dream process integration." Dataquest believes that portable applications in the Japanese market will contribute to technological progress in the areas of ultra-low operating voltage below 1.0V, embedded flash memory, mixed-signal designs, and high-density packages, such as chip-scale packaging (CSP) and direct chip attach (DCA), thereby driving the SLI ASIC market.

Challenge to the Vendors

Traditional ASICs were mainly single-function products that integrated glue logic. With the introduction of a new business model in 1990 based on intellectual property cores, the whole ASIC industry has been moving toward SLI, and ASIC vendors have been in the process of restructuring their businesses. Japanese companies are no exception.

In this new ASIC business model, vendors first prepare a large number of IP cores, based on each vendor's own research, either developed internally or acquired from the outside. Then, in the development environment of IP cores, description languages such as Verilog Hardware Description Language (Verilog-HDL) and VHSIC HDL Roger's Interface Language (VHDL-RIL), for standardization, enable vendors to provide the appropriate set of IP cores at the request of ASIC users, which enables the design of a large, complex system with a short turnaround time. This SLI business model is advantageous to users because they can develop and market their new systems with minimum investment and risk, and within a short range of time. For ASIC vendors, users' recognition of IP cores as value-added will help differentiate them from competitors. In the ASIC business, where differentiation has been difficult, this SLI move is expected to help improve profitability.

In putting system-level functions on a single chip, traditional ASIC process technology is not sufficient. Also required are an understanding of requirements from each target application and the most advanced EDA, IP core development environment, and analog/mixed-signal technologies for designing embedded MPUs. Those are the key factors for ASIC vendors to be successful in the SLI business.

In this sense, the Virtual Socket Interface (VSI) Alliance, in which worldwide semiconductor vendors as well as system makers and EDA vendors participate, will standardize IP cores, establish their distribution system, and dramatically change the ASIC industry.

In the current market, continuing DRAM oversupply and pricing weakness have prompted semiconductor companies to shift emphasis from memories to logic, resulting in a crowded market in the latter half of 1997. This supply/demand situation has caused the price fall of logic products, and expectations about the profitability of the SLI business are being questioned. The needs for embedded DRAM and flash are increasing from the application side, and, leveraging on profitable applications such as graphics and mobile equipment, embedded memories will contribute to the market growth of SLI ASIC.

Another factor that poses challenges to vendors is the development of process technology. The main technology has shifted from 0.5 micron to 0.35 micron, and now it is shifting toward 0.25 micron and 0.18 micron concurrently. This trend may cause Japanese ASIC vendors currently investing in 0.25-micron process technology and manufacturing capacity to lose competitiveness.

©1998 Dataquest

The semiconductor industry has observed silicon cycles many times, but in this round, ASIC technology progress, in centering on graphics, data processing, and communications, may change the market positioning for various ASIC vendors. Americas companies have enjoyed high market share, leveraging on embedded MPU and DSP core technology. Korean companies are aiming to catch up with the forerunners by focusing on DRAM as a technology driver. Taiwanese companies have established a business model of dedicated foundry, supporting fabless companies. Japanese companies have an advantage in overall SLI technology, with their embedded technology and IP cores, based on MCU business experience. The SLI ASIC market will be more competitive with all of these vendors, and all SLI companies will be required to equip themselves with the necessary ASIC technologies, an understanding of various technical requirements for each target application, and a strategic analysis of competitors.

Chapter 7
Japanese Analog IC, Discrete Device, and Optical Semiconductor Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese market saw healthy growth for analog, discrete, and optical semiconductor products. Among those, the analog market recorded a more than 20 percent increase over the previous year for the first time in the 1990s. Contributing to this strong growth were factors such as strong unit demand because of improved electronics production, stable pricing trends, and an increase in mixed-signal products with higher average selling prices than conventional linear products.

At a time when new systems are emerging, system designers resort to discrete function chips, such as general-purpose analog ICs and discrete semiconductor devices, until system designs become stable and circuits become integrated into larger devices, including ASSP and ASIC. The year 1997, which can be marked when the shift to digital consumer systems becomes a solid move, was another example of this trend. The increase in demand for analog and discrete semiconductor products has been observed since 1995, but the acceleration in 1997 was more than the industry expected, and the tightened supply/demand balance helped to keep the prices stable, contributing to profits for vendors.

Major contributions came from segments such as telecom analog, disk-drive analog, special-function analog, and power-management analog products. Among discrete semiconductor products, it was power transistors—not only the emerging isolated gate bipolar transistors (IGBTs) but also MOS field-effect transistors (FETs) and even bipolar transistors—that marked two-digit growth over the previous year. The increase in those products was supported by PC and peripheral equipment as well as mobile communications applications. The driver for the growth in optical semiconductors in Japan was the laser diode, whose consumption was pumped by optical storage devices and audio players such as CD-ROM drive and MD players.

Ranking Trends

In the 1997 Japanese analog market, Texas Instruments Inc. continued to lead while all the rest of the top 10 companies were domestic vendors (see Table 7-1). However, other Americas and European vendors, too, increased their sales rapidly, and as a result, the combined share of non-Japanese vendors has become one-third of the market. TI's revenue growth came both from general-purpose products and ASSPs such as disk drive and automotive. Toshiba, ranked No. 2, also enjoyed growth in general-purpose product revenue as well as an increase in applications in consumer and automotive. Matsushita Electronics switched places with NEC, helped by increases in telecom and disk drives. SANYO Electric Company Ltd. and Sony remained in their respective positions of the previous year, although they recorded growth rates that were higher than the market average.

The Japanese discrete and optical semiconductor markets have traditionally been dominated by domestic vendors, and 1997 was no exception.

In the 1997 Japanese discrete semiconductor market, Toshiba maintained the lead by growing faster than the market, leveraging on its coverage in all three power transistor areas (see Table 7-2). NEC replaced Hitachi as the No. 2 vendor in Japan, showing two-digit growth rates in most of the product areas except for thyristors. Companies such as Rohm Company Ltd., Mitsubishi Electric, and SANYO kept their respective positionings, but they have a marked difference in product coverage—Rohm benefits from bipolar, SANYO from MOSFET, and Matsushita Electronics from both bipolar and MOS.

In the optical semiconductor market in Japan, Sharp Electronics Corporation widened the lead by growing at 24 percent (see Table 7-3). Contributions came from a wide range of segments, including couplers, charge-coupled devices (CCDs), and laser diodes. Companies following Sharp maintained their respective positions, with Rohm and SANYO each showing over 20 percent growth and both benefiting from the demand increase for laser diodes. Included in the survey from 1997 is Stanley Electric, which jumped in at No. 8 with its focused product coverage of LED lamps and displays.

Analog IC, Discrete Device, and Optical Semiconductor Forecast through 2002

The outlook for the analog, discrete, and optical semiconductor markets has been adjusted downward from the previous forecast. It should be noted that the analog market was partially affected by the reclassification of linear array and mixed-signal ASICs (although small in size) into total ASICs.

