Chapter 1
Introduction

This Market Statistics report represents Dataquest's forecast for China/Hong Kong electronic equipment production in units, revenue, semiconductor content, and available markets for semiconductors. Dataquest has selected 37 key application systems that have high-volume production in China/Hong Kong. These key systems are identified by Dataquest as the leading indicators of semiconductor consumption trends by end-application market segment.

The 37 leading indicators selected by Dataquest are as follows:

- Electronic data processing
  - Personal computer
  - Motherboard
  - Workstation
  - Midrange computer
  - Mainframe/supercomputer
  - Page printer
  - Serial printer
  - Rigid disk drive
  - Optical disk drive
  - Monitor
- Communications
  - LAN card
  - Fax
  - Modem
  - Central office/premise line card
  - Corded telephone
  - PBX
  - Answering machine
  - Analog cordless telephone
  - Digital cordless telephone
  - Analog cellular telephone
  - Digital cellular telephone
  - Pager
  - Mobile communications infrastructure
- Consumer
  - Color TV
  - VCR
  - Analog camcorder
  - Digital camcorder
  - Digital still camera
  - Personal/portable stereo
  - Digital video disc (DVD) player
  - Set-top box—analog

  - Auto engine control unit
  - Antilock brake system (ABS) control unit
  - Air bag control unit

This Market Statistics report contains detailed information on Dataquest's view of China/Hong Kong's electronic equipment production. Electronic equipment production is an important determinant of semiconductor market activity because semiconductor demand is derived, in part, from the underlying demand for the systems that use semiconductors. Therefore, the forecast of electronic equipment production is an essential component to assessing future semiconductor market activity. China/Hong Kong production is estimated for the years 1996 to 2001.

Economic Assumptions and Exchange Rates

Actual exchange rates for the major countries in Asia/Pacific are contained in Table 1-1. The exchange rates are applied to all historical figures. Dataquest does not forecast currency fluctuations. In looking at Dataquest's historical numbers, it is important to note fluctuations in currencies. The Chinese renminbi was quite stable in 1995 and 1996, compared with its fluctuation in 1994. The Korean won appreciated 4.49 percent in 1996. In conducting market forecasts, Dataquest uses constant exchange rates across technologies and regions.

Table 1-1
Asia/Pacific Exchange Rate against the U.S. Dollar, 1993 to 1997

Currency	1993	1994	1995	1996	1997	U.S. Dollar Appreciation (%) 1996 to 1997
China (Renminbi)	5.76	8.54	8.35	8.34	8.32	-0.24
Hong Kong (Dollar)	7.74	7.73	7.74	7.73	7.74	0.13
India (Rupee)	30.84	31.15	32.38	35.52	36.36	2.36
Malaysia (Ringgit)	2.58	2.62	2.51	2.52	2.82	11.90
Singapore (Dollar)	1.62	1.53	1.43	1.41	1.49	5.67
South Korea (Won)	799.52	802.84	770.57	805.16	954.14	18.50
Taiwan (Dollar)	26.16	26.45	26.48	27.47	28.79	4.81
Thailand (Baht)	25.31	25.36	24.91	25.36	31.07	22.52

Regional Definitions

Dataquest has revised its regional definitions effective this year. The region formerly known as "Rest of World" has been eliminated and its components have been redistributed across the remaining regions. The remaining regions, in turn, have been redefined in response to this change. Former Rest of World constituents Central America, South America, and the Caribbean have been combined with North America in a new region redefined as "Americas." The Middle East (including Israel) and Africa have been combined with Europe in the redefined region "Europe, Middle East, and Africa." The Pacific Island nations of Oceania, formerly considered Rest of World, have been rolled into Asia/Pacific to create a larger redefined region still called "Asia/Pacific."

The Americas

- North America: Includes Canada, Mexico, and the United States (50 states)
- Central America
- South America
- Caribbean

Japan

- Japan is the only single-country region.

Europe, Middle East, and Africa

- Europe
  - Western Europe—Includes Austria, Belgium, Denmark, Eire (Ireland), Finland, France, Germany (including former East Germany), Greece, Italy, Luxembourg, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, the United Kingdom, and rest of western Europe (Andorra, Cypress, Gibraltar, Iceland, Liechtenstein, Malta, Monaco, San Marino, Turkey, and Vatican City)
  - Eastern Europe—Includes Albania, Bulgaria, the Czech Republic and Slovakia, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, the republics of the former Yugoslavia, and the republics of the former USSR (including Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, Kyrgyzstan, Moldova, Russian Federation, Tajikistan, Turkmenistan, Ukraine, and Uzbekistan)
- Middle East (Includes Israel)
- Africa

 ©1998 Dataquest

Asia/Pacific

Includes Asia/Pacific's newly industrialized economies (NIEs) and the remainder of Asia/Pacific, including Oceania. Asia/Pacific NIEs include Hong Kong, Korea, Singapore, and Taiwan. The remainder of Asia/Pacific includes Australia, Bangladesh, Brunei, Cambodia, China, India, Indonesia, Laos, Malaysia, Maldives, Myanmar, Nepal, New Zealand, Pakistan, the Philippines, Sri Lanka, Thailand, and Vietnam as well as the Pacific Island nations that make up Oceania.

Line Item Definitions

The objective of analyzing electronic systems production is to estimate its important implications for semiconductor consumption. Therefore, general economic concepts such as production and consumption are tailored to best isolate these implications.

The value of production is estimated as factory revenue. For the purposes of this report, Dataquest defines factory revenue as the money exchange value of the commodity transaction between the original equipment manufacturer and the point of entry into distribution. In the case of a direct sale that involves no distribution—as is the case with military systems—factory revenue is equal to the final user cost, net of sales taxes.

Production is the value-adding process by which the factors of production (labor and capital) and material inputs are transformed into the finished goods that are desired for consumption and investment. As such, production can and increasingly does span both time and geography. For example, a North American-owned disk drive company may minimize its cost of production by manufacturing (that is, consuming chips) its products in Taiwan, for eventual sale in Europe.

We would classify this as Asia/Pacific data storage device production, because we are interested in that stage of the production process that relates particularly to semiconductor consumption. Production would be valued as the exchange value of the transaction between the North American company's Taiwanese operation (which is factory revenue) and the European distributor or final user.

Product Definitions

Electronic Data Processing

The key application systems under this category are discussed in the following sections.

Personal Computer

A personal computer is a general-purpose computer that is distinguished from other computers by its adherence to hardware and software compatibility. This compatibility drives high unit volumes of commodity-like products that do not require on-site technical support. High-performance features (such as networking, graphics, floating-point coprocessor, and a virtual multiuser/multitasking operating system) are normally optional and not integral system features. IBM/IBM-compatible and Macintosh personal computers are two platforms in this product segment. A single-user PC's resident operating system is typically DOS, OS/2, or Mac OS. PCs have a performance ceiling that is lower in system

©1998 Dataquest

compute performance, I/O channel speed, and disk speed than workstations; normally, standard graphics are in the 640 x 480-pixel range and optional high-end graphics are limited, compared to workstations. Dataquest views a PC system as a single unit that includes a CPU, a monitor, and a keyboard. Furthermore, Dataquest PC shipment data does not include systems assembled from component parts purchased in electronic stores or other outlets.

Motherboard

A motherboard is a PC system board consisting of a printed circuit board with semiconductor and nonsemiconductor components that are all soldered down. The list of semiconductor components will include a minimum of core logic chipset, clock controller, real-time clock, keyboard controller, and any additional glue logic required to interface between the core logic chipset and CPU, cache memory, main memory, and expansion bus (such as PCI). The list of semiconductor components may include a graphics controller, mass storage interface, serial and parallel I/O, voltage converter, or audio controller, as long as they are soldered down.

Workstation

Dataquest classifies workstations by a composite of features, including their hardware and software features. Workstations are typically based on RISC CPU architecture with a high-performance bus structure, graphics, and operating system. In general, a workstation must come standard with integrated floating-point processing, integrated networking, and a 32-bit multitasking operating system, as well as offer a configuration that has high-resolution graphics capabilities (typically 1-megapixel display). We do not determine a workstation architecture by its usage (that is, single user, server, or multiuser).

Once the system passes these criteria, we examine whether it is designed to be a server or a workstation (that is, if the system is marketed with graphics capabilities). If it is designed to be a server (examples are the SPARCserver 1000 and RS/6000 POWERserver 900 series), the system is classified in Dataquest's midrange category. If it is marketed with graphics capabilities, we further classify the workstation and its server configuration (for example, SPARCstation 10 and SPARCserver10) into one of three categories: entry-level workstation, midrange workstation, and superworkstation.

Midrange Computer

The midrange product category includes all systems that fall between workstations and mainframes. These are multiuser systems that may or may not run proprietary operating systems. With the evolution of client/server computing and the systems that define this market, traditional midrange product categories are becoming obsolete. The HP 9000 and the HP 3000, Digital's VAX systems, and the IBM AS/400 line are joined by the dedicated server products from vendors such as Auspex, NetFRAME, and Tricord to make up the midrange product category. Office systems, proprietary turnkey computing solutions common in Japan, are also included in the midrange category. Systems designed as servers from workstation vendors are also included here. Midrange-class servers consist of high-end PC server systems that are manufactured and marketed by traditional PC vendors as well as system vendors. A server is

 ©1998 Dataquest

a shared computer on a network that can be used for simple and complex tasks. The key distinction between midrange-class servers and server-marketed PCs is price and the average number of CPUs included in the base system. Midrange class servers ship with more than one CPU and generally cost more than $15,000. Examples of this segment include the Compaq ProLiant 4000, IBM PC Server 700, and the HP NetServer LM2. The midrange-class server category comprises PC servers that compete with leading symmetric multiprocessing (SMP) and scalable products marketed by dedicated server vendors.

Mainframe/Supercomputer
A supercomputer is a high-performance computer designed for numerically intensive applications; current prices range from $100,000 to $20 million. Typically, these systems run in cool rooms (with or without raised floors); performance speeds range upward from 50 mflops. Massively parallel systems are defined as machines that have more than 32 relatively inexpensive processors linked together to act as one system.

A mainframe is a general-purpose information system with a starting price of over $100,000; CPU bit width ranges from 32 to 64 bits. Physical environment can be with or without environmental controls.

Page Printer
A page printer prints one page at a time.

Serial Printer
A serial printer prints one character at a time.

Rigid Disk Drive
The rigid disk drive (RDD) industry is the collective body of companies manufacturing rotating magnetic disk drives for use in storing computer programs and data. Some products are used in noncomputer applications; those are not included in the data presented in these market statistics. A rigid disk drive stores digital information on a round platter made of polished aluminum or a ceramic material. The information is written and read from the platters by recording heads mounted on the end of an arm. The arm is positioned over the desired area of the disk by a sophisticated control circuit that guides an actuator motor's movement. The data is amplified, decoded, and transmitted to the computer by the disk drive electronic circuits. The manner in which the information is presented to the computer is determined by the interface characteristics of the disk drive. Examples of interfaces include the small computer system interface (SCSI) and the PC-AT bus, sometimes called IDE.

Optical Disk Drive
An optical disk drive (ODD) is a data storage device that uses laser technology. Its categories are as follows: CD ROM drive, 12cm in diameter; CD-Recordable; write-once read-many (WORM) optical drive; rewritable ODD; magneto-optical (MO) multifunction, which has a hidden code read at disk spin-up time; and PC multifunction drive (WORM media that cannot be erased).

©1998 Dataquest

Removable Magnetic Storage

Removable magnetic storage comprises floppy disk drives (FDDs) and tape.

Monitors

A self-contained video display device that attaches directly to a computer and displays the contents of the computer's video memory. A monitor contains no data formatting or editing capability, nor does it contain any type of networking capability. Included are: color monitors that have interfaces capable of interpreting signals containing separate color components, normally the three primary colors red, green, and blue, and monochrome monitors that are based on a single color CRT. These monitors normally display in shades of white, green, or amber. They may or may not have the ability to display multiple shades of a monochromatic color.

Communications

The key application systems under this category are discussed in the following sections.

LAN Card

A LAN card is the printed circuit board that plugs into the expansion slots of a PC, workstation, or host terminal to allow connection to a LAN. Network interface cards (NICs) are designed in accordance with either IEEE or ANSI protocol standards; the most common are Ethernet, token ring, and fiber-distributed data interface (FDDI). Workstation and host NICs are segmented only into FDDI, ATM, and Others.

Fax

Facsimile machines include those with answering machines and cordless handsets.

Modem

A modem is an electronic device that provides modulation and demodulation functions for data signals transmitted over telephone lines. Modems convert digital data to analog data for transmission over leased lines or the analog public switched telephone network.

Central Office/Premise Line Card

A telecommunications switch used by public carriers

Corded Telephone

This category includes both standard and feature phones.

PBX

Private branch exchange

Answering Machine

Answering machines include both standalone and integrated answering machines, including any telephone terminal with an answering machine. To avoid double counting, any corded or home cordless telephone that has an integrated answering machine will be counted in the answering machine category. They are not counted again in the corded or cordless category.

 ©1998 Dataquest

Analog Cordless Telephone
Telephone-home cordless handsets and base stations include analog (single-channel, 10-channel, 24-channel, CT-0, CT-1) cordless telephones and 900-MHz analog cordless telephones. These handsets are usually distinguished by the ability to communicate with only one base station in the home or small business. Therefore, a unit would consist of the combination of a handset and base station. The chip content in both the handset and base station should be added together on the semiconductor content line.

Digital Cordless Telephone
These are cordless handsets that can be used to roam outside the home and can communicate with a service provider's infrastructure or multiple base stations in an office environment. They are usually distinguished from cellular by being able to communicate only at pedestrian speeds. Examples of handsets are PHS, DECT, and CT-2.

Analog Cellular Telephone
This includes all Advanced Mobile Phone Service (AMPS), Total Access Communications System (TACS), and Nordic Mobile Telephone (NMT) cellular handsets, among others.

Digital Cellular Telephone
This includes all digital cellular and broadband Personal Communications Services (PCS) handsets, including handsets that conform to the following standards: GSM, DCS1800, PCS1900, NA-TDMA (IS-54/136), CDMA (IS-95), PDC, and Omnipoint.

Pager
A pager is a small, pocket-size receiver that can be activated when the pager number is dialed from a telephone. Includes both one-way and two-way pagers.

Mobile Communications Infrastructure
Two components are the base station controller (BSC) and the switch. The BSC controls the voice channels and power controls.

Consumer
The key application systems under this category are discussed in the following sections.

Color TV
Color TVs include LCD-based and TV-VCR combinations.

VCR
VCRs do not include TV-VCR combinations.

Personal/Portable Stereo
This category includes headphone stereos, portable CDs, and boom boxes.

Digital Video Disc (DVD) Player
Includes only DVD products that are used with a television for playback of video content. Does not include DVD products targeted at the PC market. These would be included as a subcategory of optical disk drives.

Set-Top Box—Analog

A set-top box that decodes and enables access to analog-based TV services

Set-Top Box—Digital

Digital cable converter boxes that sit on top of TVs and act as converter devices for digital information over CATV, telephone, or wireless networks to television sets. These boxes contain a general-purpose microprocessor or a high-powered digital signal processor capable of digital transmission, reception, and decompression.

Video Game Controllers

The board with the chips on it that drives the hardware of the game player

Transportation

The key application systems under this category are discussed in the following sections.

Auto Stereo Systems

Includes integrated AM/FM stereo radio receivers; includes AM/FM radio/cassette combinations, AM/FM radio/cassette/CD combinations, and all in-car audio stereo AM/FM radio-based systems. In the future, this will include terrestrial Digital Audio Broadcast FM receivers (any estimates for DAB radios should become available for inclusion to this category as a separate line item).

Auto Engine Control Unit

Includes electronic engine control units (ECUs) for gasoline (petrol) and diesel (derv) fuel carburetor/injection engines for cars, trucks, and lorries. Electronic engine control units for gasoline engine cars include electronically controlled carburetor systems, single-point injection systems, and multipoint injection systems. Also includes electronic control units where ignition control (breakerless/distributorless, or adaptive/digitally programmed) is integrated with carburetor or injection control unit. Electronic engine control units for diesel engine cars include electronically controlled direct injection systems and indirect injection (distributor) systems. (Please note: Engine control unit excludes standalone electronic ignition control units.) Manages spark or fuel injection or both.

Antilock Brake System Control Unit

Includes electronic ABS control units for two-wheel ABS systems, and four-wheel ABS systems for passenger cars; includes electronic ABS control units for two-wheel and four-wheel ABS systems for light trucks. Includes electronic ABS control units for commercial vehicles, ABS systems for trailers/juggernauts, and electronic ABS control units for motorcycles. Includes ABS with integrated traction control systems

Air Bag Control Unit

Includes electronic control units for single and/or dual air bag systems for driver/front passenger, electronic control units for rear-seat air bag systems for rear passengers, electronic control units for side-impact air bag systems for front-/rear-seat passengers.

 ©1998 Dataquest

Data Sources

The historical information presented in the production data has been consolidated from a variety of sources, each of which focuses on a specific part of the market. From time to time, Dataquest conducts production surveys for specific types of electronic equipment, and the data gathered is also incorporated into the database. Other sources include the following:

- Dataquest's estimates of systems manufacturers' end-user revenue
- Trade association data
- Various government agency statistics of the countries in Asia/Pacific
- Estimates presented by knowledgeable and reliable industry spokespersons
- Published product literature and prices
- Other Dataquest research groups (including Computer Systems and Peripherals and Telecommunications)

Forecast Methodology

Dataquest uses a variety of forecasting techniques (both qualitative and quantitative) that vary by technology area. Dataquest follows a three-step process to forecast electronic equipment production. First, current and expected future worldwide and European macroeconomic conditions are assessed and forecast.

This forecast identifies trends in the economic health of the world-leading consumers and producers of electronic equipment. Using this forecast in conjunction with input from other Dataquest industry sources (as identified earlier), Dataquest estimates the overall business climates in which the electronic systems market will operate.

Second, Dataquest analyzes and forecasts the significant long-range trend and outlook in the various electronic system research groups (within Dataquest). This establishes a five-year trend growth path for electronic system production.

The final step in the forecast process is to reconcile expected fluctuations about market trends so that the two do not inexplicably diverge. Dataquest anticipates that in the absence of shocks to the market, market fluctuations converge toward a long-term trend.

Because the time series data contained in this document comprises, in general, annual observations and is sparse in terms of the number of observations, the data generally does not satisfy the requirements of quantitative empirical techniques such as econometric or statistical time series models. Therefore, in most cases, we have used judgmental models (that is, intuitive judgments, expert opinions, and subjective probabilities) or technological models (that is, curve fitting and the use of analogous data).

Project Analysts: Kelvin Fu and Daniel Heyler

Chapter 1
Introduction

Electronic equipment production is an important determinant of semiconductor market activity because semiconductor demand is derived, in large part, from the underlying demand for the systems that use semiconductors. Therefore, the forecast of expected future electronics system production is an essential tool to assess expected future semiconductor market activity.

This Market Statistics report contains detailed information on Dataquest's view of the electronic equipment markets in which semiconductors are used. This is the fall forecast that Dataquest will publish this year; the first forecast was published in spring. This second forecast reflects changes in China/Hong Kong production and worldwide consumption outlooks since spring. It also incorporates data revisions and updates suggested by Dataquest's continuing research of the world's dynamic electronic equipment markets. Two key databases previously published on China/Hong Kong are incorporated into this forecast.

The market statistics in this report include the following databases:

- High-volume electronic equipment unit production forecast and semiconductor consumption estimates (1996 to 2001)
- Company-level electronic equipment production and semiconductor consumption estimates (1996 and 1997)

Production is aggregated into one geographic region, China/Hong Kong. Because the majority of semiconductors consumed in China are billed in Hong Kong or shipped by multinationals, Dataquest treats China and Hong Kong as one single market. For regional estimates within China/Hong Kong, Dataquest refers to the recent company-level equipment research. The list of tables details the type of production data by region, application market, and unit of measure.

Segmentation

Dataquest's objective is to provide data along the lines of segmentation that are logical, appropriate to the industry in question, and immediately useful to clients. Dataquest's segmentation for China/Hong Kong is applied across Asia/Pacific and the rest of the world.

Dataquest defines the electronic equipment industry as the group of competing companies primarily engaged in manufacturing electronic goods. For the purposes of this report, important products of the electronics industry include data processing equipment, communications equipment, selected types of industrial equipment, consumer electronics, selected types of military and civilian aerospace and defense-oriented electronics, and automotive electronics.

For forecasting purposes, Dataquest segments the electronics industry into six broad semiconductor application markets, disaggregated into narrower electronic system groups, as follows:

- Data Processing
  - Computers
  - Data storage
  - Input/output sevices
  - Dedicated systems
  - Other data processing
- Communications
  - Premise telecom
  - Public telecom
  - Mobile communications
  - Broadcast and studio equipment
  - Other communications
- Industrial
  - Security and energy management systems
  - Manufacturing systems and instruments
  - Medical equipment
  - Other industrial equipment
- Consumer
  - Audio
  - Video
  - Personal electronics
  - Appliances
  - Other consumer equipment
- Military/Civilian Aerospace
- Transportation

Electronic Equipment Definitions

Electronic system groups comprise the specific electronic equipment types described in the following sections.

Data Processing

Data processing definitions are as follows:

- **Computer systems**: Includes supercomputers, mainframe computers, midrange computers (also known as superminicomputers and minicomputers), workstations, and PC/motherboard upgrades (including portable computers). Computer systems estimate does not include the

 ©1998 Dataquest

value of the following systems: rigid disk drives, flexible disk drives, keyboards, and displays. Computer systems estimate does include the value of aftermarket sales of the following: graphic boards, motherboards, memory cards-SIMMs, storage host adapters, and serial and parallel I/O boards.

- **Data storage**: Includes rigid disk drives, flexible disk drives, optical disk drives, and tape drives.
- **Input/output devices**: Includes alphanumeric terminals and graphics terminals (for example, X terminals), monitors, funds transfer terminals, printers, media-to-media data conversion, magnetic ink character recognition, optical scanning equipment, plotters, mice, keyboards, and digitizers.
- **Dedicated systems**: Includes electronic copiers, electronic calculators and personal organizers, smart cards (IC cards), dictation/transcribing equipment, electronic typewriters and dedicated word processors, point-of sale terminals and electronic cash registers, and mailing/letter-handling/addressing equipment.
- **Other data processing**: Includes sound/audio boards, digital video boards, accelerator boards, and embedded CPU boards.

Note: The category PC/motherboard upgrades has been revalued and revised from 1995 onward to better reflect the geographic distribution of PC production adjusted for PC motherboard production (see "Line Item Definitions" section for further discussion).

Communications

Communications definitions are as follows:

- **Premise telecom equipment**: Includes image and text communication, such as facsimile and facsimile cards, and video teleconferencing; data communications equipment such as modems and modem cards, digital WAN systems, front-end processors, (local area) network interface cards, LAN hubs and internetworking equipment, remote access systems and VSAT terminals; premise voice systems, such as premise switching equipment (PBX telephone equipment and key telephone systems) and call processing equipment (voice messaging, interactive voice response systems, and automatic call distributors); and desktop terminal equipment, such as telephone sets/pay telephones and cordless telephones, and teleprinters.
- **Public telecom equipment**: Includes transmission equipment, such as multiplexers, carrier systems, microwave radio, laser and infrared transmission equipment, and satellite communications equipment; and central office switching equipment.
- **Mobile communications equipment**: Includes cellular terminals (digital and analog), pagers (one- and two-way), mobile communications infrastructure, and other mobile communications equipment such as mobile radio systems.
- **Broadcast and studio equipment**: Includes audio equipment, video equipment, transmitters and RF power amplifiers, studio transmitter links, cable TV (headend) equipment, closed-circuit TV equipment, and other equipment, such as studio and theater equipment.

 ©1998 Dataquest

- **Other telecom equipment**: Includes intercom equipment and electrical amplifiers, and communications equipment not elsewhere classified.

Note: "Remote access systems" and "VSAT terminals" are new categories introduced to the forecast this year. Also note that mobile communications has been resegmented to better reflect the realities of this rapidly growing market segment.

Industrial

Industrial definitions are as follows:

- **Security/energy management**: Includes alarm systems, such as intrusion detection and fire detection systems, and energy management systems.
- **Manufacturing systems/instruments**: Includes semiconductor production equipment, controls, process controls, control and processing displays, and robots; and test and measuring equipment such as semiconductor-dedicated automatic test equipment (ATE), other test and measurement equipment, and nuclear electronics.
- **Medical equipment**: Includes diagnostic equipment, therapeutic equipment, patient monitoring equipment, surgical support systems, and irradiation equipment.
- **Other industrial equipment**: Includes vending machines, power supplies, traffic control equipment, and industrial equipment not elsewhere classified.

Consumer

Consumer definitions are as follows:

- **Audio equipment**: Includes compact disc players, radios, portable/personal stereos, stereo components, musical instruments, and tape recorders.
- **Video equipment**: Includes VCRs and VTRs, video cameras and camcorders, video disc players (including video CD and DVD), color and monochrome TVs, and cable/satellite set-top decoders.
- **Personal electronics**: Includes electronic games and toys (systems and cartridges), cameras (traditional and digital), watches, and clocks.
- **Appliances**: Includes air conditioners, microwave ovens, washers and dryers, refrigerators, dishwashers, and ranges and ovens.
- **Other consumer equipment**: Includes automatic garage door openers, and consumer equipment not elsewhere classified.

Military/Civil Aerospace

Military/civil aerospace definitions are as follows:

- **Military/civil aerospace**: Includes radar/sonar/reconnaissance systems, missile/space-related electronics, navigation equipment, electronic warfare, aircraft flight systems, and command and control systems.

 ©1998 Dataquest

Transportation

Transportation definitions are as follows:

- **Transportation electronics**: Includes in-car entertainment systems such as AM/FM radios, cassette and compact disc players, and radio/cassette combination systems; body control electronics such as four-wheel steering control, 2WD/4WD control; multiplex systems such as driver's door, door locks, windshield wipers, heated rear windows, memory seats, memory steering wheel, remote security systems, and suspension control and traction control systems; lighting controls including automatic headlight systems, timers, reminders, and sequential signal controls; and other body control electronics including aerodynamic aid control and power roof/window controls; driver information systems including electronic dashboard/instrument clusters, analog or digital clusters, electronic analog/digital clocks and compasses, electronic thermometers, head-up displays, navigation and location systems, signal and warning lights, and trip computers; powertrain systems including engine management systems, powertrain sensors, ignition control, fuel injection systems, fuel flow, engine temperature, air temperature, coolant level, wheel speed sensors, and transmission control; and safety and convenience systems including climate control systems (air conditioning/heating), air purifier systems, air bag control systems, antilock braking systems, collision warning systems, and cruise control.

Worldwide Geographic Regions

Dataquest segments the world into four principal geographic regions: Americas; Japan; Europe, Middle East, and Africa; and Asia/Pacific. These regions are further subdivided into various subregions. Dataquest collects and forecasts market data for various subsets of these regions and subregions. Dataquest's worldwide electronic equipment forecast is an aggregate of forecasts for the four principal world geographic regions delineated. Subregional forecast detail for Dataquest's regional forecasts is not developed. The following outlines and defines Dataquest's Asia/Pacific geographic segmentation.

Asia/Pacific

Includes mainland China, Hong Kong Special Administrative Region (SAR), Korea, Singapore, and Taiwan. The rest of Asia/Pacific includes Australia, Bangladesh, Brunei, Cambodia, India, Indonesia, Laos, Malaysia, Maldives, Myanmar, Nepal, New Zealand, Pakistan, the Philippines, Sri Lanka, Thailand, and Vietnam, as well as the Pacific Island nations that make up Oceania.

Line Item Definitions

The objective of analyzing electronic systems production is to estimate its implications for semiconductor consumption. Therefore, general economic concepts such as production and consumption are tailored to best isolate these implications.

The value of production is estimated as factory revenue. For the purposes of this report, Dataquest defines factory revenue as the money value of the commodity transaction between the original equipment manufacturer

©1998 Dataquest

(OEM) and the point of entry into distribution. In the case of a direct sale that involves no distribution—as is the case with military systems—factory revenue is equal to the final user cost, net of sales taxes.

Production is the value-adding process by which the factors of production (labor and capital) are combined to transform material inputs into the finished goods that are desired for consumption and investment. As such, production can and increasingly does span both time and geography. For example, a North America-owned disk drive company may minimize cost of production by manufacturing products in Singapore (where semiconductors are used as one of many material inputs), for eventual sale in Europe. Dataquest would classify this activity as Asia/Pacific data storage device production, because Dataquest is interested in that stage of the production process that relates particularly to semiconductor consumption. Production would be valued as the money value of the transaction between the North American company's Singapore operation (which is factory revenue) and the European distributor or final user.

Personal computers (PCs) are a particularly challenging example of an electronic product whose production increasingly spans both time and geography. Today, it is not at all uncommon for PCs to be assembled from components manufactured throughout the world. Moreover, the final assembly of a PC often occurs at a locale far removed from the source of its semiconductors. This is true largely because the geographic distribution of PC motherboard production differs substantially from the distribution of final PC assembly and production. Large numbers of PC motherboards are produced in Asia/Pacific. However, the vast majority are incorporated into PCs produced elsewhere in the world. Dataquest has developed a unique methodology to handle the challenge presented by PCs and PC motherboards. Dataquest's forecast for the category PC/Motherboard Upgrades reflects the geographic distribution of PC production adjusted for PC motherboard production. Dataquest does this by estimating the value of PCs produced in each region, exclusive of their motherboards. Dataquest also estimates separately the value of motherboards produced in each region. Dataquest's regional forecasts for the category PC/Motherboard Upgrades is then developed by summing these separate estimates. Dataquest reports a combined value for PCs and PC motherboards because the two products are so closely linked in the minds of consumers, distributors, and producers. Dataquest's separate treatment of PC and PC motherboard production guarantees that the value reported for the category PC/Motherboard Upgrades conforms to the concept of factory revenue applied elsewhere in the forecast.

Data Sources

The historical information presented in the production data has been consolidated from a variety of sources, each of which focuses on a specific part of the market. These sources include the following:

- Dataquest's estimates of systems manufacturers' factory revenue
- U.S. Department of Commerce estimates of manufacturers' shipments
- Japanese production statistics compiled and published by the Ministry of International Trade and Industry (MITI)

- Various European and Asian nations' government agency statistics
- Trade associations
- Estimates presented by knowledgeable and reliable industry spokespersons
- Published product literature and prices

Dataquest believes that the estimates presented here represent the most accurate and meaningful generally available today.

Forecast Methodology for China/Hong Kong

Dataquest feels strongly that quantifying and forecasting electronic equipment production in China/Hong Kong is best achieved in a worldwide collaborative process. Our statistics include surveys of actual manufacturers in China/Hong Kong, as well as worldwide consumption inputs in the key regions consuming China-made products. Dataquest applies a "bottom-up" and "top-down" approach to China/Hong Kong forecasting. Dataquest's knowledge of worldwide semiconductor technologies also enables the assessment of growth potentional of new products, such as DVDs and set-top boxes.

Dataquest uses a variety of forecasting techniques (both qualitative and quantitative) that vary by technology area. An overview of Dataquest forecasting techniques can be found in the *Dataquest Research Methodology* report.

Dataquest follows a three-step process to forecast electronic equipment production. First, current and expected future worldwide macroeconomic conditions are assessed and forecast. Economic information from various public and private sources is used to develop macroeconomic forecasts for the world's major economies. These forecasts identify trends in the economic health of the world's leading consumers and producers of electronic equipment. Using this forecast in conjunction with input from Dataquest's regional offices, Dataquest estimates the overall business climate in which the electronic systems markets will operate.

Second, Dataquest analyzes and forecasts the significant long-range trends and outlook in the various electronic system groups. This analysis establishes a five-year trend growth path or "envelope" for electronic system production.

The final step in the forecast process is to reconcile expected fluctuations about the market trends so that the two do not inexplicably diverge. Dataquest anticipates that, in the absence of shocks to the market, market fluctuations converge toward a long-term trend.

Because the time-series data contained in this document in general is composed of annual observations and is sparse in terms of the number of observations, the data generally does not satisfy the requirements of quantitative empirical techniques such as econometric or statistical time-series models. Therefore, in most cases, Dataquest has used judgmental models (that is, intuitive judgments, expert opinions, and subjective probabilities) or technological models (that is, curve fitting and the use of analogous data).

 ©1998 Dataquest

Macroeconomic Outlook: Third Quarter 1997

Global Outlook: Prospects Remain Bright despite Pessimism about Transition Economies

The latest forecast for global economic growth from the WEFA Group indicates that the real world gross domestic product (GDP) is expected to grow 3.1 percent in 1997, comparing to 2.7 percent in 1996. Beyond 1997, global real GDP growth is expected to average 3.3 percent. (Note: These figures are dollar-based growth rates that assume 1990 prices and exchange rates). Although the new forecast reflects little change in WEFA's overall outlook for the global economy as a whole, WEFA has changed to the outlooks for several individual countries, especially for the near-term period from 1997 to 1998. WEFA's near-term forecast for the United States has been significantly revised upward in response to continued strong economic growth. In contrast, the near-term outlooks for Eastern Europe and the economies of the former Soviet Union have been substantially downgraded in response to continuing economic difficulties. WEFA has also downgraded its outlook for Latin America's near-term prospects.

Among advanced economies, WEFA now anticipates aggregate real GDP growth for 1997 to average 2.7 percent. Growth is forecast to range from a torrid 3.5 percent in the United States to a tepid 0.9 percent in Italy. Beyond 1997, aggregate real GDP of the world's advanced economies is forecast to average 2.5 percent as U.S. growth returns to more sustainable levels. Canada is expected to average the most rapid economic growth between 1997 and 2001, roughly 3.6 percent, while Italy is forecast to average the slowest, roughly 2.1 percent. Although slight accelerations of inflation are forecast for most advanced economies, WEFA generally expects inflation to remain subdued across developed economies. For advanced economies as a group, inflation is forecast to average 2.5 percent by 2001. Among individual advanced economies, forecast inflation for 2001 ranges from a paltry 3.0 percent in the United States to a mere 1.1 percent in Canada.

WEFA continues to expect the world's developing or emerging economies to outperform their developed counterparts, at least for real GDP growth. Based on WEFA's forecast, Dataquest estimates aggregate emerging economy growth will be at 4.3 percent in 1997. Dataquest estimates that the emerging economy's growth will average even higher between 1997 and 2001, roughly 5.4 percent. Both these averages, however, mask considerable variation in both the near-term and long-term outlooks for individual economies. Once again, WEFA expects China to experience the greatest real GDP growth among emerging nations in 1997. China's 1997 real GDP is forecast to grow 9.8 percent. In contrast, the economies that make up the former Soviet Union are expected to experience the least growth, just 0.1 percent.

Over the longer term, WEFA expects Chinese real GDP growth to slow somewhat, falling to 8.6 percent by 2001. Nonetheless, growth is forecast to average roughly 8.8 percent between 1997 and 2001. This average seems unlikely to be surpassed by any other emerging country or region over the period. As for the economies of the former Soviet Union, WEFA is forecasting a gradual pickup in growth that should raise average real GDP growth among these economies to 4.9 percent by 2001. At this rate, growth among former Soviet economies would rival growth in Latin America and Eastern Europe by 2001. All told, the world's developing economies have significantly reduced inflation in recent years. Nevertheless, inflation across emerging economies is likely to remain above the rates WEFA anticipates for advanced economies.

Regional Outlooks: Americas Temporarily Buoyed by Surging U.S. Growth; Asia/Pacific Braces for Fallout from Currency Crisis

WEFA is continuing to forecast marked differences in regional economic performance. Based on WEFA's forecast, Dataquest estimates that real GDP growth in 1997 will be the fastest in Asia/Pacific (6.8 percent), and the slowest in Europe, Middle East, and Africa (2.1 percent). Americas is expected to experience especially strong growth on account of surging U.S. real GDP at an estimated 3.7 percent, while Japan is forecast to experience a 2.1 percent growth. Generally speaking, WEFA expects these patterns to hold through the longer term. Asia/Pacific should continue to spearhead world economic growth between 1997 and 2001 with an estimated average growth rate of 6.8 percent. Americas' growth is expected to decline somewhat as U.S. real GDP returns to more sustainable levels; Dataquest estimates that Americas' growth will average 2.8 percent between 1997 and 2001. Meanwhile, a general quickening of growth throughout the Europe, Middle East, and Africa region should place that region's average growth on a par with Americas between 1997 and 2001. Finally, Japan is expected to experience a modest pickup in economic activity that should cause Japanese real GDP to average an estimated 2.6 percent growth between 1997 and 2001.

The outlooks for Americas and Asia/Pacific deserve a special comment. As indicated earlier, WEFA's near-term outlook for the Americas has been strongly influenced by bullish GDP growth in the United States. In the first quarter of 1997, U.S. real GDP grew at the whopping annualized rate of 4.9 percent. Recent statistical releases indicate that the annualized real GDP growth in the second quarter of 1997 was more moderate but still a strong 3.3 percent. U.S. real GDP has grown at an annualized rate of 3.4 percent during last year (third quarter 1996 to second quarter 1997). Most economists agree that this rate of economic expansion is not sustainable and must return to more modest levels (between 2.0 percent and 2.5 percent) if an acceleration of inflation is to be avoided. Optimists have been quick to point out that no sign of increased inflation is to be found anywhere in the economy. But for pessimists, this is more like whistling in the dark than anything else because the increased inflation induced by excessive economic growth usually appears with a lag.

WEFA's forecast is based on the assumption that the Fed will increase the Federal Funds Rate, its short-term interest rate target, 25 basis points to 5.75 percent before the end of the year. This assumption also appears to be the expectation currently priced into U.S. financial markets. All told, this expectation may be too optimistic. If annualized, third quarter 1997's real GDP growth equals or is better than the pace of economic expansion set during the past year. A considerably larger boost in interest rates may be necessary to slow the economy to more sustainable levels. Although especially strong real GDP growth in the third quarter of 1997 would certainly raise U.S. growth above WEFA's forecast for 1997, it would, given a likely sharp policy response from the Fed, probably reduce actual growth below WEFA's forecast between 1998 and 2001.

WEFA's Asia/Pacific forecasts may also prove too optimistic. This summer, the region was overwhelmed by a currency crisis that reminded some of Mexico's meltdown in 1994. In retrospect, the crisis had been in the making for sometime. It began to gather steam in late spring when rising concern about Thailand's mounting current account deficit and its means of financing this deficit precipitated devaluation pressure on Thailand's currency, the baht. The Thai government initially responded with a series of policy moves intended to avert devaluation of its currency. Unfortunately, these moves proved unsuccessful and Thailand eventually agreed to devalue the baht nearly 20 percent in July as part of rescue package negotiated with international financial agencies.

As Thailand's troubles progressed, several of its developing neighbors also came under pressure to devalue their currencies. In particular, Malaysia, Indonesia, and the Philippines found their currencies subjected to strong devaluation pressure through June and July. Like Thailand, these countries have experienced rising current account deficits in recent years. However, the size of their deficits relative to GDP have been far smaller than in the case of Thailand, and their means of financing these deficits appear to have been somewhat sounder. Nonetheless, all three countries eventually bowed to devaluation pressures and depreciated their currencies in July.

All the countries involved in the crisis have found it necessary to impose much stricter fiscal and monetary policies. In addition, Thailand will probably have to restructure its financial system significantly. Although the contractionary impacts of these policy moves will be somewhat offset by the effects of currency depreciation, it remains likely that regional growth will be adversely effected, especially over the near term. Several forecasters have already lowered their expectations for the countries impacted by the crisis. Outlooks for Thailand in particular have been sharply curtailed.

Although they have been willing to acknowledge some of Thailand's more egregious sins, several Asia leaders have characterized this summer's currency crisis as an unwarranted speculative attack on their currencies. There have even been calls from some to ban currency trading except where needed to finance trade. No doubt, some of the frenzied currency trading that eventually pressured Thailand and its neighbors to devalue their currencies was speculative. But the initial spark that gave rise to that trading appears to have been quite justified by economic fundamentals. The combination of rising current account deficits, slowing GDP growth, and most especially, greatly extended financial systems served to make all four countries likely candidates for eventual currency devaluation. While it is true that many Asian countries have made great economic strides in recent years, it is equally true that most still have a long way to go on the road to economic maturity. One of the last and most important steps on that road is the development of an independent and mature financial sector fully integrated into world financial markets. The bottom line is that Asian leaders would be best advised to focus attention on their own financial failings rather than pointing blame at speculative bogeymen for this summer's crisis.

WEFA's real GDP growth forecasts for a variety of countries and regions are reported in Table 1-1.

Table 1-1
Forecast Real GDP Growth, 1996 to 2001 (Percent)

	1996	1997	1998	1999	2000	2001
Americas

Source: The WEFA Group

Reported real GDP and consumer price index (CPI) growth rates are taken from the most recently available quarterly world forecast of the WEFA Group contained in Table 1-1, "World Forecast Summary," *World Outlook, Executive Summary,* August 1, 1997, page 3. Economic commentary is based on independent research by Dataquest.

China/Hong Kong Forecast Highlights

The China/Hong Kong semiconductor market is positioned for accelerating growth during the next five years. With electronic equipment industries on an upturn and the worldwide semiconductor industry recovering in 1998, China/Hong Kong will achieve at least 31 percent CAGR from 1996 to 2001. Dataquest foresees the immature personal computer and communications industries in China as leading the broad-based growth during the next silicon cycle. Growth in China during the past five years has been led by consumer electronics, largely because of Japanese electronic equipment investments and local demand within China. With leadership from China's Ministry of Electronics, computers and communications have moved to the center of China's industrial development policy. Furthermore, business applications for computer and communication is swelling in an economy where the gross domestic product (GDP) will expand 9 percent to 12 percent during the next five years.

 ©1998 Dataquest

The combination of foreign investments plus high market growth will continue to be key drivers to electronics. Dataquest expects varied investments into a variety of electronics products from every major region (Americas, Europe, Japan, Korea, Taiwan, Singapore, and Hong Kong). Efficient manufacturing, unlimited cheap skill labor, currency stability backed by the governments of Hong Kong SAR and China, and rapidly growing demand from blistering economic growth are all reasons for investing in China relative to other Asia/Pacific countries. The combination of these competitive advantages cannot fundamentally change in the short term and are likely to accelerate in the long term.

Worldwide Forecast Highlights

Worldwide electronic equipment production is now forecast to grow 8.2 percent in 1997, compared to 7.1 percent growth in 1996. Continued equipment production growth is forecast through 2001. However, annual growth is expected to slow in the coming years as electronic equipment markets continue to mature. Overall, equipment production growth is now forecast to average 8.0 percent growth between 1996 and 2001. Not surprisingly, production of data processing equipment will continue to fuel growth in electronic equipment production. Dominated by PC and PC motherboard production, data processing equipment is expected to experience average annual growth in excess of 11.5 percent between 1996 and 2001. As a result, its share of total electronic equipment production is expected to rise from a current level of about 33 percent to about 38 percent by 2001.

Worldwide production growth of communications, industrial, and transportation equipment will roughly mirror overall equipment production growth. As a result, their shares of total equipment production are expected to hold more or less steady at about 22 percent, 14.5 percent, and 5 percent, respectively. Consumer and military/civil aerospace electronics production is forecast to experience below-average growth relative to overall equipment. As a result, their shares of total electronic equipment production are expected to decline. By 2001, consumer electronics are expected to account for about 16 percent of total electronics production, while military/civil aerospace electronics will constitute just more than 5 percent of production.

Regionally, total electronic equipment production is still forecast to grow fastest in Asia/Pacific and slowest in Japan during the forecast period. Europe, Middle East, and Africa will experience the second-fastest growth, closely followed by the Americas. Asia/Pacific's electronic equipment production is now forecast to grow 14.9 percent in 1997, compared to 7.7 percent growth in 1996. Production growth is forecast to be strong through 2001 but is expected slow in unison with worldwide growth. Overall, Asia/Pacific electronic equipment production is now forecast to average 13.5 percent annual growth between 1996 and 2001. Europe, Middle East, and Africa's electronic equipment production is now forecast to grow 9 percent in 1997, compared to 8.8 percent growth in 1996. Production growth is forecast to slow beginning next year but remain at healthy levels through 2001. Overall, electronic equipment production in Europe, Middle East, and Asia is now forecast to average 8.4 percent annual growth between 1996 and 2001.

 ©1998 Dataquest

Americas will actually experience stronger growth than Europe, Middle East, and Africa in 1997. Americas' electronic equipment production is now forecast to grow 11.3 percent in 1997, compared to 12 percent growth in 1996. As in Europe, Middle East, and Africa, however, production growth is expected to slow beginning next year. Dataquest believes that Americas' production growth rates will settle at levels below Europe for the remainder of the decade. Overall, electronic equipment production in Americas is now forecast to average 7.9 percent annual growth between 1996 and 2001. Finally, dollar-valued Japanese electronics equipment production is now forecast to contract 1.8 percent in 1997, comparing to a 1.1 percent dollar-valued contraction in 1996. Unfortunately, these figures are somewhat misleading on account of the yen's continuing movements relative to the dollar.

Dataquest's forecast assumes the yen will depreciate 7.7 percent relative to the dollar in 1997, following a 13.7 percent depreciation in 1996. When expressed in yen, Japanese electronic equipment production is forecast to grow 6.4 percent in 1997, following a 14.7 percent yen-valued growth in 1996. In the longer term, dollar-valued Japanese electronic equipment production growth is expected to revive. Assuming no continued depreciation of the yen beyond that assumed in our forecast, Japanese electronic equipment production is expected to average 3.8 percent annual dollar-valued growth between 1997 and 2001. Growth is forecast to be especially strong in 1998 at 5.5 percent. All told, Dataquest now forecasts Japanese electronic equipment production to average 2.7 percent annual dollar-valued growth between 1996 and 2001.

Still, when all is said and done, Americas should continue to lead all other regions in total electronics equipment production throughout the forecast period. Americas' share of total worldwide production should remain near its current level of roughly 36 percent throughout the forecast period. However, thanks to continued rapid production growth, the gap between Asia/Pacific electronic equipment production and production in other regions will close quickly. Although Asia/Pacific's production is expected to remain well below Americas' production even by 2001, it is now expected to surpass Japanese production in 1999 and then overtake European production in 2001. By 2001, Asia/Pacific is expected to command a 23.1 percent share of total worldwide electronic equipment production. Europe, Middle East, and Africa should garner about a 22 percent share, while Japan's share is forecast to fall to just about 19 percent.

For specific application areas, Dataquest anticipates the following:

- Dataquest now expects worldwide data processing electronics equipment production to grow 12.9 percent in 1997, compared to 9.2 percent in 1996. In the longer term, production growth will remain strong, but it is expected slow somewhat toward the end of the decade. Overall, data processing equipment is expected to average 11.6 percent production growth annually between 1996 and 2001. Not surprisingly, this growth will be fueled by computer production, specifically combined PC and PC motherboard production. Worldwide factory revenue from the production of PCs and PC motherboards is expected to grow 18.6 percent in 1997, compared to 17.3 percent growth in 1996. In the longer term, production growth is expected to average 14.8 percent between 1996 and 2001. Rigid disk and optical disc drives will also contribute significantly to data processing equipment production growth. Worldwide rigid disk drive production is now forecast to grow 27 percent in 1997. In the longer term, rigid disk drives are expected to experience 20.9 percent average growth between 1996 and 2001. Worldwide optical disc drive production is now forecast to grow 28.4 percent in 1997. In the longer term, optical disc drives will experience 13.3 percent growth between 1996 and 2001. Regionally, Americas is expected to retain its lead share of data processing equipment production during the forecast period. However, continued production growth in Asia/Pacific will raise that region's production of data processing equipment to levels approaching Americas by 2001. Strong production growth in Europe, Middle East, and Africa combined with sluggish production growth in Japan will result in Europe overtaking Japan in data processing production by 1999.

- Dataquest now expects worldwide communications electronic equipment production to grow 12.1 percent in 1997, compared with 18.4 percent growth in 1996. In the longer term, production growth is forecast to slow through the end of the decade. Overall, communications equipment is expected to average 6.9 percent production growth annually between 1996 and 2001. Products at the forefront of the digital revolution in communications are anticipated to spur worldwide communications equipment production growth. Digital cellular and digital cordless phones and terminals will make significant contributions to communications equipment production growth. Production of digital cellular phones is forecast to experience 36.9 percent growth in 1997 and to average 13.3 percent growth annually between 1996 and 2001. Production of digital cordless phones is forecast to experience 15.1 percent growth in 1997 and to average 12.8 percent growth annually between 1996 and 2001. Mobile communications infrastructure will also make an important contribution to communications equipment production growth. Production of mobile communications infrastructure equipment is forecast to grow 34.4 percent in 1997 and to average 12.2 percent growth annually between 1996 and 2001. Regionally, Americas is forecast to maintain its lead share of total worldwide communications equipment production over the forecast period. Dataquest estimates that the Americas currently produces about 40.5 percent of all communications electronics. Dataquest expects the Americas to preserve this share of production through 2001. However, production of specific communications equipment in other regions is forecast to rival Americas' production. For example, production of digital cellular phones and mobile communications infrastructure equipment in Europe, Middle East, and Africa will amply exceed Americas production throughout most of the forecast period.

- Dataquest now expects worldwide industrial electronics equipment production to grow 5.3 percent in 1997, compared to 3.6 percent in 1996. In the longer term, production growth is forecast to quicken through the end of the decade. Overall, industrial equipment is expected to average 7.3 percent growth annually between 1996 and 2001. Manufacturing systems and instruments are anticipated to be the lead growing industrial electronics equipment segment. Production of these electronics is expected to grow 6.6 percent in 1997 and to average 7.8 percent annually between 1996 and 2001. Medical electronics are also forecast to sustain solid growth. Medical electronics are expected to experience a 5.2 percent growth in 1997 and to average 7 percent annually between 1996 and 2001. Here again, Dataquest expects the Americas to maintain its lead share of overall worldwide equipment production. Dataquest estimates that the Americas currently produces approximately 47 percent of the world's industrial electronics. The remainder, minus a marginal share for Asia/Pacific, is split fairly evenly between Japan and Europe. Dataquest expects little change in this division over the forecast period. Dataquest also expects little change in the division of individual industrial segments, especially for manufacturing systems and instruments, as well as for medical electronics. Americas' production predominates both these segments and should continue to do so despite respectable growth in Japanese and European production.

- Dataquest now expects worldwide production of consumer electronics equipment to grow just 0.9 percent in 1997, compared to a 1.8 percent contraction in 1996. In the longer term, production growth is forecast to accelerate. Dataquest believes consumer electronic growth to average 4.5 percent annual growth between 1996 and 2001. As with communications electronics, products at the forefront of the digital consumer revolution will make significant contributions to consumer electronics production growth throughout the forecast period. Key products to watch include DVD, digital still cameras, digital camcorders, and digital set-top boxes. DVD is expected to average annual production growth approaching an astounding 270 percent between 1996 and 2001. Dataquest forecasts digital still cameras to average a somewhat more modest 35 percent annual production growth between 1996 and 2001. Digital camcorders and digital set-top boxes are expected to average 22 percent and 21.7 percent annual production growth, respectively, between 1996 and 2001. Regionally, Americas and European consumer electronics production will take a distant backseat to Japan and Asia/Pacific. Japan has developed many of the new digital products commercially expected to spur consumer electronics growth. However, Dataquest believes that once production reaches full gear, it will be migrated to Asia/Pacific. As a result, Asia/Pacific is forecast to consolidate its lead share of worldwide consumer electronics production. One notable exception is the digital set-top boxes. Here, Americas and Europe are expected to retain significant shares of worldwide production. Still, Asia/Pacific is likely to garner an ever-increasing share of digital set-top box production.

- Dataquest now expects worldwide production of military/civil aerospace electronics to grow 3.0 percent in 1997, compared to 1.7 percent growth in 1996. In the longer term, Dataquest forecasts a continued acceleration of aerospace electronics production. Overall, aerospace electronics production is forecast to average 3.3 percent annual production growth between 1996 and 2001. Regionally, Americas and Europe, Middle East, and Africa will continue to dominate aerospace electronics production. Americas' production is forecast to average 3.3 percent annual growth between 1996 and 2001, while European production is expected to average near-zero growth. Still, these two regions combined will continue to account for more than 80 percent of worldwide aerospace electronics production through 2001. Asia/Pacific is forecast to sustain double-digit production growth throughout the forecast period.

 ©1998 Dataquest

As a result, its share of worldwide production will nearly double by 2001. Japan, however, is expected to experience continued contraction of aerospace electronics production. As a result, Dataquest forecasts Japan to garner about 2.5 percent of worldwide aerospace production by 2001.

- Dataquest now expects worldwide production of transportation/automotive electronics to grow 4.9 percent in 1997, compared to 2.6 percent growth in 1996. In the longer term, Dataquest forecasts higher rates of production through the end of the decade. Overall, automotive electronics production is expected to average 7.8 percent annual growth between 1996 and 2001. Automotive navigation systems will make a significant contribution to transportation electronics growth throughout the forecast period. Dataquest forecasts production of these systems to grow 43 percent in 1997. In the longer term, Dataquest expects production to average 44.6 percent annual growth between 1996 and 2001. Antilock braking systems will also buoy automotive electronics production growth. Dataquest expects production of these systems to grow 13.4 percent in 1997 and to average 7.8 percent annual growth between 1996 and 2001. Not surprisingly, the regional distribution of total automotive electronics production should continue to mirror the distribution of automotive production. Americas and Europe, Middle East, and Africa are forecast to garner the leading shares of production, followed by Japan and then Asia/Pacific. As elsewhere, however, the regional distribution of production for specific products will vary from the pattern for total production. For instance, Dataquest expects Japan to be the principal producer of automotive navigation systems throughout the forecast period. Dataquest also expects Asia/Pacific to rival Japan as the world's leading producer of automotive stereo systems before the end of the forecast period.

Exchange Rates

Dataquest's worldwide electronic equipment forecast combines data from many countries, each of which uses a currency that has a different and fluctuating exchange rate relative to the U.S. dollar. Because Dataquest forecasts electronic equipment production in several regions of the world, Dataquest uses the U.S. dollar as a common currency for comparisons and aggregation. As a rule, Dataquest calculates the forecasts in local currencies and then convert them to U.S. dollars using projected average annual exchange rates. Dataquest does not forecast exchange rates per se. Instead, Dataquest calculates projected average annual exchange rates from the current exchange rate. Dataquest's projections are based on estimates of the latest available monthly exchange rate at the time the forecast is developed. Table 1-2 presents the average annual exchange rates incorporated in this forecast. These rates are based on monthly exchange rates observed through July 1997. Additional information about historical exchange rates and Dataquest's methodology of calculating future average exchange rates may be requested through Dataquest's client inquiry service.

Chapter 2
Market Statistics Tables

Tables 2-1 to 2-13 present the production revenue of electronic equipment manufacturing in China/Hong Kong between 1996 and 2002. Figures 2-1 to 2-10 illustrate production revenue trends of various types of electronic equipment manufacturing in China/Hong during this same time period.

Table 2-1

Chapter 1
Executive Summary

To what extent will Japanese and Asian currency devaluation affect China's once-insatiable appetite for information technology (IT)? China/Hong Kong has been the main force for IT sales in the Asia/Pacific region, but how long can it sustain this role? Dataquest isolates and discusses the key equipment and companies that have the most impact on China/Hong Kong's semiconductor market. Dataquest also stratifies its analysis across computer, communications, and consumer electronics industries.

Dataquest's goal in publishing this report is to present a concise report of China's electronics industry and its company-level outlook in 1998 and 1999. This Focus Report serves the following four simple research purposes:

- Summarizes key industry trends and lists forecast assumptions
- Presents company-level production units in 1998 and 1999 for high-volume products
- Forecasts long-term, high-volume electronic equipment production growth from 1998 to 2002 in terms of units, revenue, and semiconductor consumption
- Provides semiconductor consumption forecasts for 1998 and 1999 by product, application group, company, and origin of ownership

Format and Scope

This Focus Report emphasizes demand-side analysis of the semiconductor market and focuses on electronic equipment production. For supply-side semiconductor shipment information by product or company (with vendor market share analysis), please see Dataquest's Market Trends report, *An Analysis of China/Hong Kong's Semiconductor Market: Suppliers, Drivers, and Forecasts*. The company data is provided by responsible representatives of those companies or knowledgeable industry contacts.

Key Findings

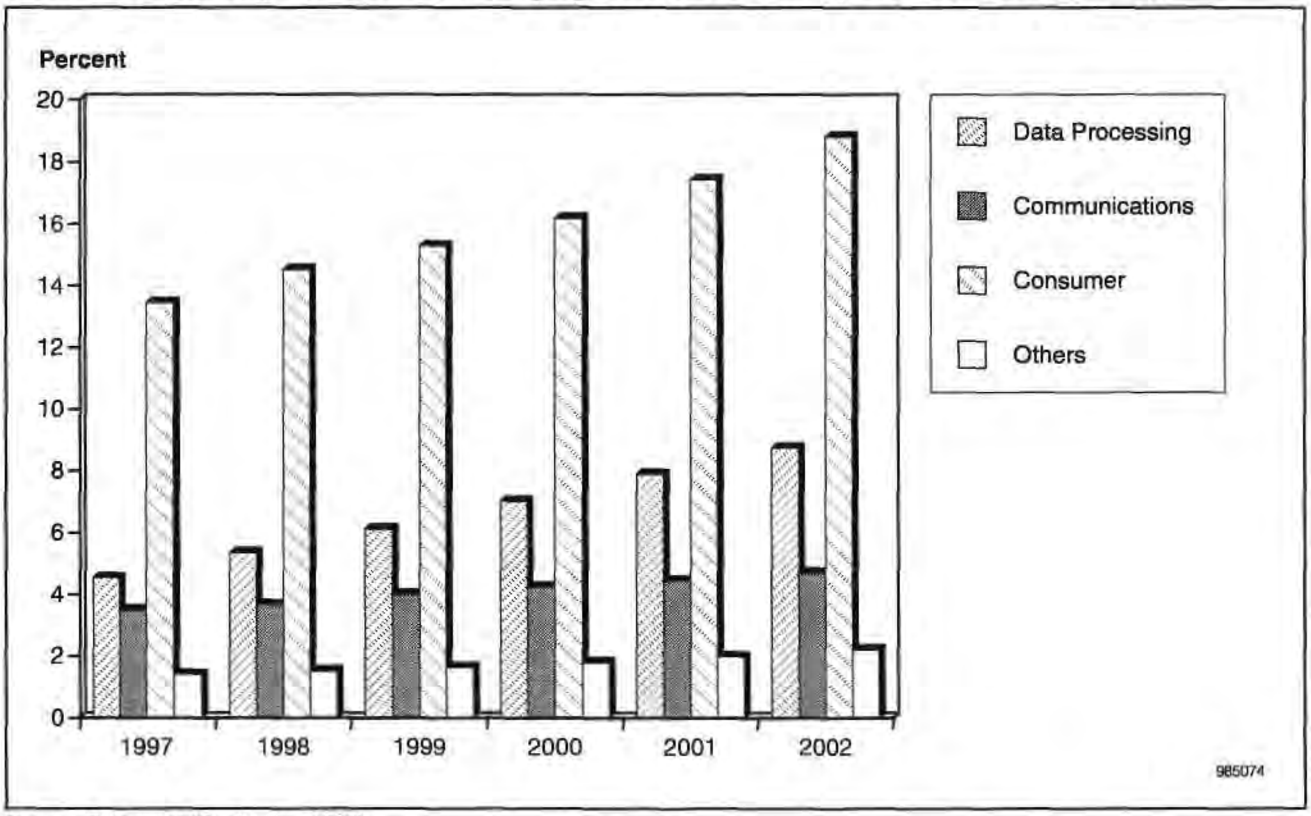
Despite some mature IT segments, Dataquest expects the worldwide IT's overall health to be influenced by emerging communications, Internet, digital consumer, and PC industries' 15 percent average unit growth. Dataquest forecasts an overall IT hardware shipment growth in the next five years of 7 percent. Asia/Pacific's production accounted for only 15 percent of the world's total electronic equipment production in 1993, but reached 19 percent in 1997. By 2002, Dataquest forecasts that 24 percent of worldwide electronic equipment production will take place in Asia/Pacific.

China Now a Global Force

As shown in Figure 1-1, Dataquest concludes that China/Hong Kong will outpace the rest of Asia/Pacific and substantially increase its share of worldwide electronic equipment production from approximately 5 percent in 1997 to 8 percent in 2002. In 1996, it accounted for only 4 percent of output. Dataquest will explain how consumer electronics will represent the largest share of 19 percent of world production, up from 13 percent in 1997. Data processing will increase its market share the fastest, doubling from 4.5 percent in 1997 to 9 percent in 2002. Communications equipment will grow substantially, from a small base of 3.5 percent to 5 percent by 2002.

China/Hong Kong's share of Asia/Pacific production will increase from 27 percent in 1997 to 32 percent in five years. In revenue terms, China/Hong Kong's electronics production will grow from U.S.$37 billion to $98 billion, representing a compound annual growth rate (CAGR) of 16 percent.

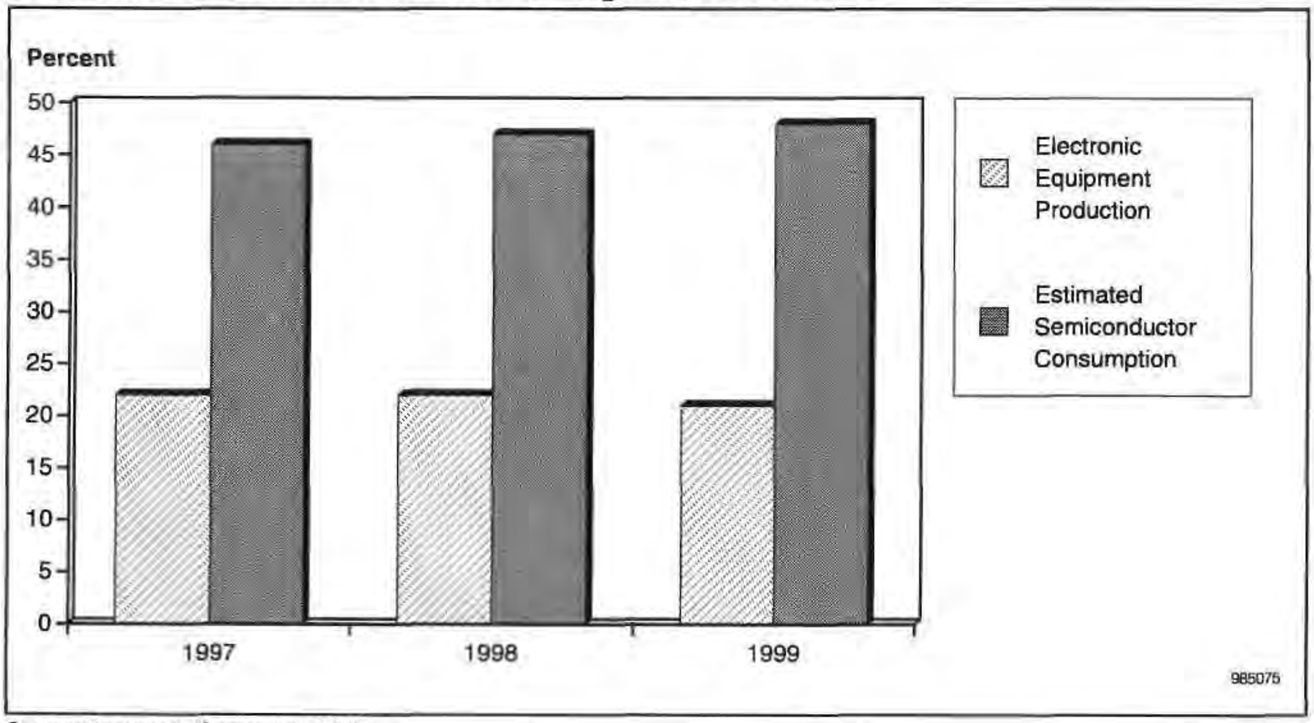
Figure 1-1
China/Hong Kong's Share of Worldwide Total Electronic, Data Processing, Communications, and Consumer Equipment Production, 1997 to 2002 (Percent)



Source: Dataquest (September 1998)

Dataquest conducted a survey of 64 major electronic equipment manufacturers, which are listed throughout this report in respective product discussions. Dataquest has identified the factories, products, and production quantities for 1997 and forecast for 1998 and 1999. Dataquest's basis for selecting these companies was subjective. Clients expressed a high interest in Chinese companies since last year, so we increased our sample size of local manufacturers relative to multinational vendors. Companies that had large production capacity or had aggressive expansion plans were also selected. The main purpose is to support Dataquest's high-volume electronic equipment production forecast that is also included in this report. Upon completing the research, Dataquest discovered that these companies represent approximately 24 percent of the 1998 production. As illustrated in Figure 1-2, the sample size within each application segment varies. These findings indicate that China/Hong Kong's manufacturers are scaling back production in certain areas, but the overall industry will sustain formidable growth in the next few years.

Figure 1-2
Surveyed Companies' Share of Total China/Hong Kong Electronic Equipment Production and Semiconductor Consumption, 1997 to 1999

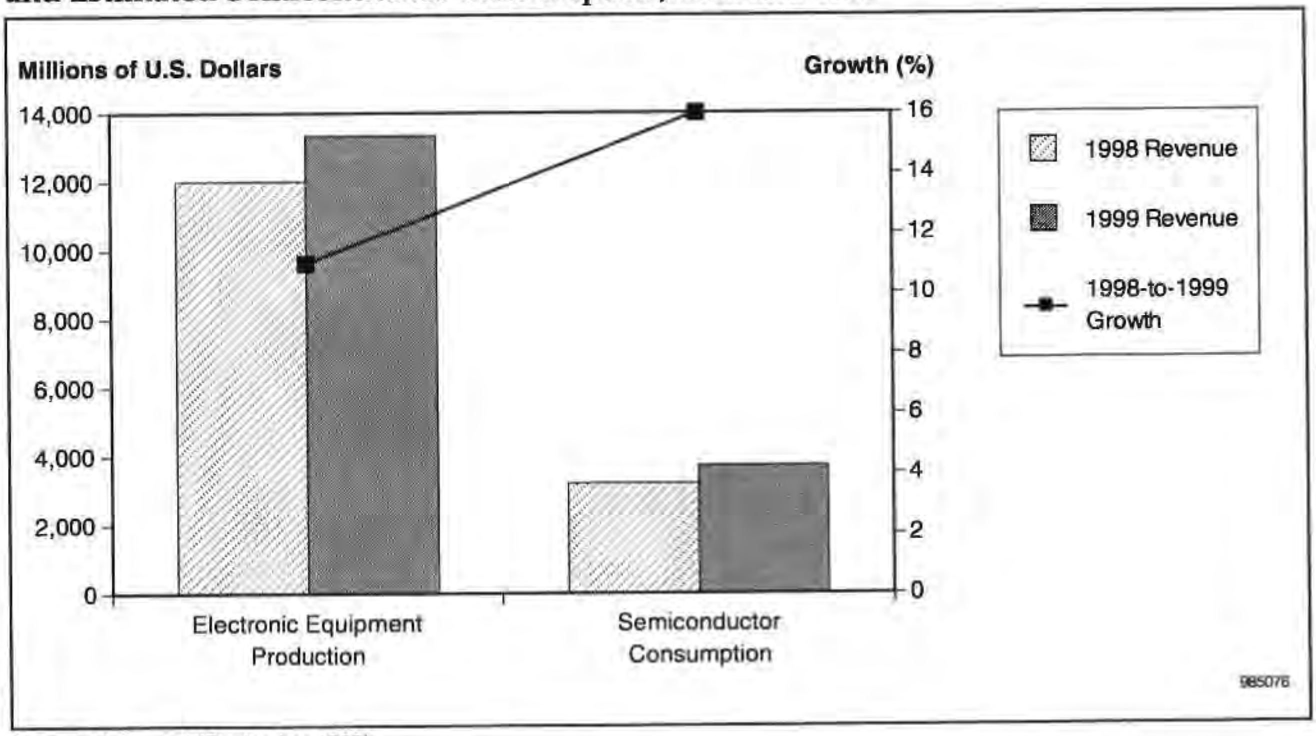


Source: Dataquest (September 1998)

In terms of semiconductor consumption, Dataquest observes that because major manufacturers will expand by 11 percent in revenue terms, their semiconductor consumption will increase by approximately 16 percent (see Figure 1-3). As discussed earlier, Dataquest's survey group will consume an estimated 24 percent of semiconductors consumed in China/Hong Kong in 1998. Note that these semiconductors were either shipped internally by multinational companies, purchased direct from manufacturers, or supplied by distributors. Dataquest forecasts that this same group of companies will consume 48 percent of all 1999 semiconductor shipments. This consumption level reveals the following trends:

- Rising semiconductor richness and technology level of products being manufactured in China/Hong Kong
- Larger multinational and Chinese manufacturers are achieving economies of scale faster and for higher-end products than the smaller companies
- Small and medium-size companies will face further difficulty competing against large companies that have efficient sourcing and distribution systems
- State-owned enterprises (SOEs) are being restructured, merged, or sold

Figure 1-3
Surveyed Companies' China/Hong Kong Electronic Equipment Production Revenue and Estimated Semiconductor Consumption, 1998 and 1999



Source: Dataquest (September 1998)

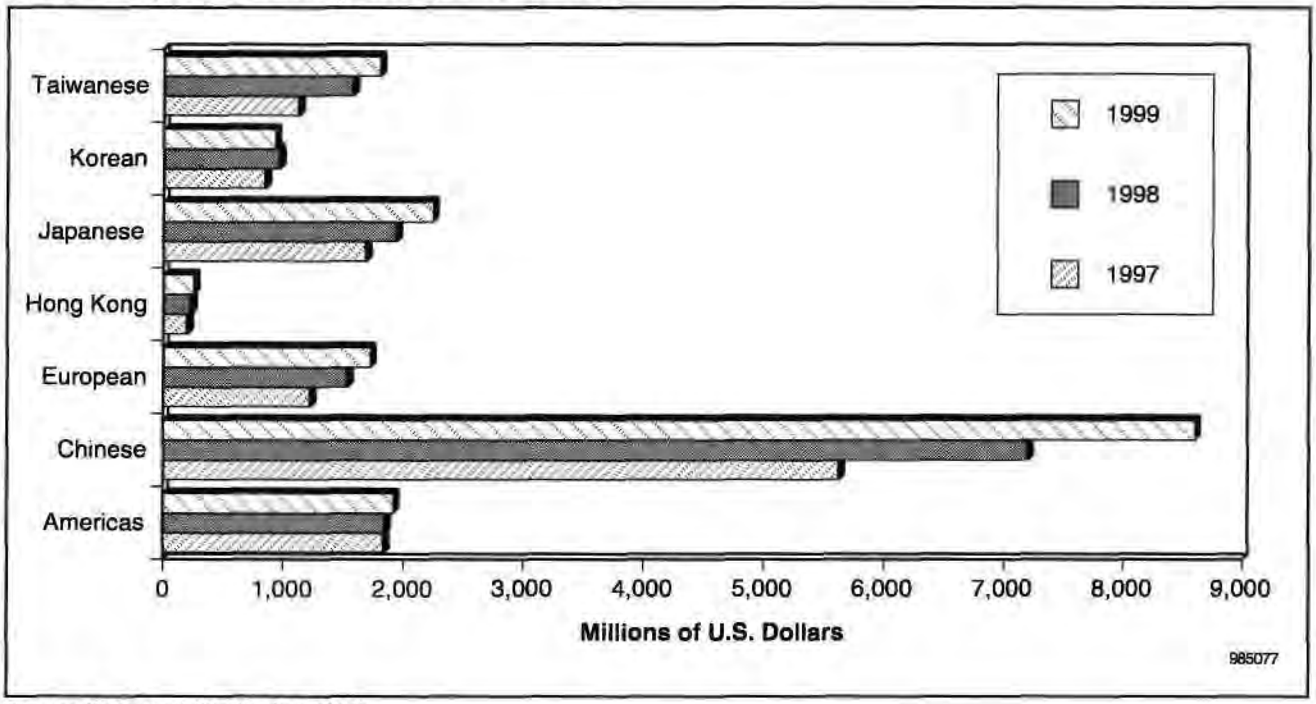
Electronics Production Growth by Ownership

Figure 1-4 lists production revenue of the 64 companies surveyed in China/Hong Kong by grouping their home base ownership. Figure 1-5 illustrates these companies' percentage share. The Americas companies surveyed had doubled production in China/Hong Kong in 1997, after investments made in 1995 and 1996. However, these companies have halted expansion plans in 1998 with about 1 percent growth. Dataquest had expected U.S. manufacturers to surpass Japanese manufacturers in 1997 and 1998, but this will not happen because of investment slowdowns. As discussed in Chapters 3 and 4, computer and communications investments are leading the next wave of growth, while consumer growth is expected to remain modest.

Semiconductor Consumption by Users' Home Base of Ownership

Each manufacturer's semiconductor consumption is derived by multiplying the units of equipment produced by an average semiconductor content per piece. Dataquest estimates each equipment's semiconductor content and manufacturers' semiconductor consumption revenue. The scope of the survey did not include surveys of procurement offices to ascertain total semiconductor purchase by factory. Such a methodology would have had to account for local purchases, internal transfers, and global procurement contracts. Dataquest believes that the methodology used provides a realistic average consumption by product and accurate trend analysis on a year-on-year comparative basis.

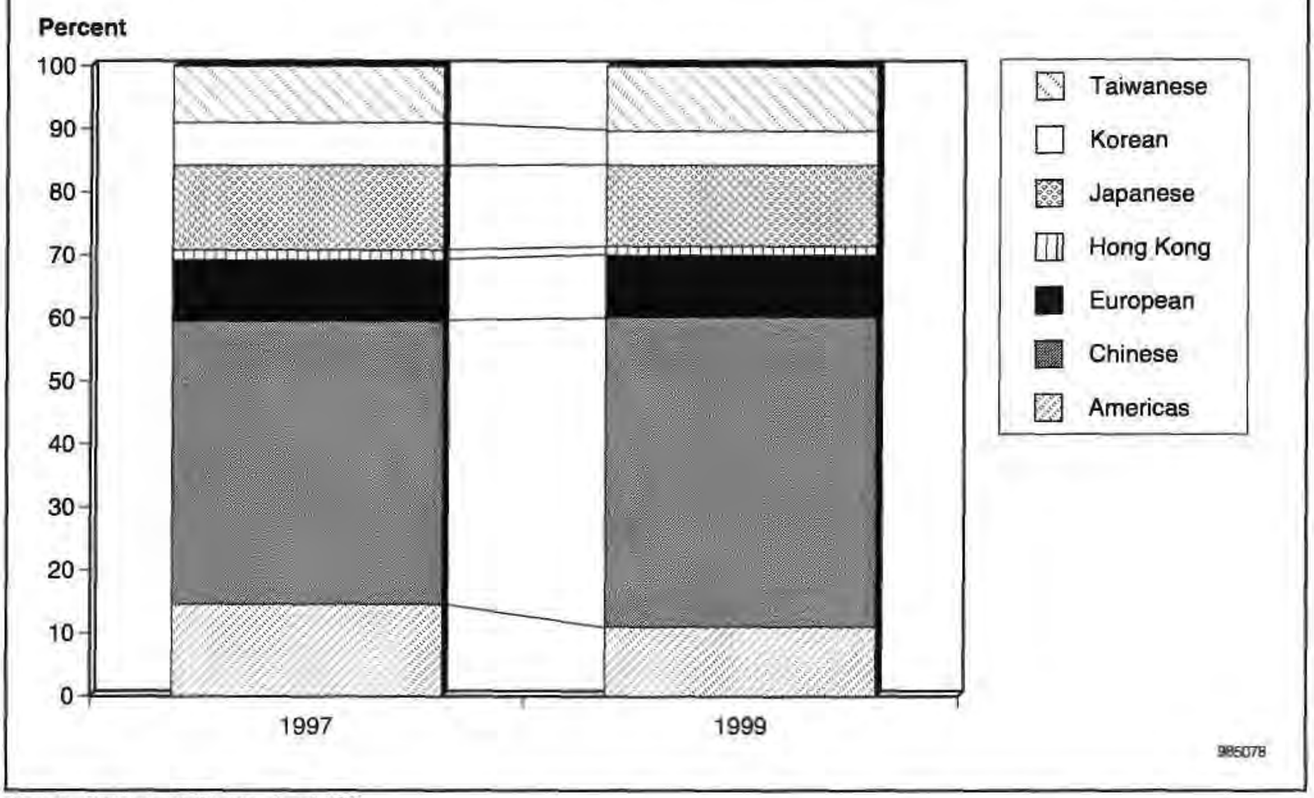
Figure 1-4
China/Hong Kong's Electronic Equipment Production Revenue by Home Base of Ownership of 64 Companies, 1997 to 1999



Source: Dataquest (September 1998)

 ©1998 Dataquest

Figure 1-5
China/Hong Kong's Electronic Equipment Production Revenue by Home Base of Ownership of 64 Companies, 1997 and 1999

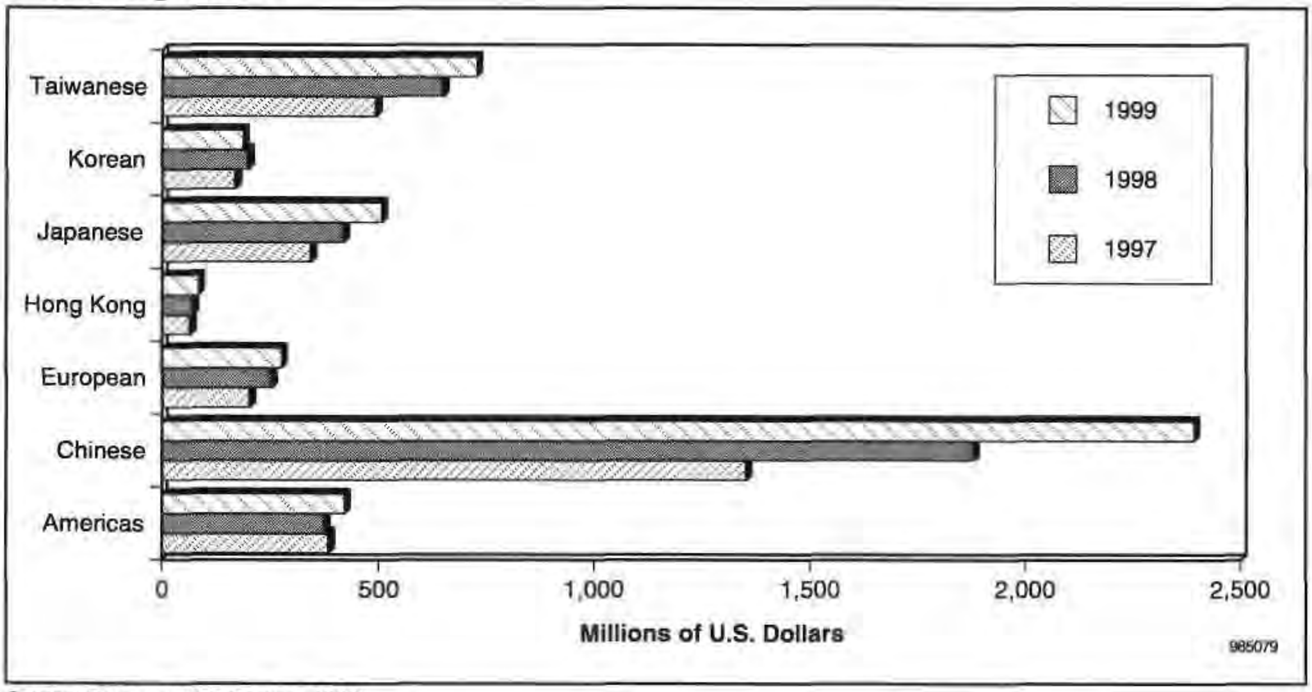


Source: Dataquest (September 1998)

Figures 1-6 and 1-7 illustrate the revenue and percentage of total semiconductor consumption estimates aggregated for the 64 users. Chinese companies occupy the largest share and are the fastest-growing in equipment production and semiconductor consumption, with 28 percent and 39 percent growth, respectively. Americas companies were the second largest, representing 13 percent of consumption, but they will expand only 1 percent in 1998. These companies expected semiconductor consumption will improve next year, based on a 13 percent growth in the value of semiconductors used. Japanese companies will increase semiconductor consumption by 22 percent in 1998 and 23 percent in 1999. Dataquest believes the main reason for this discrepancy between Chinese and multinational companies' growth is a result of local Chinese manufacturers' particularly strong video compact disc (VCD) and PC production and sales in 1998.

 ©1998 Dataquest

Figure 1-6
China/Hong Kong's Semiconductor Consumption by 64 Company Users' Home Base of Ownership in 1998



Source: Dataquest (September 1998)

Figure 1-8 summarizes all information by comparing growth rates by ownership for both equipment and semiconductor consumption. Figure 1-9 illustrates China/Hong Kong's electronic equipment production in 1998 and 1999. After the Chinese companies, Taiwanese producers are the fastest-growing consumers of semiconductors. Taiwanese companies, like the Americas, focused on the computer segment in China/Hong Kong. While both experienced rapid electronic equipment production growth, their semiconductor consumption growth is less than equipment factory revenue primarily because of pricing declines of memories, microprocessors, and microperipherals. European companies are the third-fastest-growing semiconductor user group, but they represent only 7 percent of Dataquest's survey group. Japanese companies appear to be maintaining overall semiconductor consumption growth, ranking fourth in consumption growth. Korean companies are ranked fifth in growth, followed by Hong Kong and Americas companies.

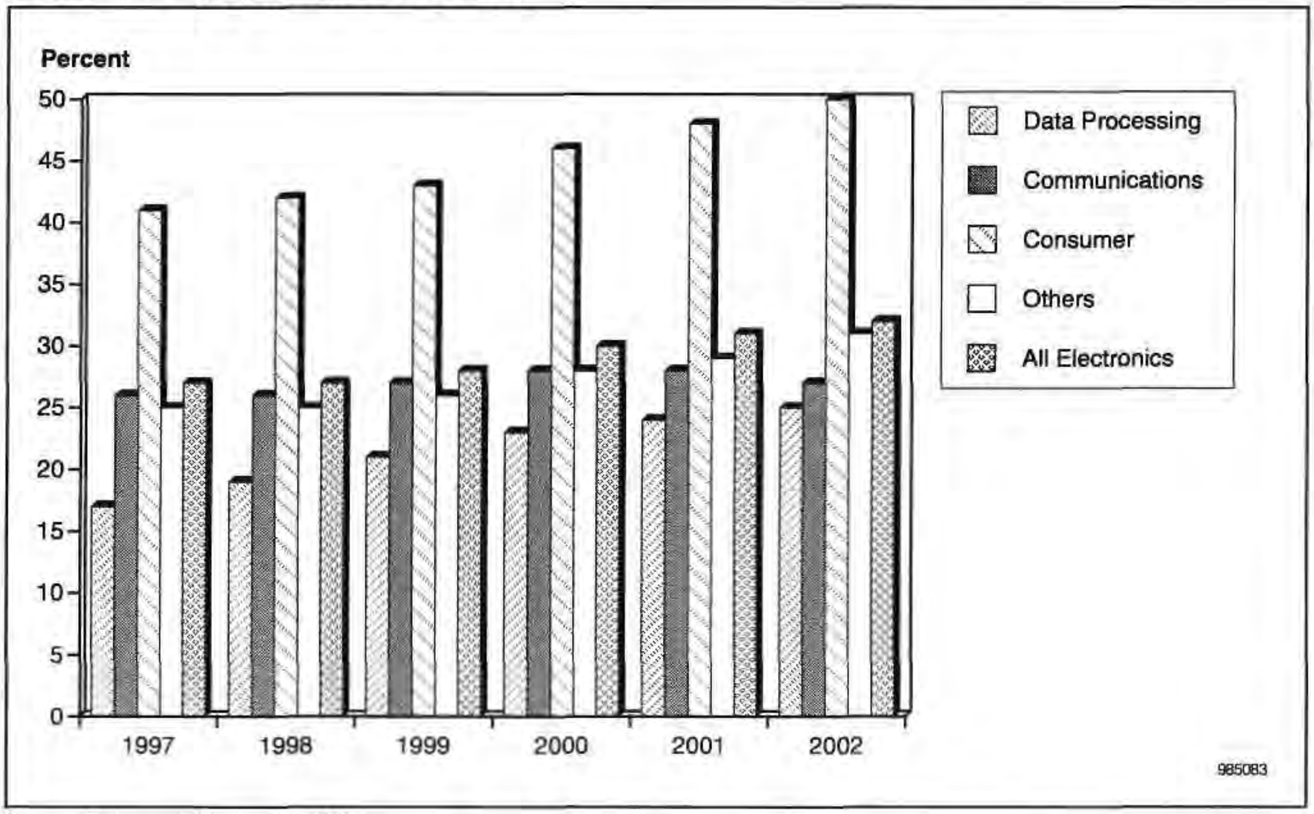
Chapter 2
Electronics Industry Trends

More than 30 Percent of Asia/Pacific Production Will Come from China

China/Hong Kong's share of Asia/Pacific production will rise from approximately 27 percent in 1997 to 32 percent in the next four years. In revenue terms, China/Hong Kong's electronics production will grow from $46 billion to $98 billion, representing an 18 percent CAGR. In a broader context, the worldwide CAGR for this period is about 6 percent to 7 percent, with the Asia/Pacific CAGR more than 10 percent. China/Hong Kong's lectronic equipment production quantity outpaces worldwide averages because of export competitiveness and unsatisfied local demand, especially within the healthier economies such as China and Taiwan. At the same time, semiconductor content is increasing faster in Asia/Pacific than in the rest of the world. This trend suggests that semiconductor consumption will outpace electronics in the next five-year period (taking out cyclicality). Foreign investments to China/Hong Kong are accelerating for the purpose of gaining market access and time-to-market competitive advantage, a necessity in an oversupplied market. Figure 2-1 illustrates China/Hong Kong's share of total data processing, communications, and consumer equipment production.

Figure 2-1
China/Hong Kong's Share of Total Electronic, Data Processing, Communications, and Consumer Equipment, 1997 to 2002



Source: Dataquest (September 1998)

 ©1998 Dataquest

In comparing the past five years with the next five years, it is clear that revenue in Table 2-1 shows an electronics production deceleration in Asia/Pacific. In relative terms, the region has doubled in revenue and expanded from one-third the size of Japanese electronics industry to more than 90 percent of Japan's 1997 revenue. The region was half the size of Europe's industry in 1991, but it will continue to converge with that of Europe. The region will not sustain this phenomenal growth because of lasting effects of the Asian financial crisis, but it is expected to outpace other regions in the next five years.

Data Processing Electronic Equipment Overview

Although Asia/Pacific succeeded early in consumer electronics manufacturing , its data processing industry has kept pace with worldwide trends, and its revenue is expected to more than double from $78 billion in 1997 to $157 billion in 2002. In the past three years, Asia/Pacific communications markets' and industries' rapid growth has enabled this sector to reach $29 billion in 1997. Dataquest forecasts strong growth in a few key sectors, bringing revenue to $47 million in 2002. Consumer electronics production surged in the early 1990s because of transplanted Japanese manufacturing. Dataquest expects it to remain the second-largest segment in Asia/Pacific. A worldwide consumer electronics consumption slowdown through 1998 has translated into slower growth in Asia/Pacific production, although Dataquest expects Asia/Pacific to grow at double the worldwide production growth rate.

Asia/Pacific countries that bet their industrial development on PCs have reaped the rewards. The impressive manufacturing efficiencies of Singapore and, later, Malaysia, have enabled Asia/Pacific to increase its share of global mass-storage production. Dataquest sees no signs of this trend changing. The combined revenue from monitors, PCs, and motherboards was 65 percent of total data processing revenue. Storage makes up most of the rest of data processing revenue. By 2002, Dataquest believes that these five products will represent 80 percent of data processing revenue, and data processing will represent 52 percent of total Asia/Pacific electronics production.

Table 2-1
Asia/Pacific Electronic Equipment Production Forecast by Sector, 1997 to 2002 (Millions of U.S. Dollars)

The PC markets show slower but steady growth worldwide, and Asia/Pacific has proved well-suited to meet those market needs. What will enable the PC to continue to add value to home and private citizens is that it continues to evolve in its functionality and integration into people's lives. Recently, PCs evolve from a productivity tool for spreadsheet, word processing, and other data processing tasks into an information, communications, and entertainment multimedia system. Technology barriers are eventually overcome, and new multimedia PCs now offer 3-D graphics, MPEG-2 video, AC-3 audio, fax/modem, telephony functions, and videophone. The world of system-level integration will engender the next quantum leap in performance and functions.