The strong demand growth for analog ICs in the past few years has caused the industry to hold unduly high expectations. With the rapid progress of system diversification, accompanied by LSI implementations over several generations, demand for analog ICs and discrete devices has been experiencing a surge in momentum (see Tables 7-4 and 7-5). Nevertheless, the expansion of mixed-signal analog IC markets will ultimately lead to CBICs absorbing analog functions, so that suppliers will tend to overestimate long-term demand by extrapolating the recent high-growth trends. Also, sluggish electronics production causes demand for generic analog devices to slow down.

In the first quarter of 1998, suppliers do not seem to be accelerating analog capacity, partly because of heavy constraints on investment resources. If supply capacity expands abruptly, prices will plummet, resulting in unit growth without revenue growth. Given this cap for capacity expansion, Dataquest believes that it will be difficult for the Japanese analog market to continue double-digit growth. (In the downside scenario mentioned in Chapter 2, analog price erosion has been incorporated into the Japanese market growth.)

Challenge to the Vendors

Japanese analog vendors have enjoyed two advantages in the domestic market: IC demand and system technology from Japan-based consumer electronics makers. Now that even Japan-based consumer companies have shifted a large portion of their equipment production overseas and non-Japanese markets are growing much faster, Japanese analog vendors can no longer expect the same pattern. Also, the system technology required in digital consumer applications derives from basic technologies developed by non-Japanese system makers in the Americas and European markets. As system-oriented semiconductor suppliers, Japanese analog companies need to strengthen their design support capability in markets outside of Japan, focusing on target applications in each region.

Chapter 8
Japanese Companies' Capital Spending Trends

Overall Spending Trends

In 1997, capital spending in Japan saw a decline over the previous year, for the first time since 1992 (see Table 8-1). This was caused mainly by the Japanese companies, whose worldwide spending shrank by 1.7 percent. The outlook for 1998 is even gloomier because the capital expenditure in Japan is expected to be cut by 30 percent on a dollar basis—the largest reduction among all four regions. In the section below, the spending trends of Japanese companies are analyzed, as Japanese companies represent the majority of spending in Japan.

The regional distribution of Japanese companies' spending this year shows a clear preference: Domestic investment declines by one-third, while spending in the Americas and Europe is being reduced by one-half. The only region to show an increase is Asia/Pacific. This does not actually mean that Japanese companies on the whole are focusing on that region. Rather, the increase comes from a large commitment by NEC to the Shanghai joint venture.

During the boom years, Japanese companies took an aggressive approach to high-growth markets overseas by increasing the supply capacity near the markets, just like they did in the past boom years, and, just like they did after the past boom years, they are reducing overseas spending again. This trend can be attributed first to a big reduction in funds caused by lessened profits or increased loss from the semiconductor business in recent years. Realizing the need to focus on next-generation investments, Japanese companies have given up on the idea of enforcing local supply capacity. The second reason can be found in exchange rate trends, where the Japanese yen has depreciated to the level it saw about seven years ago when Japanese companies were less motivated to produce outside of Japan.

Spending trends by product also show a sharp contrast. Investment into memories is to be cut by one-third, while the microcomponent and logic segments combined show a much milder reduction of 7.6 percent. As a result, memories' share of Japanese companies' capital spending is to be surpassed by those two other categories for the first time since DRAM has become a major segment of business for Japanese semiconductor companies. The focus on microcomponent and logic clearly shows their determination to pursue SLI trends. Analog and discrete, two major product categories that represent a large portion of the profits, are given ample share in the investment this year. This, however, poses a threat to the near-future supply/demand of those categories, because the progress of SLI may imply a reduced rate of growth in demand—not reduced demand—for analog and discrete products.

Looking at facilities, the expenditure in property and land is being cut in half, while wafer fab equipment spending is to be reduced by 20 percent, and back-end facilities show only a 6 percent reduction. In view of the continuing overcapacity in the market, Japanese companies are discouraged about increasing overall supply capacity; once again they are carefully filling the shells that they build during the boom years. Most of the wafer fab equipment is aimed at upgrades to 0.25-micron technology, while in a limited number of cases, investments in deep submicron fab equipment are included. The efforts in 300mm wafer technology have been slowed for several reasons, including reduced overall spending, technology/equipment problems, and a market condition of prolonged overcapacity. The ultimate question for semiconductor manufacturers in pursuit of large wafer technology is whether they will really need production capacity of that magnitude. Not many companies can fully enjoy the increased efficiency in production of commodity products including DRAMs, but not many companies are ready to offer SLI products that can utilize 300mm wafer fab capacity. Shifting product preference is seen in back-end investment trends, where the focus on microcomponent and logic requires additional equipment for the interconnect/metal layer.

 ©1998 Dataquest

In the past down-cycle years, Japanese companies sought to increase foundry shipment to improve fab utilization. Ever since the emergence of dedicated foundry providers equipped with advanced logic technology, however, that "opportunistic foundry shipment" practice has become a less easy choice. Dedicated foundries are well prepared to cope with fabless companies' requirements. Foundry providers in Taiwan have a strong tie with the U.S. semiconductor industry, and the tie—especially with fabless companies—has brought them ample orders, taking away business opportunities from other companies. Thus, the decrease in foundry shipments has been another reason for Japanese companies' reduction in additional supply capacity.

The current weak revenue and pricing trends, and consequential dwindling profits, hardly justify strong spending in manufacturing equipment. The question then lies in deciding how much spending is the appropriate amount. There has been a general, empirical belief in the industry that capital spending of over 20 percent of revenue is not necessarily a safe practice unless a company has good reasons to do so and understands the financial risks involved. Looking at Japanese companies' spending, this criterion seems to apply to larger suppliers, while medium-size companies have spent over 20 percent of their revenue, and companies with specific product orientation in discrete and optical areas have spent characteristically less than 15 percent of their revenue. Noteworthy is the ratio for NEC, the largest semiconductor supplier and capital spender among Japanese companies, which is less than 15 percent. Taking into consideration that NEC tends to construct its own proprietary fabs with the exception of recent two cases in China, NEC's investment efficiency is strikingly high among Japanese companies. With the exception of NEC, however, major Japanese companies have started to seek alliances in outsourcing manufacturing at a pace never seen before. This is causing a restructuring of the Japanese semiconductor industry, and Dataquest believes that this is an unavoidable step for Japanese companies to regain strength in the semiconductor business.

Taking into consideration the current trends toward SLI, as well as prolonged DRAM oversupply, it is not likely that Japanese companies will resume a high pace of spending in manufacturing capacity. Even 300mm wafer production has dropped from the list of top priorities, while some companies have not given up technology development and pilot production. Some Japanese companies are facing the ultimate question of whether to make or buy in some product areas where investment efficiency cannot easily be achieved, given their own product portfolio and large amount of expenditure. Dataquest believes that semiconductor vendors that make the bold but required decision to refocus their business, with ample consideration of and emphasis on SLI, will come out shining beyond the current turmoil in the semiconductor industry.