Consumer Electronics Overview

Asia/Pacific is already a player in the new wave of digital consumer electronics that is now entering the marketplace. These emerging electronics include digital video disks (DVDs), digital cameras, digital camcorders, digital VCR, digital TVs, video CDs, advanced games, and direct broadcast satellite, or set-top boxes.

Asia/Pacific benefits several ways in manufacturing consumer electronics. It receives investments from high-cost production regions, such as Japan, and its broad economic growth provides new growth for old products. China's color television production is an example of an undeveloped market revitalizing a mature industry. In 1997, China manufactured approximately $6 billion in video equipment. Dataquest expects China to experience a two-year slowdown in consumer electronics, but the five-year future of digital consumer equipment production is bright. New products, such as set-top boxes and DVDs, will find a way into these huge potential markets in inexpensive ways. Governments are eager to establish digital broadcast standards that will pave the way for broadcasting after 2000.

Communications Electronics Overview

Communications electronics are the third-largest sector in China/Hong Kong and Asia/Pacific. In China/Hong Kong, communications equipment production dominates consumer products such as phones, cordless handsets, answering machines, and analog cellular equipment. Furthermore, digital cellular products are now playing a pivotal role in communications semiconductor market growth. In 1995, digital cellular shipments accounted for only 38 percent of the total analog and digital cellular unit market, but in 1998, it will account for more than 80 percent of the 123 million phones shipped.

Unlike data processing and consumer electronic equipment production Asia/Pacific's communications production is significantly less than it consumes. These are market opportunities that the local companies are exploring, and multinational companies are starting to invest in this area. In the short term, most of the advanced infrastructure equipment will be imported. For many other products, Dataquest sees production continuing to expand in the region because this is where the world's fastest market growth is expected for the next 10 years. Central office/premises and cellular phones will surpass cordless phones to become the second- and third-largest markets.

©1998 Dataquest

China/Hong Kong a Critical Growth Source for Asia/Pacific

The following key factors enable China/Hong Kong electronics to avoid dramatic production swings as these sectors fell in most other parts of Asia/Pacific, except Taiwan:

- China, unlike the other regions, is showing growth in all three electronics sectors. The net consequence is an impressive overall growth.
- China's domestic market attracts investors from all major regions.
- China's industry is balanced between exports and local consumption, each representing about one-half of total output.
- Economic planners are focusing on sustaining macroeconomic stability vis-à-vis microeconomic policy. Without floating its currency, China has maintained control of its economy without suffering the economic woes seen in the Russian republics.

As shown in Table 2-2, Dataquest expects strong growth in China's three major electronics sectors, but with data processing leading the growth, while communications and consumer sectors followed.

Dataquest's Electronic Equipment Producers Survey Results: The Big Are Getting Bigger—and a Lot Faster, Too

China/Hong Kong has become the No. 1 investment destination by electronic equipment companies in Asia/Pacific. The currency and economic woes in several Southeast Asian countries may further depress their long-term growth. China's rapid reforms, strong economy, growing consumption, and advancing production base continue to attract major investments from various sectors.

Table 2-3 lists major multinational and Chinese companies that were surveyed for production quantities detailed in this report. Dataquest surveyed 38 manufacturers and has itemized the top 20. Note that the revenue was derived from estimated unit production of major electronic equipment and applying a factory ASP.

Table 2-2

Dataquest lists 31 major manufacturing companies, representing 20 percent (or $11 billion) of electronics production in China/Hong Kong. Dataquest's analysis of these manufacturers indicates a rapid expansion of production capacity for both local consumption and export, but that this expansion is decelarating, particularly in the consumer electronics area. These 31 companies are expected to increase revenue by about 13 percent in 1999 after growing approximately 22 percent in 1998 (see Table 2-4).

Company-Level Semiconductor Consumption Ranking Forecast

As expected,China's semiconductor consumption is rising even faster for the major manufacturers. However, semiconductor consumption rankings differ from electronics production rankings. Legend Group will become the largest consumer of semiconductors in China/Hong Kong in 1998, after surpassing PC Chips Manufacturing Limited, a low-end motherboard manufacturer based in Taiwan (see Table 2-5). The combined consumption of these companies will be more than 30 percent of semiconductors used in China/Hong Kong. Dataquest's total sample group of 64 will consume 42 percent of semiconductors used in China/Hong Kong.

Electronics Equipment Production Assumptions

China's growth in exports, local consumption, foreign investment, and government support are some basic positive factors behind its electronics production growth. Underlying and supporting all these trends is the fact that local production is becoming more efficient, and economies of scale are being achieved.

Does China Need to Devalue Its Currency?

The currency devaluation created critical problems for Asia/Pacific semiconductor suppliers and users that are almost entirely dependent on imports. Although most vendors denominate their prices in dollars, cash-flow problems—attributed to rising credit costs and falling sales—have resulted in weakened demand from local manufacturers. Indonesia's currency devalued more than 80 percent during the past six months, and its equity market dropped by more than 80 percent. As a result of the financial turmoil, stock markets in Korea, Thailand, the Philippines, and Malaysia declined by more than 60 percent. Equity markets in China and Hong Kong have also dropped, but their strong cash account reserves have enabled them to support the Hong Kong dollar and the Chinese renminbi.

Source: Dataquest (August 1998)

Few economists expect a renminbi devaluation in 1998, but there are concerns in the region that falling exports and a slowing economy will force China to devalue, potentially sparking another round of disastrous currency depreciation in Asia. It is a question of time. For sure, China will devalue, but whether it is before or after the region has recovered is the issue. In 1998, the Chinese government is under extreme pressure to maintain strong economic growth and create new jobs because of the dismantling of state-owned industries, which is creating millions of surplus workers. So far, the Chinese leadership has responsibly held its currency at the expense of economic growth, in addition to committing U.S.$250 billion in infrastructure spending projects to increase its gross domestic product (GDP) vis-à-vis domestic consumption.

 ©1998 Dataquest

Gross Domestic Product Remains Robust

China's economic growth has slowed substantially since March of 1998. Data from the Organization of Economic Cooperation and Development (OECD) had forecast China's economy to grow between 7.5 percent to 8.0 percent in 1998. However, because of the region's worsening economies and slowing exports, GDP is expected by numerous sources in Hong Kong to fall between 6.5 percent and 7.5 percent. GDP in the first quarter of 1998 had slowed to 7.2 percent, and it is expected to slow to 7.0 percent in the second quarter. The trend is expected to continue, with the second half of 1998 averaging less than 7 percent. One of the advantages China has over the rest of Asia/Pacific is that its economy is far more diversified, with economic expansion taking place in heavy industries, manufacturing, electronics, services, and agriculture. This broad-based growth, including electronics, buffered it from Asia's economic woes. In fact, the major growth burden has been from the SOEs that account for about 60 percent the economy. Prime Minister Zhu Rongji is in the process of structuring SOEs, which is the main factor behind slower growth and rising unemployment. However, China depends heavily on foreign capital and markets to sustain its current growth rate.

Foreign Investment Will Not Dry Up

In addition to increased efficiencies in Chinese companies, economic growth has been boosted by direct foreign investment. Foreign investments need to continue to flow into China for it to achieve a 7 percent GDP growth. Hong Kong, which has been hurt financially by its falling stock market, accounted for 59 percent of foreign-invested capital in China from 1980 to 1997. In the past few years, contracted investments in China had declined from $88 billion in 1994 to $72 billion in 1997. However, the actual utilized investment increased from $33 billion to $44 billion during this period. There is uncertainty in 1998, and most forecasts indicate a decline in utilized investments to $35 billion for the first time in at least five years.

Dataquest also expects contracted investments to decline because of the investor uncertainty that is the short-term outcome of China's aggressive reforms to be undertaken in 1998. However, once the dust settles, investment flow is expected to resume in 1999 because the current slowdown is macroeconomic rather than microeconomic in nature. In the first quarter of 1998, figures show more than 10 percent growth over 1997, but the second quarter is expected to decline. However, Dataquest continues to see communications, computer, and consumer electronic companies maintain a high strategic interest in investing in manufacturing in China for long-term needs: to increase market access, reduce distribution costs, and improve time to the market.

Exports Still Competitive, Southeast Asian Companies Face Cash-Flow Problems

China's GDP will exceed $900 billion in 1998, yet its total trade is nearly $400 billion. China's export machine has proved to be a formidable global force, particularly in the past three years. The economy's trade surplus was expected to increase beyond $50 billion in 1998 prior to the financial crisis; but as result of the financial crisis, it is expected to decrease to the $30 billion range. The first two months of 1998 show exports to the United States to be at the same levels as 1997, while imports are slightly down.

China is exposed to the Asian financial crisis by about 11 percent because 11 percent of its exports go to Southeast Asia and Korea. In the past few years, China's exports to Japan have declined to about 15 percent of total exports, but exports to Europe, North America, and Taiwan increased to more than 60 percent. Based on export exposure, a dramatic trade downturn as experienced by the rest of Asia is not likely. The free-falling yen was clearly a threat, but China still holds a (dangerous) wild card: devaluing the renminbi.

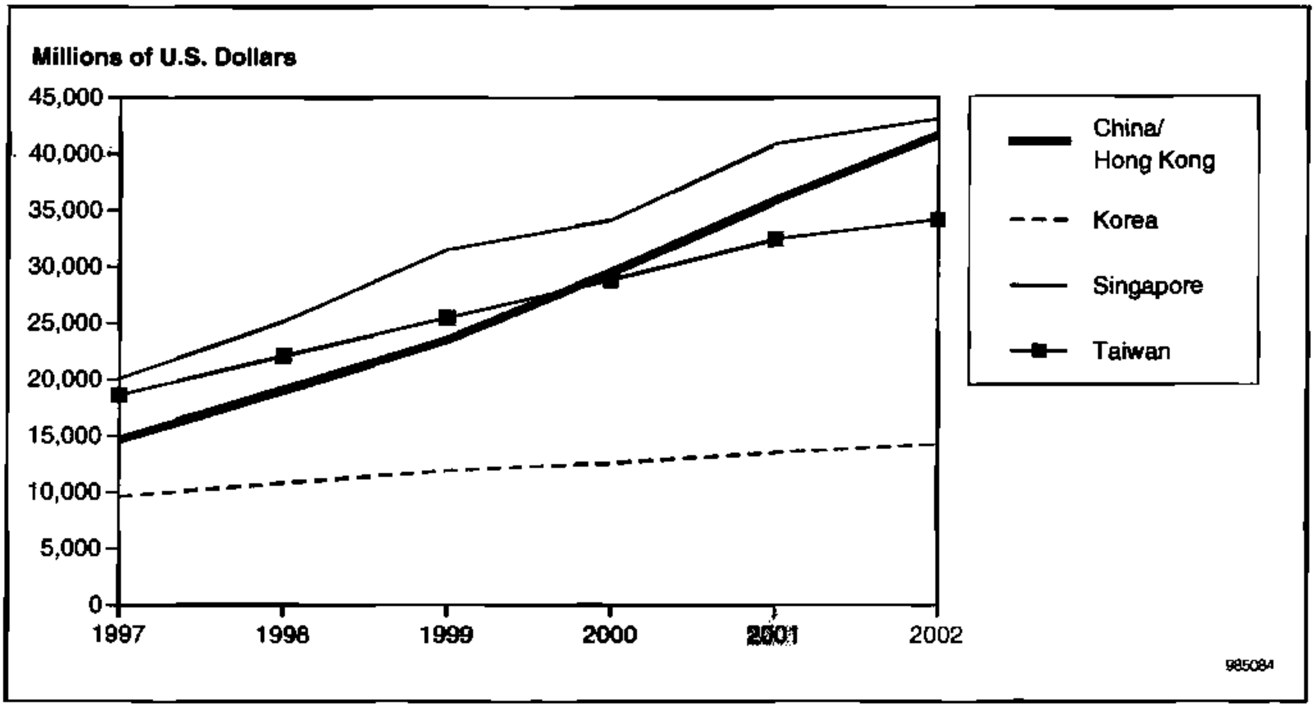
Chapter 3
Computers and Peripherals Industry Trends

Dataquest forecasts that data processing-related electronic equipment production revenue will grow from $19 billion in 1998 to $42 billion in 2002. In 1998, PC production will increase 55 percent to 4 million units, representing a semiconductor opportunity of approximately $900 million. Dataquest expects data processing, led by strong PC industry and market growth, to undergo an average annual growth rate of 36 percent during this period for reasons discussed later in this chapter. During this period, China will surpass Taiwan to become the second-largest data processing equipment producer in Asia/Pacific (see Figure 3-1).

Data Processing Segment Analysis

Dataquest expects data storage to become the fastest-growing sector during the 1997-to-2002 forecast period, although it was the smallest sector in 1997. Dataquest expects that most of the 1998 production will be exported. Seagate Technology Inc. is the sole manufacturer of rigid disk drives (RDDs) in China, operating two major facilities. Dataquest believes that this $2.4 billion industry in 1998 will grow fivefold to $9.4 billion by 2002, based on Seagate's plans, and new entrants are likely in the 1999-to-2000 time frame.

Figure 3-1
Data Processing Equipment Production in China/Hong Kong, Korea, Singapore, and Taiwan: 1997 to 2002 (Millions of U.S. Dollars)



Source: Dataquest (September 1998)

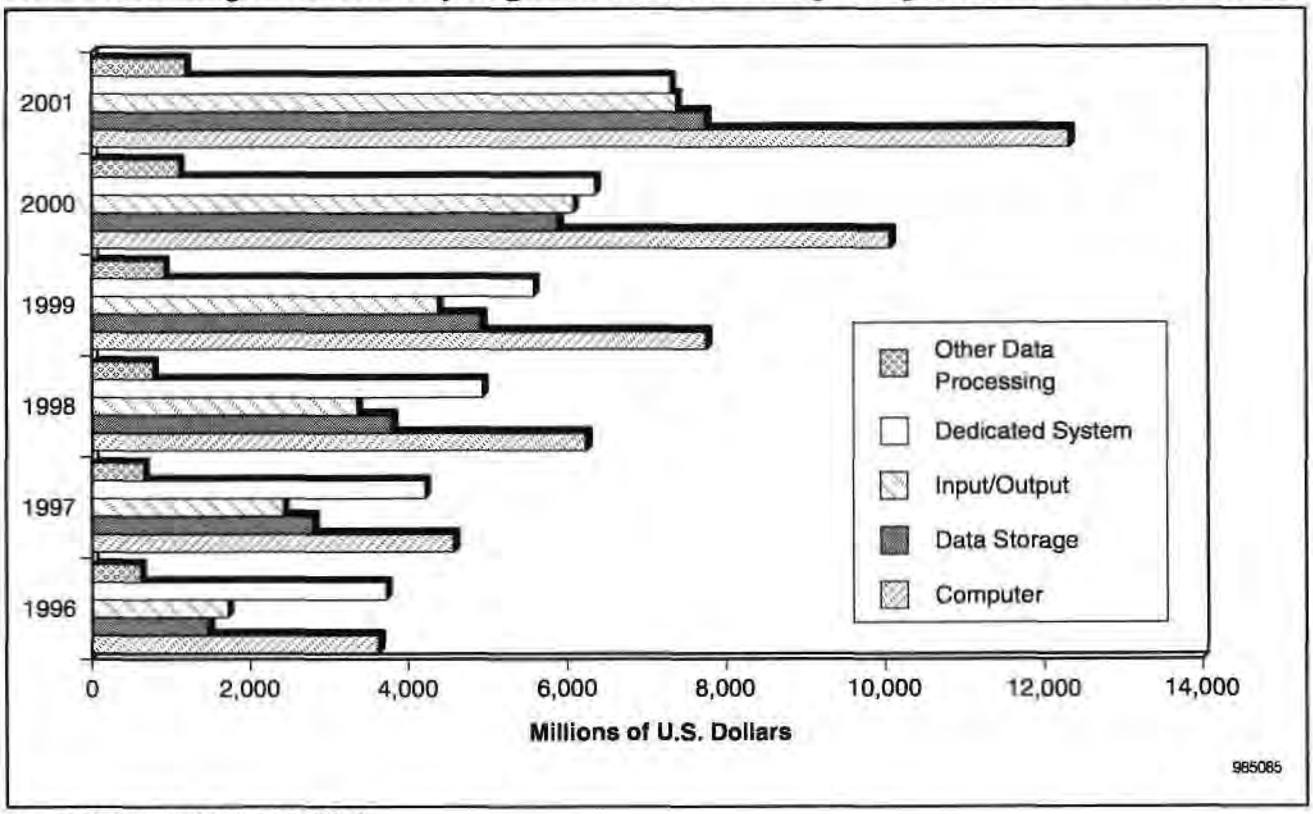
Computer peripherals, defined as input/output devices, will expand at an average annual growth rate of 30 percent to reach $9 billion, up from $2.4 billion in 1997. Monitors represent about 54 percent of this category.

The largest data processing sector is the computers, which is expected to grow 32 percent in 1998 and average 28 percent in the next four years, reaching a $13.3 billion revenue level in 2002. PCs and motherboards will increase in importance from 21 percent to 28 percent share of data processing production (see Figure 3-2). PCs and motherboards represent about 71 percent of computer revenue in 1998.

Computer Production

Computer equipment production in China is being driven first and foremost by consumption. However, improved quality and competitiveness now mean that foreign and Chinese companies are also exporting from China. China's growing computer demand will support the country's economic modernization. Chinese banks, insurance companies, and tax agencies are in the rudimentary stages of computer use, and they lack networks for information sharing. For the future convertibility of the renminbi (or Chinese yuan), Chinese officials are integrating banks with better computing systems. The State Bureau of Taxation is looking to connect 30,000 offices across the country.

Figure 3-2
Data Processing Production by Segment in China/Hong Kong (Millions of U.S. Dollars)



Source: Dataquest (September 1998)

 ©1998 Dataquest

Computer and computer peripheral sales in China are expected to increase by more than 30 percent in 1997. Domestic demand for PCs this year is expected to approach 3 million units in 1997. China's domestic computer manufacturers currently account for about 25 percent of domestic sales. Most leading foreign PC vendors have already established manufacturing facilities in China to anticipate this growing domestic demand. Among other forecasts, China's annual demand for high-powered computer workstations is expected to grow to about 5,000 units this year.

PC Production Spurred by Domestic Market's Pull

Furthering PC production growth is the parts and components production in major production centers: Shenzhen, Shanghai, and Beijing. Time-to-market concerns, familiarity with local distribution channels and customer concerns, lower tariffs, and locally produced parts translate into competitive advantages and lower costs for Chinese producers. In addition to small-scale producers, major brands—such as Legend Group, the Beida Founder Group, China Great Wall Computer Group, Beijing Stone Group, Donghai Co., and others—have emerged in China's booming retail markets. Legend Group's recent initiatives indicate that the company is trying to duplicate its newfound success in the international markets. Legend moved its PC division headquarters to Hong Kong to break into the global PC market, which was Legend's first step to become one of the top five vendors in Asia/Pacific, while maintaining domestic market leadership by 2000. Legend forecasts its sales to reach 1 million units annually by 2000. Table 3-1 shows China/Hong Kong's PC production forecast.

Table 3-2 provides a ranking of China/Hong Kong's PC manufacturers in terms of 1996 and 1997 production units ranking. The top manufacturers correspond closely with the top vendors in terms of market share because of the above advantages. Table 3-3 provides company production trend lines and a forecast for 1999 production.

Over the long run, Dataquest expects China/Hong Kong's PC production to reach 35 percent CAGR. China's PC market represents about one-third of all shipments to the Asia/Pacific region (excluding Japan) in 1998. At the same time, its unit growth will likely double the regional average.

Business Markets Dominate and Still Show High Growth

China's PC market continues to show strong growth and attract multinational investors and domestic suppliers. Table 3-4 ranks all major vendors according to PC units shipped in 1997.

Table 3-4

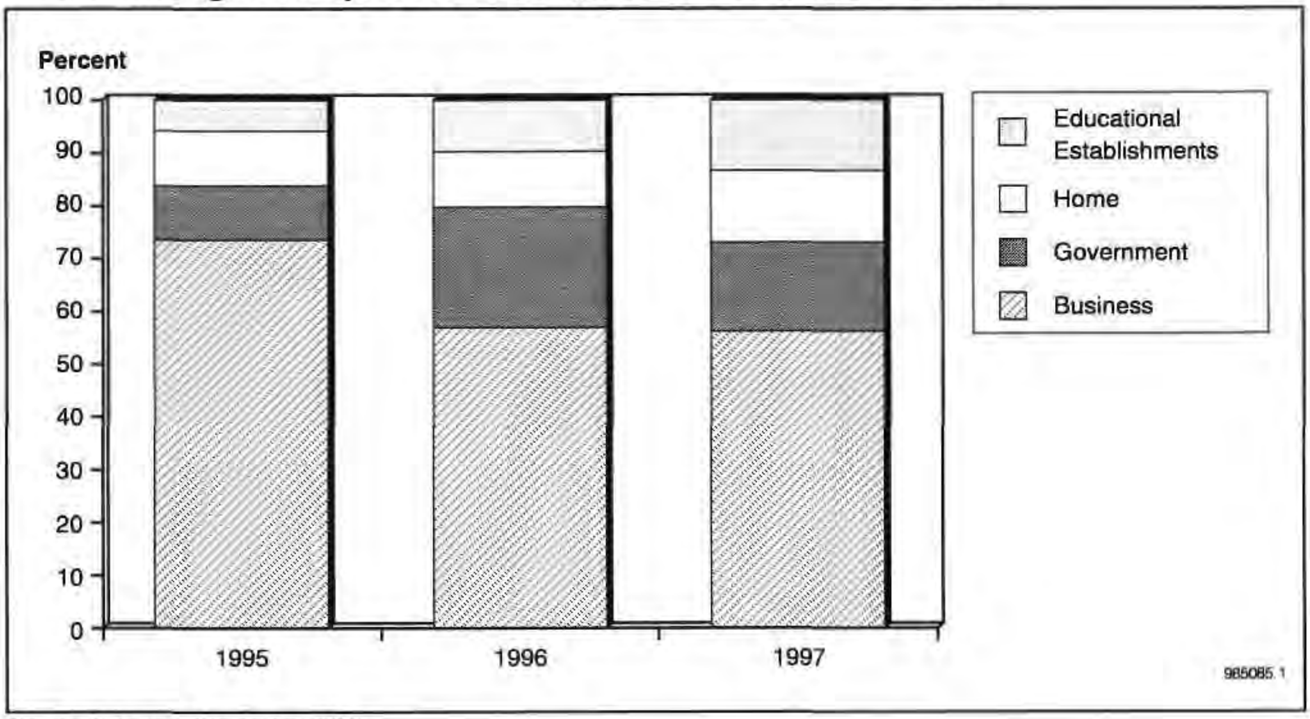
 ©1998 Dataquest

To understand the source of the business markets' growth, Dataquest segments the market by customer, form factor, and processor class. China's business market was the first to adopt PCs in the country. In 1995, the business segment absorbed nearly three-fourths of all PCs shipped in China (see Figure 3-3). Strong demand from foreign businesses in China later spilled over into local export-oriented companies. Foreign brands will not be the automatic product of choice because many local vendors now produce credible quality and are learning to provide aftersales service. The private sector remains China's engine for economic growth, and PCs will be rapidly deployed in this large and booming sector. However, the emergence of government, home, and education markets lowered business segment's share to 56 percent in 1997. But the PC market more than doubled, so PCs for business use still grew from 700,000 units to 1.2 million units from 1995 to 1997.

Government Sector Shows Strength

The government market accounted for about 10 percent of the PC market in 1995 and nearly doubled in share to 17 percent by 1997. The government and home markets each purchased only about 100,000 units in 1995. But the government segment grew faster, reaching 372,000 units in 1997. The government's recent initiative to streamline government, reduce ministries, and cut red tape will necessitate the computerization of administrative functions across China's central government. However, the pace at which China can achieve such a mammoth task will be slow, and the funds available will be increasingly scarce.

Figure 3-3
PC Market Segments by User in China, 1995 to 1997 (Percent Share)



Source: Dataquest (September 1998)

Home Market Awakes

There are few reasons to believe that the Chinese will have any less of a desire for home PCs than is seen in the United States, where approximately 40 percent of homes have PCs. This is another example of high nascent demand, because urban families have shown a high interest in PCs to educate their children to get ahead in China's competitive education system. In China, about 0.05 percent of the population own PCs, and only about 0.25 percent of 1 percent of families own PCs (assuming an average family size of five persons). The current economic growth rate, resulting in higher disposable incomes, would suggest that it takes about 10 years for 20 percent of Chinese families to own PCs. Another way to look at this trend is as follows: If an average of 5 percent of PCs are retired per year in the next decade, and the home market grows by 50 percent per year, then 85 million PCs would be sold just to families in China between now and 2008.

Education Users Surge

China's education market was the fastest-growing PC market segment during the past three years. Only 6 percent of PCs sold in 1995 went to educational establishments, but by 1997, this more than doubled to 13 percent. The university environment is the heaviest user on a per-PC basis, with hundreds of students sharing one or two PCs. But it is also the least funded. Vendors are wise to develop market share in this segment (providing discounts) as an efficient means of building brand recognition with China's next generation of business and government leaders.

Form-Factor Trends

In addition to market segmentation by end user, Dataquest segments PC shipments by form factor. The Chinese market has been dominated by desktop computers. But in 1997, the notebook computer market doubled to 173,000 units after several years of slow growth. Dataquest forecasts the market to continue this growth level through 1999, and then settle to a 50 percent average growth from 2000 to 2002. Dataquest has yet to see a local notebook computer manufacturer in China, but it expects volume production to begin in 1999. Significant semiconductor opportunities will emerge as portables grow from a mere 9 percent in 1997 to 26 percent in 2002. Desktop PCs remain the "bread and butter" of the industry. Desktop PC shipments will grow from 1.7 million units in 1997 to 6.5 million units in 2002. The overall PC shipment share will fall from a high of 88 percent in 1997 to 68 percent in 2002.

Long-Term PC Production and Semiconductor Consumption Forecast

PC manufacturers surveyed by Dataquest expect a significant production expansion slowdown in 1998 relative to 1997—from 97 percent in 1997 to 46 percent in 1998. Approximately 84 percent of China/Hong Kong-based PC manufacturers' unit output was surveyed in both periods. These manufacturers, as a group, had exceeded their production plans of 88 percent growth in September 1997 and reported their final 1997 growth to be 97 percent. This performance is consistent with local Chinese companies' local market share gains, which expanded by 44 percent to 2.2 million units in 1997.

 ©1998 Dataquest

Dataquest estimates that total PC production in 1998 will reach 4 million units, a 55 percent increase over 1997. The estimated factory average selling price (ASP) of PCs (excluding motherboard, monitor, keyboard and disk drive) in 1998 will reach $686, up from was about $670 in 1997 (see Table 3-5).

Motherboard Production to Drop in 1999

Table 3-6 lists Dataquest's 1996 and 1997 PC motherboard manufacturer ranking and production share for the surveyed companies. The largest manufacturer in terms of units was PC Chips, a low-end, volume-driven motherboard manufacturer based in Taiwan. Dataquest believes that this group of manufacturers represents 96 percent of total motherboard production in China/Hong Kong.

The production forecast of these manufacturers is presented in Table 3-7, which shows 1998 and 1999 unit production by company. As stated earlier, these manufacturers are cautious with their expansion plans. Dataquest's surveys of these companies indicate that growth will fall off from 60 percent in 1998 to 15 percent in 1999, because of few new investments.

Table 3-5
PC Production Forecast in China/Hong Kong, 1996 to 2002

Source: Dataquest (August 1998)

Dataquest's long-term outlook is presented in Table 3-8, which indicates a recovery caused by underinvesting during these next two years. Dataquest forecasts China/Hong Kong's motherboard production to expand by 32 percent CAGR from 1997 to 2002. PCs are growing at a faster rate because Dataquest believes that some of China's market will continue to be served effectively by drop shipments of motherboards to assemblers in China. The semiconductor opportunity of $760 million in 1998 is approximately the same size as the $900 million shipped to the PC market. Combined semiconductor consumption of PC and motherboard vendors will exceed $1.6 billion in 1998 and will grow to more than $5 billion in 2002. This amount is nearly 20 percent of the entire semiconductor market in 2002 (see Table 3-8).

Computer Monitors

Domestic monitor shipments to the Chinese market has been growing at 40 percent during the past several years. Production expanded by 39 percent in 1997 and accelerated to 65 percent in 1998 because of new investments. Table 3-9 ranks the top manufacturers that account for about 50 percent of total production. As indicated, Chinese companies have rapidly entered this market, but the multinational vendors still dominate.

As shown in Table 3-10, the growth Dataquest had forecast is attributed to increased capacity by the large three producers, Philips Electronics NV, Acer Computer International Ltd., and First International Computer Inc. (FIC). These three companies occupied 25 percent of the industry in 1997. Dataquest segments monitors in the input/output equipment market, which is part of the overall data processing market. Monitors will remain the primary growth driver and have the largest share of input/output production. Dataquest forecasts this segment to expand by 30 percent from $2.5 billion in 1997 to $9 billion in 2002. Monitors' 1998 revenue of $2 billion will represent 54 percent of all 1998 input/output revenue.

Table 3-11 presents Dataquest's history and forecast of total computer monitor production in China/Hong Kong. Dataquest's survey of monitor production in China/Hong Kong covered one-half of the region's total monitor production, which is a large sample size. Dataquest estimates the total production in 1998 to reach 12.5 million units, compared to 7.6 million units in 1997.

Storage Equipment

Seagate is the sole producer of RDDs in China/Hong Kong. Most components are internally transferred from Singapore; however, Dataquest has estimated Seagate's semiconductor consumption at two facilities. Table 3-12 provides Seagate's historical units and growth, while Table 3-13 provides Dataquest's forecast for 1998 and 1999.

Dataquest expects data storage to be a major semiconductor growth source for the next four years. We expect that at least 90 percent production will continue to be exported by Seagate for global export because of the nature of these facilities. Dataquest believes that the $1.6 billion storage industry in 1998 will grow fivefold to reach $3.9 billion in 2002, with Seagate leading the way. This 19 percent CAGR is lower than unit growth of 24 percent, as price erosion continues, but at a slower rate (see Table 3-14).

Seagate Technology Inc.

Seagate has been expanding production in China and will inject $32 million into its Wuxi facility, bringing total direct investment to more than $52 million. Total investment in China was reported to be $90 million, including the Wuxi plant. Employing about 3,300 workers, the Wuxi plant's aggregate production reached 3 million units in 1996. This investment adds about 1,600 workers and doubles Seagate's capacity in China, which serves both local and export markets. It is said that the production line for magnetic disk drivers, which is now in the old building, will be shifted to the new one, and the old one will be used mainly for the production of E-BIKS, with an expected daily capacity of 25,000 units.

The new Wuxi facility is Seagate's second RDD plant in China, after operating the Shenzhen plant for more than two years. The acquisition of Conner Peripherals Inc. by Seagate enabled it to buy market share in China by acquiring Conner's Shenzhen RDD plant. It also enabled Seagate to adopt a successful business model for selling in China, which Seagate has successfully expanded upon. Since then, the combined efforts have proved effective for Seagate, which now controls more than 50 percent of the market and exports RDDs from China.

Dataquest estimates the PC production growth rates to keep pace with China's breakneck PC market growth. This rapid growth resulted in a voracious demand for RDDs. However, RDD competition is increasing for Seagate as it is attempting to hang on to its reign of China's computers mass-storage market. By expanding production, Seagate is leveraging its current competitive advantage in the market to combat the new market entrants.

 ©1998 Dataquest

Printers

Dataquest researched production for Fujitsu Ltd., Stone/Fujitsu, and Sharp Electronics Corporation, but we did not include Hewlett-Packard, which also manufactures printers in China. From Dataquest's research, these four companies represent almost the entire page printer production industry in China/Hong Kong. Fujitsu and its joint venture, Fujitsu/Stone, together represented about 22 percent of production in 1997 (see Table 3-15). Sharp produces a small quantity that represents only approximately 4 percent of overall production.

Table 3-16 provides production forecasts for these three companies in 1998 and 1999. Dataquest observes aggressive expansion in 1998 because of investments that were made in 1997. However, as Dataquest observes in many segments, investments have become somewhat cautious in 1998, hence unit production is expected to expand by a slower, but robust, 35 percent.

The long-term printer production outlook growth and semiconductor consumption is quantified in Table 3-17. In general, the 33 percent CAGR should not be a surprise here because printer production is keeping track with PC production and electronics market growth. Semiconductor content is increasing because of expectations that higher-end printers will be built in China and because of increasing demand from business, government, and even personal users.

Communications Electronics Equipment

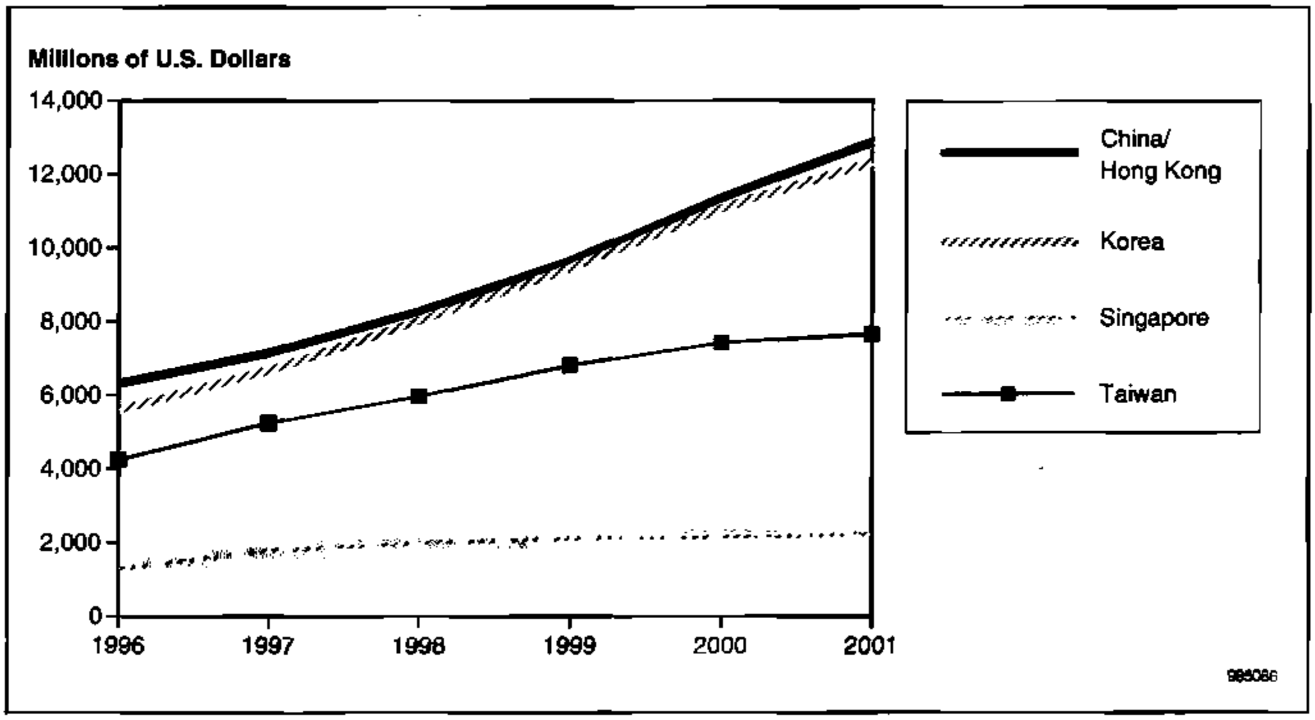
Introduction

Dataquest assesses the communications equipment production in 1998 and 1999 with an up close look at key manufacturers. Dataquest also assesses each product's semiconductor usage from 1997 to 2002. Because of the importance of communications market to driving investments in local production, Dataquest has provided additional market-related information as part of its baseline assumptions.

Communications Sector Trends

China/Hong Kong has become Asia/Pacific's largest manufacturer of communications equipment because of its rapid rise in premises and, more recently, mobile communications production. Dataquest expects communications production to maintain its current pace because of broad-based products that are both exported and shipped locally in China. The Chinese government continues to provide significant support and investments in developing its telecommunications infrastructure, which will lead to increases in local content and foreign investment. Figure 4-1 illustrates Dataquest's forecast by Asia/Pacific country, which shows that China/Hong Kong and Korea both maintain dominance of Asia/Pacific's communications production.

Figure 4-1
Communications Production Revenue Forecast in China/Hong Kong, Korea, Singapore, and Taiwan: 1997 to 2002 (Millions of U.S. Dollars)



Source: Dataquest (September 1998)

©1998 Dataquest

Communications equipment production will generate $8.3 billion in China/Hong Kong in 1998, which represented 4 percent of Asia/Pacific's total electronics production. China/Hong's production represented 27 percent of all communications-related production (revenue) in Asia/Pacific. Dataquest forecasts that China/Hong Kong's communications production will grow at an 11 percent CAGR from 1997 to 2002. At its current growth trajectory, China/Hong Kong will maintain its share of Asia/Pacific communications production despite its high consumption growth of communications equipment. Dataquest believes that China/Hong Kong will still have to import the majority of its infrastructure equipment because of technological complexity and the need for turnkey solutions. Some standardized systems, such as Global System for Mobile Communications (GSM), can lead to local production but new technologies, such as xDSL, will continue to be imported in entirety (and probably from only a few vendors).

As illustrated in Figure 4-2, which splits China/Hong Kong's communication production by major market segment, Dataquest forecasts that premises will continue to dominate in production share, while mobile leads the industry growth. Substantial production volume, particularly in southern China, of corded and cordless telephone handsets will enable premises production to sustain more than 50 percent of production. It will account for 55 percent of production in 1998 but will fall to 50 percent because of mobile's faster growth. Premises are followed by mobile with 21 percent share, public telecom (18 percent), broadcast/studio (3 percent), and others (0.8 percent).

Digital Cellular

Table 4-1 presents Dataquest's list of major mobile cellular phone producers in China/Hong Kong, their production units, and production share. Dataquest includes all cellular handset production in this segment, including digital cellular and broadband PCS handsets to include handsets that conform to the following standards: GSM, Digital Cellular System (DCS) 1800, personal communications services (PCS) 1900, NA-TDMA (IS-54/136), code division multiple access or CDMA (IS-95), Personal Data Cartridge (PDC), and Omnipoint.

Dataquest's sample survey of six major multinational manufacturers included about 74 percent of cellular phone production in China. Motorola Incorporated is a Goliath and overshadows all other manufacturers with 39 percent production share in 1997. Despite its 41 percent increase in output, Motorola still lost 3 percentage points production share because of NEC Corporation's rapid expansion, which enabled NEC to move from No. 4 to No. 2 in production ranking.

Table 4-2 presents production plans of these major six manufacturers in 1998 and 1999. As shown, there is a dramatic deceleration from 60 percent growth in 1997 to 27 percent in 1998 among these top producers. Consequently, the overall industry will only grow 25 percent, which is high by global standards but slow for China/Hong Kong. One would expect this slowdown to occur in 1998 because all manufacturers have expanded production. It appears this slowdown is temporary because production among these companies is expected to accelerate to 33 percent in 1999. Dataquest expects the next year to see new entrants to the market attributed to turnkey GSM technology transfers that are taking place this year. Dataquest expects to see one or two Chinese companies start producing cellular phones by 1999. Hence, overall cellular phone production will jump to 39 percent according to Dataquest's forecast.

Table 4-1
Cellular Phone Manufacturers Production Share and Ranking, 1996 and 1997 (Thousands of Units)

					Production Share (%)		Accumulated Share (%)	
Rank 1996	Rank 1997	Company	1996	1997	1996	1997	1996	1997

Table 4-3 presents Dataquest's long-term perspective on cellular phone production and semiconductor consumption. Dataquest forecasts a significant production growth of 39 percent CAGR from 1997 to 2002. This growth level translates into a production capacity of 16 million cellular phones by 2002 in China/Hong Kong.

Mobile telecommunications business has developed rapidly in China, but with faster expansion in the eastern coastal areas than the central and western areas. Competition is sizzling in the mobile telecommunications service market between China Telecom, under the Ministry of Posts and Telecommunications (MPT), and its main rival, China Unicom.

Table 4-3
Cellular Telephone Production Forecast in China/Hong Kong, 1996 to 2002

Source: Dataquest (August 1998)

China's mobile phone subscribers in 1997 reached nearly 10 million. The Chinese government predicted last year that the number of mobile phone subscribers would reach 7 million by the end of 1997. Recent estimates put the 1997 figure closer to 10 million. But most of them are still based on the analog system because of its earlier introduction in the 1980s. Cellular phone subscribers in 1997 are estimated to be 4 million by MPT. In Shanghai alone, the number of cellular phone subscribers were 600,000 in 1997, from about 360,000 in 1996.

Major players in the mobile telecommunications market include China Telecom, Telecom United, Motorola, Nokia Telecommunications, Oki Telecom, Ericsson, and Siemens AG.

With the addition of 130 GSM networks run by China Unicom, the GSM networks increased to about 5 million. This addition will add an estimated 250,000 to 300,000 radio channels. Mobile phones made by the world's three leading telecommunications companies, Ericsson, Nokia, and Motorola, have captured about 95 percent of Beijing's GSM mobile phone market. The remaining 5 percent of the market is shared by a mixture of products from other companies, including Siemens and NEC.

China is one of the world's most underserved telecommunications markets today. It had a cellular phone penetration rate of only 0.6 percent last year. But the market is expected to quadruple to 28 million subscribers by 2000. Even with this increase, it is still a tiny percent of the 1.3 billion people in China today. If Taiwan is an indicator, then this rate is only about 4 percent of Taiwan's 21 million mobile telephones subscribers today. Provincial governments are taking many initiatives to expand their mobile markets, as detailed below. For example, the economically vibrant coast province of Shandong has an estimated 750,000 mobile phone and 800,000 pager customers in 1997. The number of mobile subscribers in Henan Province is not in line with the size of its population. Henan had 95 million people, but had only 121,708 cellular phone subscribers in 1995.

GSM Developments in China

China is going mobile to meet the growing demands of the country's telecommunications explosion. GSM continues to build momentum in China as digital technology provides high-traffic-carrying capacity.

In the face of rapidly growing public demand, the MPT has decided to expand its sophisticated digital mobile communications systems dramatically in China in the next few years. MPT officials say that foreign telecommunications companies will be allowed to market their own digital or GSM mobile phones in China if their products are found to be of high quality, which, the officials say, will help increase market competition and force prices of GSM mobile phones here to fall.

CDMA Developments

China is now building several trial code division multiple access (CDMA) networks in populous cities such as Guangzhou, Beijing, and Shanghai. The handling capacity of the CDMA networks is reported to be 10 times higher than the present analog mobile telecommunications standard.

©1998 Dataquest

Representatives of Lucent Technologies (China) Ltd.—one of the global telecommunications giants leading the CDMA trend—said that China dialed the first CDMA call on the trial network launched by Lucent Technologies in Guangzhou on December 31, 1996. It is the first commercial CDMA system operational in China.

Lucent said that China—the fastest-growing market in the Asia/Pacific region and in which the company has won CDMA contracts worth $250 million—is now technically qualified to adopt the CDMA technology countrywide.

Motorola, another major CDMA supplier from the United States, is also accelerating the construction work on two trial networks in Beijing and Fujian Province. It made the first CDMA call in Beijing early this month. Meanwhile, other CDMA manufacturers, including Canada's Northern Telecom Inc., Samsung Electronics Company Ltd., and, to a lesser extent, LG Electronics Inc., are entering the Chinese CDMA marketplace.

Once the country decides to open the market to foreign CDMA suppliers, the telecommunications administrative body will encourage the foreign companies to make technical transfer. China has always adhered to the principle of trading market for technology. Therefore, the earlier the CDMA technology is transferred, the easier it will be for the company to make its way into the Chinese market.

Lucent Technologies (China) Ltd.

In September, Lucent's CDMA system was successfully tested to roam between two different networks in Guangdong and Beijing. The tests were conducted with China Telecom Greatwall Network, a cooperative entity between China's MPT and China Electronic System Engineering Co. Lucent's CDMA system passed both the C7 signaling tests and the IS-41B tests, in addition to also achieving successful roaming between the networks in Guangdong and Shanghai. LG is a latecomer in the booming China market for wireless handheld phones and is constructing an assembly plant, like the other major vendors. LG will be bucking up against CDMA phone suppliers that already have assembly plants in China.

Samsung Electronics Company Ltd.

China is also showing interest in Korea's experience in the commercial use of CDMA mobile telecommunications. Korea's Samsung Electronics signed a contract in June to supply CDMA digital mobile telecommunications equipment to China's Shanghai Great Wall Mobile Communications Co. Under the contract, Samsung will supply one switch station with a capacity of 68,000 lines, 67 base stations, and services on a turnkey basis. The CDMA digital cellular phone services are expected to go into commercial operation in Shanghai beginning in 1998.

Samsung bid against foreign rivals that included Lucent Technologies, Motorola, and QUALCOMM Incorporated. Samsung plans to use Shanghai as its regional base for communications equipment because of high market potential, with the number of cellular phone subscribers expecting to reach 600,000 in 1997 from 380,000 in 1996.

©1998 Dataquest

Thus, Samsung plans to explore the market in Shanghai for PCS, wireless local loop (WLL), and asynchronous transfer mode (ATM). Samsung operates a joint-venture company in Shanghai for WLL operation. In 1996, it supplied wireless paging systems capable of accommodating 1 million subscribers.

CDMA Production Developments

Major CDMA market players, including Lucent, Motorola, Samsung, and LG all have assembly plants in China. LG is a latecomer in the booming China market for wireless handheld phones. LG will be bucking up against CDMA phone suppliers that already have assembly plants in China.

In April, China Samsung Electronics has been selected as the official CDMA hardware provider for Shanghai. The turnkey contract calls for the company to provide China Shanghai Changcheng Mobile Communications Co. Ltd. with a switching station that has the capacity to handle 68,000 subscribers, as well as 67 base stations and follow-up services. Installation is scheduled to begin in the first half of this year, and the system will be fully operational within the second half of the year.

Mitsubishi Electric Corporation announced plans to set up a digital mobile phone production base in China and to increase Mitsubishi's share in the world mobile phone market from present 6.5 percent to more than 10 percent by 2000. So far, Mitsubishi has established production bases in the United States and France, with annual output reaching 1 million units in 1996. Because China forms an increasing demand for mobile phones, Mitsubishi predicted that Asia/Pacific will represent 40 percent in the world digital cellular market.

Personal Communications Services (PCS) Developments

The changeover of Hong Kong sovereignty also could have a positive impact on PCS implementation in China. PCS licenses in Hong Kong are on track to generate an estimated $700 million in the next two years and as much as $5 billion in total revenue in the next 10 years. In underdeveloped countries where limited wireline infrastructure is installed, the existing infrastructure may not support the growing population or their service needs. The large cost and projected scope of laying more wireline networks suggest a wireless solution such as a PCS network. A PCS microcell base station that will support 100 people is estimated to cost somewhere between $60,000 and $65,000. By 2001, the number of cellular and PCS users in China, for example, could reach 12 million, representing $20 billion in revenue. The current worldwide wait for phone service for an estimated 40 million to 50 million people is 1.2 years. The average density of phone lines for the world is about 10 percent (or 10 lines per 100 people), with industrialized nations averaging about 50 percent. A key challenge will be for GSM, CDMA, and PCS companies to ensure that Chinese government understands the relationships among the cost of regulation and the speed of approvals, and the affordability of services with its effect on universal service.

 ©1998 Dataquest

Pagers

Dataquest's survey of China/Hong Kong's pager producers represented about 90 percent of production in 1997. Table 4-4 presents Dataquest's ranking of the three major pager manufacturers in China/Hong Kong. Dataquest estimates that China produced 7 million pagers in 1997, led by Motorola, Matsushita, and the joint venture, TCL/NEC (between Huizhou TCL Mobile Communication Co. Ltd. and NEC). Motorola dominates pager production with 67 percent of production share or 4.8 million sets in 1997. Matsushita's production quantity increased 76 percent in 1997 to 95,000. This expansion enables Matsushita to move to rank second and capture 14 percent production share, at the expense of Motorola that lost 7 percentage points production share. TCL/NEC cut production from 650,000 to 400,000, as the industry suffered overcapacity in 1997.

Table 4-5 presents the unit production forecasts for TCL/NEC, Motorola, and Matsushita in 1998 and 1999. Production expansion by Motorola and Matsushita appears to be coming to a standstill to better align with slowing demand. However, TCL/NEC plans to boost production from 400,000 units in 1997 to 1 million units in 1998. This expansion will further exacerbate ASP declines, as Dataquest forecasts in Table 4-6.

Table 4-4
Pager Manufacturers Production Share and Ranking, 1996 and 1997 (Thousands of Units)

TAM = Total available market
Source: Dataquest (August 1998)

Dataquest believes that pager unit production will grow at only 5 percent CAGR from 1997 to 2002. This growth represents a semiconductor market expansion of 9 percent, from $93 million in 1998 to $122 million in 2002.

At the end of 1997, there were 8 million new subscribers. But MPT's projections showed paging subscriptions to reach 117 million by 2000, which Dataquest believes to be overstated. By the end of 1996, MPT had started national paging networks in 22 Chinese cities. The new systems have adopted FLEX/multifrequency roaming modules, as well as VSAT interconnection technology. ChinaSat has contracted Hughes Network System to provide VSAT equipment in more than 300 subnetworks across China. MPT has experimented with new frequencies, particularly the 150 MHz.

Dataquest believes that paging services may continue to be a major means of communications, but the falling cellular phone service prices make pagers obsolete for many consumers.

Paging Companies and Developments

China Unicom and other non-MPT paging service providers have merged or sought vertically integrated networks under other ministries. Other strategies adopted include seeking foreign partners for direct investment or new technologies. Beijing Jingxin Electronics Co. Ltd. and HP signed a cooperative agreement in December 1996 for codeveloping wireless, high-speed beeping coding system. The project received support from the State Science and Technology Commission. China's wireless, high-speed beeping business was projected to develop rapidly in 1997.

Tianjin Municipal Posts and Telecommunications Administration in the north China's Tianjin started two new paging services in cooperation with independent paging service centers in May. Tianjin now has more than 70 separate paging services with 1.2 million subscribers. A majority of the services are small in scale, except for the local posts and telecommunications departments, which are financially and technically stronger.

A dozen of these paging centers have more than 10,000 subscribers each, but some have only about 2,000 subscribers. To woo more subscribers, paging service operators have been competing by cutting costs, a move that has put some operators in a tough situation. A total of 37 other separate paging services have also agreed to join the unified new paging services and are now making preparations, according to local sources.

Samsung said it has completed construction of a $1 million paging system in Shanghai, which can handle 1.2 million subscribers in 1997. The company said it delivered the turnkey project to Shanghai Guomai Communications Co. Ltd. Samsung estimates that the paging networks will cover 20 percent of China's 30 million citizens by the turn of the century.

NEC had acquired an additional 35 percent in a Guangdong-based pager manufacturing and marketing joint venture, established in 1993 by a Hong Kong company and a local Chinese entity. NEC purchased all holdings of the Hong Kong partner with about $1.75 million investment.

Central Office Line Cards

Dataquest surveyed 11 major central office/PBX switching suppliers in Table 4-7. Dataquest typically tracks central office by number of line cards, but data available from manufacturers is in the form of number of lines. Furthermore, companies are less comfortable splitting PBX and central office numbers, so Dataquest has combined the figures into one category. A central office line cards is typically defined as a telecommunications switch by public carriers, excluding PBX—a private branch exchange—but Dataquest's company figures include PBXs. Dataquest has estimated pure central office line cards, exclusive of PBXs later in this section.

As shown in Table 4-7, leading central office/PBX manufacturers in China/Hong Kong are a mix of foreign and domestic manufacturers. These companies more than doubled output as measured in lines in 1997 because of China's rapid infrastructure expansion. Shanghai Bell Telephone Equipment Manufacturing Co. Ltd. is the dominant player with a formidable 37 percent production share. The top five companies are market makers because they control about 85 percent of the market. Table 4-8 indicates that these market makers will lose market share caused by several rapid-growth competitors gaining share in 1998 and 1999.

Dataquest's long-term outlook for central office/premises line card production and semiconductor consumption in China/Hong Kong is presented in Table 4-9. Dataquest expects 1997's output of 16 million line cards to expand at a 17 percent CAGR to 35 million units in 2002. Dataquest believes that this will generate semiconductor consumption growth in this segment of 14 percent, from about $200 million in 1998 to $360 million 2002. This market's high competition level is resulting in semiconductor ASP erosion.

Switching Competitive Environment

As of 1997, China had approved more than 43 manufacturers of commercial switching equipment, of which 12 were joint ventures with foreign suppliers. The number has continued to grow. Estimated capacity of the industry is more than 24 million lines per year. China's MPT plans to expand China's switching capacity to more than 200 million lines by 2002. The ninth five-year plan aimed at increasing program-controlled switching by 84 million by 2000. Long-distance switching is planned to reach 6 million accesses with customers exceeding 130 million. These figures represent a penetration rate of about 10 percent nationwide and between 30 percent and 40 percent in urban areas.

Huawei Technology Ltd.

Shenzhen-based Huawei Technology Ltd. is one of China's leading switching equipment manufacturers. The company has supplied switching equipment throughout China. In February, the company supplied 24,000 lines of switches attributed, in part, to China's efforts to localize exchange systems. China's ability to supply switching equipment has improved because of government's support, increased access to technology, and improved manufacturing productivity, as evidenced by Huawei's success.

Shandong Province

There are plans to build telephone exchanges with combined capacity of 1.5 million lines and 20,000-terminal long distance automatic telephone exchanges in the economically booming coastal Shandong province. The number of telephone customers will increase at least 1 million this year, thus providing an average of 6.5 telephones per 100 people in the province.

PBX Telephone Exchanges

Oki Electric Industry Company Limited announced in 1997 that it would set up its first joint venture in China with a telecommunications manufacturer, Guoguang Electronic Corp. Oki Electric has set up a joint venture, Changzhou OKI-GEG Telecoms Ltd., which makes PBX telephone

 ©1998 Dataquest

exchanges and key telephone systems. Markets would include China, Europe, Oceania, Japan, and Southeast Asia. Oki Electric would hold a 70 percent stake in the venture, with Guoguang Electric holding the balance, and the Changzhou-based joint venture would be capitalized at $7.3 million. Guoguang Electric has been making key telephone and PBX systems for Oki Electric since 1995 and is the local distributor for PBXs.

Cordless Telephones

Southern China is the world's largest production base for cordless telephone. China/Hong Kong's cordless telephone industry will ship 23 million telephones in 1998, a 12 percent increase. Dataquest's survey of seven major manufacturers covered approximately 42 percent of China/Hong Kong's total cordless phone production in 1998. Table 4-10 lists the major manufacturers of cordless phones, their units, ranking, and production share. Uniden Electronics Products (Shenzhen) Co. Ltd. is the largest manufacturer of cordless phones in China/Hong Kong, with 28 percent share of production in 1998. Vtech Holdings Ltd. is the fastest-growing manufacturer in 1998 since it doubled production volume from 1.5 million units to 3.3 million units. Its production market share expanded from 10 percent to 16 percent.

Table 4-11 provides Dataquest's outlook on these manufacturers in 1998 and 1999. These manufacturers' strong growth is likely to continue in 1998, but it is expected to slow in 1999. These seven major manufacturers will expand by 42 percent in 1998, but they will slow to 24 percent in 1999. Uniden and Vtech will remain in their respective ranking and slow their expansion to about 16 percent in 1999 after growing an estimated 22 percent in 1998. Several new second-tier companies are adding significant capacity, which will take production share from the top two producers. Table 4-12 shows a forecast of China/Hong Kong's cordless telephone production forecast.

 ©1998 Dataquest

The deceleration observed from Dataquest's company survey will continue after 1999 because of persistent overcapacity from overinvestments in 1996 and 1997. Dataquest's 1997-to-2002 CAGR is expected to reach 8 percent unit growth and 7 percent revenue increase. This semiconductor market segment will, however, experience substantial revenue growth, outpacing equipment unit and revenue growth by a large margin. Dataquest forecasts the cordless telephone semiconductor market to expand from $724 million in 1998 to $1.3 billion in 2002, which is a 17 percent CAGR. This is a highly competitive market in which manufacturers will differentiate their product on functionality, and thereby requiring higher-performance digital signal processors (DSPs), memory, and microcontrollers. Cordless phone customers have a particularly high expectation of performance, quality, and functionality.

Mobile Communications Infrastructure

Dataquest presents revenue estimates on three mobile communications infrastructure equipment manufacturers in Table 4-13. Nokia, Ericsson, and Siemens manufacture approximately 90 percent of the mobile communications equipment produced in China/Hong Kong. Nokia is the largest maker, with a 46 percent production market share. Table 4-14 provides production forecasts for these three manufacturers in 1998 and 1999. While 1997 and 1998 showed substantial growth—similar to cellular and pager trends—mobile communications equipment manufacturing expansion is expected to decelerate in 1999. Dataquest expects this segment's revenue to grow by 15 percent in 1999, after growing by 33 percent in 1998 and 40 percent in 1997.

Table 4-14 provides a forecast of these three manufacturers in 1998 and 1999. Both Nokia and Ericsson are slowing expansion growth in 1999 after several years of rapid expansion. Siemens is accelerating expansion from 20 percent in 1998 to 25 percent in 1999, but from a small revenue base of $24 million.

Table 4-15 presents Dataquest's 1997-to-2002 forecast for all of China/Hong Kong production and semiconductor consumption in this segment. Dataquest estimates that China/Hong Kong's $243 million production revenue in 1998 represents approximately $20 million in semiconductor consumption. By 2002, Dataquest forecasts revenue to reach a modest $366 million, which represents a semiconductor market of $28 million. At this time, most design wins are outside of China/Hong Kong, but by 2002, Dataquest expects most production and design wins to occur within China/Hong Kong.

Corded Telephones

Dataquest sizes the corded phone industry at 99 million units in 1998, a 5 percent growth. Dataquest believes that China/Hong Kong will produce about 123 million corded telephones by 2002, which is a 5 percent CAGR from 1997 to 2002. This is a $349 million semiconductor opportunity (see Table 4-16). There are several hundred telephone manufacturers in China, and competition is acute. Telecommunications infrastructure in the vast rural areas of the country remains poor. Most of the telephones will be produced in Shanghai, Fujian province, and Guangdong province, with annual output in Guangdong's Huizhou city alone at 30 million in 1997.

Source: Dataquest (August 1998)

The Ministry of Posts of Telecommunications (MPT) predicted that 10 out of every 100 people will become telephone subscribers by the turn of the century. However, only about six out of every 100 people had a telephone services at the end of 1997. China's serious plans to raise its national telecommunications network capacity are formidable. To increase subscribers and meet a government plan, China will need 85 million telephone lines before 2000. China is on its way to achieving this goal, since about 17 million new telephone lines were installed in 1997. With more than 130 million telephones to be connected, 30 percent to 40 percent of urban residents are targeted to have a phone by 2000. China's urban population is estimated at 300 million to 400 million people, depending on whether or not suburbs are counted.

All Chinese rural villages are planned to be connected by phones during the Ninth Five-Year Plan period (1996 to 2000). The number of rural telephone customers is expected to increase annually by 6 million to 7 million, according to China's telecommunications departments. Because of high priority given to rural areas, China's rural telecommunications business—with a generally poorer economic base—has not been ignored. In fact, the rural installation rate has been steadily increasing in recent years (at a rate higher than in urban areas in 1995). In some economically thriving eastern regions, the number of customers in rural areas is increasing faster than in urban areas. However, in much of China's central and western regions, almost half of the villages still have no access to a telephone.

Fax Machines

Table 4-17 provides Dataquest's long-term forecast of facsimile machine production and semiconductor consumption. Like corded phones, fax machines are a mature market with overproduction and severe competition. Dataquest forecasts production to grow at a 6 percent CAGR from 841,000 units in 1997 to 1.1 million units in 2002. There are more than

20 fax machine manufacturers in China, but domestically made fax machines are of poor quality, compared with imported products. Hence, the domestic manufacturers import the fax thermal reading heads, scanners, and high-speed modems. The demand for fax machines has increased, as more telephones are installed and the switch capacity expands. Japanese products have dominated China's fax machine market and account for 80 percent of the imported fax machines, which occupy 90 percent of the domestic market. Demand for fax machines is expected to stand at 300,000 units in 1997.

Popular fax machine brands in China include Panasonic Communications and Systems Company, Canon Inc., and Oki Telecom. In 1997, more than 200,000 machines were approved in government projects, and about half were Panasonic products. Oki products have been widely used in railways, electronics, and public security sectors. Fax machines from Korean companies such as Samsung and Daewoo Telecommunications Company Ltd. have also expanded their market share in China with an edge on prices.

LAN Cards

China/Hong Kong's PC market boom has recently increased LAN market growth. Local manufacturers are entering the market and expanding production capacity. Table 4-18 presents Dataquest's 1997-to-2002 production and semiconductor consumption forecast for LAN cards. Of the 2.2 million PCs sold in China in 1997, nearly 100,000 units, or 40 percent, were sold as part of networks. Production in 1998 increased by 45 percent to 5.8 million units, representing a $41 million semiconductor market. Dataquest forecasts LAN card production to grow at a 22 percent CAGR from 4 million units in 1997 to 11 million units in 2002. Semiconductor consumption in LAN cards will reach $71 million by 2002.

On the networking market front, networking companies are making a convincing case that China's attention has turned to networking equipment. Greater China—which includes China, Hong Kong, and Taiwan—emerged as the Cisco System Inc.'s largest market in Asia/Pacific (excluding Japan) as the fastest-growing sales region worldwide. Cisco's sales to greater China in fiscal 1997 climbed 120 percent over the previous fiscal year, with sales in mainland China jumping almost 280 percent.

In a multimillion dollar deal, Hong Kong-based China Internet Corp. (CIC) and the U.S. networking giant Bay Networks Inc. joined forces to set up a network of powerful Web servers that bring vital information to businesses in China. In January 1998, Bay Networks was chosen to provide the infrastructure for the project, dubbed the China Wide Web (CWW), which will place servers strategically located in more than 50 major cities across China. The first phase of the network, covering five major cities, is now being installed and was operational in the first quarter of 1997. Network control centers will be set up in Beijing and Hong Kong. The first CWW branch nodes will be in Shanghai, Shenyang, and Guangzhou. CIC has plans to add an additional five cities to the network each quarter, reaching a minimum of 20 cities by the end of the year. The Bay Networks System 5000 hubs are now shipping to the CWW's phase-one sites in Beijing, Hong Kong, Shanghai, and Guangzhou.

Following desktop computers and notebook computers, Philips Electronics NV recently announced to enter network market in Beijing. It also designated the Beijing Yasuo Network Technology Ltd. its general agent in mainland China. The first-released products include 10/100M PnP ISA/PCI/PCMCIA network card (NIC), 10M PnP PCMCIA FAX/MODEM/NIC card, 10M/100M concentrators (HUB), and exchangers.

China has leaped to become Digital Equipment Corporation's fastest-increasing market. Digital expected to expand its network market by 60 percent in China in 1997. Digital's network products will further tap the Chinese market, particularly the banking and financial market.

Talking about exchange systems, Digital will put stress on school net exchange systems and long distance net systems. In addition, Digital will engage itself in developing new technology suitable for China's condition.

Modems

China's modem production in 1997 reached 575,000 units and is expected to grow 21 percent in 1998. Production is decelerating to 16 percent in 1999 and 14 percent in 2000. Semiconductor consumption is forecast to grow from $17 million in 1998 to $26 million in 2002, a 13 percent CAGR. Table 4-19 provides Dataquest's modem production and semiconductor consumption unit and revenue forecasts from 1997 to 2002.

Table 4-19
Local Area Network Card Production and Semiconductor Consumption Forecast, 1996 to 2002

Chapter 5

Consumer Electronics Equipment

China/Hong Kong produced approximately 40 percent of Asia/Pacific's consumer electronic equipment in 1997 and approximately 13 percent of worldwide consumer electronics. Dataquest forecasts China/Hong Kong's consumer electronics production share in Asia/Pacific's to increase to 50 percent by 2002, and its share in the worldwide production to reach 19 percent 2002. However, this growth will need to come after a slowdown in 1998 and 1999. If digital consumer expands at a worldwide level as expected, then China/Hong Kong will meet this forecast. Otherwise, Dataquest expects a worst-case scenario in which production will grow at an 8 percent CAGR rather than the 12 percent Dataquest forecasts.

China/Hong Kong's large and rapidly-growing domestic market is the main factor behind China's high production level relative to other Asia/Pacific countries. Moreover, Japanese and Korean consumer manufacturers continue to shift production to China faster than to any other Asia/Pacific country. Dataquest expects China/Hong Kong to remain the main destination for these investments in the next five years. As discussed in Chapter 2, China/Hong Kong is now the Asia/Pacific growth center because of stronger economic fundamentals. Both exports and domestic consumption are maintaining reasonable growth even after the Asian financial crisis. However, Dataquest has observed that, at the same time, the new era of digital consumer is already showing up in China in the form of digital broadcasting and digital video compact disc (VCD) players. Figure 5-1 illustrates consumer electronics equipment production forecast for four major Asian countries.

Production Growth Sectors in Consumer Electronics

Figure 5-2 illustrates each market segment of China/Hong Kong's consumer electronics industry. Audio equipment is the largest of the five major segments with a $7.8 million revenue in 1998. Dataquest expects video equipment production to match or surpass audio by 2002 because of China's imminent expansion into digital consumer equipment and broadcast. In addition to audio's slow growth, Dataquest expects a personal electronics maturation on a revenue basis in China/Hong Kong. Personal electronics and audio equipment will expand at a 7 percent to 8 percent CAGR from 1997 to 2002, while video will expand by 12 percent.

Home appliance production is the fastest-growing segment of the consumer electronics industry. Production will reach $6.2 billion in 1998 and will expand at a 16 percent CAGR at $10 billion by 2002. Dataquest's outlook for continuous and expanding growth is tied mainly to the belief that the economy, as indicated by GDP, will average 6 percent to 8 percent growth during this period. New areas of economic development will absorb local production. Wealthier urban areas will continue to upgrade their to new gadgets, such as air conditioners, heaters, or dehumidifiers. Furthermore, Dataquest's survey of producers discovered a high percentage of exported consumer electronics production by multinational companies, as discussed later in the chapter.

Color Television Production Forecast

Dataquest's survey covered 14 major color television (CTV) manufacturers in China/Hong Kong, which combined to account for 85 percent of total production in 1997.

Table 5-1 lists these companies' unit output in ranking order according to production share. Changhong Electric Appliances Company is, by far, the industry leader, accounting for a whopping 28 percent of all China/Hong Kong CTV production. The company is the technology and manufacturing leader in China/Hong Kong, which is why it continues to gain production share as well as local market share. In China/Hong Kong, as elsewhere in the world, the large manufacturers are consolidating their leadership through superior operational efficiency from production to marketing and distribution. The top five manufacturers in China/Hong Kong control 64 percent of total production.

Table 5-2 provides Dataquest's company-level forecast for CTVs in 1998 and 1999. Dataquest sees a clear drop in industry output in 1998 and 1999 primarily attributed to worsening economic conditions in China/Hong Kong, rising unemployment, and consumer pessimism about future employment and the economic growth of China. Because Dataquest does not have 1997 data for all 14 companies, a comparison of the seven companies surveyed in 1996 and 1997 will be done instead. These seven manufacturers are estimated to have a combined annual production expansion of 40 percent in 1997. In 1998, these same seven companies are forecast to have only a 10 percent production, but Dataquest expects improvement in 1999 and forecasts a 15 percent year-on-year unit growth.

Source: Dataquest (August 1998)

Color television production represented approximately 55 percent of the consumer video segment (as illustrated in Figure 5-2) in 1997 and will grow to a 67 percent share by 2002. Dataquest has mentioned that consumer video is forecast to grow by 12 percent from $6 billion in 1997 to $11 billion in 2002. Color television factory revenue is forecast to grow at a 17 percent CAGR, from $3 billion in 1997 to $7.1 billion in 2002. Semiconductor consumption in the CTV market segment will grow from $400 million in 1997 to $1.2 billion in 2002, a 23 percent CAGR (see Table 5-3).

The relatively large proportion of multinational manufacturers, with the exception of Changhong, adds to China's production prowess in that a large percent of CTVs are exported. Dataquest expects export success to help boost the industries' long-term growth, and the government will likely support about five major manufacturers by providing export incentives.

Video Compact Disc Players (VCDs)

Table 5-4 presents the 10 large VCD manufacturers' units and production share in 1996 and 1997, which combined to account for 68 percent of China's total unit output in 1997.

China's VCD player market follows a typical product life cycle: It has gone through the introduction stage and high-growth stage and is now approaching the maturity stage. The declining stage will start in 1999 when DVD players begin to penetrate the market.

Table 5-4
Video Compact Disk (VCD) Player Manufacturers Production Share and Ranking, 1996 and 1997 (Thousands of Units)

Source: Dataquest (August 1998)

At the current maturity stage, manufacturers are competing on prices to achieve volume and fighting for market shares. Efforts are being put into efficiency and cost reduction. Meanwhile, market leaders such as Jiangsu province's Jiangsu Shinco Electronic Group Company and Guangdong Idall Co. Ltd. are advertising heavily to emphasize brand differentiation and special product features. Manufacturers extend the product life by means of incorporating more functions into their VCD players. Built-in karaoke functions are now a standard. Other choices are integrated VCD hi-fi systems, multidisk changers, and two-in-one TV/VCD sets. There are also many manufacturers that are concerned with improving the picture quality. Table 5-5 presents China/Hong Kong's VCD production forecast by vendor.

The top five VCD player makers are all Chinese brands; they combine to account for 53.6 percent of the total VCD player market. About one-fifth of this market is occupied by the largest market leader, Jiangsu Province's Shinco. The top three manufacturers occupy nearly half of the overall player market.

In view of the VCD player market's explosive growth, many manufacturers want to share the piece of the pie that belongs to the leading manufacturers. The television giant, Changhong Electronic Group Co., has planned to expand its VCD player production capacity from 400,000 units to 3 million units in 1998.

Taiwanese makers are also eyeing China's VCD player market. The Acer Group and Sampo Corporation are both supplying VCD technology and OEM kits to their Chinese partner for assembly. Their ultimate goal, however, is to make and distribute DVD players to this market.

Table 5-5

Source: Dataquest (August 1998)

Table 5-6 presents Dataquest's long-term forecast of China/Hong Kong's VCD production, which shows accelerating growth and then decline because of maturation and the introduction of DVD replacement technology. CCD players have been proliferating in the Chinese market for some simple reasons. The hardware is cheap and simple in technology. VCD players combine CD players with a MPEG decoder to produce acceptable video-playing capabilities. The majority of manufacturers get key components from a few suppliers: Sony Corporation and Philips for CD mechanisms, and C-Cube Microsystems Inc. and ESS Technology Inc. for decoding chips.

The proliferation of private software has fueled the demand for China's VCD market. The intellectual-copyright concept is still weakly understood among Chinese consumers. They can easily get low-cost pirate software or even rent VCD movies at a cost below U.S.$1 in some cities. The third reason is the lack of an installed base of VCRs and audio CDs in China. The popularity of color TV and karaoke among the Chinese has also contributed to the strong demand of VCD players.

In terms of the substitution by DVD players, the price and software gap will lengthen the time needed for DVD players to take off in the market. Although DVD players provide consumers with high-quality pictures and sounds, better performance, and a wider range of features, Chinese consumers do not currently have the purchasing power to buy them. The higher price is not the only barrier for DVD players to enter the China market. Consumers are concerned about the limited availability of DVD titles that cost much more than VCD titles. Also, the existing color television sets, limited by 350-line, cannot produce a high-resolution effect required by DVD players.

On the other hand, the DVD player emergence will encourage VCD player manufacturers to improve the quality of their VCD products. Because of the backward compatibility of DVD players, VCD software will still prevail, unless DVD titles' prices can match. VCD players will be able to survive in the presence of DVD players until 2001 when a precipitous decline is expected.

Table 5-6
VCD Player Production Forecast in China/Hong Kong, 1996 to 2002

Video Cassette Recorders (VCR)

Table 5-7 presents Dataquest's list of surveyed VCR manufacturers and their respective production volume and industry share. Dataquest's survey of five manufacturers represents 42 percent of combined production units. These companies appear to be increasing production share, while smaller manufacturers are exiting the market.

Table 5-8 presents these five manufacturers' 1998 and 1999 production plans. The VCR industry is a mature but lingering market. Slow growth but large-scale production is sustained by a large infrastructure of inexpensive tapes and demand from remote regions where VCDs and media are not readily available. Nevertheless, because of China's population advantage, there will be growth, but less than 4 percent in units for the next five years. In addition, revenue is expected to contract (see Table 5-9).

Personal Stereo

Personal/portable stereo production of $655 million in 1997 accounted for only 9 percent of total audio equipment production in China/Hong Kong. Dataquest's survey of personal stereo manufacturers represented only 2.9 percent of total personal/portable stereo equipment production in this highly dispersed market segment. Personal stereo was one of the earliest consumer electronics markets to grow since China's economic reform and "open door" policy took hold in mid-1980s. Now this market is plagued by overcapacity and efficient state-owned enterprises that will undergo consolidation in the next five years. Table 5-10 shows personal/portable stereo manufacturers' ranking and market share in China/Hong Kong.

Table 5-10
Personal / Portable Stereo Manufacturers Production Share and Ranking, 1996 and 1997 (Thousands of Units)

					Production Share (%)		Accumulated Share (%)	
Rank 1996	Rank 1997	Company	1996	1997	1996	1997	1996	1997
2	1	Samsung	80	300	0.3	0.9	0.3	0.9
1	1	Matsushita	300	300	1.0	0.9	1.2	1.8
4	3	LG	70	200	0.2	0.6	1.5	2.4
2	4	Philips	80	100	0.3	0.3	1.7	2.7

		Others	30,307	32,132	98.2	97.1	-	-
		Total	**30,875**	**33,098**	**100**	**100**	-	-

Source: Dataquest (August 1998)

Table 5-11 presents 1998 and 1999 forecasts for these major multinational vendors. Samsung and LG Electronics are the only two companies that expanded in 1997, while the others' production remained flat. Most manufacturers show a clear slowing trend in 1998 and 1999 because of difficult market conditions.

Dataquest's long-term industry outlook is shown in Table 5-12. Dataquest expects personal and portable stereo shipments to grow approximately 5 percent in the next five years, like other mature electronics equipment markets in China. China/Hong Kong's estimated 33 million units will increase at a rate slower than GDP growth to 42 million units in 2002. Semiconductor consumption in this segment will climb only 3 percent from $200 million in 1998 to $260 million in 2002.

Camcorders

Analog camcorders are providing new growth opportunities for consumer electronic equipment manufacturers in China/Hong Kong. Dataquest's survey of Sony and Hitachi Ltd. found that these multinational manufacturers are rapidly expanding production capacity in China/Hong Kong and are taking advantage of the local market to absorb their production. As shown in Table 5-13, both companies rapidly expanded production in 1997, by a whopping 350 percent, from 78,000 units in 1996 to 275,000 in 1997. Dataquest estimates that this combined production volume represents 94 percent of total personal and portable stereo production.

Source: Dataquest (August 1998)

Table 5-14 provides Sony's and Hitachi's production outlook in 1998 and 1999, which is leveling off after 1997's surge in capacity. Sony will expand unit production from 220,000 units per year to 260,000 units per year in 1999, a 14 percent growth rate. Hitachi will expand from 90,000 units in 1998 to about 120,000 units in 1999, a 33 percent growth rate.

For the long term, China/Hong Kong's camcorder production will surge because of a strong market demand, and Dataquest expects new manufacturers to enter this industry after technology becomes readily available. Table 5-15 provides Dataquest's long-term forecast of camcorder production and semiconductor consumption from 1997 to 2002.

Chapter 1

Executive Summary

To what extent will Japanese and Asian currency devaluation affect China's once-insatiable appetite for information technology (IT)? China/Hong Kong has been the main force for IT sales in the Asia/Pacific region, but how long can it sustain this role? Dataquest isolates and discusses the key equipment and companies that have the most impact on China/Hong Kong's semiconductor market. Dataquest also stratifies its analysis across computer, communications, and consumer electronics industries.

Dataquest's goal in publishing this report is to present a concise report of China's electronics industry and its company-level outlook in 1998 and 1999. This Focus Report serves the following four simple research purposes:

- Summarizes key industry trends and lists forecast assumptions
- Presents company-level production units in 1998 and 1999 for high-volume products
- Forecasts long-term, high-volume electronic equipment production growth from 1998 to 2002 in terms of units, revenue, and semiconductor consumption
- Provides semiconductor consumption forecasts for 1998 and 1999 by product, application group, company, and origin of ownership

Format and Scope

This Focus Report emphasizes demand-side analysis of the semiconductor market and focuses on electronic equipment production. For supply-side semiconductor shipment information by product or company (with vendor market share analysis), please see Dataquest's Market Trends report, *An Analysis of China/Hong Kong's Semiconductor Market: Suppliers, Drivers, and Forecasts*. The company data is provided by responsible representatives of those companies or knowledgeable industry contacts.

Key Findings

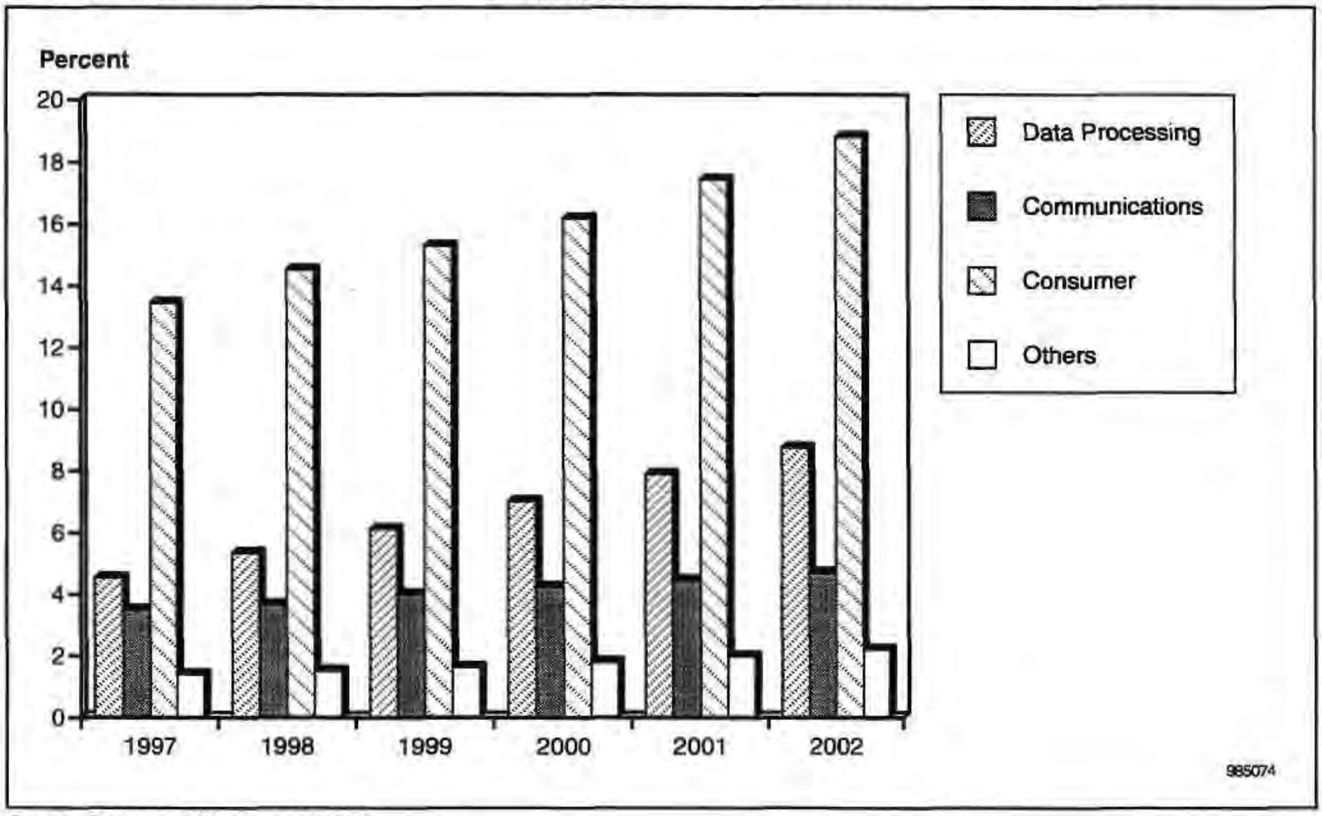
Despite some mature IT segments, Dataquest expects the worldwide IT's overall health to be influenced by emerging communications, Internet, digital consumer, and PC industries' 15 percent average unit growth. Dataquest forecasts an overall IT hardware shipment growth in the next five years of 7 percent. Asia/Pacific's production accounted for only 15 percent of the world's total electronic equipment production in 1993, but reached 19 percent in 1997. By 2002, Dataquest forecasts that 24 percent of worldwide electronic equipment production will take place in Asia/Pacific.

China Now a Global Force

As shown in Figure 1-1, Dataquest concludes that China/Hong Kong will outpace the rest of Asia/Pacific and substantially increase its share of worldwide electronic equipment production from approximately 5 percent in 1997 to 8 percent in 2002. In 1996, it accounted for only 4 percent of output. Dataquest will explain how consumer electronics will represent the largest share of 19 percent of world production, up from 13 percent in 1997. Data processing will increase its market share the fastest, doubling from 4.5 percent in 1997 to 9 percent in 2002. Communications equipment will grow substantially, from a small base of 3.5 percent to 5 percent by 2002.

China/Hong Kong's share of Asia/Pacific production will increase from 27 percent in 1997 to 32 percent in five years. In revenue terms, China/Hong Kong's electronics production will grow from U.S.$37 billion to $98 billion, representing a compound annual growth rate (CAGR) of 16 percent.

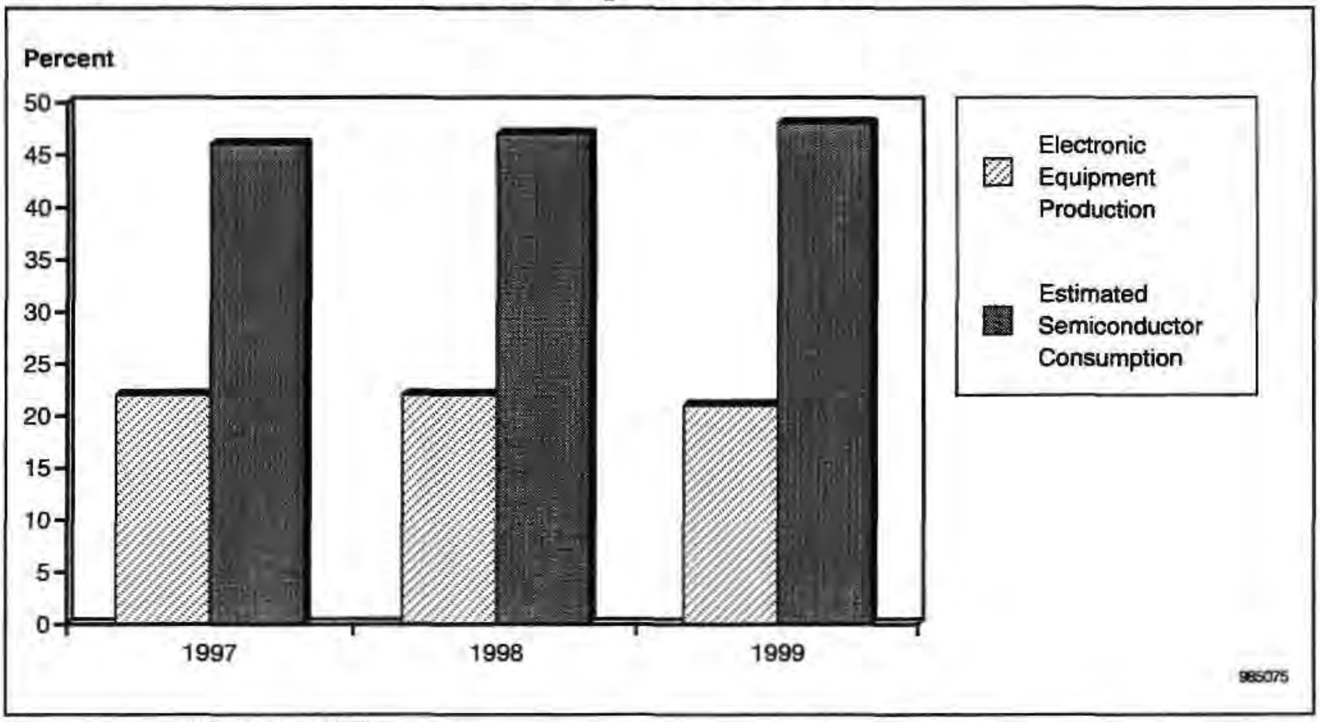
Figure 1-1
China/Hong Kong's Share of Worldwide Total Electronic, Data Processing, Communications, and Consumer Equipment Production, 1997 to 2002 (Percent)



Source: Dataquest (September 1998)

Dataquest conducted a survey of 64 major electronic equipment manufacturers, which are listed throughout this report in respective product discussions. Dataquest has identified the factories, products, and production quantities for 1997 and forecast for 1998 and 1999. Dataquest's basis for selecting these companies was subjective. Clients expressed a high interest in Chinese companies since last year, so we increased our sample size of local manufacturers relative to multinational vendors. Companies that had large production capacity or had aggressive expansion plans were also selected. The main purpose is to support Dataquest's high-volume electronic equipment production forecast that is also included in this report. Upon completing the research, Dataquest discovered that these companies represent approximately 24 percent of the 1998 production. As illustrated in Figure 1-2, the sample size within each application segment varies. These findings indicate that China/Hong Kong's manufacturers are scaling back production in certain areas, but the overall industry will sustain formidable growth in the next few years.

Figure 1-2
Surveyed Companies' Share of Total China/Hong Kong Electronic Equipment Production and Semiconductor Consumption, 1997 to 1999



Source: Dataquest (September 1998)

 ©1998 Dataquest

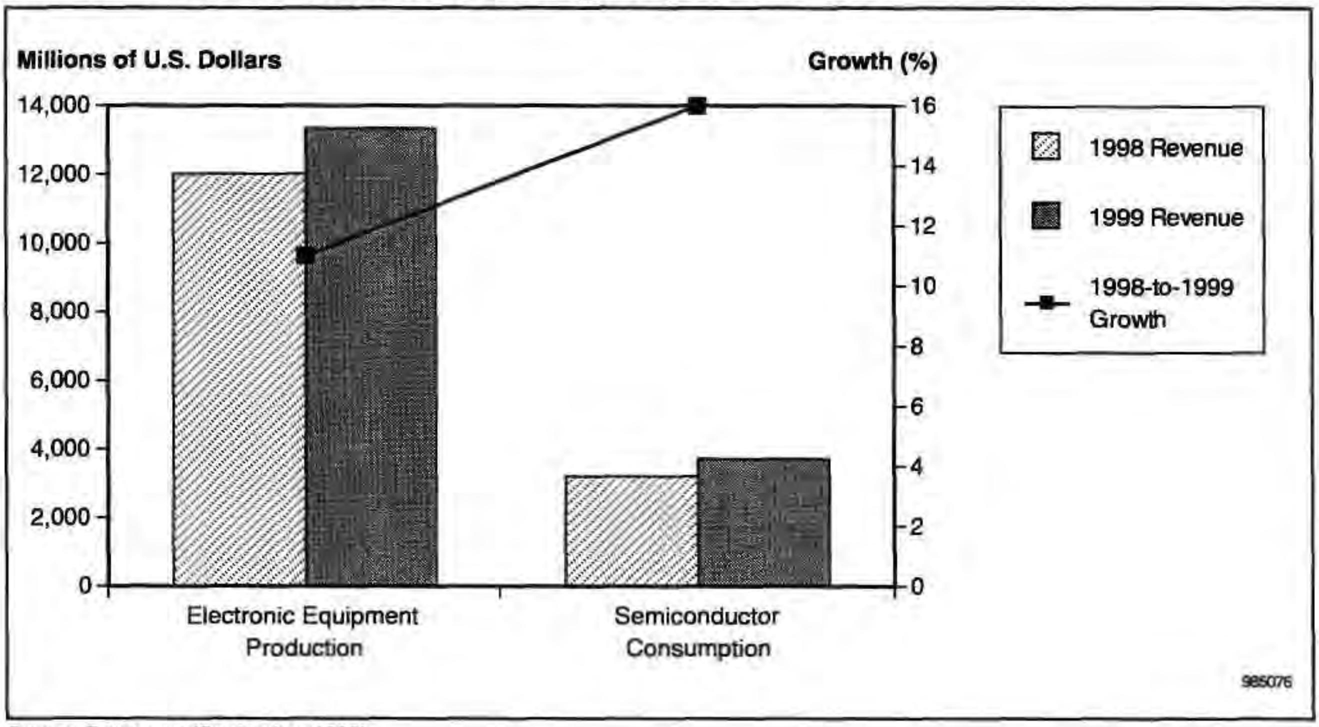
In terms of semiconductor consumption, Dataquest observes that because major manufacturers will expand by 11 percent in revenue terms, their semiconductor consumption will increase by approximately 16 percent (see Figure 1-3). As discussed earlier, Dataquest's survey group will consume an estimated 24 percent of semiconductors consumed in China/Hong Kong in 1998. Note that these semiconductors were either shipped internally by multinational companies, purchased direct from manufacturers, or supplied by distributors. Dataquest forecasts that this same group of companies will consume 48 percent of all 1999 semiconductor shipments. This consumption level reveals the following trends:

- Rising semiconductor richness and technology level of products being manufactured in China/Hong Kong
- Larger multinational and Chinese manufacturers are achieving economies of scale faster and for higher-end products than the smaller companies
- Small and medium-size companies will face further difficulty competing against large companies that have efficient sourcing and distribution systems
- State-owned enterprises (SOEs) are being restructured, merged, or sold

Figure 1-3
Surveyed Companies' China/Hong Kong Electronic Equipment Production Revenue and Estimated Semiconductor Consumption, 1998 and 1999



Source: Dataquest (September 1998)

Electronics Production Growth by Ownership

Figure 1-4 lists production revenue of the 64 companies surveyed in China/Hong Kong by grouping their home base ownership. Figure 1-5 illustrates these companies' percentage share. The Americas companies surveyed had doubled production in China/Hong Kong in 1997, after investments made in 1995 and 1996. However, these companies have halted expansion plans in 1998 with about 1 percent growth. Dataquest had expected U.S. manufacturers to surpass Japanese manufacturers in 1997 and 1998, but this will not happen because of investment slowdowns. As discussed in Chapters 3 and 4, computer and communications investments are leading the next wave of growth, while consumer growth is expected to remain modest.