Chapter 1
Japanese Fab Database

Background and Methodology

This report contains the Japanese portion of Dataquest's wafer fab database. The records in these tables are fabs located in the Japan region. The Semiconductor Equipment, Materials, and Manufacturing Worldwide (SEMM) program conducts extensive annual surveys, complemented with quarterly secondary research to maintain this database. Published once a year, this document represents Dataquest's best insights and estimates into the end-market of semiconductor equipment.

The tables in this report cover planned and existing merchant, captive, and foundry fab lines. A fab line is a series of equipment to do front-end (from initial oxide through wafer probe) semiconductor manufacturing. Occasionally, two or more separate product-specific fab lines or wafer sizes operate in a single clean room or physical plant. In this situation, Dataquest divides the clean room as separate fab lines if the company dedicates equipment to each wafer size or product line. If a company installs substantially different equipment during an expansion (for example, equipment to increase its maximum wafer diameter), again Dataquest divides the clean room and creates two entries into the database. Therefore, a company may operate many fab lines at one location.

Worldwide Geographic Region Definitions and Regional Roll-Ups

Americas

Includes Central America (all nations), Canada, Mexico, United States, Puerto Rico, and South America (all nations).

Japan

Japan is the only single-country region.

Europe, Africa, and Middle East

Includes Africa (all nations), Albania, Andorra, Armenia, Azerbaijan, Belarus, Belgium, Bulgaria, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Georgia, Germany, Gibraltar, Hungary, Iceland, Israel, Italy, Kazakhstan, Kyrgyzstan, Latvia, Liechtenstein, Lithuania, Luxembourg, Malta, Middle East (all nations), Moldova, Monaco, Netherlands, Norway, Poland, Romania, Russia, San Marino, Scandinavia, Slovakia, Spain, Sweden, Sweden, Switzerland, Tajikistan, Turkey, Turkmenistan, Ukraine, United Kingdom, Uzbekistan, Vatican City, and all nations within the former Yugoslavia.

Asia/Pacific

Includes Australia, Bangladesh, Cambodia, China, Hong Kong, India, Indonesia, Laos, Malaysia, Maldives, Myanmar, Nepal, New Zealand, Pakistan, Philippines, Singapore, South Korea, Sri Lanka, Taiwan, Thailand, and Vietnam.

Field Definitions

The Company field indicates the operator of the fab line. For contract manufacturers that trade capacity for capital investment in the fab, Dataquest lists the contract manufacturer. For incorporated joint ventures, Dataquest lists either the incorporated entity or the major investors, separated with slashes.

The City field displays the most detailed location information. This reference is usually a city or town, but could be an often-used district name (for example, Science Park in the city of Hsinchu, Taiwan). If this field lists a district, Dataquest will list the city in the State or Province field. In some cases, a reference to a state or province will be included in the City or District field to create a unique identifier for this location.

The Prefecture field denotes the second most detailed location. This reference is usually a state (for the United States), province (for Canada and many European and Asian countries), or a prefecture (for Japan). For countries within the United Kingdom, Dataquest lists the country name (for example, "Scotland") in this field so Dataquest can list the descriptor "U.K." in the Country field.

The Country field indicates the broadest location identifier in this report. This reference is usually a country, except in the case of the United Kingdom (see "State or Province" above). Because Japan is a single-country region, there is no regional qualifier for fabs in Japan.

The Fab Name field provides a reference to a particular fab or fab line to distinguish it from other fabs or lines owned by that company. Although Dataquest makes every attempt to match the nomenclature used by the company, occasionally some additional qualifiers (for example, "Phase 1") will appear to provide insight to the facility's history or organization.

The Products field lists the products manufactured at this site. The listings generally fall into five product groups, with the following nomenclature and definitions (when warranted):

- MOS memory
  - DRAM: Dynamic RAM
  - EEPROM: Electrically erasable PROM
  - EPROM: Ultraviolet erasable PROM
  - FERRAM: Ferroelectric RAM
  - FIFO: First-in/first-out memory
  - Flash: Flash memory
  - Mem: Memory
  - NV Mem: Nonvolatile memory (ROM, PROM, EPROM, EEPROM, and FERRAM)
  - PROM: Programmable ROM
  - RAM: Random-access memory

- ROM: Read-only memory
- SGRAM: Synchronous graphics RAM
- Sp Mem: Other specialty memory (such as dual-port, shift-register, or color lookup)
- SRAM: Static RAM
- VRAM: Video RAM

■ MOS microcomponent/digital logic

- Array: Gate array
- ASIC: Application-specific IC
- ASSP: Application-specific standard product
- Bit: Bit slice (subset of MPU functions)
- CBIC: Cell-based IC
- Custom: Full-custom IC (single user)
- DSP: Digital signal processor
- FPGA: Field-programmable gate array
- LISP: 32-bit list instruction set processor for AI
- Logic: Standard logic
- LSI: Large-scale integration
- MCU: Microcontroller unit
- MixSig ASIC: Mixed-signal ASIC
- MPR: Microperipheral
- MPRCom: MPR digital communication (ISDN, LAN, UART, or modem)
- MPU: Microprocessor unit
- PLD: Programmable logic device
- RISC: Reduced-instruction-set computation 32-bit MPU
- Telecom: Telecommunications chip

■ Power/discrete/analog (including bipolar power)

- A/D D/A: Analog-to-digital, digital-to-analog converter
- Automotive: Dedicated to automobile applications
- CODEC: Coder/decoder
- Diode
- Discrete
- FET: Field-effect transistor
- GTO: Gate turn-off thyristor
- HEMT: High-electron-mobility transistor
- IGBT: Insulated-gate bipolar transistor

 ©1999 Dataquest

- Interface: Interface IC
- Linear: Linear/analog device
- MDiode: Microwave diode
- MESFET: Metal semiconductor field-effect transistor
- MFET: Microwave field-effect transistor
- Modem: Modulator/demodulator
- MMIC: Monolithic Microwave IC
- MOSFET: MOS-based field-effect transistor
- Op Amp: Operational amplifier
- Pwr IC: Power IC
- Pwr Tran: Power transistor
- Rectifier
- Reg: Voltage regulator
- RF: Radio frequency
- SCR: Schottky rectifier
- Sensor
- Smart Pwr: Smart power
- SST: Small-signal transistor
- Switches: Switching device
- Thyristor
- Tran: Transistor
- Zener Diode

- Optoelectronic
  - CCD: Charge-coupled device (imaging)
  - Coupler: Photocoupler
  - IED: Infrared-emitting diode
  - Image Sensor
  - Laser: Semiconductor laser or laser IC
  - LED: Light-emitting diode
  - Opto: Optoelectronic
  - PDiode: Photo diode
  - PTran: Photo transistor
  - SAW: Surface acoustic wave device
  - SIT Image Sensor: Static induction transistor image sensor

- Bipolar Digital and Other Devices (includes all digital ICs using a bipolar process)
  - Darlington
  - Micromachining sensors
  - MilStd: Military Standard Logic
  - RadHard: Radiation hardened

The Process Technology field indicates each fab's use of five major types of processes. The process grouping is as follows:

- P/CMOS: P-channel metal-oxide semiconductor (PMOS) or complementary metal-oxide semiconductor (CMOS)
- NMOS: N-channel metal-oxide semiconductor (NMOS)
- BiCMOS: Bipolar and CMOS combined on a chip
- Bipolar
- III-V: Gallium arsenide and other compound semiconductor processes

The Estimated Minimum Geometry is the smallest linewidth feature size, measured in microns, attainable in production volume.

The Wafer Diameter represents the maximum wafer size that the fab or fab line can process. Wafer diameters, although expressed colloquially in inches, conform to metric specifications. For wafers greater than 3 inches in diameter, expression in inches becomes inaccurate. When calculating square inches, Dataquest uses the following approximations:

- Stated diameter of 4 inches (100mm) = Approximate diameter of 3.938 inches
- Stated diameter of 5 inches (125mm) = Approximate diameter of 4.922 inches
- Stated diameter of 6 inches (150mm) = Approximate diameter of 5.906 inches
- Stated diameter of 8 inches (200mm) = Approximate diameter of 7.87 inches
- Stated diameter of 12 inches (300 mm) = Approximate diameter of 11.84 inches.

The Year and Quarter of Initial Production displays the year (and quarter, if available) in which this line, having completed all qualifications, began manufacturing in production volumes. The format for this reference is "year.quarter" (for example, 1994.3 translates to the third calendar quarter of 1994).

The Initial Monthly Wafer Starts field indicates the initial monthly volume of production wafer throughput.

The Estimated Maximum Monthly Wafer Starts field contains the equipment-limited wafer start capacity per four-week period. Only the throughput of the installed equipment and the process complexity limits the maximum starts. Dataquest does not consider current staffing or the number of shifts operating in determining this metric.

©1999 Dataquest

The Fab Type field shows the types of semiconductor manufacturing performed at this location. The fab types include the following:

- "F" indicates that this is a production-based fab.
- "R" indicates a semiconductor R&D and/or trial production facility.
- "P" means that this location produces a pilot line.
- "T" means that this location performs assembly or testing.
- "N" indicates that this location performs foundry production, or contract manufacturing.
- "VD" means that this location performs VHDL design.
- "PD" means that this location performs IC place and route design.

Chapter 1

Japanese Electronic Equipment Production Forecast

Introduction

Electronic equipment production is an important determinant of semiconductor market activity. This is true because semiconductor demand is derived, in part, from the underlying demand for the systems that use semiconductors. That is, the demand for semiconductors is a positive (or increasing) function of the demand for electronic systems. Therefore, forecasting electronic systems production is an essential component of assessing expected semiconductor market activity.

This document contains tables detailing the fall 1998 electronic equipment production forecast. Japanese production is estimated for the years 1992 to 2002. Production tables contain both historical data and forecasts. In most tables, historical data begins with 1992 and ends with 1997, while forecast data provides estimates for 1998 through 2002. The tables detail the type of production data by application market.

Definitions and Conventions

The objective of analyzing electronic systems production activity is to estimate the important implications for semiconductor consumption. In this document, the value of production is estimated as factory revenue. Dataquest defines factory revenue as the exchange value of the commodity transaction between the original equipment manufacturer and the point of entry into distribution. In the case of a direct sale that involves no distribution, as is the case with military systems, factory revenue is equal to the final user cost, net of sales taxes.

Production is the value-adding process by which the factors of production (labor and capital) and material input are transformed into the goods and services that are desired for consumption and investment. As such, production can span both time and geography. For example, a Japanese color television company may minimize its cost of production by manufacturing its products (that is, consuming chips) in Asian countries. Dataquest would estimate this as Asia/Pacific production, because we are interested in that portion of the production process that relates specifically to semiconductor consumption.

Electronic equipment is divided into the following six semiconductor application markets and is further divided into the designated segments:

- Data processing
  - Computers
  - Data storage
  - Input/output
  - Dedicated systems
  - Other data processing

©1998 Dataquest

- Communications
  - Premise telecom
  - Public telecom
  - Mobile and radio equipment
  - Broadcast and studio
  - Other communications
- Industrial
  - Security/energy management
  - Manufacturing systems/instrumentation
  - Medical equipment
  - Other industrial
- Consumer
  - Audio
  - Video
  - Personal electronics
  - Appliances
  - Other consumer
- Military/civil aerospace
- Transportation

Data Sources

The historical information presented in the production data has been consolidated from a variety of sources, each of which focuses on a specific part of the market. These sources include the following:

- Japanese production statistics compiled and published by the Ministry of International Trade and Industry (MITI)
- Estimates presented by knowledgeable and reliable industry spokespersons
- Published information on products and prices

Valuation of Production

Japanese production is expressed in Japanese yen and translated into U.S. dollars. To make the tables in this document useful in comparing different regions, it is necessary to express all values in a common currency, and Dataquest chose the U.S. dollar for convenience. However, the choice of the U.S. dollar or any other currency brings with it some problems that require the readers' careful consideration in interpreting the data.

 ©1998 Dataquest

Exchange rates are an example of this. When forecasting electronic equipment production, it is important to ensure consistency and continuity. The preliminary 1998 exchange rate estimate is based on actual monthly exchange rates through July 1998, and we assume that the July rate applies for all the future months in 1998. For the years 1999 through 2002, we maintain exchange rates at constant 1999 calendar-year values. This prevents any inconsistencies in the conversion of growth projections and currency fluctuations. The estimates in this Market Statistics report are generated primarily on a yen basis and then are converted to U.S. dollars.

Japanese Electronic Equipment Production Definitions

Data Processing Equipment

Defined as computers, data storage, input/output devices, dedicated systems, and other data processing, as follows:

- Computers include supercomputers, mainframe computers, midrange computers, entry-level servers, workstations, PCs, motherboards, and handheld computers.
- Data storage includes rigid disk drives, removable disk drives, optical disk drives, tape drives, and other data storage.
- Input/output includes all equipment that transfers data between the CPU and a peripheral device, such as printers, monitors, and other input/output devices.
- Dedicated systems include dedicated data processing systems such as copiers, personal organizers, chip cards, and other systems.
- Other data processing includes sound/audio, digital, and graphics accelerator boards. This category also includes the value of aftermarket sales of single in-line memory modules (SIMMs) and dual in-line memory modules (DIMMs).

Communications Equipment

Defined as premise telecom, public telecom, mobile and radio communications, broadcast and studio, and other communications, as follows:

- Premise telecom includes telecommunications equipment on private premises such as image and test communications equipment, data communications equipment (WAN/LAN and remote access), premise voice systems, and desktop terminals (telephones excluding mobile handsets).
- Public telecom includes key equipment involved in the public switching and transmission markets.
- Mobile and radio communications includes cellular/broadband personal communications services (PCS)/enhanced special mobile radio (ESMR) handsets, pagers, and mobile communications infrastructure, among others.
- Broadcast and studio includes audio, video, and other broadcast and studio equipment.
- Other communications includes other communications equipment not counted elsewhere, such as intercommunications systems.