Semiconductor Consumption by Users' Home Base of Ownership

Each manufacturer's semiconductor consumption is derived by multiplying the units of equipment produced by an average semiconductor content per piece. Dataquest estimates each equipment's semiconductor content and manufacturers' semiconductor consumption revenue. The scope of the survey did not include surveys of procurement offices to ascertain total semiconductor purchase by factory. Such a methodology would have had to account for local purchases, internal transfers, and global procurement contracts. Dataquest believes that the methodology used provides a realistic average consumption by product and accurate trend analysis on a year-on-year comparative basis.

Figure 1-4
China/Hong Kong's Electronic Equipment Production Revenue by Home Base of Ownership of 64 Companies, 1997 to 1999

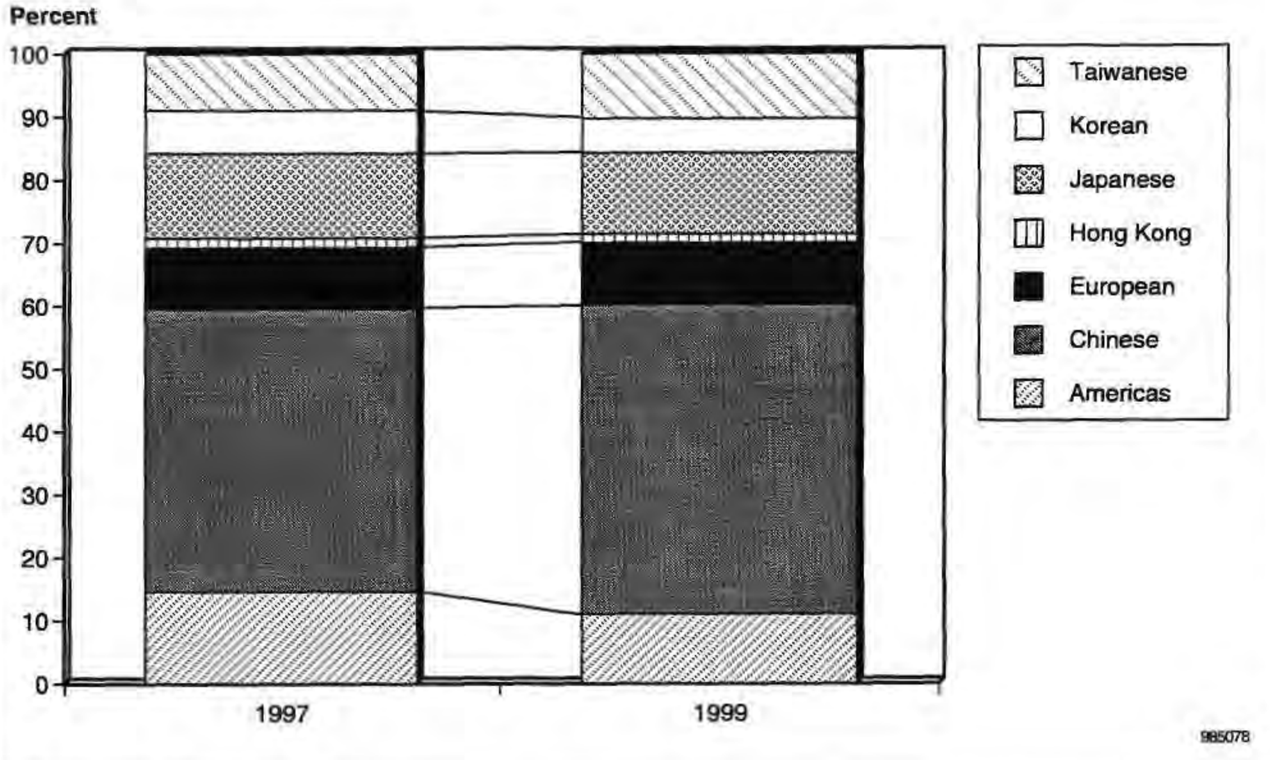
Figure 1-5
China/Hong Kong's Electronic Equipment Production Revenue by Home Base of Ownership of 64 Companies, 1997 and 1999



Source: Dataquest (September 1998)

Figures 1-6 and 1-7 illustrate the revenue and percentage of total semiconductor consumption estimates aggregated for the 64 users. Chinese companies occupy the largest share and are the fastest-growing in equipment production and semiconductor consumption, with 28 percent and 39 percent growth, respectively. Americas companies were the second largest, representing 13 percent of consumption, but they will expand only 1 percent in 1998. These companies expected semiconductor consumption will improve next year, based on a 13 percent growth in the value of semiconductors used. Japanese companies will increase semiconductor consumption by 22 percent in 1998 and 23 percent in 1999. Dataquest believes the main reason for this discrepancy between Chinese and multinational companies' growth is a result of local Chinese manufacturers' particularly strong video compact disc (VCD) and PC production and sales in 1998.

 ©1998 Dataquest

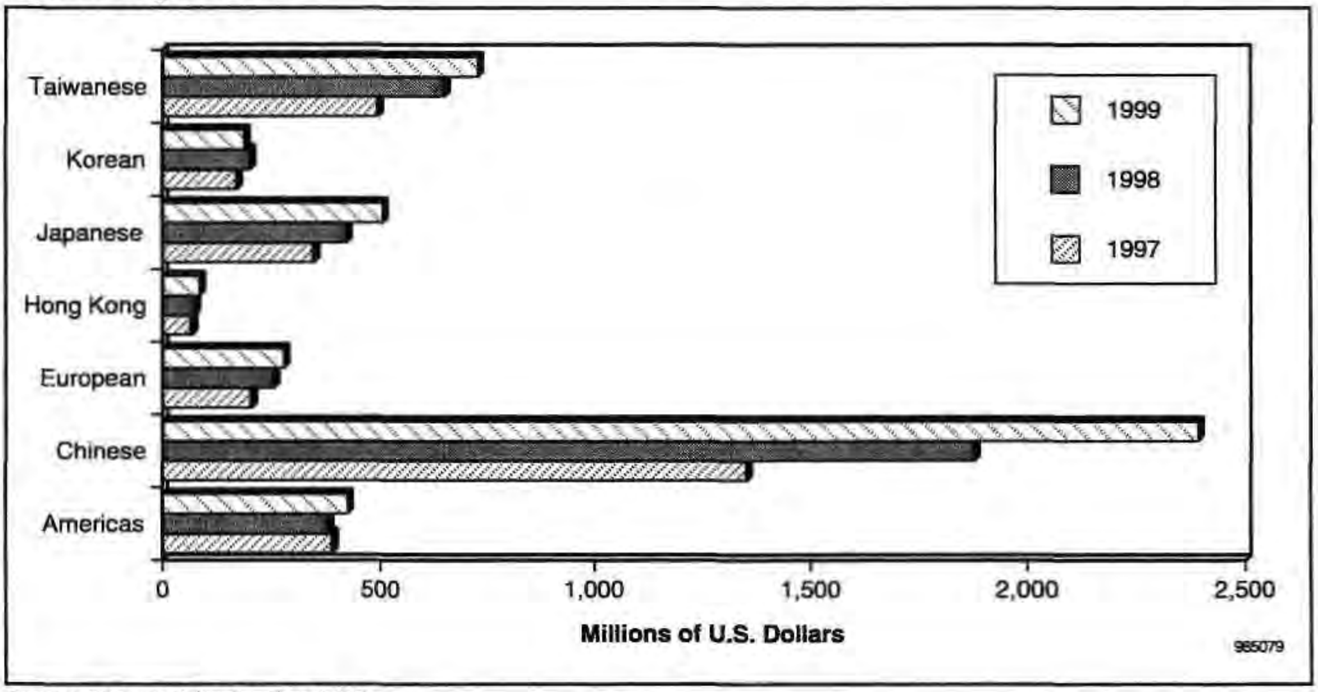
Figure 1-6
China/Hong Kong's Semiconductor Consumption by 64 Company Users' Home Base of Ownership in 1998



Source: Dataquest (September 1998)

Figure 1-8 summarizes all information by comparing growth rates by ownership for both equipment and semiconductor consumption. Figure 1-9 illustrates China/Hong Kong's electronic equipment production in 1998 and 1999. After the Chinese companies, Taiwanese producers are the fastest-growing consumers of semiconductors. Taiwanese companies, like the Americas, focused on the computer segment in China/Hong Kong. While both experienced rapid electronic equipment production growth, their semiconductor consumption growth is less than equipment factory revenue primarily because of pricing declines of memories, microprocessors, and microperipherals. European companies are the third-fastest-growing semiconductor user group, but they represent only 7 percent of Dataquest's survey group. Japanese companies appear to be maintaining overall semiconductor consumption growth, ranking fourth in consumption growth. Korean companies are ranked fifth in growth, followed by Hong Kong and Americas companies.

Chapter 2
Electronics Industry Trends

More than 30 Percent of Asia/Pacific Production Will Come from China

China/Hong Kong's share of Asia/Pacific production will rise from approximately 27 percent in 1997 to 32 percent in the next four years. In revenue terms, China/Hong Kong's electronics production will grow from $46 billion to $98 billion, representing an 18 percent CAGR. In a broader context, the worldwide CAGR for this period is about 6 percent to 7 percent, with the Asia/Pacific CAGR more than 10 percent. China/Hong Kong's lectronic equipment production quantity outpaces worldwide averages because of export competitiveness and unsatisfied local demand, especially within the healthier economies such as China and Taiwan. At the same time, semiconductor content is increasing faster in Asia/Pacific than in the rest of the world. This trend suggests that semiconductor consumption will outpace electronics in the next five-year period (taking out cyclicality). Foreign investments to China/Hong Kong are accelerating for the purpose of gaining market access and time-to-market competitive advantage, a necessity in an oversupplied market. Figure 2-1 illustrates China/Hong Kong's share of total data processing, communications, and consumer equipment production.

Figure 2-1

©1998 Dataquest

In comparing the past five years with the next five years, it is clear that revenue in Table 2-1 shows an electronics production deceleration in Asia/Pacific. In relative terms, the region has doubled in revenue and expanded from one-third the size of Japanese electronics industry to more than 90 percent of Japan's 1997 revenue. The region was half the size of Europe's industry in 1991, but it will continue to converge with that of Europe. The region will not sustain this phenomenal growth because of lasting effects of the Asian financial crisis, but it is expected to outpace other regions in the next five years.

Data Processing Electronic Equipment Overview

Although Asia/Pacific succeeded early in consumer electronics manufacturing , its data processing industry has kept pace with worldwide trends, and its revenue is expected to more than double from $78 billion in 1997 to $157 billion in 2002. In the past three years, Asia/Pacific communications markets' and industries' rapid growth has enabled this sector to reach $29 billion in 1997. Dataquest forecasts strong growth in a few key sectors, bringing revenue to $47 million in 2002. Consumer electronics production surged in the early 1990s because of transplanted Japanese manufacturing. Dataquest expects it to remain the second-largest segment in Asia/Pacific. A worldwide consumer electronics consumption slowdown through 1998 has translated into slower growth in Asia/Pacific production, although Dataquest expects Asia/Pacific to grow at double the worldwide production growth rate.

Asia/Pacific countries that bet their industrial development on PCs have reaped the rewards. The impressive manufacturing efficiencies of Singapore and, later, Malaysia, have enabled Asia/Pacific to increase its share of global mass-storage production. Dataquest sees no signs of this trend changing. The combined revenue from monitors, PCs, and motherboards was 65 percent of total data processing revenue. Storage makes up most of the rest of data processing revenue. By 2002, Dataquest believes that these five products will represent 80 percent of data processing revenue, and data processing will represent 52 percent of total Asia/Pacific electronics production.

The PC markets show slower but steady growth worldwide, and Asia/Pacific has proved well-suited to meet those market needs. What will enable the PC to continue to add value to home and private citizens is that it continues to evolve in its functionality and integration into people's lives. Recently, PCs evolve from a productivity tool for spreadsheet, word processing, and other data processing tasks into an information, communications, and entertainment multimedia system. Technology barriers are eventually overcome, and new multimedia PCs now offer 3-D graphics, MPEG-2 video, AC-3 audio, fax/modem, telephony functions, and videophone. The world of system-level integration will engender the next quantum leap in performance and functions.

Consumer Electronics Overview

Asia/Pacific is already a player in the new wave of digital consumer electronics that is now entering the marketplace. These emerging electronics include digital video disks (DVDs), digital cameras, digital camcorders, digital VCR, digital TVs, video CDs, advanced games, and direct broadcast satellite, or set-top boxes.

Asia/Pacific benefits several ways in manufacturing consumer electronics. It receives investments from high-cost production regions, such as Japan, and its broad economic growth provides new growth for old products. China's color television production is an example of an undeveloped market revitalizing a mature industry. In 1997, China manufactured approximately $6 billion in video equipment. Dataquest expects China to experience a two-year slowdown in consumer electronics, but the five-year future of digital consumer equipment production is bright. New products, such as set-top boxes and DVDs, will find a way into these huge potential markets in inexpensive ways. Governments are eager to establish digital broadcast standards that will pave the way for broadcasting after 2000.

Communications Electronics Overview

Communications electronics are the third-largest sector in China/Hong Kong and Asia/Pacific. In China/Hong Kong, communications equipment production dominates consumer products such as phones, cordless handsets, answering machines, and analog cellular equipment. Furthermore, digital cellular products are now playing a pivotal role in communications semiconductor market growth. In 1995, digital cellular shipments accounted for only 38 percent of the total analog and digital cellular unit market, but in 1998, it will account for more than 80 percent of the 123 million phones shipped.

Unlike data processing and consumer electronic equipment production Asia/Pacific's communications production is significantly less than it consumes. These are market opportunities that the local companies are exploring, and multinational companies are starting to invest in this area. In the short term, most of the advanced infrastructure equipment will be imported. For many other products, Dataquest sees production continuing to expand in the region because this is where the world's fastest market growth is expected for the next 10 years. Central office/premises and cellular phones will surpass cordless phones to become the second- and third-largest markets.

 ©1998 Dataquest

China/Hong Kong a Critical Growth Source for Asia/Pacific

The following key factors enable China/Hong Kong electronics to avoid dramatic production swings as these sectors fell in most other parts of Asia/Pacific, except Taiwan:

- China, unlike the other regions, is showing growth in all three electronics sectors. The net consequence is an impressive overall growth.
- China's domestic market attracts investors from all major regions.
- China's industry is balanced between exports and local consumption, each representing about one-half of total output.
- Economic planners are focusing on sustaining macroeconomic stability vis-à-vis microeconomic policy. Without floating its currency, China has maintained control of its economy without suffering the economic woes seen in the Russian republics.

As shown in Table 2-2, Dataquest expects strong growth in China's three major electronics sectors, but with data processing leading the growth, while communications and consumer sectors followed.

Dataquest's Electronic Equipment Producers Survey Results: The Big Are Getting Bigger—and a Lot Faster, Too

China/Hong Kong has become the No. 1 investment destination by electronic equipment companies in Asia/Pacific. The currency and economic woes in several Southeast Asian countries may further depress their long-term growth. China's rapid reforms, strong economy, growing consumption, and advancing production base continue to attract major investments from various sectors.

Table 2-3 lists major multinational and Chinese companies that were surveyed for production quantities detailed in this report. Dataquest surveyed 38 manufacturers and has itemized the top 20. Note that the revenue was derived from estimated unit production of major electronic equipment and applying a factory ASP.

Dataquest lists 31 major manufacturing companies, representing 20 percent (or $11 billion) of electronics production in China/Hong Kong. Dataquest's analysis of these manufacturers indicates a rapid expansion of production capacity for both local consumption and export, but that this expansion is decelarating, particularly in the consumer electronics area. These 31 companies are expected to increase revenue by about 13 percent in 1999 after growing approximately 22 percent in 1998 (see Table 2-4).

Company-Level Semiconductor Consumption Ranking Forecast

As expected,China's semiconductor consumption is rising even faster for the major manufacturers. However, semiconductor consumption rankings differ from electronics production rankings. Legend Group will become the largest consumer of semiconductors in China/Hong Kong in 1998, after surpassing PC Chips Manufacturing Limited, a low-end motherboard manufacturer based in Taiwan (see Table 2-5). The combined consumption of these companies will be more than 30 percent of semiconductors used in China/Hong Kong. Dataquest's total sample group of 64 will consume 42 percent of semiconductors used in China/Hong Kong.

Electronics Equipment Preduction Assumptions

China's growth in exports, local consumption, foreign investment, and government support are some basic positive factors behind its electronics production growth. Underlying and supporting all these trends is the fact that local production is becoming more efficient, and economies of scale are being achieved.

Does China Need to Devalue Its Currency?

The currency devaluation created critical problems for Asia/Pacific semiconductor suppliers and users that are almost entirely dependent on imports. Although most vendors denominate their prices in dollars, cashflow problems—attributed to rising credit costs and falling sales—have resulted in weakened demand from local manufacturers. Indonesia's currency devalued more than 80 percent during the past six months, and its equity market dropped by more than 80 percent. As a result of the financial turmoil, stock markets in Korea, Thailand, the Philippines, and Malaysia declined by more than 60 percent. Equity markets in China and Hong Kong have also dropped, but their strong cash account reserves have enabled them to support the Hong Kong dollar and the Chinese renminbi.

Source: Dataquest (August 1998)

Few economists expect a renminbi devaluation in 1998, but there are concerns in the region that falling exports and a slowing economy will force China to devalue, potentially sparking another round of disastrous currency depreciation in Asia. It is a question of time. For sure, China will devalue, but whether it is before or after the region has recovered is the issue. In 1998, the Chinese government is under extreme pressure to maintain strong economic growth and create new jobs because of the dismantling of state-owned industries, which is creating millions of surplus workers. So far, the Chinese leadership has responsibly held its currency at the expense of economic growth, in addition to committing U.S.$250 billion in infrastructure spending projects to increase its gross domestic product (GDP) vis-à-vis domestic consumption.

 ©1998 Dataquest

Gross Domestic Product Remains Robust

China's economic growth has slowed substantially since March of 1998. Data from the Organization of Economic Cooperation and Development (OECD) had forecast China's economy to grow between 7.5 percent to 8.0 percent in 1998. However, because of the region's worsening economies and slowing exports, GDP is expected by numerous sources in Hong Kong to fall between 6.5 percent and 7.5 percent. GDP in the first quarter of 1998 had slowed to 7.2 percent, and it is expected to slow to 7.0 percent in the second quarter. The trend is expected to continue, with the second half of 1998 averaging less than 7 percent. One of the advantages China has over the rest of Asia/Pacific is that its economy is far more diversified, with economic expansion taking place in heavy industries, manufacturing, electronics, services, and agriculture. This broad-based growth, including electronics, buffered it from Asia's economic woes. In fact, the major growth burden has been from the SOEs that account for about 60 percent the economy. Prime Minister Zhu Rongji is in the process of structuring SOEs, which is the main factor behind slower growth and rising unemployment. However, China depends heavily on foreign capital and markets to sustain its current growth rate.

Foreign Investment Will Not Dry Up

In addition to increased efficiencies in Chinese companies, economic growth has been boosted by direct foreign investment. Foreign investments need to continue to flow into China for it to achieve a 7 percent GDP growth. Hong Kong, which has been hurt financially by its falling stock market, accounted for 59 percent of foreign-invested capital in China from 1980 to 1997. In the past few years, contracted investments in China had declined from $88 billion in 1994 to $72 billion in 1997. However, the actual utilized investment increased from $33 billion to $44 billion during this period. There is uncertainty in 1998, and most forecasts indicate a decline in utilized investments to $35 billion for the first time in at least five years.

Dataquest also expects contracted investments to decline because of the investor uncertainty that is the short-term outcome of China's aggressive reforms to be undertaken in 1998. However, once the dust settles, investment flow is expected to resume in 1999 because the current slowdown is macroeconomic rather than microeconomic in nature. In the first quarter of 1998, figures show more than 10 percent growth over 1997, but the second quarter is expected to decline. However, Dataquest continues to see communications, computer, and consumer electronic companies maintain a high strategic interest in investing in manufacturing in China for long-term needs: to increase market access, reduce distribution costs, and improve time to the market.

Exports Still Competitive, Southeast Asian Companies Face Cash-Flow Problems

China's GDP will exceed $900 billion in 1998, yet its total trade is nearly $400 billion. China's export machine has proved to be a formidable global force, particularly in the past three years. The economy's trade surplus was expected to increase beyond $50 billion in 1998 prior to the financial crisis; but as result of the financial crisis, it is expected to decrease to the $30 billion range. The first two months of 1998 show exports to the United States to be at the same levels as 1997, while imports are slightly down.

 ©1998 Dataquest

China is exposed to the Asian financial crisis by about 11 percent because 11 percent of its exports go to Southeast Asia and Korea. In the past few years, China's exports to Japan have declined to about 15 percent of total exports, but exports to Europe, North America, and Taiwan increased to more than 60 percent. Based on export exposure, a dramatic trade downturn as experienced by the rest of Asia is not likely. The free-falling yen was clearly a threat, but China still holds a (dangerous) wild card: devaluing the renminbi.

Chapter 3

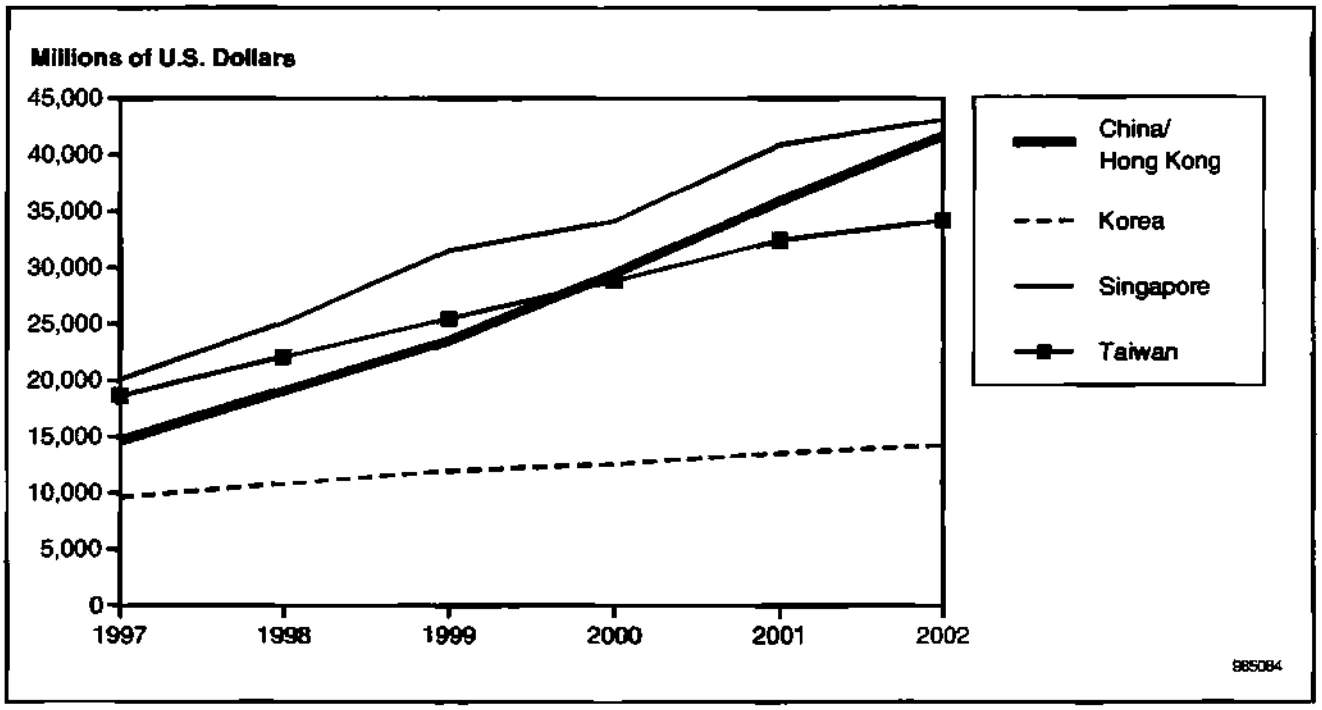
Computers and Peripherals Industry Trends

Dataquest forecasts that data processing-related electronic equipment production revenue will grow from $19 billion in 1998 to $42 billion in 2002. In 1998, PC production will increase 55 percent to 4 million units, representing a semiconductor opportunity of approximately $900 million. Dataquest expects data processing, led by strong PC industry and market growth, to undergo an average annual growth rate of 36 percent during this period for reasons discussed later in this chapter. During this period, China will surpass Taiwan to become the second-largest data processing equipment producer in Asia/Pacific (see Figure 3-1).

Data Processing Segment Analysis

Dataquest expects data storage to become the fastest-growing sector during the 1997-to-2002 forecast period, although it was the smallest sector in 1997. Dataquest expects that most of the 1998 production will be exported. Seagate Technology Inc. is the sole manufacturer of rigid disk drives (RDDs) in China, operating two major facilities. Dataquest believes that this $2.4 billion industry in 1998 will grow fivefold to $9.4 billion by 2002, based on Seagate's plans, and new entrants are likely in the 1999-to-2000 time frame.

Figure 3-1
Data Processing Equipment Production in China/Hong Kong, Korea, Singapore, and Taiwan: 1997 to 2002 (Millions of U.S. Dollars)



Source: Dataquest (September 1998)

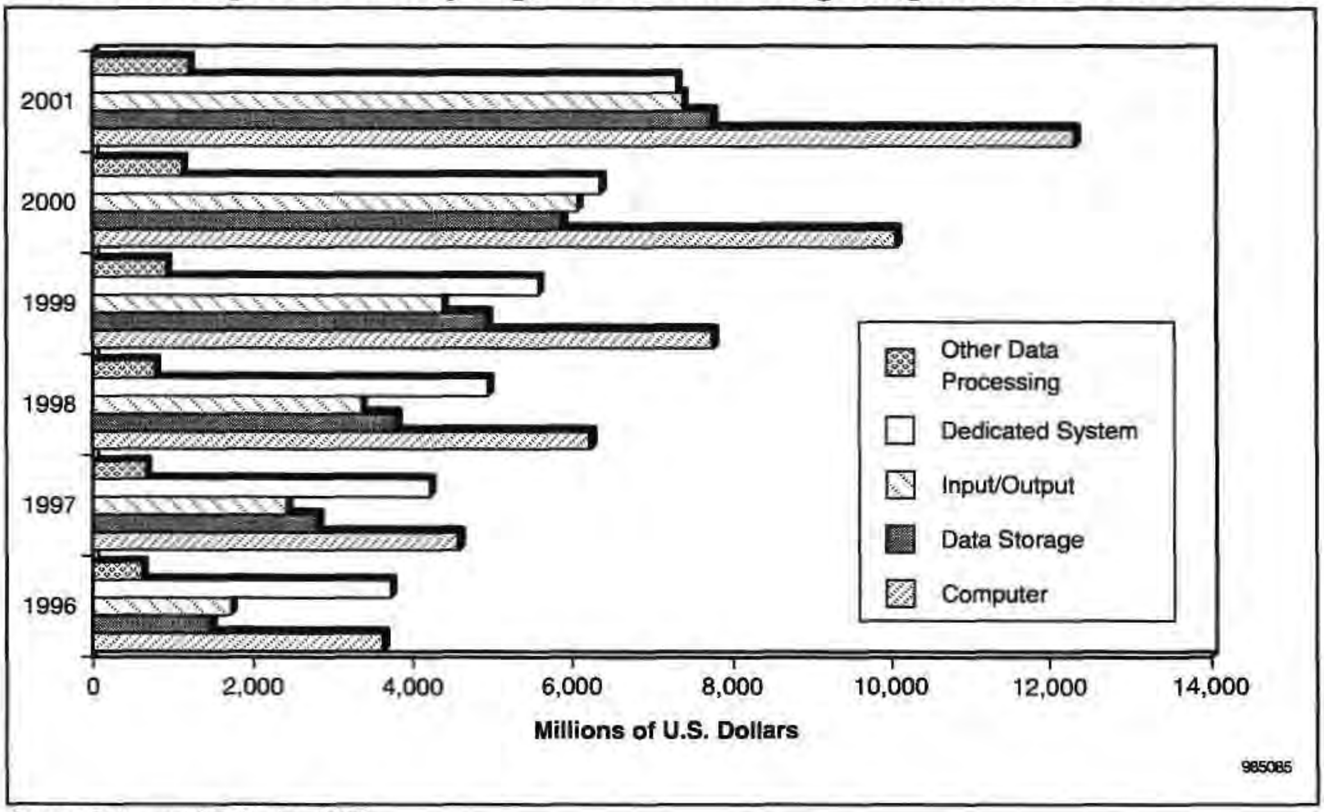
Computer peripherals, defined as input/output devices, will expand at an average annual growth rate of 30 percent to reach $9 billion, up from $2.4 billion in 1997. Monitors represent about 54 percent of this category.

The largest data processing sector is the computers, which is expected to grow 32 percent in 1998 and average 28 percent in the next four years, reaching a $13.3 billion revenue level in 2002. PCs and motherboards will increase in importance from 21 percent to 28 percent share of data processing production (see Figure 3-2). PCs and motherboards represent about 71 percent of computer revenue in 1998.

Computer Production

Computer equipment production in China is being driven first and foremost by consumption. However, improved quality and competitiveness now mean that foreign and Chinese companies are also exporting from China. China's growing computer demand will support the country's economic modernization. Chinese banks, insurance companies, and tax agencies are in the rudimentary stages of computer use, and they lack networks for information sharing. For the future convertibility of the renminbi (or Chinese yuan), Chinese officials are integrating banks with better computing systems. The State Bureau of Taxation is looking to connect 30,000 offices across the country.

Figure 3-2
Data Processing Production by Segment in China/Hong Kong (Millions of U.S. Dollars)



Source: Dataquest (September 1998)

Computer and computer peripheral sales in China are expected to increase by more than 30 percent in 1997. Domestic demand for PCs this year is expected to approach 3 million units in 1997. China's domestic computer manufacturers currently account for about 25 percent of domestic sales. Most leading foreign PC vendors have already established manufacturing facilities in China to anticipate this growing domestic demand. Among other forecasts, China's annual demand for high-powered computer workstations is expected to grow to about 5,000 units this year.

PC Production Spurred by Domestic Market's Pull

Furthering PC production growth is the parts and components production in major production centers: Shenzhen, Shanghai, and Beijing. Time-to-market concerns, familiarity with local distribution channels and customer concerns, lower tariffs, and locally produced parts translate into competitive advantages and lower costs for Chinese producers. In addition to small-scale producers, major brands—such as Legend Group, the Beida Founder Group, China Great Wall Computer Group, Beijing Stone Group, Donghai Co., and others—have emerged in China's booming retail markets. Legend Group's recent initiatives indicate that the company is trying to duplicate its newfound success in the international markets. Legend moved its PC division headquarters to Hong Kong to break into the global PC market, which was Legend's first step to become one of the top five vendors in Asia/Pacific, while maintaining domestic market leadership by 2000. Legend forecasts its sales to reach 1 million units annually by 2000. Table 3-1 shows China/Hong Kong's PC production forecast.

Table 3-2 provides a ranking of China/Hong Kong's PC manufacturers in terms of 1996 and 1997 production units ranking. The top manufacturers correspond closely with the top vendors in terms of market share because of the above advantages. Table 3-3 provides company production trend lines and a forecast for 1999 production.

Over the long run, Dataquest expects China/Hong Kong's PC production to reach 35 percent CAGR. China's PC market represents about one-third of all shipments to the Asia/Pacific region (excluding Japan) in 1998. At the same time, its unit growth will likely double the regional average.

Business Markets Dominate and Still Show High Growth

China's PC market continues to show strong growth and attract multinational investors and domestic suppliers. Table 3-4 ranks all major vendors according to PC units shipped in 1997.

Table 3-4

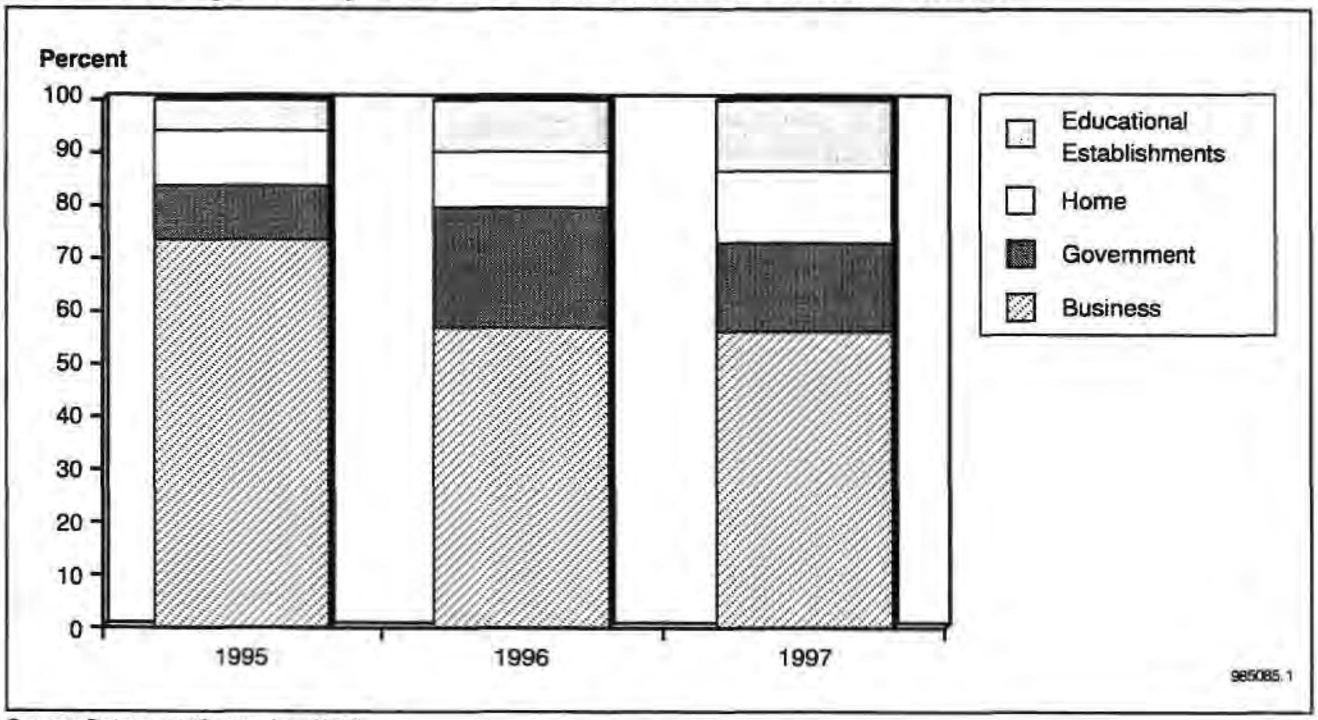
To understand the source of the business markets' growth, Dataquest segments the market by customer, form factor, and processor class. China's business market was the first to adopt PCs in the country. In 1995, the business segment absorbed nearly three-fourths of all PCs shipped in China (see Figure 3-3). Strong demand from foreign businesses in China later spilled over into local export-oriented companies. Foreign brands will not be the automatic product of choice because many local vendors now produce credible quality and are learning to provide aftersales service. The private sector remains China's engine for economic growth, and PCs will be rapidly deployed in this large and booming sector. However, the emergence of government, home, and education markets lowered business segment's share to 56 percent in 1997. But the PC market more than doubled, so PCs for business use still grew from 700,000 units to 1.2 million units from 1995 to 1997.

Government Sector Shows Strength

The government market accounted for about 10 percent of the PC market in 1995 and nearly doubled in share to 17 percent by 1997. The government and home markets each purchased only about 100,000 units in 1995. But the government segment grew faster, reaching 372,000 units in 1997. The government's recent initiative to streamline government, reduce ministries, and cut red tape will necessitate the computerization of administrative functions across China's central government. However, the pace at which China can achieve such a mammoth task will be slow, and the funds available will be increasingly scarce.

Figure 3-3
PC Market Segments by User in China, 1995 to 1997 (Percent Share)



Source: Dataquest (September 1998)

Home Market Awakes

There are few reasons to believe that the Chinese will have any less of a desire for home PCs than is seen in the United States, where approximately 40 percent of homes have PCs. This is another example of high nascent demand, because urban families have shown a high interest in PCs to educate their children to get ahead in China's competitive education system. In China, about 0.05 percent of the population own PCs, and only about 0.25 percent of 1 percent of families own PCs (assuming an average family size of five persons). The current economic growth rate, resulting in higher disposable incomes, would suggest that it takes about 10 years for 20 percent of Chinese families to own PCs. Another way to look at this trend is as follows: If an average of 5 percent of PCs are retired per year in the next decade, and the home market grows by 50 percent per year, then 85 million PCs would be sold just to families in China between now and 2008.

Education Users Surge

China's education market was the fastest-growing PC market segment during the past three years. Only 6 percent of PCs sold in 1995 went to educational establishments, but by 1997, this more than doubled to 13 percent. The university environment is the heaviest user on a per-PC basis, with hundreds of students sharing one or two PCs. But it is also the least funded. Vendors are wise to develop market share in this segment (providing discounts) as an efficient means of building brand recognition with China's next generation of business and government leaders.

Form-Factor Trends

In addition to market segmentation by end user, Dataquest segments PC shipments by form factor. The Chinese market has been dominated by desktop computers. But in 1997, the notebook computer market doubled to 173,000 units after several years of slow growth. Dataquest forecasts the market to continue this growth level through 1999, and then settle to a 50 percent average growth from 2000 to 2002. Dataquest has yet to see a local notebook computer manufacturer in China, but it expects volume production to begin in 1999. Significant semiconductor opportunities will emerge as portables grow from a mere 9 percent in 1997 to 26 percent in 2002. Desktop PCs remain the "bread and butter" of the industry. Desktop PC shipments will grow from 1.7 million units in 1997 to 6.5 million units in 2002. The overall PC shipment share will fall from a high of 88 percent in 1997 to 68 percent in 2002.

Long-Term PC Production and Semiconductor Consumption Forecast

PC manufacturers surveyed by Dataquest expect a significant production expansion slowdown in 1998 relative to 1997—from 97 percent in 1997 to 46 percent in 1998. Approximately 84 percent of China/Hong Kong-based PC manufacturers' unit output was surveyed in both periods. These manufacturers, as a group, had exceeded their production plans of 88 percent growth in September 1997 and reported their final 1997 growth to be 97 percent. This performance is consistent with local Chinese companies' local market share gains, which expanded by 44 percent to 2.2 million units in 1997.

 ©1998 Dataquest

Dataquest estimates that total PC production in 1998 will reach 4 million units, a 55 percent increase over 1997. The estimated factory average selling price (ASP) of PCs (excluding motherboard, monitor, keyboard and disk drive) in 1998 will reach $686, up from was about $670 in 1997 (see Table 3-5).

Motherboard Production to Drop in 1999

Table 3-6 lists Dataquest's 1996 and 1997 PC motherboard manufacturer ranking and production share for the surveyed companies. The largest manufacturer in terms of units was PC Chips, a low-end, volume-driven motherboard manufacturer based in Taiwan. Dataquest believes that this group of manufacturers represents 96 percent of total motherboard production in China/Hong Kong.

The production forecast of these manufacturers is presented in Table 3-7, which shows 1998 and 1999 unit production by company. As stated earlier, these manufacturers are cautious with their expansion plans. Dataquest's surveys of these companies indicate that growth will fall off from 60 percent in 1998 to 15 percent in 1999, because of few new investments.

Source: Dataquest (August 1998)

Dataquest's long-term outlook is presented in Table 3-8, which indicates a recovery caused by underinvesting during these next two years. Dataquest forecasts China/Hong Kong's motherboard production to expand by 32 percent CAGR from 1997 to 2002. PCs are growing at a faster rate because Dataquest believes that some of China's market will continue to be served effectively by drop shipments of motherboards to assemblers in China. The semiconductor opportunity of $760 million in 1998 is approximately the same size as the $900 million shipped to the PC market. Combined semiconductor consumption of PC and motherboard vendors will exceed $1.6 billion in 1998 and will grow to more than $5 billion in 2002. This amount is nearly 20 percent of the entire semiconductor market in 2002 (see Table 3-8).

Computer Monitors

Domestic monitor shipments to the Chinese market has been growing at 40 percent during the past several years. Production expanded by 39 percent in 1997 and accelerated to 65 percent in 1998 because of new investments. Table 3-9 ranks the top manufacturers that account for about 50 percent of total production. As indicated, Chinese companies have rapidly entered this market, but the multinational vendors still dominate.

As shown in Table 3-10, the growth Dataquest had forecast is attributed to increased capacity by the large three producers, Philips Electronics NV, Acer Computer International Ltd., and First International Computer Inc. (FIC). These three companies occupied 25 percent of the industry in 1997. Dataquest segments monitors in the input/output equipment market, which is part of the overall data processing market. Monitors will remain the primary growth driver and have the largest share of input/output production. Dataquest forecasts this segment to expand by 30 percent from $2.5 billion in 1997 to $9 billion in 2002. Monitors' 1998 revenue of $2 billion will represent 54 percent of all 1998 input/output revenue.

Table 3-11 presents Dataquest's history and forecast of total computer monitor production in China/Hong Kong. Dataquest's survey of monitor production in China/Hong Kong covered one-half of the region's total monitor production, which is a large sample size. Dataquest estimates the total production in 1998 to reach 12.5 million units, compared to 7.6 million units in 1997.

Storage Equipment

Seagate is the sole producer of RDDs in China/Hong Kong. Most components are internally transferred from Singapore; however, Dataquest has estimated Seagate's semiconductor consumption at two facilities.
Table 3-12 provides Seagate's historical units and growth, while Table 3-13 provides Dataquest's forecast for 1998 and 1999.

Dataquest expects data storage to be a major semiconductor growth source for the next four years. We expect that at least 90 percent production will continue to be exported by Seagate for global export because of the nature of these facilities. Dataquest believes that the $1.6 billion storage industry in 1998 will grow fivefold to reach $3.9 billion in 2002, with Seagate leading the way. This 19 percent CAGR is lower than unit growth of 24 percent, as price erosion continues, but at a slower rate (see Table 3-14).

Seagate Technology Inc.