 ©1998 Dataquest

Industrial Equipment

Defined as security/energy management, manufacturing systems/instruments, medical equipment, and other industrial systems, as follows:

- Security and energy management includes alarm systems and energy management.
- Manufacturing systems/instrumentation includes semiconductor production equipment, control and process control equipment, control and processing display equipment, and robots. This category also includes automatic test equipment (ATE) semiconductor equipment, nuclear electronics, and other test and measurement equipment.
- Medical equipment includes diagnostic, therapeutic, patient monitoring and measuring systems, surgical support equipment, and irradiation equipment.
- Other industrial includes vending machines, automatic service equipment, commercial clothes-washing equipment, teaching machines and aids, particle accelerator electronic equipment, electron microscopes, and scientific equipment not counted elsewhere.

Consumer Equipment

Defined as audio, video, personal electronics, appliances, and other consumer equipment, as follows:

- Audio includes consumer audio equipment.
- Video includes consumer video equipment.
- Personal electronics includes video games, cameras, electronic watches, clocks, and toys.
- Appliances include consumer appliances.
- Other consumer includes automatic garage door openers, electronic tape measures, electronic tire gauges, and other consumer equipment not counted elsewhere.

Military/Civil Aerospace Equipment

Defined as radar/sonar/reconnaissance, missile/space, navigation, electronic warfare, aircraft flight systems, and command/control systems.

Transportation Equipment

Defined as entertainment, vehicle/body control, driver information, power train, and safety and convenience electronics.

Project Analyst: Motoya Ohgami

Chapter 2
Market Statistics Tables

Tables 2-1 through 2-24 contain statistics for Japanese electronic equipment production. Tables 2-1 through 2-6 contain historical data and forecasts for six semiconductor application markets divided into major segments. Tables 2-7 through 2-24 show more detailed forecasts for each application market.

Preface

Dataquest's *Japanese Semiconductor Consumption Forecast by Electronics Application, Fall 1998* is a revised and reformatted version of our long-standing semiannual semiconductor consumption by electronics application market forecast. We have made several changes to this publication in an effort to make it more relevant and meaningful; we have also included a new category of information that shows unit production trends for selected systems. Major changes include:

- Categorization changes to secure consistency with electronic equipment production forecasts
- Addition of high-volume electronic equipment unit production forecast data for 40 major systems

Dataquest has directed its semiconductor applications research toward better understanding the dynamics of production and semiconductor use across individual electronic systems. We have developed forecast models capable of tracking production and estimating total semiconductor consumption for some 40 different individual electronic systems, shown in full scale for the first time in this report.

Project Analyst: Motoya Ohgami

©1998 Dataquest

Chapter 1
Introduction and Discussion

Introduction

This document contains Dataquest's forecast of Japanese semiconductor consumption by electronics application, 1997 to 2002, based both on U.S. dollars and Japanese yen. It also contains our forecast of worldwide semiconductor consumption by broad categories over the same period. This is the second of two semiannual forecasts. This forecast reflects changes since this spring in Dataquest's view of semiconductor consumption by electronic equipment worldwide and in Japan. It incorporates changes suggested by Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments.

The tables in this document present data intended to answer the following questions:

- What is the estimated semiconductor consumption of various categories of electronic equipment?
- What is the estimated semiconductor consumption of the key individual electronic systems that make up these broad categories?

The estimates offered in this document are intended to provide very general answers to these questions. They are meant as a broad guide to semiconductor consumption by electronic equipment production in Japan. The most detailed information about estimated semiconductor consumption by individual electronic systems is available in the last chapter of this document.

The semiconductor consumption forecasts presented here complement Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments. Updated Japanese electronic equipment forecasts can be found in the Market Statistics report *Japanese Electronic Equipment Production Forecast, Fall 1998* (November 1998). Our updated semiconductor forecast is found in the Market Trends report *Worldwide Semiconductor Forecast ~~and Trends, Fall 1998~~* ~~(November~~ 1998). Additional regional and semiconductor device details for this forecast can also be requested through Dataquest's inquiry service.

The tables in this document are organized as follows:

- Tables 2-1 and 2-2 summarize the worldwide semiconductor consumption forecast and compare it to the worldwide semiconductor shipments forecast.
- Tables 2-3 and 2-4 summarize the Japanese semiconductor consumption forecast on a dollar basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-5 to 2-12 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a dollar basis.

©1998 Dataquest

- Tables 2-13 and 2-14 summarize the Japanese semiconductor consumption forecast on a yen basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-15 to 2-22 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a yen basis.
- Tables 3-1 to 3-40 present unit production and semiconductor consumption forecasts in Japan for 40 major electronic systems.
- Figures 3-1 to 3-40 show Japan's share of the worldwide unit production for 40 major electronic systems for 1997 and 2002.

Segmentation of Semiconductor Applications

Dataquest forecasts semiconductor consumption by end-use electronic application. We divide electronic applications into six broad groups in accordance with our segmentation of electronic equipment production. These groups are, in turn, disaggregated into more narrow electronic systems categories, as follows:

- Data processing
  - Computers
  - Data storage
  - Input/output devices
  - Dedicated systems
  - Other data processing
- Communications
  - Premise telecommunications
  - Public telecommunications
  - Mobile communications
  - Broadcast and studio equipment
  - Other communications
- Industrial
  - Security and energy management systems
  - Manufacturing systems and instruments
  - Medical equipment
  - Other industrial equipment
- Consumer
  - Audio
  - Video
  - Personal electronics
  - Appliances
  - Other consumer equipment

 ©1998 Dataquest

- Military/civil aerospace
- Transportation

As part of the forecast process, Dataquest develops forecasts for about 40 individual electronic systems within these various categories and subcategories. These include the following:

- Data processing
  - Mainframes/supercomputers (computers)
  - Midrange computers (computers)
  - Workstations (computers)
  - PCs (computers)
  - Motherboards (computers)
  - Rigid disk drives (data storage)
  - Optical disk drives (data storage)
  - Removable magnetic storage (data storage)
  - Page printers (input/output)
  - Serial printers (input/output)
  - Monitors (input/output)
- Communications
  - LAN cards (premise telecommunications)
  - Premise line cards (premise telecommunications)
  - Answering machines (premise telecommunications)
  - Fax machines (premise telecommunications)
  - Modems (premise telecommunications)
  - Corded telephones (premise telecommunications)
  - Analog cordless phones (premise telecommunications)
  - Digital cordless phones (premise telecommunications)
  - Central office line cards (public telecommunications)
  - Analog cellular phones (mobile telecommunications)
  - Digital cellular phones (mobile telecommunications)
  - Pagers (mobile telecommunications)
  - Mobile telecommunications infrastructure (mobile telecommunications)
  - Other mobile telecommunications products (mobile telecommunications)