Seagate has been expanding production in China and will inject $32 million into its Wuxi facility, bringing total direct investment to more than $52 million. Total investment in China was reported to be $90 million, including the Wuxi plant. Employing about 3,300 workers, the Wuxi plant's aggregate production reached 3 million units in 1996. This investment adds about 1,600 workers and doubles Seagate's capacity in China, which serves both local and export markets. It is said that the production line for magnetic disk drivers, which is now in the old building, will be shifted to the new one, and the old one will be used mainly for the production of E-BIKS, with an expected daily capacity of 25,000 units.

The new Wuxi facility is Seagate's second RDD plant in China, after operating the Shenzhen plant for more than two years. The acquisition of Conner Peripherals Inc. by Seagate enabled it to buy market share in China by acquiring Conner's Shenzhen RDD plant. It also enabled Seagate to adopt a successful business model for selling in China, which Seagate has successfully expanded upon. Since then, the combined efforts have proved effective for Seagate, which now controls more than 50 percent of the market and exports RDDs from China.

Dataquest estimates the PC production growth rates to keep pace with China's breakneck PC market growth. This rapid growth resulted in a voracious demand for RDDs. However, RDD competition is increasing for Seagate as it is attempting to hang on to its reign of China's computers mass-storage market. By expanding production, Seagate is leveraging its current competitive advantage in the market to combat the new market entrants.

 ©1998 Dataquest

Printers

Dataquest researched production for Fujitsu Ltd., Stone/Fujitsu, and Sharp Electronics Corporation, but we did not include Hewlett-Packard, which also manufactures printers in China. From Dataquest's research, these four companies represent almost the entire page printer production industry in China/Hong Kong. Fujitsu and its joint venture, Fujitsu/Stone, together represented about 22 percent of production in 1997 (see Table 3-15). Sharp produces a small quantity that represents only approximately 4 percent of overall production.

Table 3-16 provides production forecasts for these three companies in 1998 and 1999. Dataquest observes aggressive expansion in 1998 because of investments that were made in 1997. However, as Dataquest observes in many segments, investments have become somewhat cautious in 1998, hence unit production is expected to expand by a slower, but robust, 35 percent.

The long-term printer production outlook growth and semiconductor consumption is quantified in Table 3-17. In general, the 33 percent CAGR should not be a surprise here because printer production is keeping track with PC production and electronics market growth. Semiconductor content is increasing because of expectations that higher-end printers will be built in China and because of increasing demand from business, government, and even personal users.

Chapter 4

Communications Electronics Equipment

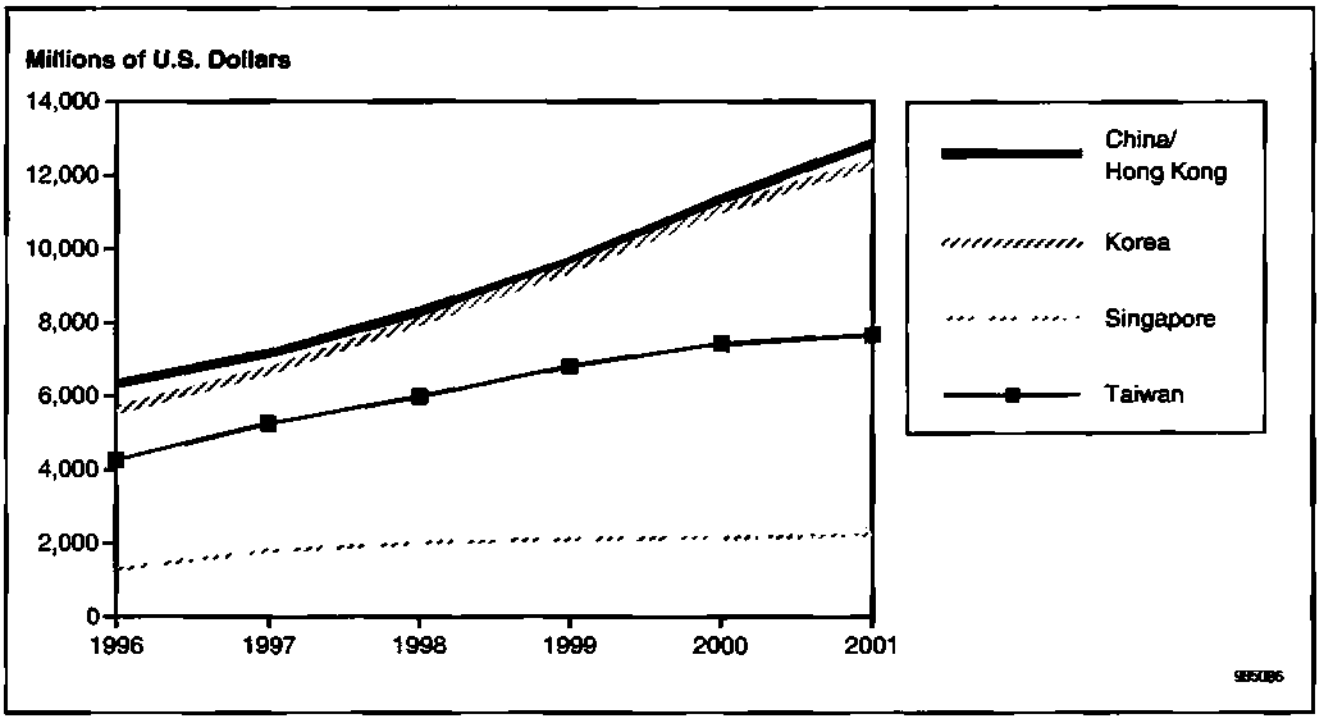
Introduction

Dataquest assesses the communications equipment production in 1998 and 1999 with an up close look at key manufacturers. Dataquest also assesses each product's semiconductor usage from 1997 to 2002. Because of the importance of communications market to driving investments in local production, Dataquest has provided additional market-related information as part of its baseline assumptions.

Communications Sector Trends

China/Hong Kong has become Asia/Pacific's largest manufacturer of communications equipment because of its rapid rise in premises and, more recently, mobile communications production. Dataquest expects communications production to maintain its current pace because of broad-based products that are both exported and shipped locally in China. The Chinese government continues to provide significant support and investments in developing its telecommunications infrastructure, which will lead to increases in local content and foreign investment. Figure 4-1 illustrates Dataquest's forecast by Asia/Pacific country, which shows that China/Hong Kong and Korea both maintain dominance of Asia/Pacific's communications production.

Figure 4-1
Communications Production Revenue Forecast in China/Hong Kong, Korea, Singapore, and Taiwan: 1997 to 2002 (Millions of U.S. Dollars)



Source: Dataquest (September 1998)

©1998 Dataquest

Communications equipment production will generate $8.3 billion in China/Hong Kong in 1998, which represented 4 percent of Asia/Pacific's total electronics production. China/Hong's production represented 27 percent of all communications-related production (revenue) in Asia/ Pacific. Dataquest forecasts that China/Hong Kong's communications production will grow at an 11 percent CAGR from 1997 to 2002. At its current growth trajectory, China/Hong Kong will maintain its share of Asia/ Pacific communications production despite its high consumption growth of communications equipment. Dataquest believes that China/Hong Kong will still have to import the majority of its infrastructure equipment because of technological complexity and the need for turnkey solutions. Some standardized systems, such as Global System for Mobile Communications (GSM), can lead to local production but new technologies, such as xDSL, will continue to be imported in entirety (and probably from only a few vendors).

As illustrated in Figure 4-2, which splits China/Hong Kong's communication production by major market segment, Dataquest forecasts that premises will continue to dominate in production share, while mobile leads the industry growth. Substantial production volume, particularly in southern China, of corded and cordless telephone handsets will enable premises production to sustain more than 50 percent of production. It will account for 55 percent of production in 1998 but will fall to 50 percent because of mobile's faster growth. Premises are followed by mobile with 21 percent share, public telecom (18 percent), broadcast/studio (3 percent), and others (0.8 percent).

Digital Cellular

Table 4-1 presents Dataquest's list of major mobile cellular phone producers in China/Hong Kong, their production units, and production share. Dataquest includes all cellular handset production in this segment, including digital cellular and broadband PCS handsets to include handsets that conform to the following standards: GSM, Digital Cellular System (DCS) 1800, personal communications services (PCS) 1900, NA-TDMA (IS-54/136), code division multiple access or CDMA (IS-95), Personal Data Cartridge (PDC), and Omnipoint.

Dataquest's sample survey of six major multinational manufacturers included about 74 percent of cellular phone production in China. Motorola Incorporated is a Goliath and overshadows all other manufacturers with 39 percent production share in 1997. Despite its 41 percent increase in output, Motorola still lost 3 percentage points production share because of NEC Corporation's rapid expansion, which enabled NEC to move from No. 4 to No. 2 in production ranking.

Table 4-2 presents production plans of these major six manufacturers in 1998 and 1999. As shown, there is a dramatic deceleration from 60 percent growth in 1997 to 27 percent in 1998 among these top producers. Consequently, the overall industry will only grow 25 percent, which is high by global standards but slow for China/Hong Kong. One would expect this slowdown to occur in 1998 because all manufacturers have expanded production. It appears this slowdown is temporary because production among these companies is expected to accelerate to 33 percent in 1999. Dataquest expects the next year to see new entrants to the market attributed to turnkey GSM technology transfers that are taking place this year. Dataquest expects to see one or two Chinese companies start producing cellular phones by 1999. Hence, overall cellular phone production will jump to 39 percent according to Dataquest's forecast.

Table 4-3 presents Dataquest's long-term perspective on cellular phone production and semiconductor consumption. Dataquest forecasts a significant production growth of 39 percent CAGR from 1997 to 2002. This growth level translates into a production capacity of 16 million cellular phones by 2002 in China/Hong Kong.

Mobile telecommunications business has developed rapidly in China, but with faster expansion in the eastern coastal areas than the central and western areas. Competition is sizzling in the mobile telecommunications service market between China Telecom, under the Ministry of Posts and Telecommunications (MPT), and its main rival, China Unicom.

China's mobile phone subscribers in 1997 reached nearly 10 million. The Chinese government predicted last year that the number of mobile phone subscribers would reach 7 million by the end of 1997. Recent estimates put the 1997 figure closer to 10 million. But most of them are still based on the analog system because of its earlier introduction in the 1980s. Cellular phone subscribers in 1997 are estimated to be 4 million by MPT. In Shanghai alone, the number of cellular phone subscribers were 600,000 in 1997, from about 360,000 in 1996.

Major players in the mobile telecommunications market include China Telecom, Telecom United, Motorola, Nokia Telecommunications, Oki Telecom, Ericsson, and Siemens AG.

With the addition of 130 GSM networks run by China Unicom, the GSM networks increased to about 5 million. This addition will add an estimated 250,000 to 300,000 radio channels. Mobile phones made by the world's three leading telecommunications companies, Ericsson, Nokia, and Motorola, have captured about 95 percent of Beijing's GSM mobile phone market. The remaining 5 percent of the market is shared by a mixture of products from other companies, including Siemens and NEC.

China is one of the world's most underserved telecommunications markets today. It had a cellular phone penetration rate of only 0.6 percent last year. But the market is expected to quadruple to 28 million subscribers by 2000. Even with this increase, it is still a tiny percent of the 1.3 billion people in China today. If Taiwan is an indicator, then this rate is only about 4 percent of Taiwan's 21 million mobile telephones subscribers today. Provincial governments are taking many initiatives to expand their mobile markets, as detailed below. For example, the economically vibrant coast province of Shandong has an estimated 750,000 mobile phone and 800,000 pager customers in 1997. The number of mobile subscribers in Henan Province is not in line with the size of its population. Henan had 95 million people, but had only 121,708 cellular phone subscribers in 1995.

GSM Developments in China

China is going mobile to meet the growing demands of the country's telecommunications explosion. GSM continues to build momentum in China as digital technology provides high-traffic-carrying capacity.

In the face of rapidly growing public demand, the MPT has decided to expand its sophisticated digital mobile communications systems dramatically in China in the next few years. MPT officials say that foreign telecommunications companies will be allowed to market their own digital or GSM mobile phones in China if their products are found to be of high quality, which, the officials say, will help increase market competition and force prices of GSM mobile phones here to fall.

CDMA Developments

China is now building several trial code division multiple access (CDMA) networks in populous cities such as Guangzhou, Beijing, and Shanghai. The handling capacity of the CDMA networks is reported to be 10 times higher than the present analog mobile telecommunications standard.

©1998 Dataquest

Representatives of Lucent Technologies (China) Ltd.—one of the global telecommunications giants leading the CDMA trend—said that China dialed the first CDMA call on the trial network launched by Lucent Technologies in Guangzhou on December 31, 1996. It is the first commercial CDMA system operational in China.

Lucent said that China—the fastest-growing market in the Asia/Pacific region and in which the company has won CDMA contracts worth $250 million—is now technically qualified to adopt the CDMA technology countrywide.

Motorola, another major CDMA supplier from the United States, is also accelerating the construction work on two trial networks in Beijing and Fujian Province. It made the first CDMA call in Beijing early this month. Meanwhile, other CDMA manufacturers, including Canada's Northern Telecom Inc., Samsung Electronics Company Ltd., and, to a lesser extent, LG Electronics Inc., are entering the Chinese CDMA marketplace.

Once the country decides to open the market to foreign CDMA suppliers, the telecommunications administrative body will encourage the foreign companies to make technical transfer. China has always adhered to the principle of trading market for technology. Therefore, the earlier the CDMA technology is transferred, the easier it will be for the company to make its way into the Chinese market.

Lucent Technologies (China) Ltd.

In September, Lucent's CDMA system was successfully tested to roam between two different networks in Guangdong and Beijing. The tests were conducted with China Telecom Greatwall Network, a cooperative entity between China's MPT and China Electronic System Engineering Co. Lucent's CDMA system passed both the C7 signaling tests and the IS-41B tests, in addition to also achieving successful roaming between the networks in Guangdong and Shanghai. LG is a latecomer in the booming China market for wireless handheld phones and is constructing an assembly plant, like the other major vendors. LG will be bucking up against CDMA phone suppliers that already have assembly plants in China.

Samsung Electronics Company Ltd.

China is also showing interest in Korea's experience in the commercial use of CDMA mobile telecommunications. Korea's Samsung Electronics signed a contract in June to supply CDMA digital mobile telecommunications equipment to China's Shanghai Great Wall Mobile Communications Co. Under the contract, Samsung will supply one switch station with a capacity of 68,000 lines, 67 base stations, and services on a turnkey basis. The CDMA digital cellular phone services are expected to go into commercial operation in Shanghai beginning in 1998.

Samsung bid against foreign rivals that included Lucent Technologies, Motorola, and QUALCOMM Incorporated. Samsung plans to use Shanghai as its regional base for communications equipment because of high market potential, with the number of cellular phone subscribers expecting to reach 600,000 in 1997 from 380,000 in 1996.

 ©1998 Dataquest

Thus, Samsung plans to explore the market in Shanghai for PCS, wireless local loop (WLL), and asynchronous transfer mode (ATM). Samsung operates a joint-venture company in Shanghai for WLL operation. In 1996, it supplied wireless paging systems capable of accommodating 1 million subscribers.

CDMA Production Developments

Major CDMA market players, including Lucent, Motorola, Samsung, and LG all have assembly plants in China. LG is a latecomer in the booming China market for wireless handheld phones. LG will be bucking up against CDMA phone suppliers that already have assembly plants in China.

In April, China Samsung Electronics has been selected as the official CDMA hardware provider for Shanghai. The turnkey contract calls for the company to provide China Shanghai Changcheng Mobile Communications Co. Ltd. with a switching station that has the capacity to handle 68,000 subscribers, as well as 67 base stations and follow-up services. Installation is scheduled to begin in the first half of this year, and the system will be fully operational within the second half of the year.

Mitsubishi Electric Corporation announced plans to set up a digital mobile phone production base in China and to increase Mitsubishi's share in the world mobile phone market from present 6.5 percent to more than 10 percent by 2000. So far, Mitsubishi has established production bases in the United States and France, with annual output reaching 1 million units in 1996. Because China forms an increasing demand for mobile phones, Mitsubishi predicted that Asia/Pacific will represent 40 percent in the world digital cellular market.

Personal Communications Services (PCS) Developments

The changeover of Hong Kong sovereignty also could have a positive impact on PCS implementation in China. PCS licenses in Hong Kong are on track to generate an estimated $700 million in the next two years and as much as $5 billion in total revenue in the next 10 years. In underdeveloped countries where limited wireline infrastructure is installed, the existing infrastructure may not support the growing population or their service needs. The large cost and projected scope of laying more wireline networks suggest a wireless solution such as a PCS network. A PCS microcell base station that will support 100 people is estimated to cost somewhere between $60,000 and $65,000. By 2001, the number of cellular and PCS users in China, for example, could reach 12 million, representing $20 billion in revenue. The current worldwide wait for phone service for an estimated 40 million to 50 million people is 1.2 years. The average density of phone lines for the world is about 10 percent (or 10 lines per 100 people), with industrialized nations averaging about 50 percent. A key challenge will be for GSM, CDMA, and PCS companies to ensure that Chinese government understands the relationships among the cost of regulation and the speed of approvals, and the affordability of services with its effect on universal service.

©1998 Dataquest

Pagers

Dataquest's survey of China/Hong Kong's pager producers represented about 90 percent of production in 1997. Table 4-4 presents Dataquest's ranking of the three major pager manufacturers in China/Hong Kong. Dataquest estimates that China produced 7 million pagers in 1997, led by Motorola, Matsushita, and the joint venture, TCL/NEC (between Huizhou TCL Mobile Communication Co. Ltd. and NEC). Motorola dominates pager production with 67 percent of production share or 4.8 million sets in 1997. Matsushita's production quantity increased 76 percent in 1997 to 95,000. This expansion enables Matsushita to move to rank second and capture 14 percent production share, at the expense of Motorola that lost 7 percentage points production share. TCL/NEC cut production from 650,000 to 400,000, as the industry suffered overcapacity in 1997.

Table 4-5 presents the unit production forecasts for TCL/NEC, Motorola, and Matsushita in 1998 and 1999. Production expansion by Motorola and Matsushita appears to be coming to a standstill to better align with slowing demand. However, TCL/NEC plans to boost production from 400,000 units in 1997 to 1 million units in 1998. This expansion will further exacerbate ASP declines, as Dataquest forecasts in Table 4-6.

TAM = Total available market
Source: Dataquest (August 1998)

Dataquest believes that pager unit production will grow at only 5 percent CAGR from 1997 to 2002. This growth represents a semiconductor market expansion of 9 percent, from $93 million in 1998 to $122 million in 2002.

At the end of 1997, there were 8 million new subscribers. But MPT's projections showed paging subscriptions to reach 117 million by 2000, which Dataquest believes to be overstated. By the end of 1996, MPT had started national paging networks in 22 Chinese cities. The new systems have adopted FLEX/multifrequency roaming modules, as well as VSAT interconnection technology. ChinaSat has contracted Hughes Network System to provide VSAT equipment in more than 300 subnetworks across China. MPT has experimented with new frequencies, particularly the 150 MHz.

Dataquest believes that paging services may continue to be a major means of communications, but the falling cellular phone service prices make pagers obsolete for many consumers.

Paging Companies and Developments

China Unicom and other non-MPT paging service providers have merged or sought vertically integrated networks under other ministries. Other strategies adopted include seeking foreign partners for direct investment or new technologies. Beijing Jingxin Electronics Co. Ltd. and HP signed a cooperative agreement in December 1996 for codeveloping wireless, high-speed beeping coding system. The project received support from the State Science and Technology Commission. China's wireless, high-speed beeping business was projected to develop rapidly in 1997.

Tianjin Municipal Posts and Telecommunications Administration in the north China's Tianjin started two new paging services in cooperation with independent paging service centers in May. Tianjin now has more than 70 separate paging services with 1.2 million subscribers. A majority of the services are small in scale, except for the local posts and telecommunications departments, which are financially and technically stronger.

©1998 Dataquest

A dozen of these paging centers have more than 10,000 subscribers each, but some have only about 2,000 subscribers. To woo more subscribers, paging service operators have been competing by cutting costs, a move that has put some operators in a tough situation. A total of 37 other separate paging services have also agreed to join the unified new paging services and are now making preparations, according to local sources.

Samsung said it has completed construction of a $1 million paging system in Shanghai, which can handle 1.2 million subscribers in 1997. The company said it delivered the turnkey project to Shanghai Guomai Communications Co. Ltd. Samsung estimates that the paging networks will cover 20 percent of China's 30 million citizens by the turn of the century.

NEC had acquired an additional 35 percent in a Guangdong-based pager manufacturing and marketing joint venture, established in 1993 by a Hong Kong company and a local Chinese entity. NEC purchased all holdings of the Hong Kong partner with about $1.75 million investment.

Central Office Line Cards

Dataquest surveyed 11 major central office/PBX switching suppliers in Table 4-7. Dataquest typically tracks central office by number of line cards, but data available from manufacturers is in the form of number of lines. Furthermore, companies are less comfortable splitting PBX and central office numbers, so Dataquest has combined the figures into one category. A central office line cards is typically defined as a telecommunications switch by public carriers, excluding PBX—a private branch exchange—but Dataquest's company figures include PBXs. Dataquest has estimated pure central office line cards, exclusive of PBXs later in this section.

As shown in Table 4-7, leading central office/PBX manufacturers in China/Hong Kong are a mix of foreign and domestic manufacturers. These companies more than doubled output as measured in lines in 1997 because of China's rapid infrastructure expansion. Shanghai Bell Telephone Equipment Manufacturing Co. Ltd. is the dominant player with a formidable 37 percent production share. The top five companies are market makers because they control about 85 percent of the market. Table 4-8 indicates that these market makers will lose market share caused by several rapid-growth competitors gaining share in 1998 and 1999.

Dataquest's long-term outlook for central office/premises line card production and semiconductor consumption in China/Hong Kong is presented in Table 4-9. Dataquest expects 1997's output of 16 million line cards to expand at a 17 percent CAGR to 35 million units in 2002. Dataquest believes that this will generate semiconductor consumption growth in this segment of 14 percent, from about $200 million in 1998 to $360 million 2002. This market's high competition level is resulting in semiconductor ASP erosion.

Switching Competitive Environment

As of 1997, China had approved more than 43 manufacturers of commercial switching equipment, of which 12 were joint ventures with foreign suppliers. The number has continued to grow. Estimated capacity of the industry is more than 24 million lines per year. China's MPT plans to expand China's switching capacity to more than 200 million lines by 2002. The ninth five-year plan aimed at increasing program-controlled switching by 84 million by 2000. Long-distance switching is planned to reach 6 million accesses with customers exceeding 130 million. These figures represent a penetration rate of about 10 percent nationwide and between 30 percent and 40 percent in urban areas.

Huawei Technology Ltd.

Shenzhen-based Huawei Technology Ltd. is one of China's leading switching equipment manufacturers. The company has supplied switching equipment throughout China. In February, the company supplied 24,000 lines of switches attributed, in part, to China's efforts to localize exchange systems. China's ability to supply switching equipment has improved because of government's support, increased access to technology, and improved manufacturing productivity, as evidenced by Huawei's success.

Shandong Province

There are plans to build telephone exchanges with combined capacity of 1.5 million lines and 20,000-terminal long distance automatic telephone exchanges in the economically booming coastal Shandong province. The number of telephone customers will increase at least 1 million this year, thus providing an average of 6.5 telephones per 100 people in the province.

PBX Telephone Exchanges

Oki Electric Industry Company Limited announced in 1997 that it would set up its first joint venture in China with a telecommunications manufacturer, Guoguang Electronic Corp. Oki Electric has set up a joint venture, Changzhou OKI-GEG Telecoms Ltd., which makes PBX telephone

 ©1998 Dataquest

exchanges and key telephone systems. Markets would include China, Europe, Oceania, Japan, and Southeast Asia. Oki Electric would hold a 70 percent stake in the venture, with Guoguang Electric holding the balance, and the Changzhou-based joint venture would be capitalized at $7.3 million. Guoguang Electric has been making key telephone and PBX systems for Oki Electric since 1995 and is the local distributor for PBXs.

Cordless Telephones

Southern China is the world's largest production base for cordless telephone. China/Hong Kong's cordless telephone industry will ship 23 million telephones in 1998, a 12 percent increase. Dataquest's survey of seven major manufacturers covered approximately 42 percent of China/Hong Kong's total cordless phone production in 1998. Table 4-10 lists the major manufacturers of cordless phones, their units, ranking, and production share. Uniden Electronics Products (Shenzhen) Co. Ltd. is the largest manufacturer of cordless phones in China/Hong Kong, with 28 percent share of production in 1998. Vtech Holdings Ltd. is the fastest-growing manufacturer in 1998 since it doubled production volume from 1.5 million units to 3.3 million units. Its production market share expanded from 10 percent to 16 percent.

Table 4-11 provides Dataquest's outlook on these manufacturers in 1998 and 1999. These manufacturers' strong growth is likely to continue in 1998, but it is expected to slow in 1999. These seven major manufacturers will expand by 42 percent in 1998, but they will slow to 24 percent in 1999. Uniden and Vtech will remain in their respective ranking and slow their expansion to about 16 percent in 1999 after growing an estimated 22 percent in 1998. Several new second-tier companies are adding significant capacity, which will take production share from the top two producers. Table 4-12 shows a forecast of China/Hong Kong's cordless telephone production forecast.

Source: Dataquest (August 1998)

The deceleration observed from Dataquest's company survey will continue after 1999 because of persistent overcapacity from overinvestments in 1996 and 1997. Dataquest's 1997-to-2002 CAGR is expected to reach 8 percent unit growth and 7 percent revenue increase. This semiconductor market segment will, however, experience substantial revenue growth, outpacing equipment unit and revenue growth by a large margin. Dataquest forecasts the cordless telephone semiconductor market to expand from $724 million in 1998 to $1.3 billion in 2002, which is a 17 percent CAGR. This is a highly competitive market in which manufacturers will differentiate their product on functionality, and thereby requiring higher-performance digital signal processors (DSPs), memory, and microcontrollers. Cordless phone customers have a particularly high expectation of performance, quality, and functionality.

Mobile Communications Infrastructure

Dataquest presents revenue estimates on three mobile communications infrastructure equipment manufacturers in Table 4-13. Nokia, Ericsson, and Siemens manufacture approximately 90 percent of the mobile communications equipment produced in China/Hong Kong. Nokia is the largest maker, with a 46 percent production market share. Table 4-14 provides production forecasts for these three manufacturers in 1998 and 1999. While 1997 and 1998 showed substantial growth—similar to cellular and pager trends—mobile communications equipment manufacturing expansion is expected to decelerate in 1999. Dataquest expects this segment's revenue to grow by 15 percent in 1999, after growing by 33 percent in 1998 and 40 percent in 1997.

Table 4-14 provides a forecast of these three manufacturers in 1998 and 1999. Both Nokia and Ericsson are slowing expansion growth in 1999 after several years of rapid expansion. Siemens is accelerating expansion from 20 percent in 1998 to 25 percent in 1999, but from a small revenue base of $24 million.

Table 4-15 presents Dataquest's 1997-to-2002 forecast for all of China/Hong Kong production and semiconductor consumption in this segment. Dataquest estimates that China/Hong Kong's $243 million production revenue in 1998 represents approximately $20 million in semiconductor consumption. By 2002, Dataquest forecasts revenue to reach a modest $366 million, which represents a semiconductor market of $28 million. At this time, most design wins are outside of China/Hong Kong, but by 2002, Dataquest expects most production and design wins to occur within China/Hong Kong.

Corded Telephones

Dataquest sizes the corded phone industry at 99 million units in 1998, a 5 percent growth. Dataquest believes that China/Hong Kong will produce about 123 million corded telephones by 2002, which is a 5 percent CAGR from 1997 to 2002. This is a $349 million semiconductor opportunity (see Table 4-16). There are several hundred telephone manufacturers in China, and competition is acute. Telecommunications infrastructure in the vast rural areas of the country remains poor. Most of the telephones will be produced in Shanghai, Fujian province, and Guangdong province, with annual output in Guangdong's Huizhou city alone at 30 million in 1997.

Source: Dataquest (August 1998)

The Ministry of Posts of Telecommunications (MPT) predicted that 10 out of every 100 people will become telephone subscribers by the turn of the century. However, only about six out of every 100 people had a telephone services at the end of 1997. China's serious plans to raise its national telecommunications network capacity are formidable. To increase subscribers and meet a government plan, China will need 85 million telephone lines before 2000. China is on its way to achieving this goal, since about 17 million new telephone lines were installed in 1997. With more than 130 million telephones to be connected, 30 percent to 40 percent of urban residents are targeted to have a phone by 2000. China's urban population is estimated at 300 million to 400 million people, depending on whether or not suburbs are counted.

All Chinese rural villages are planned to be connected by phones during the Ninth Five-Year Plan period (1996 to 2000). The number of rural telephone customers is expected to increase annually by 6 million to 7 million, according to China's telecommunications departments. Because of high priority given to rural areas, China's rural telecommunications business—with a generally poorer economic base—has not been ignored. In fact, the rural installation rate has been steadily increasing in recent years (at a rate higher than in urban areas in 1995). In some economically thriving eastern regions, the number of customers in rural areas is increasing faster than in urban areas. However, in much of China's central and western regions, almost half of the villages still have no access to a telephone.

Fax Machines

Table 4-17 provides Dataquest's long-term forecast of facsimile machine production and semiconductor consumption. Like corded phones, fax machines are a mature market with overproduction and severe competition. Dataquest forecasts production to grow at a 6 percent CAGR from 841,000 units in 1997 to 1.1 million units in 2002. There are more than

20 fax machine manufacturers in China, but domestically made fax machines are of poor quality, compared with imported products. Hence, the domestic manufacturers import the fax thermal reading heads, scanners, and high-speed modems. The demand for fax machines has increased, as more telephones are installed and the switch capacity expands. Japanese products have dominated China's fax machine market and account for 80 percent of the imported fax machines, which occupy 90 percent of the domestic market. Demand for fax machines is expected to stand at 300,000 units in 1997.

Popular fax machine brands in China include Panasonic Communications and Systems Company, Canon Inc., and Oki Telecom. In 1997, more than 200,000 machines were approved in government projects, and about half were Panasonic products. Oki products have been widely used in railways, electronics, and public security sectors. Fax machines from Korean companies such as Samsung and Daewoo Telecommunications Company Ltd. have also expanded their market share in China with an edge on prices.

LAN Cards

China/Hong Kong's PC market boom has recently increased LAN market growth. Local manufacturers are entering the market and expanding production capacity. Table 4-18 presents Dataquest's 1997-to-2002 production and semiconductor consumption forecast for LAN cards. Of the 2.2 million PCs sold in China in 1997, nearly 100,000 units, or 40 percent, were sold as part of networks. Production in 1998 increased by 45 percent to 5.8 million units, representing a $41 million semiconductor market. Dataquest forecasts LAN card production to grow at a 22 percent CAGR from 4 million units in 1997 to 11 million units in 2002. Semiconductor consumption in LAN cards will reach $71 million by 2002.

On the networking market front, networking companies are making a convincing case that China's attention has turned to networking equipment. Greater China—which includes China, Hong Kong, and Taiwan—emerged as the Cisco System Inc.'s largest market in Asia/Pacific (excluding Japan) as the fastest-growing sales region worldwide. Cisco's sales to greater China in fiscal 1997 climbed 120 percent over the previous fiscal year, with sales in mainland China jumping almost 280 percent.

In a multimillion dollar deal, Hong Kong-based China Internet Corp. (CIC) and the U.S. networking giant Bay Networks Inc. joined forces to set up a network of powerful Web servers that bring vital information to businesses in China. In January 1998, Bay Networks was chosen to provide the infrastructure for the project, dubbed the China Wide Web (CWW), which will place servers strategically located in more than 50 major cities across China. The first phase of the network, covering five major cities, is now being installed and was operational in the first quarter of 1997. Network control centers will be set up in Beijing and Hong Kong. The first CWW branch nodes will be in Shanghai, Shenyang, and Guangzhou. CIC has plans to add an additional five cities to the network each quarter, reaching a minimum of 20 cities by the end of the year. The Bay Networks System 5000 hubs are now shipping to the CWW's phase-one sites in Beijing, Hong Kong, Shanghai, and Guangzhou.

Following desktop computers and notebook computers, Philips Electronics NV recently announced to enter network market in Beijing. It also designated the Beijing Yasuo Network Technology Ltd. its general agent in mainland China. The first-released products include 10/100M PnP ISA/PCI/PCMCIA network card (NIC), 10M PnP PCMCIA FAX/MODEM/NIC card, 10M/100M concentrators (HUB), and exchangers.

China has leaped to become Digital Equipment Corporation's fastest-increasing market. Digital expected to expand its network market by 60 percent in China in 1997. Digital's network products will further tap the Chinese market, particularly the banking and financial market.

 ©1998 Dataquest

Talking about exchange systems, Digital will put stress on school net exchange systems and long distance net systems. In addition, Digital will engage itself in developing new technology suitable for China's condition.

Modems

China's modem production in 1997 reached 575,000 units and is expected to grow 21 percent in 1998. Production is decelerating to 16 percent in 1999 and 14 percent in 2000. Semiconductor consumption is forecast to grow from $17 million in 1998 to $26 million in 2002, a 13 percent CAGR. Table 4-19 provides Dataquest's modem production and semiconductor consumption unit and revenue forecasts from 1997 to 2002.

Chapter 5
Consumer Electronics Equipment

China/Hong Kong produced approximately 40 percent of Asia/Pacific's consumer electronic equipment in 1997 and approximately 13 percent of worldwide consumer electronics. Dataquest forecasts China/Hong Kong's consumer electronics production share in Asia/Pacific's to increase to 50 percent by 2002, and its share in the worldwide production to reach 19 percent 2002. However, this growth will need to come after a slowdown in 1998 and 1999. If digital consumer expands at a worldwide level as expected, then China/Hong Kong will meet this forecast. Otherwise, Dataquest expects a worst-case scenario in which production will grow at an 8 percent CAGR rather than the 12 percent Dataquest forecasts.

China/Hong Kong's large and rapidly-growing domestic market is the main factor behind China's high production level relative to other Asia/Pacific countries. Moreover, Japanese and Korean consumer manufacturers continue to shift production to China faster than to any other Asia/Pacific country. Dataquest expects China/Hong Kong to remain the main destination for these investments in the next five years. As discussed in Chapter 2, China/Hong Kong is now the Asia/Pacific growth center because of stronger economic fundamentals. Both exports and domestic consumption are maintaining reasonable growth even after the Asian financial crisis. However, Dataquest has observed that, at the same time, the new era of digital consumer is already showing up in China in the form of digital broadcasting and digital video compact disc (VCD) players. Figure 5-1 illustrates consumer electronics equipment production forecast for four major Asian countries.

Production Growth Sectors in Consumer Electronics

Figure 5-2 illustrates each market segment of China/Hong Kong's consumer electronics industry. Audio equipment is the largest of the five major segments with a $7.8 million revenue in 1998. Dataquest expects video equipment production to match or surpass audio by 2002 because of China's imminent expansion into digital consumer equipment and broadcast. In addition to audio's slow growth, Dataquest expects a personal electronics maturation on a revenue basis in China/Hong Kong. Personal electronics and audio equipment will expand at a 7 percent to 8 percent CAGR from 1997 to 2002, while video will expand by 12 percent.

Home appliance production is the fastest-growing segment of the consumer electronics industry. Production will reach $6.2 billion in 1998 and will expand at a 16 percent CAGR at $10 billion by 2002. Dataquest's outlook for continuous and expanding growth is tied mainly to the belief that the economy, as indicated by GDP, will average 6 percent to 8 percent growth during this period. New areas of economic development will absorb local production. Wealthier urban areas will continue to upgrade their to new gadgets, such as air conditioners, heaters, or dehumidifiers. Furthermore, Dataquest's survey of producers discovered a high percentage of exported consumer electronics production by multinational companies, as discussed later in the chapter.

Color Television Production Forecast

Dataquest's survey covered 14 major color television (CTV) manufacturers in China/Hong Kong, which combined to account for 85 percent of total production in 1997.

Table 5-1 lists these companies' unit output in ranking order according to production share. Changhong Electric Appliances Company is, by far, the industry leader, accounting for a whopping 28 percent of all China/Hong Kong CTV production. The company is the technology and manufacturing leader in China/Hong Kong, which is why it continues to gain production share as well as local market share. In China/Hong Kong, as elsewhere in the world, the large manufacturers are consolidating their leadership through superior operational efficiency from production to marketing and distribution. The top five manufacturers in China/Hong Kong control 64 percent of total production.

Table 5-2 provides Dataquest's company-level forecast for CTVs in 1998 and 1999. Dataquest sees a clear drop in industry output in 1998 and 1999 primarily attributed to worsening economic conditions in China/Hong Kong, rising unemployment, and consumer pessimism about future employment and the economic growth of China. Because Dataquest does not have 1997 data for all 14 companies, a comparison of the seven companies surveyed in 1996 and 1997 will be done instead. These seven manufacturers are estimated to have a combined annual production expansion of 40 percent in 1997. In 1998, these same seven companies are forecast to have only a 10 percent production, but Dataquest expects improvement in 1999 and forecasts a 15 percent year-on-year unit growth.

Color television production represented approximately 55 percent of the consumer video segment (as illustrated in Figure 5-2) in 1997 and will grow to a 67 percent share by 2002. Dataquest has mentioned that consumer video is forecast to grow by 12 percent from $6 billion in 1997 to $11 billion in 2002. Color television factory revenue is forecast to grow at a 17 percent CAGR, from $3 billion in 1997 to $7.1 billion in 2002. Semiconductor consumption in the CTV market segment will grow from $400 million in 1997 to $1.2 billion in 2002, a 23 percent CAGR (see Table 5-3).

The relatively large proportion of multinational manufacturers, with the exception of Changhong, adds to China's production prowess in that a large percent of CTVs are exported. Dataquest expects export success to help boost the industries' long-term growth, and the government will likely support about five major manufacturers by providing export incentives.

Video Compact Disc Players (VCDs)

Table 5-4 presents the 10 large VCD manufacturers' units and production share in 1996 and 1997, which combined to account for 68 percent of China's total unit output in 1997.

China's VCD player market follows a typical product life cycle: It has gone through the introduction stage and high-growth stage and is now approaching the maturity stage. The declining stage will start in 1999 when DVD players begin to penetrate the market.

Table 5-4
Video Compact Disk (VCD) Player Manufacturers Production Share and Ranking, 1996 and 1997 (Thousands of Units)

Source: Dataquest (August 1998)

At the current maturity stage, manufacturers are competing on prices to achieve volume and fighting for market shares. Efforts are being put into efficiency and cost reduction. Meanwhile, market leaders such as Jiangsu province's Jiangsu Shinco Electronic Group Company and Guangdong Idall Co. Ltd. are advertising heavily to emphasize brand differentiation and special product features. Manufacturers extend the product life by means of incorporating more functions into their VCD players. Built-in karaoke functions are now a standard. Other choices are integrated VCD hi-fi systems, multidisk changers, and two-in-one TV/VCD sets. There are also many manufacturers that are concerned with improving the picture quality. Table 5-5 presents China/Hong Kong's VCD production forecast by vendor.

The top five VCD player makers are all Chinese brands; they combine to account for 53.6 percent of the total VCD player market. About one-fifth of this market is occupied by the largest market leader, Jiangsu Province's Shinco. The top three manufacturers occupy nearly half of the overall player market.

In view of the VCD player market's explosive growth, many manufacturers want to share the piece of the pie that belongs to the leading manufacturers. The television giant, Changhong Electronic Group Co., has planned to expand its VCD player production capacity from 400,000 units to 3 million units in 1998.

Taiwanese makers are also eyeing China's VCD player market. The Acer Group and Sampo Corporation are both supplying VCD technology and OEM kits to their Chinese partner for assembly. Their ultimate goal, however, is to make and distribute DVD players to this market.

Source: Dataquest (August 1998)

Table 5-6 presents Dataquest's long-term forecast of China/Hong Kong's VCD production, which shows accelerating growth and then decline because of maturation and the introduction of DVD replacement technology. CCD players have been proliferating in the Chinese market for some simple reasons. The hardware is cheap and simple in technology. VCD players combine CD players with a MPEG decoder to produce acceptable video-playing capabilities. The majority of manufacturers get key components from a few suppliers: Sony Corporation and Philips for CD mechanisms, and C-Cube Microsystems Inc. and ESS Technology Inc. for decoding chips.

The proliferation of private software has fueled the demand for China's VCD market. The intellectual-copyright concept is still weakly understood among Chinese consumers. They can easily get low-cost pirate software or even rent VCD movies at a cost below U.S.$1 in some cities. The third reason is the lack of an installed base of VCRs and audio CDs in China. The popularity of color TV and karaoke among the Chinese has also contributed to the strong demand of VCD players.

In terms of the substitution by DVD players, the price and software gap will lengthen the time needed for DVD players to take off in the market. Although DVD players provide consumers with high-quality pictures and sounds, better performance, and a wider range of features, Chinese consumers do not currently have the purchasing power to buy them. The higher price is not the only barrier for DVD players to enter the China market. Consumers are concerned about the limited availability of DVD titles that cost much more than VCD titles. Also, the existing color television sets, limited by 350-line, cannot produce a high-resolution effect required by DVD players.

On the other hand, the DVD player emergence will encourage VCD player manufacturers to improve the quality of their VCD products. Because of the backward compatibility of DVD players, VCD software will still prevail, unless DVD titles' prices can match. VCD players will be able to survive in the presence of DVD players until 2001 when a precipitous decline is expected.

Table 5-6
VCD Player Production Forecast in China/Hong Kong, 1996 to 2002

Video Cassette Recorders (VCR)

Table 5-7 presents Dataquest's list of surveyed VCR manufacturers and their respective production volume and industry share. Dataquest's survey of five manufacturers represents 42 percent of combined production units. These companies appear to be increasing production share, while smaller manufacturers are exiting the market.

Table 5-8 presents these five manufacturers' 1998 and 1999 production plans. The VCR industry is a mature but lingering market. Slow growth but large-scale production is sustained by a large infrastructure of inexpensive tapes and demand from remote regions where VCDs and media are not readily available. Nevertheless, because of China's population advantage, there will be growth, but less than 4 percent in units for the next five years. In addition, revenue is expected to contract (see Table 5-9).

Table 5-7
VCR Manufacturers Production Share and Ranking, 1996 and 1997 (Thousands of Units)

Personal Stereo

Personal/portable stereo production of $655 million in 1997 accounted for only 9 percent of total audio equipment production in China/Hong Kong. Dataquest's survey of personal stereo manufacturers represented only 2.9 percent of total personal/portable stereo equipment production in this highly dispersed market segment. Personal stereo was one of the earliest consumer electronics markets to grow since China's economic reform and "open door" policy took hold in mid-1980s. Now this market is plagued by overcapacity and efficient state-owned enterprises that will undergo consolidation in the next five years. Table 5-10 shows personal/portable stereo manufacturers' ranking and market share in China/Hong Kong.

Table 5-10
Personal / Portable Stereo Manufacturers Production Share and Ranking, 1996 and 1997 (Thousands of Units)

Rank 1996	Rank 1997	Company	1996	1997	Production Share (%) 1996	Production Share (%) 1997	Accumulated Share (%) 1996	Accumulated Share (%) 1997

Source: Dataquest (August 1998)

©1998 Dataquest

Table 5-11 presents 1998 and 1999 forecasts for these major multinational vendors. Samsung and LG Electronics are the only two companies that expanded in 1997, while the others' production remained flat. Most manufacturers show a clear slowing trend in 1998 and 1999 because of difficult market conditions.

Dataquest's long-term industry outlook is shown in Table 5-12. Dataquest expects personal and portable stereo shipments to grow approximately 5 percent in the next five years, like other mature electronics equipment markets in China. China/Hong Kong's estimated 33 million units will increase at a rate slower than GDP growth to 42 million units in 2002. Semiconductor consumption in this segment will climb only 3 percent from $200 million in 1998 to $260 million in 2002.

Camcorders

Analog camcorders are providing new growth opportunities for consumer electronic equipment manufacturers in China/Hong Kong. Dataquest's survey of Sony and Hitachi Ltd. found that these multinational manufacturers are rapidly expanding production capacity in China/Hong Kong and are taking advantage of the local market to absorb their production. As shown in Table 5-13, both companies rapidly expanded production in 1997, by a whopping 350 percent, from 78,000 units in 1996 to 275,000 in 1997. Dataquest estimates that this combined production volume represents 94 percent of total personal and portable stereo production.