©1998 Dataquest

- Consumer
  - Personal/portable stereos (audio)
  - Color TVs (video)
  - VCRs (video)
  - Analog camcorders (video)
  - Digital camcorders (video)
  - DVDs (video)
  - Analog set-top boxes (video)
  - Digital set-top boxes (video)
  - Digital still cameras (personal electronics)
  - Video game controllers (personal electronics)
- Transportation
  - Automotive stereos
  - Automotive engine control units (ECUs)
  - Antilock braking systems
  - Air bags
  - Automotive navigation systems

Geographic Segmentation

Dataquest's worldwide electronic equipment production forecast is aggregated from individual forecasts for four principal geographic regions:

- Americas
- Japan
- Europe, Middle East, and Africa
- Asia/Pacific

Exchange Rates

Dataquest's worldwide electronic equipment forecast aggregates data from many countries, each of which uses a currency that has a different and fluctuating exchange rate relative to the U.S. dollar. Because we compile our worldwide forecast from individual regional forecasts, we use the U.S. dollar as a common currency for comparisons and aggregation. As a rule, Dataquest calculates forecasts in local currencies and then converts them to U.S. dollars using projected average annual exchange rates. Dataquest does not forecast exchange rates per se. Instead, we calculate projected average annual exchange rates from current exchange rates. Our projections are based on estimates of the latest available monthly exchange rate at the time the forecast is developed. These rates are based on monthly exchange rates observed through July 1998. Additional information about historical exchange rates and Dataquest's method of calculating future average exchange rates may be requested through Dataquest's client inquiry service.

Forecast Methodology

When discussing semiconductor consumption, it is critical to remember that semiconductors are not end products consumed for their own sake. They are intermediate products used as inputs for electronic end products that are eventually consumed by individuals and businesses for the utility they provide. Implicit in the concept of semiconductor consumption is the notion that the electronic end products in which semiconductors will be incorporated or consumed can be specified. A semiconductor forecast that does not or cannot specify this is not a forecast of semiconductor consumption. At best, it is merely a forecast of semiconductor shipments.

Dataquest's semiconductor consumption by electronic application forecast grew out of the recognition that a truly complete semiconductor forecast must specify the electronic end uses of semiconductors. However, specifying semiconductor end uses has proved far more difficult than recognizing that it must be done. Although it appears possible to specify semiconductor consumption by the variety of electronics produced, there are simply too many different types of semiconductor devices consumed in too large a variety of electronic products. As a result, semiconductor consumption must invariably be estimated. This can be done in any number of ways. Before this forecast, Dataquest used a mathematical model to estimate semiconductor consumption by various electronic end uses. Taking Dataquest's electronic equipment production and semiconductor shipments forecasts as inputs, this model allocated estimated semiconductor shipments across forecast electronics production subject to various assumptions about the semiconductor content of electronic products. The model also imposed several balancing conditions intended to guarantee that estimated semiconductor shipments were completely allocated across all forecast electronics production.

The model applied a top-down approach to estimating semiconductor consumption. In effect, it calculated estimates of semiconductor consumption by compelling agreement between the details of the electronics production forecast and the semiconductor shipments forecast. As a result, the estimates of semiconductor consumption were more an artifact of a mathematical process than truly independent estimates of semiconductor consumption. Although the model offered considerable flexibility, it was nonetheless limited by the validity of its semiconductor content assumptions and the balancing requirement that semiconductor consumption equal semiconductor shipments. Despite its potential drawbacks, the model provided the best estimates we could offer, given a paucity of knowledge about semiconductor applications in specific electronic systems.

Over the last several years, Dataquest's semiconductor applications research has been concentrated on the study of semiconductor use in specific individual electronic systems. We have successfully developed models to track and forecast the production and semiconductor consumption of some 40 different individual electronic systems. These include PCs and PC motherboards, rigid disk drives, LAN cards and modems, digital cellular phones, digital set-top boxes, and automotive navigation systems, among others. The electronic systems encompassed by our models account for about one-half of all electronics production and nearly two-thirds of estimated semiconductor consumption.

©1998 Dataquest

These models have allowed us not only to codify our knowledge about individual electronic systems but also to approach the task of estimating semiconductor consumption using a bottom-up forecast method. This method was used for the forecast and will be used for future forecasts. The method essentially involves building a forecast of semiconductor consumption for all electronics production by leveraging estimates of semiconductor consumption for individual electronic systems. Dataquest uses individual systems estimates as a forecast base and augments this with estimates of semiconductor consumption for other electronic equipment categories not tracked individually. Precisely because the method uses well-researched knowledge about individual electronics systems that dominate semiconductor consumption, Dataquest believes it is capable of providing far better forecasts of semiconductor consumption than our former top-down method, especially for electronic equipment categories such as computers, where individual systems forecasts account for virtually the entire category. The results of this analysis are shown in Chapter 3.

Forecast Highlights

Dataquest estimates that worldwide semiconductor consumption will decrease by 0.2 percent in 1998 to about $148.0 billion. Dataquest expects approximately two-thirds of this growth will come about because of growth in worldwide electronics production, which is now forecast to grow 2.2 percent in 1998 to about $935.8 billion. The remainder will be the result of expected growth in the average semiconductor content of electronics, which we forecast will increase to about 15.8 percent of electronics factory value. Longer-term, we estimate worldwide semiconductor consumption will average 10.3 percent annual growth through 2002. This should raise worldwide semiconductor consumption to about $241.6 billion by 2002. Dataquest expects slightly over half of the longer-term growth in worldwide semiconductor consumption to come about because of growth in worldwide electronics production, which we are now forecasting to average 6.1 percent annual growth through 2002. Once again, remaining growth in semiconductor consumption will be the result of increases in the average semiconductor content of electronics. We now expect average semiconductor content will rise to about 19.7 percent of electronics factory value by 2002.

We are now forecasting Japanese semiconductor consumption will decrease by 10.4 percent in 1998. This compares to anticipated growth rates of 3.8 percent for Asia/Pacific and 5.0 percent for Europe, the Middle East, and Africa. In the long term, Japanese consumption is expected to average just 4.6 percent annual growth between 1997 and 2002, as opposed to 13.9 percent for Asia/Pacific and 10.2 percent for Europe, the Middle East, and Africa. (Note: All of our forecasts are valued in U.S. dollars and thus reflect projected exchange rate movements in addition to expected changes in semiconductor consumption expressed in local currencies.) Underlying these marked differences in long-term growth are equally marked differences in expected sources of growth.

There is a strong desire among suppliers to believe that semiconductor shipments, and with them semiconductor revenue, can continue to post high rates of long-term growth. However, this desire needs to be tempered with the recognition that long-term shipments growth is only possible so

 ©1998 Dataquest

long as electronics makers are able to profitably increase semiconductor consumption, either by expanding electronics production or increasing semiconductor content. A number of fundamental changes are taking place in several key electronics markets that will limit the future ability of electronics makers to profitably increase semiconductor consumption. Semiconductor suppliers would be well advised to acknowledge these emerging limits because failure to do so will only intensify competition and further imperil both future shipment and revenue growth in Japan.