Table 5-14 provides Sony's and Hitachi's production outlook in 1998 and 1999, which is leveling off after 1997's surge in capacity. Sony will expand unit production from 220,000 units per year to 260,000 units per year in 1999, a 14 percent growth rate. Hitachi will expand from 90,000 units in 1998 to about 120,000 units in 1999, a 33 percent growth rate.

For the long term, China/Hong Kong's camcorder production will surge because of a strong market demand, and Dataquest expects new manufacturers to enter this industry after technology becomes readily available. Table 5-15 provides Dataquest's long-term forecast of camcorder production and semiconductor consumption from 1997 to 2002.

Chapter 1
Executive Summary

The purpose of this Market Trends report is to provide a comprehensive view of the semiconductor product markets in China/Hong Kong and their outlook from 1998 to 2002. Dataquest has provided an in-depth analysis of key market trends from 1993 to 1997, including its final 1997 market share ranking.

Dataquest believes that the major conclusions of this China/Hong Kong semiconductor market study are as follows:

- Final vendor and market estimates indicate that the China/Hong Kong semiconductor market grew 19.5 percent to $6,769 million in 1997, for a growth rate nearly double that of Asia/Pacific.
- Texas Instruments Inc. (TI) was the fastest-growing company among the top 10 vendors because of its strength in digital signal processor (DSP) and analog shipments. A 39 percent growth enabled it to move from No. 9 to No. 7 in overall revenue, capturing 4.2 percent of the China/Hong Kong market.
- Intel Corporation and Toshiba Corporation remained the dominant semiconductor suppliers, with 10.1 percent and 9.4 percent of the market. Intel's growth slowed to 23 percent in 1997 because of increased competition, but its growth still outpaced the average market growth. Toshiba's revenue increased by a remarkable 26 percent as the company aggressively marketed non-DRAM products.
- At the positive growth end, the MOS logic market expanded 38 percent, and microcomponents expanded 36 percent. Healthy growth in commodity analog and discrete parts further contributed to the total market rebound.
- China/Hong Kong's MOS memory market further declined 15 percent in 1997 after contracting 26 percent in 1996, but this was less severe than the Asia/Pacific and worldwide contraction, which declined by 19 percent. Memory shipments were surpassed by microcomponents as China/Hong Kong's largest market segment in 1996.
- Growth was led by data processing markets that expanded 24 percent to $2.7 billion, which was 41 percent of total semiconductor consumption in China/Hong Kong. Consumer electronics recovered with a 20 percent growth, after sluggish growth in 1996.
- Personal computer production in China by both foreign and domestic manufacturers nearly doubled to 2.2 million in 1997 and will expand by more than 40 percent in the next two years. China's PC consumption is forecast to grow by more than 40 percent per year for the next three to five years. China (excluding Hong Kong) expanded its lead as the largest PC consumer in Asia/Pacific with a more than 30 percent share of PC shipments.

©1998 Dataquest

- The consumer electronic recovery was led by VCDs, which jumped from 5.8 million to 14.7 million units in 1997. The color TV industry also improved its performance, as production growth had slowed to 8 percent in 1996, but expanded by 10 percent in 1997. Because China produces approximately 20 percent of the world's color televisions, this sector's performance is critical to China's overall consumer electronics growth.
- More mature stereo equipment industries declined 13 percent, but Dataquest expects overall home appliances—such as microwave ovens and air conditioners—to continue to show growth that is consistent elsewhere in the world with economic growth and rising disposable income.
- Consumer electronics will experience a revival in the next five years, as products with high appeal and affordable prices—such as DVDs, digital set-top boxes, and digital cameras—will be produced in China. Already, Dataquest has seen market movement and standards, which, as in the past, led foreign manufacturers to set up production in China.
- Dataquest's varied sources of economic data indicate slower economic growth than previously forecast because of the unexpected Asian financial crisis. The gross domestic product (GDP) growth forecast for 1998 is lowered to 6.5 percent from 8 percent. Unemployment and potential labor unrest are the Chinese government's major concerns, so the reform of money-losing state-owned enterprises will be more cautious, and fiscal policy will become more conservative.
- The domestic market is expanding faster than electronics producers' exports. China exported approximately 65 percent of its electronic equipment output in 1996 and 52 percent in 1997. Exports will continue to play a key role in the electronic industry's growth. But multinational companies manufacturing in China, as a whole, are developing local sales capabilities faster than they are growing exports. Therefore, Dataquest forecasts China to export less than 50 percent of what it produces by 2002.
- Dataquest forecasts the China/Hong Kong semiconductor market to expand at a compound annual growth rate (CAGR) of approximately 21 percent from 1997 to 2002, compared with the forecast Asia/Pacific growth of approximately 16 percent. This represents a reverse from the previous five years when China/Hong Kong underperformed relative to the market.
- China/Hong Kong's semiconductor consumption is led by strength across multiple segments, especially in microcomponents and analog, which are forecast to grow at a 24 percent and 25 percent CAGR, respectively.
- China/Hong Kong's electronic production is expected to rise from $46 billion in 1997 to $98 billion in 2002, with a 16 percent CAGR, leading all Asia/Pacific countries.

 ©1998 Dataquest

- Suppliers with electronic equipment facilities in China/Hong Kong continue to outperform importers by a significant margin. Consequently, China experienced an unprecedented number of investments from semiconductor companies in 1996 and capacity expansion in 1997. Investments and production capacity growth will slow in 1998 to allow the market to absorb current investnents.
- Current announced investments in wafer fab capacity in China will not alleviate China's dependence on imported semiconductors until after 1999. China/Hong Kong's semiconductor industry produced less than 10 percent of what it consumed in 1997. Further expansion will be moderate because of global overcapacity. With several new capital expenditure plans, China/Hong Kong will probably fabricate or assemble about 15 percent of its semiconductor market's value by 2001.

Project Analyst: Daniel Heyler

Chapter 2
Introduction

This Market Trends report on China/Hong Kong presents Dataquest's market data, competitive ranking, and forecast analysis of this major semiconductor market.

This report investigates the dynamics behind consumption growth in China/Hong Kong's dynamic and diverse markets. After Dataquest presents an analysis of historical growth and identifies key market trends in Chapter 3, it analyzes suppliers in each major semiconductor segment in Chapter 4. Chapter 5 provides Dataquest's long-term forecast and analysis of each semiconductor device market from 1998 to 2002. The following summarizes this report's structure:

- **Introduction** (Chapter 2)—Introduction, methodologies, and definitions.
- **Market trends** (Chapter 3)—Dataquest assesses the current market and identifies long-term structural trends. We present five years of device and application history and summarize key developments in 1997 and 1998. We also compare and contrast these trends with the rest of Asia/Pacific.
- **Supplier analysis** (Chapter 4)—Dataquest's competitive ranking and analysis of the revenue and market share of the top 30 suppliers worldwide are presented for each major semiconductor product area.
- **Market forecasts** (Chapter 5)—Dataquest forecasts semiconductor devices and key equipment drivers the market.

Economic Assumptions

The section highlights the key economic assumptions and Dataquest's long-term forecast assumptions.

The Next Stage of Economic Restructuring

China's economic transformation, which started 15 years ago, accelerated after the death of reform architect Deng Xiao Ping and the consolidation of power by Jiang Zemin. The focus remains on economic growth to absorb displaced workers from the restructuring or closing of state-owned enterprises. Political reform (within the current single-party system) is also an element of this next stage of reform, which is leading to stronger institutions for a 21st-century, politically practical China. The first and most important move is to build a more efficient bureaucracy, as current administration of vital functions remains backward and inhibits growth.

In March, Beijing said it would abolish or merge 15 ministries and shed 4 million government jobs in a three-year period. The cuts will begin at the central government this year and spread to the provinces next year. The government also intends to reduce the links between bureaucrats and companies. Consequently, analysts believe companies that lose valuable connections in the bureaucracy—those controlled by the central government and those that have their controlling departments dismantled—will become most vulnerable.

©1998 Dataquest

China has failed several times to trim its bureaucracy and cut the links between state enterprises and the government departments, which are their supervisors. But analysts are taking Premier Zhu Rongji's steps to reshape the government more seriously because he has an excellent record in forcing through reforms in other areas, such as taxation.

Increased IT Usage: Privatized Enterprises to Benefit Information Industry

In addition to some major state-run enterprises, Dataquest believes that small, medium-size, and large nonstate ("privatized") enterprises with high technology also play a positive role in China's electronic information industry. Nonstate enterprises usually did not have large amounts of funds when they were founded, but some of them have developed rapidly into major enterprises in the information industry by depending on advanced technology.

Government statistics indicate that 80 percent of the 52 state-level and 58 provincial high-tech development zones grew from nonstate enterprises, many of which are involved in electronic information businesses. The government's vision is promising in that it appears to identify the necessity to build China as a knowledge-based economy and will construct the infrastructure to facilitate this goal.

Growth Engines after the Asian Financial Crises Favor China

Asia will bounce back, slowly and unevenly. But the next boom—and there will be a next boom—won't look like the previous one. The cost of Asia/Pacific's financial and currency crashes of the past 10 months has been extremely great. In fact, according to the latest *World Economic Outlook*, the International Monetary Fund (IMF) looked at what happened before and after nearly 200 currency and banking crises. The news isn't good for Asia's worst-hit countries. In the past, the economic damage was greatest in countries such as South Korea, Indonesia, and Thailand, which were unfortunate enough to have banking, currency, and foreign-debt crises at the same time.

The repair bills in the worst-hit Asian countries—measured in lost output and government spending for bank restructuring—will likely make this crash among the most expensive anywhere in the past 25 years. Economists estimate that bank bailouts will cost taxpayers in Indonesia, Thailand, and South Korea an amount equal to 20 percent or more—perhaps much more—of one year's GDP. Lost economic output could equal another 30 percent of one year's GDP in Indonesia, less in Thailand and South Korea.

Education, for example, is a key concern for a few Asian nations, according to the Asian Development Bank (ADB). Thailand and Malaysia aren't producing the university graduates that at their level of development they need, the ADB says in a special chapter of its latest *Asian Development Outlook*. That's a potentially serious problem because Thailand and Malaysia need to stay one step ahead of the lower-cost countries, such as China, according to the ADB. China's education level is very high and rising faster than elsewhere in the region.

Such weaknesses in numerous countries highlight the likelihood that while boom may come back to Asia, not all Asian countries will necessarily experience the boom. After all, the so-called Asian miracle—the *East Asian* miracle, to be specific—was never a regionwide phenomenon.

Asia caught a couple of lucky breaks in the previous downturn. The Group of Seven industrialized countries decided in 1985 that the Japanese yen was undervalued. The Plaza Accord pushed the yen sharply higher, and the soaring yen, in turn, spawned a rush by Japanese manufacturers to invest in cheaper locales overseas. At roughly the same time, the U.S. personal computer industry was primed for a takeoff. Malaysia, Singapore, and Taiwan reaped the gains as the PC industry accelerated.

But in 1998, Japan's economy became severely impaired and it, in turn, hurts the rest of Asia/Pacific. Falling PC prices are squeezing suppliers in Asia. Asia's richer developing countries face an additional problem that was still over the horizon in 1985 everywhere except Japan: Growing fast gets more difficult the more one grows.

As a region, however, Asia's potential growth rate remains higher than Latin America's and Eastern Europe's largely because Asia is still poorer overall and more populous. Furthermore, China is very much a consumer society, and one needs only look at Taiwan and Hong Kong societies to forecast the future earning power and consumption growth of China. Asia's potential or growth rate "trend" is about 6 percent a year, economists say. (Estimates range from 5 percent to 7 percent.) Latin America's growth rate trend is 5 percent or so, and Eastern Europe's is perhaps a little less.

Currency and Exchange Rates

The currency devaluation created critical problems for Asia/Pacific semiconductor suppliers and users that are almost entirely dependent on imports. Although most vendors denominate their prices in dollars, cash-flow problems—attributed to rising credit costs and falling sales—have resulted in a weakened demand from local manufacturers. Indonesia's currency devalued more than 80 percent during the past six months, and its equity market dropped more than 80 percent. As a result of the financial turmoil, stock markets in Korea, Thailand, the Philippines, and Malaysia declined by more than 60 percent. Equity markets in China and Hong Kong have also shrunk, but their strong cash account reserves have enabled them to support the Hong Kong dollar and the Chinese renminbi.

Few economists expect a devaluation in 1998, but there are concerns in the region that falling exports and a slowing economy will force China to devalue, potentially sparking another round of disastrous currency depreciation in Asia. It is a question of time. For sure, China will devalue, but whether it is before or after the region has recovered is the issue. In 1998, the Chinese government is under extreme pressure to maintain strong economic growth and create new jobs because of the dismantling of state-owned industries, which is creating millions of surplus workers. So far, the Chinese leadership has responsibly held its currency at the expense of economic growth, in addition to committing U.S.$250 billion in infrastructure spending projects to increase GDP vis-à-vis domestic consumption.

Actual exchange rates for the major countries in Asia/Pacific are detailed in Table 2-1. The exchange rates are applied to all historical figures. In conducting worldwide market forecasts, Dataquest uses constant exchange rates across all regions.

Table 2-1
Asia/Pacific Exchange Rate against the U.S. Dollar, 1993 to 1997

Currency	1993	1994	1995	1996	1997	U.S. Dollar Appreciation (%) 1996 to 1997
China (Renminbi)	5.76	8.54	8.35	8.34	8.32	-0.24
Hong Kong (Dollar)	7.74	7.73	7.74	7.73	7.74	0.13
India (Rupee)	30.84	31.15	32.38	35.52	36.36	2.36
Malaysia (Ringgit)	2.58	2.62	2.51	2.52	2.82	11.90
Singapore (Dollar)	1.62	1.53	1.43	1.41	1.49	5.67
South Korea (Won)	799.52	802.84	770.57	805.16	954.14	18.50
Taiwan (Dollar)	26.16	26.45	26.48	27.47	28.79	4.81
Thailand (Baht)	25.31	25.36	24.91	25.36	31.07	22.52

Source: Dataquest (July 1998)

Inflation was also sharply reduced in China since 1996, but economic growth has also slowed from double-digit to single-digit growth, and inflation has increased to double-digit levels according to unofficial estimates. After the international accounts of many countries taking a severe beating in 1996, governments and banks were unable to stop the spiral by drastically underestimating the depth of numerous countries' financial troubles. Moreover, the crisis exposed the financial excesses of overly rapid growth throughout the region. Poor financial judgment and overextension are easily hidden and covered when economies expand rapidly. But when economies face a downturn, poor financial decisions are exposed and can pose a menacing threat to renewed economic growth.

GDP Forecast Lowered

Most banks had forecast China's GDP to grow between 7.5 percent and 8.0 percent in 1998 and 1999. However, because of the region's worsening economies, slowing exports, and yen depreciation, the economy is expected to fall between 6.5 percent and 7.5 percent. China's GDP in the first quarter of 1998 had slowed to 7.2 percent and was expected to slow to 7.0 percent in the second quarter. The trend is expected to continue, with the second half of 1998 averaging less than 7 percent. One of the advantages China has over the rest of Asia/Pacific is that its economy is far more diversified, with economic expansion taking place in heavy industries, manufacturing, electronics, services, and agriculture. This broad-based growth, including within electronics, has come as an important buffer to Asia's economic woes. In fact, the major growth burden has been from the state-owned enterprises (SOEs) that account for about 60 percent of the economy. Prime Minister Zhu Rongji is in the process of structuring SOEs, which is the main factor behind slower growth and rising unemployment. However, China depends heavily on foreign capital and foreign markets to sustain its current growth rate.

 ©1998 Dataquest

Foreign Investment Affected Moderately

Economic growth and improved output in manufacturing in China will continue to be the result of increased efficiencies within the non-SOEs and direct foreign investment by foreign or joint-venture companies. Foreign investments need to continue to flow into China for it to achieve a 7 percent GDP growth. Hong Kong, which has been hurt financially by its falling stock market, accounted for 59 percent of foreign-invested capital in China from 1980 to 1997. In the past few years, contracted investments in China had declined from $88 billion in 1994 to $72 billion in 1997. However, the actual utilized investment increased from $33 billion to $44 billion during this period. There is uncertainty in 1998, and most forecasts indicate a decline in utilized investments to $35 billion for the first time in at least five years.

Dataquest also expects contracted investments to decline because of the investor uncertainty, a short-term outcome of China's aggressive reforms to be undertaken in 1998. However, once the dust settles, investment flow is expected to resume in 1999 because the current slowdown is macroeconomic rather than microeconomic in nature. In the first quarter of 1998, figures show a growth of more than 10 percent over the 1997 level, but the second quarter is expected to decline. However, Dataquest continues to see communications, computer, and consumer electronic companies maintain a high strategic interest in investing in manufacturing in China for long-term needs: to increase market access, reduce distribution costs, and improve time to the market.

Exports Down but Not Dramatically

China's GDP will exceed $900 billion in 1998, yet its total trade is nearly $400 billion. China's export machine has proved to be a formidable global force, particularly in the past three years. The economy's trade surplus was expected to increase beyond $50 billion in 1998 prior to the financial crisis, but as the result of the financial crisis, it is expected to decrease to the $30 billion range. The first two months of 1998 show exports to the United States to be at the same levels as 1997, while imports are slightly down.

China is exposed to the Asian financial crisis by about 11 percent because 11 percent of its exports go to Southeast Asia and Korea. In the past few years, China's exports to Japan have declined to about 15 percent of total exports, but exports to Europe, North America, and Taiwan increased to more than 60 percent. Based on export exposure, a dramatic trade downturn, as experienced by the rest of Asia, is not likely. The free-falling yen was clearly a threat, but China still holds a (dangerous) wildcard: devaluing the renminbi. So when China hinted at devaluing its currency as the yen collapsed without response, the United States and Japan quietly negotiated overnight to support the yen.

Semiconductor Market Segmentation and Shipment Definitions

Dataquest publishes a complete set of product, application, and regional definitions for its semiconductor clients. This section provides a synopsis for easy reference.

Dataquest surveys semiconductor vendors to estimate market sizing and growth. The survey covers 151 semiconductor vendors worldwide (this number varies according to mergers, acquisitions, liquidation, start-ups, and so on), by 61 individual semiconductor product categories (excluding subtotals) and five world regions (Asia/Pacific is split into five subregions). This report contains market share rankings for the China/Hong Kong region that were compiled in May 1998. The Asia/Pacific subregional data is published in April.

The categories for which semiconductor revenue is reported are defined comprehensively for the purposes of clarity and guidance to survey participants. These definitions may occasionally be revised, altered, or expanded to reflect changes in the industry. To support these definitions, Dataquest issues an annual survey guide to all participants in its semiconductor market share survey program. Dataquest's definition of shipments are as follows:

- **Sales to customer**—All sales are reported according to customer location—that is, the shipping destination. The four regions that Dataquest recognizes are the Americas; Japan; Europe, the Middle East, and Africa; and Asia/Pacific. Further breakdowns of Asia/Pacific and Europe are also conducted for data verification purposes.
- **Finished semiconductor products**—Assembled and tested semiconductor products. Only count sales of finished semiconductor products to distributors and equipment manufacturers. Do not include sales of finished semiconductors to other semiconductor vendors for value-added resale. Resale revenue will be estimated separately for these companies. Also, only count sales made by an overseas subsidiary to a distributor or equipment manufacturer, as opposed to counting sales from headquarters to an overseas subsidiary.
- **Unfinished semiconductor products**—Wafer and die foundry products. Only count sales of unfinished semiconductor products to distributors and equipment manufacturers. Do not include sales of unfinished semiconductors to other semiconductor vendors for resale. Resale revenue will be estimated separately for these companies. Also, only count sales made by an overseas subsidiary to a distributor or equipment manufacturer as opposed to counting sales from headquarters to an overseas subsidiary.
- **Internal semiconductor sales**—Defined as revenue from finished or unfinished semiconductor products from intracompany (internal) transfers to divisions of the company and/or subsidiaries of the parent company that manufacture end equipment. Internal semiconductor sales are classified as in-house sales or captive sales, depending on whether this company sells semiconductors on the merchant market.

 ©1998 Dataquest

- **In-house semiconductor sales**—Defined as internal semiconductor sales if the company also sells semiconductors on the merchant market. Count all in-house semiconductor sales at market prices. Market price is defined as the price at which the same or equivalent product is sold to equipment manufacturers.
- **Captive semiconductor sales**—Defined as internal semiconductor sales if the company does not sell semiconductors on the merchant market. Do not include captive semiconductor sales.
- **Hybrid ICs**—Integrated circuits that include a semiconductor die (one or more) with other passive components in a single IC package. Hybrids are so named because they are technology *hybrids*, mixing semiconductor chips with thin/thick film resistors and chip capacitors. Multiple-chip ICs are not considered hybrids and are counted as monolithic ICs.
- **Multichip modules**—Semiconductor-based functions that include more than one semiconductor device. These may be mounted on a silicon printed substrate, polymide multilayer printed substrate, or a printed circuit board (PCB). Only count sales of multichip module (MCM) products and board-level products that conform with the definitions for "finished semiconductor products" or "unfinished semiconductor products." Multichip ICs such as MCMs are not considered hybrids and are counted as monolithic ICs.
- **System-level products**—Products that comprise a number of module and/or board-level products amounting to a single system or subsystem. Examples include development systems, hardware platforms, and box-level products. Do not include any sales from such system-level products.
- **Nonrecurring engineering charges**—Nonrecurring engineering (NRE) charges made to customers as the result of costs incurred during the design or customizing of a semiconductor device for that customer. Only count NRE charges when they occur in the following product areas:
  - Design charges for ASICs including gate arrays, cell-based ICs (CBICs), and full-custom ICs
  - Mask charges that result from the customizing of a programmable array logic (PAL), when the customer's fuse pattern is masked into it to produce a hard-wired array logic (HAL)
  - Mask charges that result from the customizing of ROMs
  - Mask charges that result from the storage of the customer's program in a microcontroller
- Only count revenue from NRE charges on active semiconductor products that conform with the definitions for "finished semiconductor products" or "unfinished semiconductor products." Include these NRE charges as part of the revenue received from associated semiconductor products. Do not include revenue from NRE charges incurred during research, feasibility studies, or facility rental to third parties.

- **Electronic design automation software**—Electronic design automation (EDA) software is used to automate the design of semiconductors. Dataquest includes revenue from ASIC semiconductor vendors that also sell their own EDA software. Include any revenue derived from EDA software in the appropriate ASIC product category. The applicable categories are programmable logic device (PLD), gate array, and CBIC.
- **IPR income**—Intellectual property rights (IPRs) income from royalties, licensing agreements, technology transfers, and dispute settlements. Do not include any such IPR income.

Market Segmentation

This section outlines the market segments that are specific to this document. Dataquest's objective is to provide data along lines of segmentation that are logical, appropriate to the industry in question, and immediately useful to clients.

Dataquest defines the semiconductor industry as the group of competing companies primarily engaged in manufacturing semiconductors and related solid-state devices. Important products of the semiconductor industry include integrated circuits, discrete devices, and optoelectronics devices.

For market share purposes, Dataquest defines the semiconductor market according to the following functional segmentation scheme:

- Total Semiconductor (including Hybrids)
- Total Semiconductor (excluding Hybrids)
  - Total Monolithic Integrated Circuit (including Hybrids)
  - Total Monolithic Integrated Circuit (excluding Hybrids)
    - Bipolar Digital IC
      - Bipolar Logic
      - Other Bipolar Memory/Microcomponent/Logic
  - MOS Digital IC
    - MOS Memory
    - MOS Microcomponent
    - MOS Logic
  - Monolithic Analog IC
  - Hybrid IC
  - Discrete Semiconductor
  - Optoelectronic Semiconductor

©1998 Dataquest

Definitions

This section lists the definitions that are used by Dataquest to present the data in this document. For a complete listing of all semiconductor market segments tracked by Dataquest, please refer to the Dataquest Semiconductor Market Definitions Guide.

Product Definitions

- Total semiconductor (total monolithic integrated circuit + total discrete + total optoelectronic)—An active semiconductor product that contains semiconducting material (such as silicon, germanium, or gallium arsenide, but excluding ceramics) and reacts dynamically to an input signal, either by modifying its shape or adding energy to it. This definition excludes standalone passive components, such as capacitors, resistors, inductors, oscillators, crystals, transformers, and relays.
- Total monolithic integrated circuit (digital monolithic bipolar IC + digital monolithic MOS IC + analog IC)—An IC is defined as a large number of passive and/or active discrete semiconductor circuits integrated into a single package. A monolithic IC is one in which discrete circuits are integrated onto a single die.
- Bipolar digital IC (bipolar digital memory + bipolar digital microcomponent + bipolar digital logic)—A monolithic semiconductor product in which 100 percent of the die area performs digital functions and 100 percent of the die area is manufactured using bipolar semiconductor technology. A digital function is one in which data-carrying signals vary in discrete values.
- Bipolar digital logic (bipolar application-specific IC + bipolar digital standard logic + other bipolar logic)—A bipolar digital semiconductor product in which more than 50 percent of the die area performs logic functions. This definition excludes bipolar digital microcomponent ICs.
- Other bipolar digital memory/microcomponent/logic—A bipolar digital semiconductor product in which binary data is stored and electronically retrieved. This definition includes ECL random-access memory (RAM), read-only memory (ROM), programmable ROM (PROM), last-in/first-out (LIFO) memory, and first-in/first-out (FIFO) memory. Not included are products made with mixed bipolar CMOS (that is, BiCMOS) with transistor-transistor logic (TTL) or emitter-coupled logic (ECL) outputs, which are classified as MOS.
- MOS digital IC (MOS digital memory + MOS digital microcomponent + MOS digital logic)—A monolithic semiconductor product in which 100 percent of the die area performs digital functions, and, concurrently, where any portion of the die area is manufactured using metal oxide semiconductor (MOS) technology. A digital function is one in which data-carrying signals vary in discrete values. This definition includes mixed technology manufacturing, such as BiMOS and BiCMOS, where there is some MOS technology employed.
- MOS digital memory (DRAM + SRAM + EPROM + EEPROM + flash memory + mask ROM + other MOS digital memory)—A MOS digital IC in which binary data is stored and electronically retrieved
- MOS digital microcomponent IC (MOS digital microprocessor + MOS digital microcontroller + MOS digital microperipheral + programmable digital signal processor)—A MOS digital IC that contains a data processing unit or serves as an interface to such a unit

 ©1998 Dataquest

- MOS digital logic IC (MOS digital logic application-specific IC + MOS digital standard logic IC + other MOS digital logic IC)—A MOS digital IC in which more than 50 percent of the die area performs logic functions. This definition excludes MOS digital microcomponent ICs.
- Total analog IC (amplifier/comparator IC + voltage regulator/reference IC + data converter/switch/multiplexer IC + interface IC + telecom IC + disk drive IC + other special-function IC + linear array/ASIC + mixed-signal ASIC + total special consumer IC + special automotive IC + smart power IC)—A semiconductor product that deals in the realm of electrical signal processing, power control, or electrical drive capability. It is one in which some of the inputs or outputs can be defined in terms of continuously or linearly variable voltages, currents, or frequencies. This definition includes only monolithic analog ICs manufactured using bipolar, MOS, or BiCMOS technologies. A monolithic IC is a single die contained in a single package.
- Hybrid integrated circuit—A semiconductor product consisting of more than one die contained in a single package. A hybrid IC may perform 100-percent linear, 100-percent digital, or mixed-signal (both linear and digital) functions. This definition includes hybrid implementation of all monolithic IC functions described in the following categories, and includes all hybrid ICs manufactured using bipolar, MOS, or BiCMOS technologies.
- Total discrete (transistor + diode + thyristor + other discrete)—A unit building block performing a fundamental semiconductor function
- Total optoelectronic (LED lamp/display + optocoupler + CCD + laser diode + photosensor + other optoelectronic)—A semiconductor product in which photons induce the flow of electrons, or vice versa. Other functions may also be integrated onto the product. This category does not include LCD, incandescent displays, fluorescent displays, cathode ray tubes (CRTs), or plasma displays.

Regional Definitions

Asia/Pacific

Includes Hong Kong, Singapore, South Korea, Taiwan, Australia, Bangladesh, Cambodia, China, India, Indonesia, Laos, Malaysia, Maldives, Myanmar, Nepal, New Zealand, Pakistan, the Philippines, Sri Lanka, Thailand, and Vietnam

Line Item Definitions

- Factory revenue—The money value received by a semiconductor manufacturer for its products. Revenue from the sale of semiconductors sold either as finished goods, dies, or wafers to another semiconductor vendor for resale is attributed to the semiconductor vendor that sells the product to a distributor or equipment manufacturer.
- Merchant versus captive consumption—All revenue, both merchant and captive, for semiconductor suppliers selling to the merchant market. The data excludes completely captive suppliers where devices are manufactured solely for the company's own use. A product that is used internally is valued at market price rather than at transfer or factory price.

Unless otherwise specified, the amounts given in this report are in U.S. dollars.

Chapter 3
Semiconductor Market Trend Analysis

Last year, Dataquest observed that "Asia/Pacific semiconductor consumption is rapidly changing, and the dynamics are likely to continue to favor China/Hong Kong for the next five years." This statement proved true in 1997, as China/Hong Kong semiconductor consumption exactly matched Dataquest's forecast of approximately 20 percent growth, while the rest of Asia/Pacific grew 8.3 percent. This chapter examines China/Hong Kong's semiconductor market trends and compares this region with the other parts of Asia/Pacific.

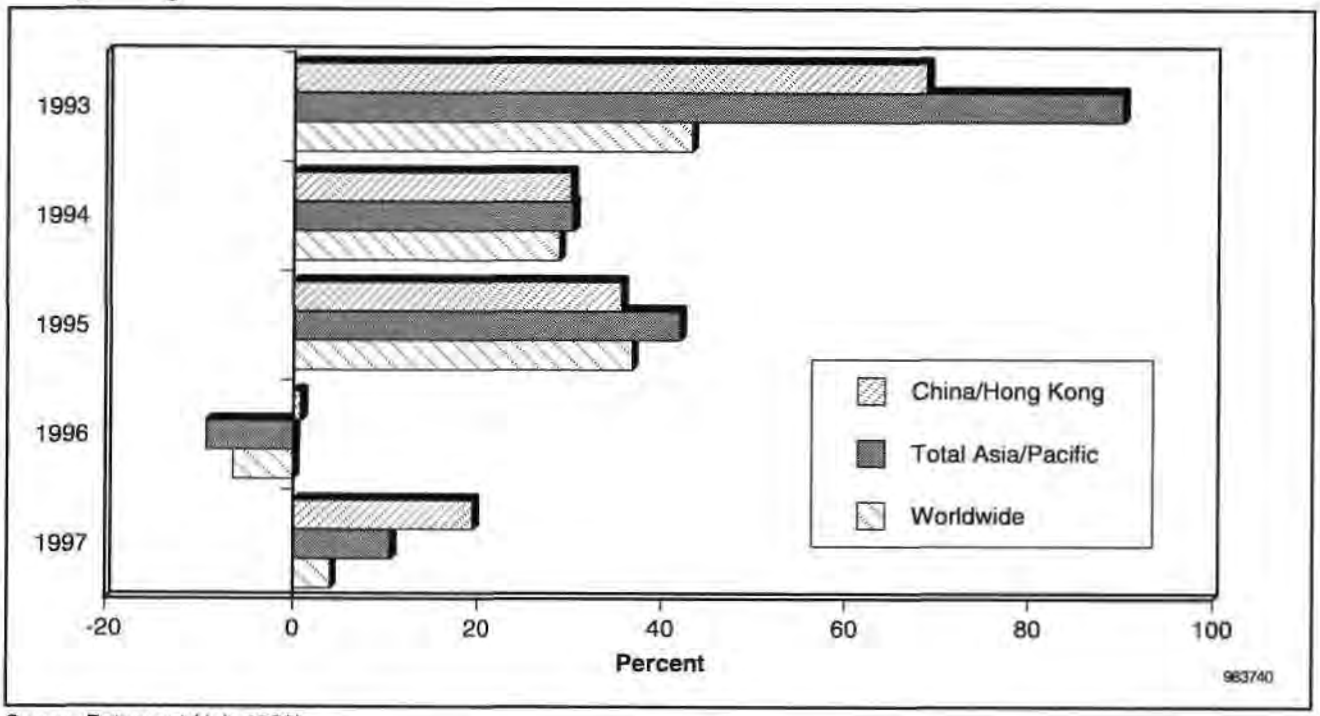
Dataquest's research presented in this report discusses China and Hong Kong as a single market (China/Hong Kong) because most semiconductors are billed in Hong Kong but used in China. It would be a distortion to discuss China without including Hong Kong and vice versa. Dataquest compares this (single) region with other major semiconductor consumption centers in the region—South Korea, Singapore, and Taiwan. Hong Kong's economic integration with China is a reality, with or without official political unification. For all intents and purposes, Hong Kong will continue to be a primary purchasing and trading center for end users throughout China for the next few years, expanding beyond Guangdong Province.

1997 China/Hong Kong, Asia/Pacific, and Worldwide Markets

After the worldwide semiconductor market contraction of 6.3 percent, 1997 experienced a slow growth of 3.5 percent to $147 billion. An unprecedented period of expansion and profits, which peaked in 1995 (36.9 percent in revenue), later collapsed to a protracted three-year downturn caused by overspending in memory capacity—especially DRAMs. The Asia/Pacific was worse off in the decline in 1996 with a 9.2 percent decline, but then returned to worldwide growth leadership in 1997 with 9.6 percent expansion. Asia/Pacific was followed by Europe (5.9 percent), Americas (5.3 percent), and Japan (negative 5 percent).

The Asia/Pacific semiconductor market expanded nearly two and half times from 1991 to the end of 1995, with the regional market growing at a 37.0 percent CAGR, compared with a growth rate of only 26.2 percent for the world semiconductor market. The years 1996, 1997, and 1998 appear to be correction and recovery years after a streak of uninterrupted growth. Figure 3-1 illustrates the comparative growth rates for the worldwide, Asia/Pacific, and China/Hong Kong markets from 1993 to 1997. The China/Hong Kong market was flat in 1996, primarily caused by semiconductor pricing weakness rather than slackening demand. Hence, electronic equipment production expanded 17.5 percent in 1996 and accelerated in 1997 with 20.9 percent growth. The semiconductor market's 19.5 percent growth was almost double the total Asia/Pacific market average of 9.6 percent.

Figure 3-1
Comparative Semiconductor Market Growth Rates, Worldwide, Asia/Pacific, and China/ Hong Kong



Source: Dataquest (July 1998)

It is important to note that China/Hong Kong became the largest semiconductor market in Asia/Pacific in 1996 and extended its lead in 1997, as was predicted. Figure 3-2 illustrates regional semiconductor consumption by Asia/Pacific's five major regions, China/Hong Kong, Singapore, South Korea, Taiwan, and rest of Asia/Pacific (including Australia, Malaysia, Thailand, Indonesia, India, Philippines, and the rest of Southeast Asia and South Pacific).

Dataquest forecasts a 21 percent CAGR growth (1997 to 2002), which is slower than the 24 percent growth rate for the similar-cycle period from 1991 to 1996. The years between 1991 and 1995 were the peak years of the last silicon cycle, and the China/Hong Kong region was able to sustain a 31.3 percent CAGR. When including the 1996 downturn, the growth from 1991 to 1996 was 24 percent. When examining Dataquest's CAGRs, readers must take note of the forecast period with respect to market cycles. Where the base year and final year of the five-year forecast begin can substantially impact the forecast figures.

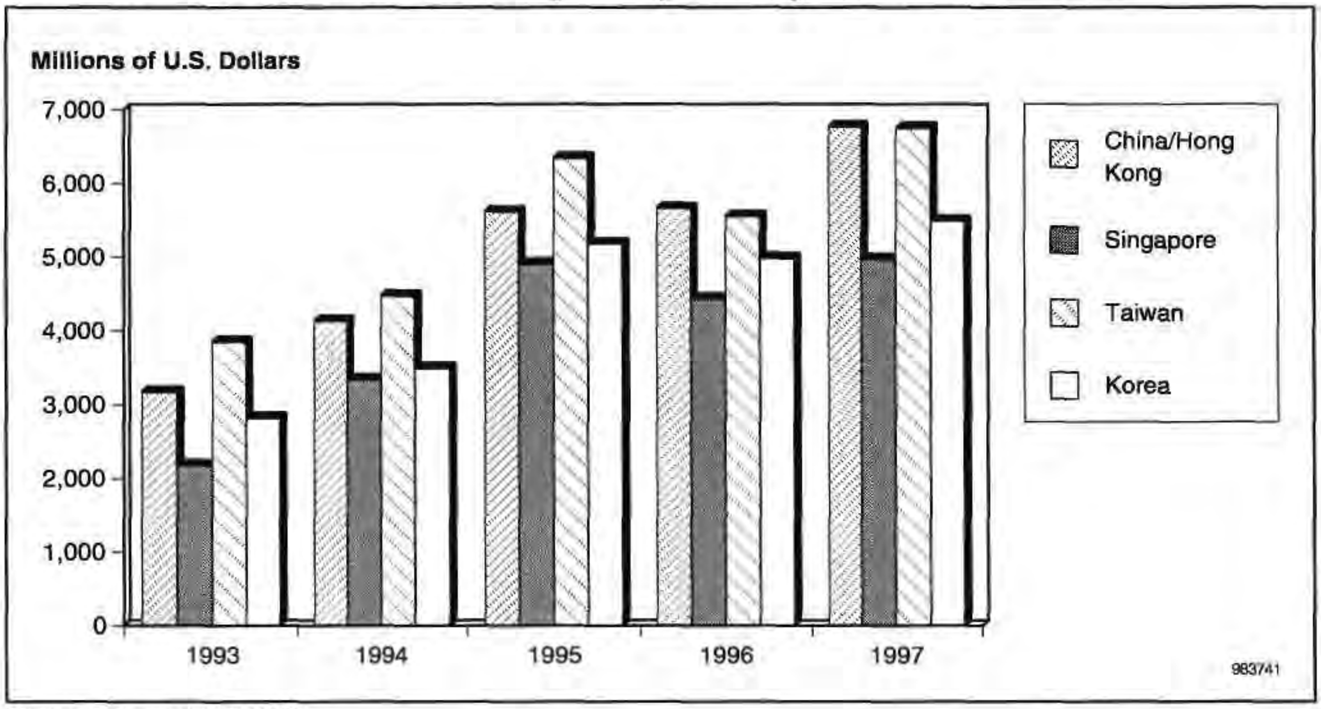
Asia/Pacific Semiconductor Consumption by Country, 1993 to 1997



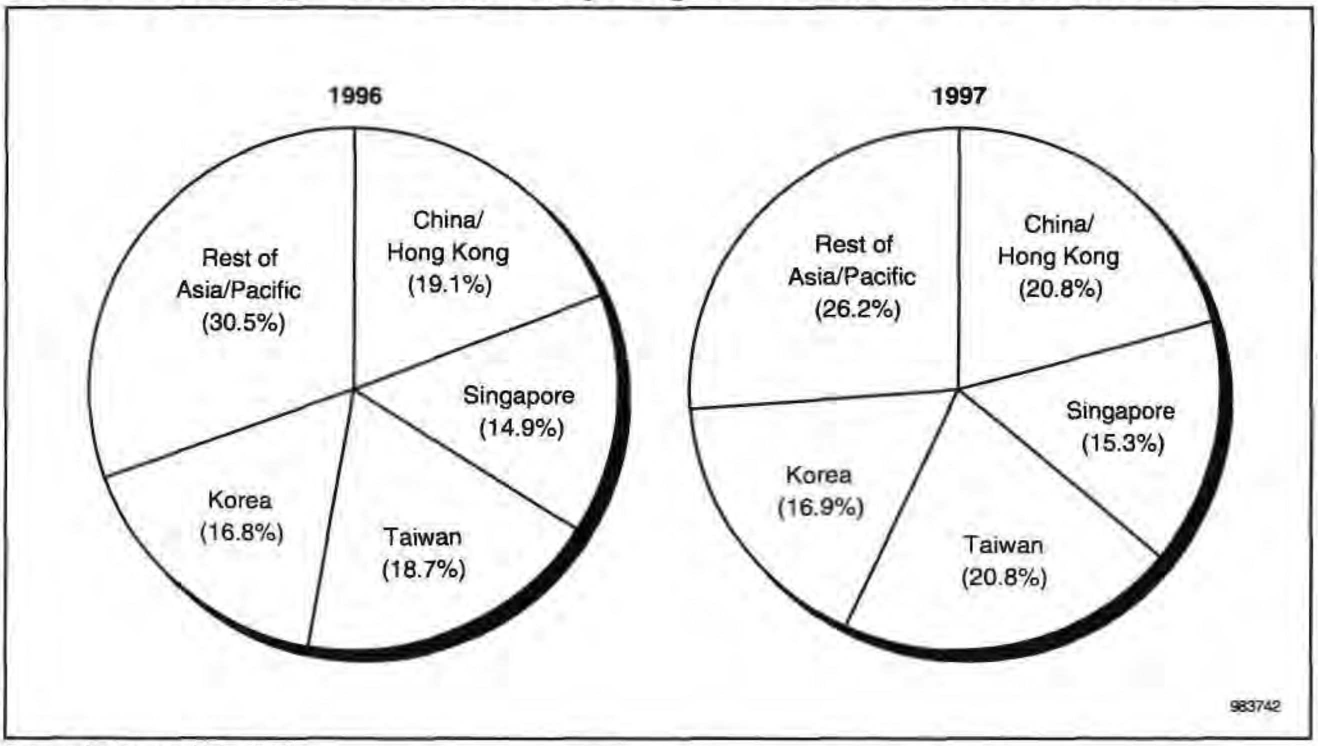
Source: Dataquest (July 1998)

Recent Market Stimulants

Dataquest's historical statistics show that China/Hong Kong performed below the Asia/Pacific average growth until 1995 largely because of Japanese investments in Southeast Asia and Taiwan's PC boom. The effect of previous dynamic RAM (DRAM) undersupply on China/Hong Kong was faster growth for large DRAM consumers Singapore and Taiwan. Overall, China/Hong Kong declined from 20 percent of Asia/Pacific consumption in 1991 to 19 percent in 1996. Singapore and Southeast Asia were the success stories of the early 1990s, increasing their share of the Asia/Pacific total consumption. Led by Malaysia and Thailand, the rest of Asia/Pacific grew from 19 percent to 31 percent of total Asia/Pacific consumption. China/Hong Kong, on the other hand, declined from 20 percent to 19 percent of the total Asia/Pacific market. The story has been changing, and China/Hong Kong is now the growth center through the next forecast period, 1997 to 2002 (as discussed in more detail in Chapter 5). Figure 3-3 illustrates a two-year comparison of China/Hong Kong's semiconductor consumption share in Asia/Pacific in 1996 and 1997.