Chapter 3
High-Volume Electronic Equipment Unit Production and Semiconductor Consumption Forecast in Japan

Tables 3-1 through 3-40 present Dataquest's forecast of electronic equipment unit production and semiconductor consumption for 40 major electronic systems. Figures 3-1 through 3-40 show the trends of Japan's share in production volume for 40 major electronic systems, 1997 versus 2002, in comparison with other regions.

Table 3-1
Production and Semiconductor Consumption Forecast for Mainframe/Supercomputers in Japan, 1997-2002

	1997	1998	1999	2000	2001	2002	CAGR (%) 1997-2002

Preface

Dataquest's *Japanese Semiconductor Consumption Forecast by Electronics Application, Spring 1998* is a revised and reformatted version of our long-standing semiannual semiconductor consumption by electronics application market forecast. We have made several changes to this publication in an effort to make it more relevant and meaningful, as well as more consistent with Dataquest's other research of semiconductor applications in electronic systems. Three major changes include:

- We are publishing only forecast data.
- We have increased the electronic systems detail reported in our forecast of total semiconductor consumption while eliminating the forecasts of specific semiconductor device consumption offered in previous reports.
- Dataquest's estimate of semiconductor consumption no longer equals the value of forecast semiconductor shipments.

The decision to publish only forecast data is significant. This decision stemmed from several considerations. On one hand, we have found that clients are generally far more interested in a forecast of semiconductor consumption than in estimates of past consumption. Given this and given that our estimates of historical consumption are always available to those who desire them through Dataquest's client inquiry services, Dataquest believes readers lose little from our decision to publish only forecast data. More important, we are in the midst of instituting an important and fundamental change in our forecast methodology. Data limitations severely restrict our ability to extend this method back into history. Rather than undertake the effort required to publish historical data consistent with the dictates and conventions of our new forecast method, we have decided to publish only forecast data.

The third change is admittedly quite significant and is related to the methodology change mentioned. Put succinctly, this forecast marks Dataquest's move away from a decidedly top-down method of estimating semiconductor consumption toward a bottom-up forecast approach, motivated by several factors. First, our forecast should more explicitly reflect the knowledge that Dataquest has rapidly been acquiring about semiconductor applications among individual electronic systems. For several years, Dataquest has directed its semiconductor applications research toward better understanding the dynamics of production and semiconductor use across individual electronic systems. We have developed forecast models capable of tracking production and estimating total semiconductor consumption for some 40 different individual electronic systems.

Dataquest believes these models are now sufficiently developed to use them as the backbone of our forecast of semiconductor consumption. Indeed, Dataquest believes that by leveraging the bottom-level knowledge provided by these models, we can provide far more accurate forecasts than ever before. Using these models as the basis for our forecast also allows us to report total semiconductor consumption for individual electronic systems, something that many clients have been requesting.

©1998 Dataquest

Unfortunately, we are still in the process of developing semiconductor device detail for many of our individual systems models. Rather than perpetuate old ways, we have opted to forgo publishing consumption forecasts of specific semiconductor devices, at least until our individual systems models are complete enough to let us generate forecasts consistent with our new methodology.

Second, Dataquest is seeking to eliminate our dependence on an assumption-sensitive mathematical model for our estimates of semiconductor consumption. Past forecasts of semiconductor consumption were created using a top-down mathematical model. Using Dataquest's forecasts of electronic equipment production and semiconductor shipments as inputs, this model generated estimates of semiconductor consumption by mathematically matching estimated semiconductor shipments to our forecast of electronics production based on a variety of assumptions about the semiconductor content of the various electronics product categories. Thus, our semiconductor consumption estimates were more by-products of a mathematical process than true estimates of consumption. In its defense, the model was extraordinarily flexible and allowed us to create very reasonable estimates of semiconductor consumption for broad categories of electronic products. Nonetheless, its results were highly sensitive to the semiconductor content assumptions needed to drive the model. Moreover, it offered little opportunity to incorporate our growing insights into the semiconductor consumption of individual electronics systems.

Above all, we are hoping to establish a truly separate and independent forecast of semiconductor consumption that can be compared and contrasted to Dataquest's long-standing semiconductor shipments forecast. One important feature of our now-discarded mathematical forecast model was its insistence that estimated semiconductor consumption always equal forecast semiconductor shipments. Putting aside its validity, this insistence essentially robbed our semiconductor consumption forecast of any independent insight into the dynamics of the semiconductor market in the future. By forsaking this insistence, Dataquest is not only able to provide an independent view of future semiconductor developments but also a view that can and should be compared to Dataquest's well-established semiconductor shipments forecast. Our hope is that readers will find contrasting views of the semiconductor market helpful in their efforts to divine its future.

As always, Dataquest welcomes readers' comments and would greatly appreciate any suggestions about improving our research.

Chapter 1

Introduction and Discussion

Introduction

This document contains Dataquest's forecast of Japanese semiconductor consumption by electronics application, 1997 to 2002, based both on U.S. dollars and Japanese yen. It also contains our forecast of worldwide semiconductor consumption by broad categories over the same period. This is the first of two semiannual forecasts; the second will be published this coming fall. This first forecast reflects changes since last fall in Dataquest's view of semiconductor consumption by electronic equipment worldwide and in Japan. It incorporates changes suggested by Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments.

Long-time readers will note significant changes in the focus and format of this forecast, compared to previous forecasts. This document reports only a forecast for 1997 to 2002. More significantly, we have greatly expanded the electronic systems detail supporting our forecast of total semiconductor consumption, and we have eliminated our forecasts of semiconductor device consumption by electronic application. These changes are related to a fundamental change in our forecast methodology. Dataquest's previous semiconductor consumption forecasts were a top-down mathematical reconciliation of updated electronic equipment production and semiconductor shipment forecasts. The forecast in this document represents an effort to independently estimate from the bottom up the semiconductor consumption generated by Dataquest's forecast of electronics production. Dataquest no longer attempts to specify how forecast semiconductor shipments will distribute themselves across electronics applications. Instead, the forecast separately estimates semiconductor consumption by electronic systems, unconstrained by the requirement that semiconductor consumption equal semiconductor shipments. It leaves open the possibility that estimated semiconductor consumption may differ from estimated semiconductor shipments. Unfortunately, this document is not the appropriate forum for discussing the consequences of the semiconductor demand/supply imbalance implied by persistent differences between estimated semiconductor consumption and estimated semiconductor shipments. That task will be left for other Dataquest publications.

The tables in this document present data intended to answer the following questions:

- What is the estimated semiconductor consumption of various broad categories of electronic equipment?
- What is the estimated semiconductor consumption of the key individual electronic systems that make up these broad categories?

The estimates offered in this document are intended to provide very general answers to these questions. They are meant as a broad guide to semiconductor consumption by electronic equipment production in Japan. More detailed information about estimated semiconductor consumption by individual electronic systems is available in other Dataquest documents.

©1998 Dataquest

The semiconductor consumption forecasts presented here complement Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments. Updated Japanese electronic equipment forecasts can be found in *Japanese Electronic Equipment Production Forecast, Spring 1998* (SEMI-JA-MS-9802, June 1998). Our updated semiconductor shipments forecast is found in *Worldwide Semiconductor Five-Year Forecast Trends: Spring 1998* (SCND-WW-MT-9801, June 1998). Additional regional and semiconductor device detail for this forecast can also be requested through Dataquest's inquiry service.

The tables in this document are organized as follows:

- Tables 2-1 and 2-2 summarize the worldwide semiconductor consumption forecast and compare it to the worldwide semiconductor shipments forecast.
- Tables 2-3 and 2-4 summarize the Japanese semiconductor consumption forecast on a dollar basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-5 to 2-12 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a dollar basis.
- Tables 2-13 and 2-14 summarize the Japanese semiconductor consumption forecast on a yen basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-15 to 2-22 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a yen basis.

Segmentation of Semiconductor Applications

Dataquest forecasts semiconductor consumption by end-use electronic application. We divide electronic applications into six broad groups in accordance with our segmentation of electronic equipment production. These groups are, in turn, disaggregated into narrower electronic systems categories, as follows:

- Data processing
  - Computers
  - Data storage
  - Input/output devices
  - Other data processing
- Communications
  - Premise telecommunications
  - Public telecommunications
  - Mobile communications
  - Broadcast and studio equipment
  - Other communications

- Industrial
  - Security and energy management systems
  - Manufacturing systems and instruments
  - Medical equipment
  - Other industrial equipment
- Consumer
  - Audio
  - Video
  - Personal electronics
  - Appliances
  - Other consumer equipment
- Military/civil aerospace
- Transportation

As part of the forecast process, Dataquest develops forecasts for about 40 individual electronic systems within these various categories and subcategories. These include:

- Data processing
  - Mainframes/supercomputers (computers)
  - Midrange computers (computers)
  - Workstations (computers)
  - PCs (computers)
  - PC motherboards (computers)
  - Rigid disk drives (data storage)
  - Optical disk drives (data storage)
  - Removable magnetic storage (data storage)
  - Page printers (input/output)
  - Serial printers (input/output)
  - Monitors (input/output)
- Communications
  - LAN cards (premise telecommunications)
  - Premise line cards (premise telecommunications)
  - Answering machines (premise telecommunications)
  - Fax machines (premise telecommunications)
  - Modems (premise telecommunications)
  - Corded telephones (premise telecommunications)
  - Analog cordless phones (premise telecommunications)
  - Digital cordless phones (premise telecommunications)

 ©1998 Dataquest

- Central office line cards (public telecommunications)
- Analog cellular phones (mobile telecommunications)
- Digital cellular phones (mobile telecommunications)
- Pagers (mobile telecommunications)
- Mobile telecommunications infrastructure (mobile telecommunications)
- Other mobile telecommunications products (mobile telecommunications)

- Consumer
  - Personal/portable stereos (audio)
  - Color TVs (video)
  - VCRs (video)
  - Analog camcorders (video)
  - Digital camcorders (video)
  - DVD (video)
  - Analog set-top boxes (video)
  - Digital set-top boxes (video)
  - Digital still cameras (personal electronics)
  - Video game controllers (personal electronics)
  - Video game cartridges (personal electronics)
- Transportation
  - Automotive stereos
  - Automotive engine control units (ECUs)
  - Antilock braking systems
  - Air bags
  - Automotive navigation systems

Geographic Segmentation

Dataquest's worldwide electronic equipment production forecast is aggregated from individual forecasts for four principal geographic regions:

- Americas
- Japan
- Europe, Middle East, and Africa
- Asia/Pacific

 ©1998 Dataquest

Exchange Rates

Dataquest's worldwide electronic equipment forecast aggregates data from many countries, each of which uses a currency that has a different and fluctuating exchange rate relative to the U.S. dollar. Because we compile our worldwide forecast from individual regional forecasts, we use the U.S. dollar as a common currency for comparisons and aggregation. As a rule, Dataquest calculates forecasts in local currencies and then converts them to U.S. dollars using projected average annual exchange rates. Dataquest does not forecast exchange rates per se. Instead, we calculate projected average annual exchange rates from current exchange rates. Our projections are based on estimates of the latest available monthly exchange rate at the time the forecast is developed. These rates are based on monthly exchange rates observed through February 1998. Additional information about historical exchange rates and Dataquest's method of calculating future average exchange rates may be requested through Dataquest's client inquiry service.

Forecast Methodology

When discussing semiconductor consumption, it is critical to remember that semiconductors are not end products consumed for their own sake. They are intermediate products used as inputs for electronic end products that are eventually consumed by individuals and businesses for the utility they provide. Implicit in the concept of semiconductor consumption is the notion that the electronic end products in which semiconductors will be incorporated or consumed can be specified. A semiconductor forecast that does not or cannot specify this is not a forecast of semiconductor consumption. At best, it is merely a forecast of semiconductor shipments.

Dataquest's semiconductor consumption by electronic application forecast grew out of the recognition that a truly complete semiconductor forecast must specify the electronic end uses of semiconductors. However, specifying semiconductor end uses has proved far more difficult than recognizing that it must be done. Although it appears possible to specify semiconductor consumption by the variety of electronics produced, there are simply too many different types of semiconductor devices consumed in too large a variety of electronic products. As a result, semiconductor consumption must invariably be estimated. This can be done in any number of ways. Before this forecast, Dataquest used a mathematical model to estimate semiconductor consumption by various electronic end uses. Taking Dataquest's electronic equipment production and semiconductor shipments forecasts as inputs, this model allocated estimated semiconductor shipments across forecast electronics production subject to various assumptions about the semiconductor content of electronic products. The model also imposed several balancing conditions intended to guarantee that estimated semiconductor shipments were completely allocated across all forecast electronics production.

 ©1998 Dataquest

The model applied a top-down approach to estimating semiconductor consumption. In effect, it calculated estimates of semiconductor consumption by compelling agreement between the details of the electronics production forecast and the semiconductor shipments forecast. As a result, the estimates of semiconductor consumption were more an artifact of a mathematical process than truly independent estimates of semiconductor consumption. Although the model offered considerable flexibility, it was nonetheless limited by the validity of its semiconductor content assumptions and the balancing requirement that semiconductor consumption equal semiconductor shipments. Despite its potential drawbacks, the model provided the best estimates we could offer, given a paucity of knowledge about semiconductor applications in specific electronic systems.

Over last several years, Dataquest's semiconductor applications research has been concentrated on the study of semiconductor use in specific individual electronic systems. We have successfully developed models to track and forecast the production and semiconductor consumption of some 40 different individual electronic systems. These include PCs and PC motherboards, rigid disk drives, LAN cards and modems, digital cellular phones, digital set-top boxes, and automotive navigation systems, among others. The electronic systems encompassed by our models account for about one-half of all electronics production and nearly two-thirds of estimated semiconductor consumption.