 ©1998 Dataquest

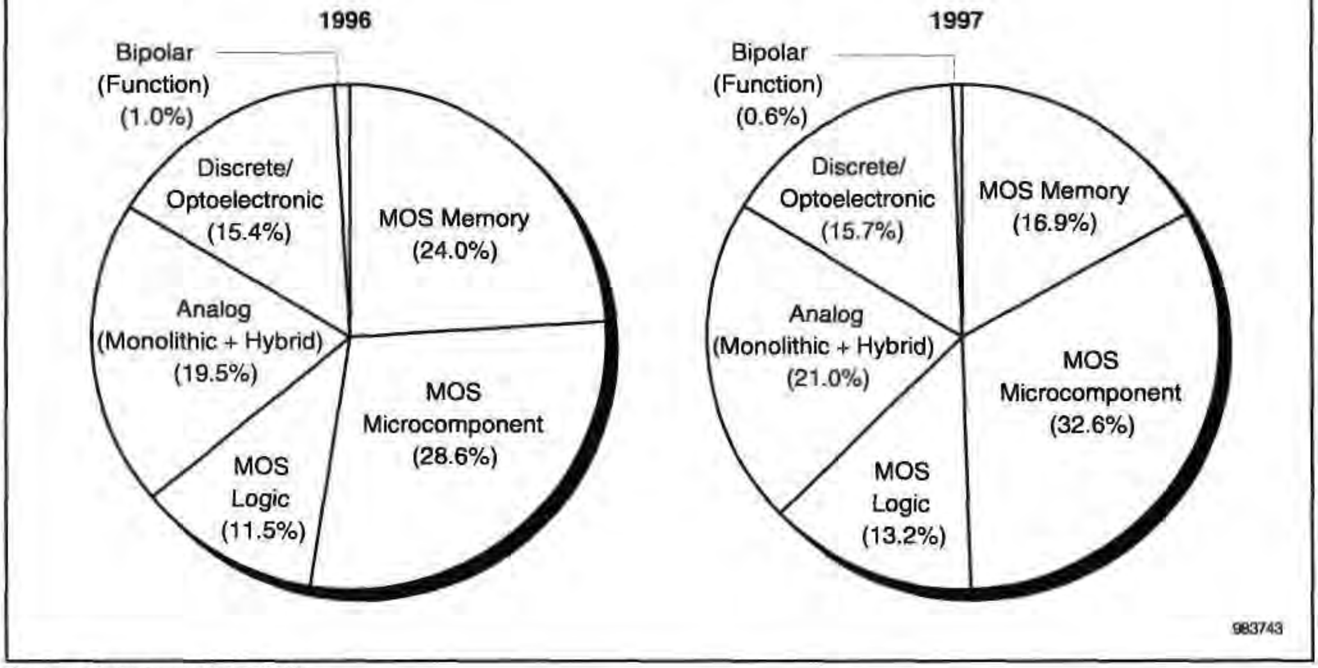
Figure 3-3
1996 and 1997 Comparison: China/Hong Kong Share of the Asia/Pacific Market



Source: Dataquest (July 1998)

Dataquest's data in Figure 3-4 shows the share of China/Hong Kong relative to other countries in Asia/Pacific increased substantially across all device areas. The main drivers for this growth were a shift in foreign investments by multinational corporations (MNCs) to China, strong economic growth, and accelerated use of information technologies in Chinese businesses and the government. For example, China's PC market surged in 1995, and PC manufacturers invested in production within China. Also, local manufacturers emerged to compete with global multinational companies (MNCs). As a result, China's memory, microprocessor, and microperipherals markets surged. Memories would have increased more share if not for the extremely aggressive pricing in the China/Hong Kong market. Furthermore, communication markets and products have surged in the past two years. In 1997, China/Hong Kong consumed a record 20.8 percent share of Asia/Pacific semiconductors. (Dataquest's forecasts of these devices and applications are explained in Chapter 5.)

Figure 3-4
1996 and 1997 Comparison: Semiconductor Segment Changes in China/Hong Kong



Source: Dataquest (July 1998)

Sustainability of Growth Stimulants

Dataquest believes that significant structural changes in China/Hong Kong's electronic equipment industries have enable it to achieve sustainable growth leadership within Asia/Pacific and, of course, worldwide. Table 3-1 quantifies revenue from China/Hong Kong's electronics industries and the value of semiconductors consumed in each end-market segment. Dataquest has revised some historical figures for communications semiconductor markets, which surpassed the consumer segment in 1996. As shown, China/Hong Kong's market growth has been enabled by rapid growth across the three main application areas of consumer, data processing, and communications electronic equipment. Much will depend on the overall health of the global economy, which is influenced by Japan's and Asia's slowdown.

Consumer Electronics Consolidation

Consumer electronics production remained as the equipment revenue leader for China/Hong Kong in 1997, accounting for 48 percent of total electronic equipment production. But the industry is plagued by inefficiencies, has been undergoing consolidation since 1995, and is experiencing a production revenue decline. By contrast, the industry accounted for only 18 percent of semiconductor consumption and has been declining. China's demand for low-end consumer electronics did translate into step-function semiconductor market growth. (As discussed later, this trend may change.)

By contrast, although Southeast Asia's consumer electronics production was slower than China's, it translated into a higher semiconductor market growth than that of China. A 1993-to-1997 CAGR of 17 percent in Southeast Asia's electronic equipment production resulted in a semiconductor market decline because of a market contraction in 1995. When comparing this to Asia/Pacific's 1993-to-1997 CAGR of about 10 percent in electronic equipment production, the result is a 13 percent semiconductor consumption growth.

China/Hong Kong's electronics industry has gone through rapid expansion as well as product technology improvements, leading to higher content per system produced. Consumer electronics has been rapidly declining in importance. In 1993, it accounted for 51 percent of electronic industry output, dropping to 48 percent in 1997. Going back to 1992, the trend is even more clear when consumer applications represented 54 percent, with data processing applications sharing 25 percent of the market.

Semiconductor shipments for consumer applications represented 47 percent of the market in 1993, declining to 18 percent by 1997. Gains were made in computer and communications, which grew on a combined basis from 48 percent of consumption in 1993 to 77 percent. Shipments to data processing applications reached $2.2 billion, or 41 percent of total shipments. As explained in Chapter 4, Intel Corporation and other PC semiconductor suppliers have become major forces in the China/Hong Kong market in 1997.

Communications and Computers Drove Semiconductor Consumption in 1997

In 1997, data processing grew to 29 percent of total electronic equipment output. Communications electronic applications have maintained an average of 15 percent to 16 percent share since 1993, but the market share has migrated from telephones to infrastructure production, thereby accelerating semiconductor consumption in 1997. Shipments of communication semiconductors, on the other hand, increased from 19 percent to 36 percent of the total market in 1997, undergoing a five-year expansion of 42 percent CAGR. The primary growth segments have been semiconductor-rich products—cordless telephones, switching equipment, and pagers.

 ©1998 Dataquest

This trend will boost this segment. A large growth in communication systems' semiconductor consumption is under way to meet China's infrastructure development. A large portion of this equipment will be imported, but a growing share is being produced by multinationals, because of the pressure from the Chinese government to localize production. Additionally, the government is supporting local Chinese suppliers, which are increasing their communications presence. Semiconductor device technology is enabling Chinese companies, with the support of key vendors, to pursue these lucrative equipment markets. Dataquest thinks that this market will keep pace with data processing during the next five years. Locally produced handsets, pagers, cordless phones, and answering machines, among others, will continue to surge to meet local demand, while semiconductor consumption for public infrastructure is predicted to surge within the next few years.

Broad-Based Semiconductor Growth (except Memories) in 1997

Dataquest continues to emphasize the importance of end-market diversity with the China/Hong Kong market. In 1997, this was truer than ever, as all major sectors experienced revenue growth faster than the rest of Asia/Pacific. But this has been a clear long-term trend. As shown in the detailed breakdown of revenue for total semiconductors shipped to China/Hong Kong in Table 3-2, the total semiconductor market of China/Hong Kong expanded with a 21 percent CAGR from 1993 to 1997. MOS microcomponents became the fastest-growing segment with a 30 percent CAGR from 1993 to 1997. This segment increased from $772 million to $2.2 billion. While MOS memory's 50 percent CAGR from 1991 to 1995 was the fastest-growing segment, its contraction of 26 percent in 1996 severely lowered its five-year average growth to 26 percent from 1992 to 1996. And MOS memories' 1993-to-1997 CAGR dropped to 16 percent—the weakest of all semiconductor products during this period. Traditionally modest-growth markets of analog, discrete, and MOS digital logic grew by 14 percent, 18 percent, and 15 percent during this same period, respectively. Dataquest expects a continuation of these trends in 1998 because of a delayed memory recovery starting in 1999 and accelerating in 2000 and 2001.

Consumer Semiconductors

As shown in Table 3-3, the analog IC market expanded by 29 percent and surpassed MOS memories to become the second-largest market after MOS microcomponents in 1997. The discrete market improved from 10 percent in 1996 (because of a general weakness in China's consumer markets) to 22 percent. Consumer electronic equipment production has been China's main application for analog and discrete devices, but the communications markets are providing new life to these products. MOS digital logic market also recovered because of stronger consumer electronics equipment growth in 1997.

 ©1998 Dataquest

Table 3-4 presents key consumer electronics segments, most of which experienced improved growth after several difficult years. The consumer electronics slump for stereo equipment declined by 12 percent in 1997. After years of consolidation, VCRs showed some improvement because of central China's economic growth. Color TV production growth slowed to 8 percent in 1996 but improved to 10 percent growth in 1997. Consolidation was sorely needed after the government had promoted and protected almost 100 manufacturers, most of which were inefficient and lacked supply of key components. Larger, more efficient manufacturers have acquired ailing companies, boosting the overall output. Because China produces approximately 20 percent of the world's color televisions, this sector's performance is critical to China's overall consumer electronics growth. Semiconductor consumption in this sector grew 14 percent in 1997. As China heads for a World Trade Organization (WTO) membership and as import tariffs decline, color television manufacturers have prepared to increase competitiveness and boost exports to exceed 10 percent growth per year.

Table 3-4
Final 1997 Consumer Equipment Production and Semiconductor Consumption in China/Hong Kong (Units and Revenue)

	1996	1997	Growth (%)
Color Television			
Units (K)	20,784	22,863	10.0

Certain home appliances, such as microwave ovens and air conditioners, experienced double-digit growth. High local demand for key commodities such as color televisions, VCRs, audio equipment, and other home appliances (refrigerators, washing machines, and rice cookers, among others) were the key to China's market growth from 1991 to 1995. As elsewhere in the world, the market is in need of new applications. However, a continued economic growth and the per-capita-income growth will, predictably, boost consumer electronic purchases. A key initiative of the Chinese government is to expand economic growth to China's heartland. Rising economic disparity between coastal versus inland, as well as urban versus rural regions, will lead to the breakup of the country unless dealt with immediately. Consequently, the government continues to implement ways to accelerate growth throughout China. For instance, special regions that report directly to Beijing have been established. So far, there are 32 Economic and Technology Development Zones, 14 Single-Planned Cities, five Special Economic Zones, and three Coastal Economic Zones. These policies enable central control, facilitate foreign investments, and accelerate economic expansion.

Aside from products tied to economic fundamentals and rising income, Dataquest expects applications that are unique to China. Dataquest's recently published report on video compact disk players (VCD) indicated that production increased eightfold, from 210,000 in 1995 to nearly 5.8 million in 1996. In 1997, Dataquest estimates the VCD production to have reached 14.7 million units. Excluding VCD semiconductors, the main markets would have expanded only 12 percent. The VCD semiconductor consumption of $437 million enabled the semiconductor total available market (TAM) to increase by 18 percent (see Table 3-4).

As elsewhere in the world, this segment's future will depend on new and affordable products, such as DVDs, set-top boxes, and digital cameras. Once there is any movement in the local market activity, Dataquest expects at least a few foreign manufacturers to set up production in China. Already, Dataquest hears of several manufacturers establishing set-top box production facilities for original equipment manufacturers (OEMs) in the United States and Europe.

Figure 3-4 illustrates a revenue comparison between 1996 and 1997. Analog and discrete both increased in share of total consumption after declining in 1996. These two sectors represent 37 percent of semiconductor consumption in China/Hong Kong.

Memories: Segment Shrank to Historic Lows

The MOS memory market experienced its second year of negative growth, falling 16 percent in 1997 after declining 14 percent in 1996. The MOS memory market segment shank to 17 percent of total semiconductor shipments to China/Hong Kong. This is the lowest level in history and even lower than 1992's share of 19 percent. At its peak in 1995, MOS memories were 28 percent of total semiconductor shipments.

 ©1998 Dataquest

Memories achieve number one segment status in 1995 after expanding by a CAGR of 49.8 percent from 1991 to 1995. Demand for MOS memory devices surged because of another large increase in local PC and motherboard production, which, in turn, caused a huge rise in the DRAM consumption level (DRAM chips constituted 74 percent of the MOS memory consumption). Despite a very strong unit growth in China/Hong Kong, falling average selling prices resulted in a revenue decline. But because of strength in demand, the overall decline in China/Hong Kong was less severe than that of Asia/Pacific's memory markets, which declined by 36 percent and 19 percent in 1996 and 1997, respectively.

All major memory subsegments contributed to decrease memory revenue in 1996. Dataquest's final market share estimates indicate that the DRAM market in China/Hong Kong declined from $1.1 billion to $0.8 billion in 1996. SRAM shipments experienced slow growth, and nonvolatile memories contracted (see Table 3-5).

Microcomponents: Every Sector Surged in 1997

The market for MOS microcomponent devices in China/Hong Kong moved from the second largest (after MOS memory) to become the largest segment in 1996. In 1997, the market grew to $2.2 billion from $772 million in 1993, a 23 percent CAGR. This segment is defined by Dataquest to include microprocessors (MPUs), microcontrollers (MCUs), microperipherals (MPRs), and digital signal processors (DSPs).

As shown in Table 3-4, Dataquest's final market share figures indicate that microprocessor growth remained robust in 1997, but decelerated from 50 percent growth in 1996 to 31 percent in 1997. This $881 million market represents 20 percent of the MPU consumption in Asia/Pacific. Because China/Hong Kong consumes about one-third of PCs shipped in Asia/Pacific, this sector is clearly positioned for continued growth. After a soft MCU and MPR market, these markets bounced back with 28 percent and 40 percent growth, respectively. About 30 percent of MCUs shipped to Asia/Pacific are used in China/Hong Kong. Microprocessors dominate this consumption with 40 percent of microcomponent revenue, followed by MCUs (31 percent), MPRs (22 percent), and DSPs (7 percent).

PC production in China by both foreign and domestic manufacturers grew from 1.1 million units in 1996 to 2.2 million units in 1997. China's PC consumption is forecast to grow by more than 40 percent per year for the next five years, while the production will expand by 45 percent. China (excluding Hong Kong) became the largest consumer of PCs in Asia/Pacific during the second quarter of 1997. With the introduction of sub-$1,000 PCs, as well as improved distribution in China, the market is positioned for continuous long-term growth stimulated by a large, nascent demand.

MOS Digital Logic: A Growth Leader in 1997 Stimulated by the Standard Logic Growth, but ASICs Yet to Gain Share

MOS digital logic, comprising primarily standard logic in the China/Hong Kong market, achieved a 39 percent growth, outpacing all semiconductor segments. The market had contracted by 9.3 percent in 1996. The 1997 market reached $895 million, according to Dataquest's final market share analysis. This number represented a 1993-to-1997 CAGR of 15 percent, thereby performing below the market, which grew 16 percent during the same period. On a worldwide level, ASICs accounted for about 72 percent of MOS logic revenue in 1997, up from 70 percent in 1996. In Asia/Pacific, ASICs shared only 43 percent in 1997, down from 48 percent. In China/Hong Kong, the ASIC market comprised only 28 percent of MOS digital logic products.

©1998 Dataquest

China/Hong Kong Device Markets' Share of Asia/Pacific

Table 3-5 shows each semiconductor segment's long-term changing share of the Asia/Pacific market. It can be seen that from 1992 to 1995, the China/Hong Kong subregion declined in its share of the overall Asia/Pacific semiconductor consumption, for reasons previously discussed. China/Hong Kong's consumption share dropped from 20 percent in 1992 to 17.2 percent in 1995. The trend reversed itself in 1996 when the share increased to 19.2 percent. Dataquest's prediction that this was a long-term trend, rather than a cyclical anomaly, was confirmed as the market increased by 2.6 percentage points to 20.8 percent share of the Asia/Pacific consumption.

In Table 3-6, we constructed a detailed device comparison for 1996 and 1997. This table indicates in real terms the significant differences in consumption patterns between China/Hong Kong and Asia/Pacific. The most significant aspect of this comparison is not that the region outpaces the rest of the region and, of course, worldwide growth, but that it achieves this result across every product market. Tables 3-7 and 3-8 present China/Hong Kong's share of the Asia/Pacific semiconductor market by segment and by device.

Chapter 4
Semiconductor Vendor Supply Trends

Introduction

Dataquest publishes market share statistics twice per year. Our survey of all merchant market suppliers to Asia/Pacific is released in April, and the China/Hong Kong statistics for the top 32 Asia/Pacific suppliers are published in July. This survey covers five major Asia/Pacific markets and publishes these results: China/Hong Kong, Korea, Singapore, Taiwan, and the rest of Asia/Pacific. The analysis of this chapter is based on survey results.

This survey is a worldwide effort by Dataquest research analysts located in Asia/Pacific, Europe, Japan, and North America. After finalizing each company's Asia/Pacific shipments, Dataquest's market share team conducts primary and secondary research to estimate country-level shipments for the largest vendors. Direct surveys are conducted with either the country or regional manager, or the responsible representative based in the headquarters of the companies surveyed. Therefore, every company has an opportunity to review, revise, or comment on these estimates. In rare cases, both headquarters and country/regional offices are surveyed to improve accuracy. Companies with large captive semiconductor markets are certainly surveyed at headquarters to ensure that all revenue is counted.

This section of Dataquest's report combines the company revenue into one China/Hong number because vendor business operations also do so. Whether a multinational transfers semiconductors to subsidiaries in China or ships semiconductors direct to distributors or end users, Dataquest counts all revenue as "shipments" to China/Hong Kong. Dataquest's definition for this China/Hong Kong survey is consistent with worldwide market share definitions and methodology.

Dataquest hopes that the estimates data will function as a benchmark to measure the future performance of semiconductor suppliers and to monitor semiconductor allocation dynamics within Asia/Pacific.

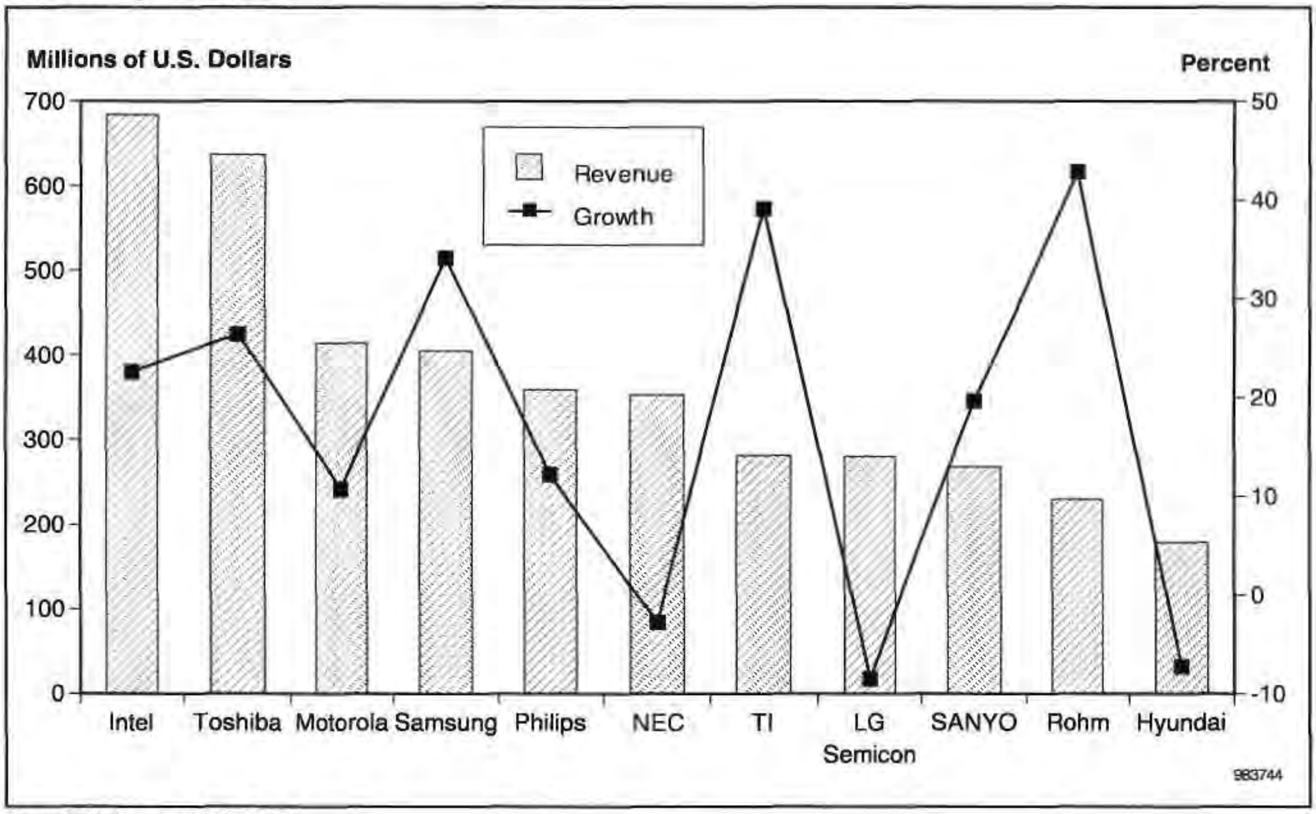
Total Semiconductor Market Share Ranking: A Year of Turmoil

As expected, China's overall market recovered in 1997 after a slowdown across most major segments. Some products, such as memories, were still plagued by price declines as a result of a worldwide oversupply. Exceptional growth-volume products included microperipherals and MOS standard logic. DSPs represented the fastest-growing emerging product. Revenue grew 120 percent to $295 million. In major segments, Dataquest sees shipments of MOS memories declined by 16 percent at the negative extreme.

©1998 Dataquest

Segment growth leaders included the MOS digital logic market, with 38 percent growth, and microcomponents, with 36 percent growth. Furthermore, strength in analog and discrete parts contributed significantly to the market rebound. As analyzed in later sections, the combination of mature and new products being introduced within the China/Hong Kong market resulted in wide disparity in company performances. This trend would be expected in a memory downturn, but nonmemory growth segments of the markets also experienced a wide shipment variance (see Figure 4-1).

Figure 4-1
China/Hong Kong's 1997 Top 10 Total Semiconductor Suppliers (Revenue and Percentage Growth)



Source: Dataquest (July 1998)

 ©1998 Dataquest

A Product Overview

Memory suppliers dealt with the downturn differently. Japanese companies either seemed to pull back from the market or lacked the ability to compete and lost market share. Japanese companies' memory shipments to China/Hong Kong consequently declined by 54 percent, while American companies gained by 7.7 percent. The DRAM market went from bad to worse as the worldwide oversupply flooded even China's elaborate distribution channels. Even the emerging flash memories increased by only 6 percent to $92 million.

Nevertheless, China's diverse semiconductor market was able to buffer the memory slump in its third year of contraction. In addition to microcomponents and MOS logic, analog and discrete enjoyed a strong price stability. MOS logic contracted 9 percent in 1996, and analog and discrete grew less than 10 percent. However, both bounced back in 1997, with analog and discrete growing 29 percent and 22 percent, respectively. Microcomponents remained the growth pillar in China. Even with microprocessor revenue slowing to 36 percent from a 50 percent growth in 1996, the overall microcomponent segment was still able to expand by 36 percent from 17 percent in 1996, because of a strong MPR, MCU, and DSP demand.

Dataquest's company-level market share statistics and demand analysis concludes that total the semiconductor market reached $6.8 billion in 1997. Excluding Rohm Company Ltd. and SANYO Semiconductor Corporation, the other eight suppliers in China's top 10 list rank within Asia/Pacific's top 10 semiconductor suppliers. China's top 10 suppliers lost share from 59 percent in 1996 to 57 percent in 1997 (see Figure 4-2). Similarly, the top 32 companies in Asia/Pacific controlled 87 percent of China's semiconductor market in 1997, as opposed to 89 percent in 1996. In Asia/Pacific, however, the top 32 companies gained market share from 83.0 percent to 83.2 percent. In China, established vendors had greater difficulty maintaining market share than other markets in the region. The top 32 companies expanded by 16.4 percent, while the overall semiconductor market grew only a few percentage points faster (19.5 percent). In previous years, these companies were controlling more and more of the market, but the following two factors explain this trend reversal:

- Major DRAM suppliers (all within the top 32) lost significant overall market share because of revenue erosion.
- Other microcomponent and MOS logic vendors entered the Chinese market either to develop entirely new segments, such as in video compact disks (VCDs), or to seek new demand for mature products, such as microcontrollers (for example, Samsung Electronics Company Ltd.) or microprocessors (for example, Advanced Micro Devices Inc.).

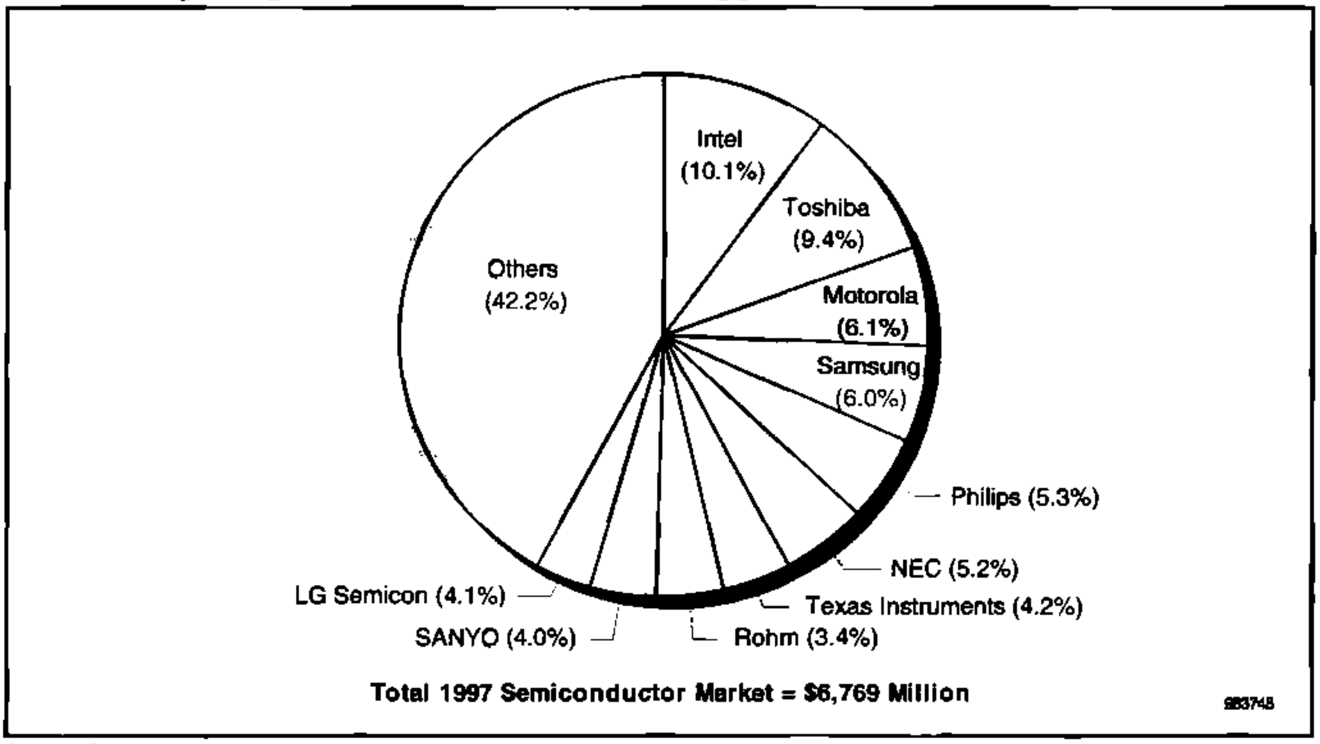
Figure 4-2
China/Hong Kong 1997 Total Semiconductor Suppliers' Market Share (Percent)



Source: Dataquest (July 1998)

No. 1, Intel Corporation

Despite increased competition and loss of market share, Intel Corporation remained the largest semiconductor supplier to China in 1997. Demand for non-Intel microprocessors increased because of AMD's aggressive marketing and pricing. Intel's revenue growth dropped sharply to 25.6 percent in 1997, compared with 48.8 percent in the previous year. Intel's share of Asia/Pacific sales to China remained at approximately 17 percent. Intel has adopted a strategy of mass-marketing and large advertising campaigns, which is difficult for any company other than Intel to match. However, the fragmented nature of the market enables a company such as AMD to gain market share through tactical wins in the marketplace. AMD doubled its revenue in China to $121 million, moving up six ranks to No. 16.

No. 2, Toshiba Corporation

Toshiba Corporation, although exiting the DRAM market, experienced a strong growth by broadened penetration into communications, monitors, and even home appliances. Exiting the DRAM market represented a critical strategic decision that quickly paid off. Toshiba's overall 26.4 percent growth exceeded Intel's 22.6 percent growth, and if the company has another good year, it could regain its No. 1 ranking after losing it in 1996. Toshiba was able to diversify its end-market applications markets. For example, its expansion in cordless phone (CT0 and 900 MHz) markets boosted the bottom line. In addition, Toshiba's flexibility further paid off as it was able to provide design support and kit solutions (MCU and combo chip) to Chinese manufacturers. This strategy had been a key to its success in China's television markets in the 1980s, and the company applied this concept to the communications electronic equipment market.

No. 3, Motorola Incorporated

Toshiba was able to exit losing markets and expand market penetration from its mainstream products. In contrast, Motorola Incorporated's growth slowed, while its own product market accelerated. There was no change in product focus or broadened end markets, hence sales penetration decline. While all of the major markets Motorola participates in recovered in 1997, Motorola's shipments expanded at half its 1996 growth rate. Semiconductor shipments, including transfer shipments, grew 10.7 percent in 1997, about half of the overall market rate. In addition to missing merchant market opportunities, Motorola's semiconductor division has been unable to capitalize on its strong communication equipment sales since the pager market slumped in 1996. In short, the company lost market share in almost every major sector in which it competes. Its 1997 worldwide restructuring process evidently impeded the company's ability to compete. The lost business and opportunity costs will take years to recover, if it recovers at all.

China was once the cornerstone of Motorola's Asian strategy, occupying about 26 percent of Asia/Pacific semiconductor sales. Now, China's share is on a declining slope, with only a 24 percent share in 1997. When one considers the fact that China increased its share of regional consumption from 19 percent to 21 percent in 1997, this decline in relative revenue is actually 5 percentage points.

No. 4, Samsung Electronics Company Ltd.

In the worst memory downturn in China's semiconductor history, Samsung still emerged from the dust with a 34 percent revenue growth and improved its market share ranking from No. 7 to No. 4. China was at the center of Samsung's Asia/Pacific sales growth. Regional sales expanded only 5 percent, while China expanded seven times faster. Samsung's decision to diversify into MCU seemed risky given the 1996 market decline. However, the company was able to expand its regional sales from $78 million to $205 million largely because of its success in China, which accounted for more than one-third of MCU sales in the region. Samsung moved from No. 12 to No. 1, replacing Motorola as the No. 1 MCU supplier in China. This shift happened because of Samsung's expanding sales from $16 million to $76 million, an impressive 375 percent growth rate. In addition to product diversification, Samsung was able to maintain or increase its market position in other key markets in which it participates (such as analog, discrete, and memories). MOS logic was the only area in which the company lost market share.

Total Integrated Circuit Market Share Rankings

For those who do not consider discrete devices to be an important business, they should think again. As shown in this section, when discrete and optoelectronics are excluded, the top 10 ranking changes significantly (see the IC rankings in Figures 4-3 and 4-4).

 ©1998 Dataquest

Figure 4-3

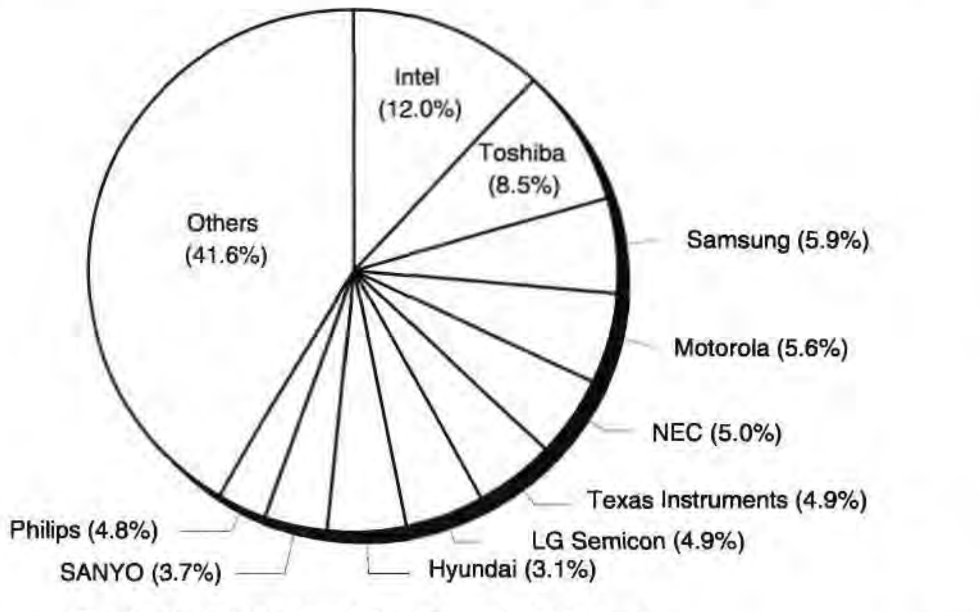
China/Hong Kong Total Integrated Circuit Market Share, 1997 (Percentage of Revenue)



Total Integrated Circuit Market = $5,705 Million

Source: Dataquest (July 1998)

 ©1998 Dataquest

China/Hong Kong's IC market grew 19.1 percent to $5.7 billion in 1997. Although Intel and Toshiba remained the top two suppliers, Samsung replaced Motorola as the No. 3 semiconductor supplier, in part, because of its 27 percent revenue growth in discrete devices. Philips Electronics NV can increase its ranking position from No. 8 (in ICs) to No. 5 in total semiconductors because of its strong position (ranked third) in discrete sales. A recovery in MCUs has enabled Motorola to move up its IC ranking from fifth to fourth place. Nevertheless, Motorola increased its IC revenue by 11 percent, much slower than the market average (see Figure 4-3). TI had a strong year in DSPs and surpassed Philips to become the sixth-largest IC supplier in China/Hong Kong. In 1997, TI ranked eighth. Philips experienced a 16 percent growth in ICs and only 12 percent in semiconductors, attributed to its mere 1.2 percent growth in discrete sales in a market that grew 22 percent.

MOS Memory Market Share

This section summarizes MOS memory market trends and analyses the top 10 suppliers.

After MOS memory devices surpassed MOS microcomponents in 1995, the two devices switched positions again in 1996, and memories further lost market share to microcomponents in 1997. As Dataquest stated in 1997, the trend is expected to hold. In other words, microcomponents will reign as king until beyond 2000.

China/Hong Kong survived, but was not immune from the region's first major downturn, while Taiwan and Singapore sustained a strong bias toward PC, peripherals, and storage manufacturing. This was the single-largest factor behind China/Hong Kong's rise to the lead in Asia/Pacific. In 1995, nearly 39 percent of all semiconductor revenue was derived from memories in Asia/Pacific. After the market correction in 1996, only 27 percent of the market was from memories. Then, the semiconductor market suffered further declines in 1997: Only 20 percent of semiconductor revenue is derived from MOS memories in Asia/Pacific. To put this downward trend in perspective, memory suppliers to Asia/Pacific, as a whole, lost a net $4.6 billion in revenue, from $12.6 billion in 1995 to $8.0 billion in 1996. In 1997, memory suppliers lost another $1.5 billion as the market declined to $6.5 billion.

These same suppliers lost less in China/Hong Kong, where the market declined from $1.6 billion to $1.3 billion in 1996. In 1997, this market hit the $1.1 billion level. The year 1997 experienced a 16 percent decline, compared to Asia/Pacific's 19 percent fall. China/Hong Kong is increasingly being impacted by the worldwide overcapacity because the market is unprotected from semiconductor dumping, in contrast to Europe and North America. China lacks the regulatory bodies of the European Economic Commission (EEC) and the International Trade Commission (ITC), which have been known to slap tariffs on alleged memory dumpers. China/Hong Kong's MOS memory market was about 28 percent of total semiconductors in 1995 but declined to just 20 percent in 1996. In 1997, the share declined to 17 percent. Although, high PC production expansion counteracted some of the ill effects of price erosion, aggressive Taiwanese and Korean pricing inhibited revenue recovery.

 ©1998 Dataquest

In no other segment do company performances vary as widely among the top 10 suppliers. The market leader Atmel Corporation moved from No. 11 to No. 5 on a 76 percent sales growth. At the other extreme, Hitachi Ltd.'s sales dropped 67 percent. Toshiba was not too far behind, with a 61 percent revenue decline. NEC Corporation also faced a 35 percent revenue decline.

Taiwanese vendor Vanguard International Semiconductor Corp. was able to increase its DRAM revenue to $50 million after negligible sales in 1996. China proved to be a prime market for cheap 16Mb DRAMs, as well as a place to dump outdated 4Mb parts. Prices for most memory parts in China's major computer markets reached price points comparable with Taipei. Pressure from the U.S. ITC on Taiwan's memory resulted in manufacturers and traders focusing more on China to shed excess inventories. Consequently, the DRAM market declined 17 percent and SRAMs declined 15 percent. The capacity and marketing might of Samsung was too powerful for most SRAM vendors to match. Samsung was able to double its revenue in a declining market. Sony Corporation and Sharp Electronics Corporation were the only two other companies able to raise revenue—but only by $2 million—while Samsung dramatically extended its SRAM market share to an impressive 23.8 percent.

Memory Vendors' Company Ranking

Figure 4-5 illustrates the revenue and growth rates of the top 10 MOS memory suppliers in China/Hong Kong. Figure 4-6 illustrates the total 1997 market sizing and company market share of ranking for the top 10 MOS memory semiconductor suppliers in China/Hong Kong during 1997. The following section analyzes the top five vendors' memory business.

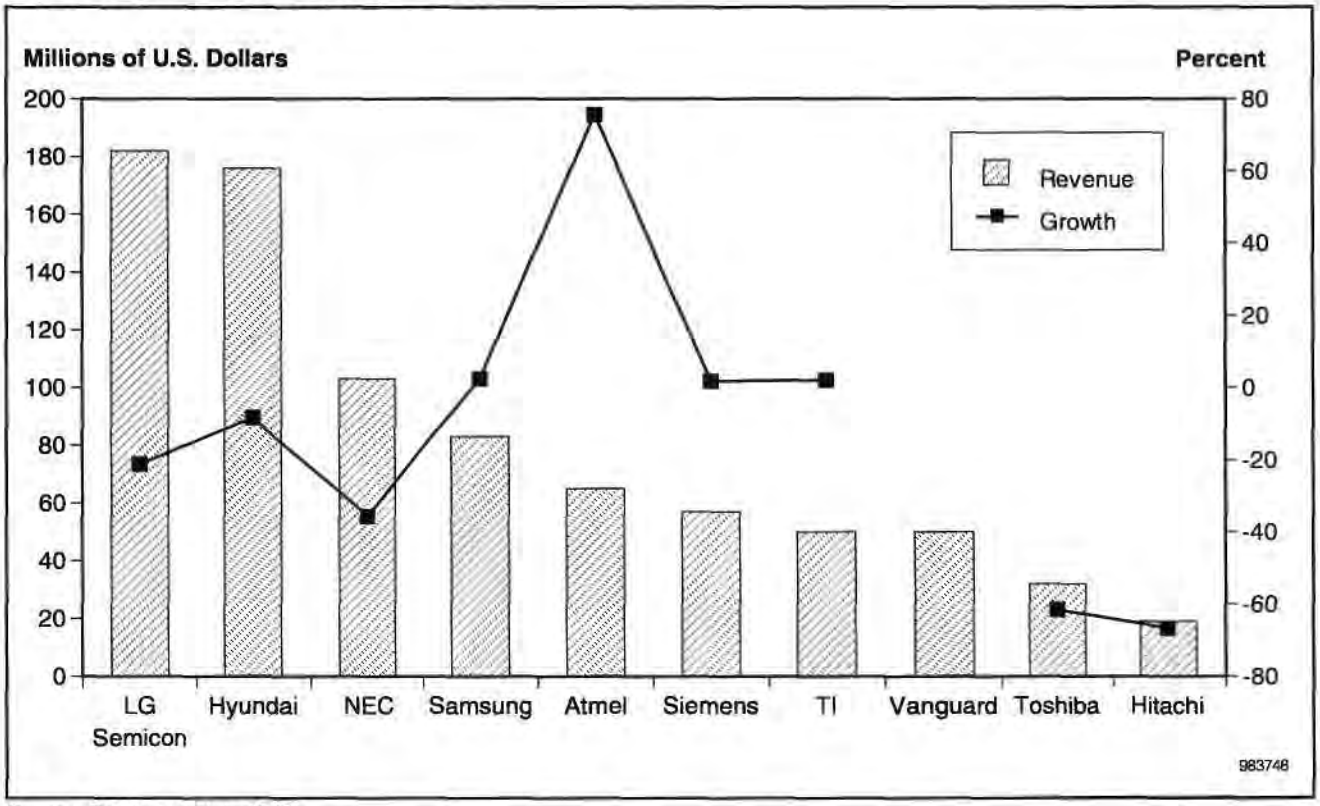
No. 1, LG Semicon Co. Ltd.

LG Semicon Co. Ltd. sustained its top spot in this category, claiming 16 percent of the memory market. This is 4 percentage points less than 1996's 20 percent share. Its DRAM share of total memory revenue declined from 74 percent in 1996 to 70 percent in 1997, indicating that the DRAM overcapacity was the main market inhibitor. LG Semicon's DRAM sales accounted for 72 percent of its semiconductor sales in China/Hong Kong in 1996, which dropped to 58 percent in 1997. As a share of Asia/Pacific total revenue, China/Hong Kong dropped from 30 percent to 28 percent of LG's total regional revenue. Even at this level, this ratio is much higher than other major memory players' ratios.

No. 2, Hyundai Electronics Company Ltd.

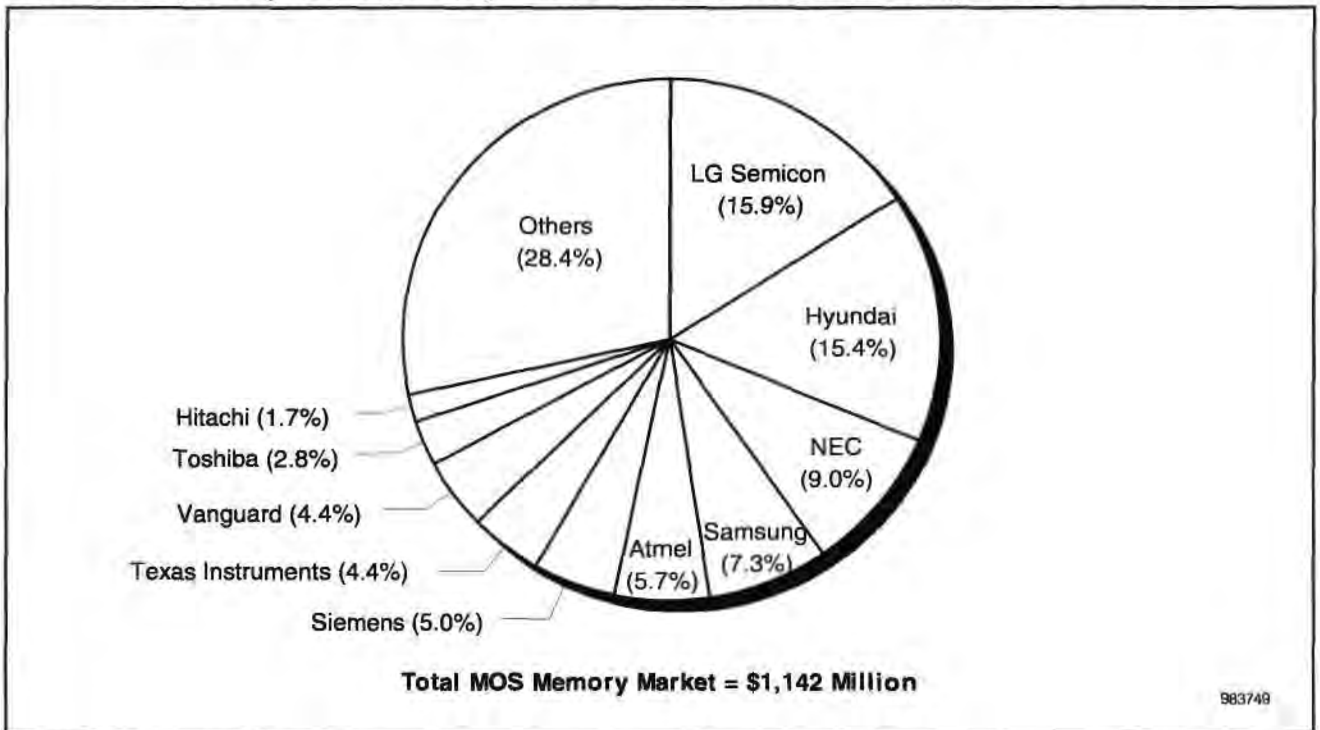
Hyundai's Electronics Company Ltd.'s revenue in China/Hong Kong increased from 23 percent of its total Asia/Pacific sales in 1996 to 25 percent in 1997. This number is between LG's 28 percent and Samsung's 21 percent concentration. For memories, China/Hong Kong also represented 23 percent of Asia/Pacific sales. This result is expected because almost all revenue comes from DRAMs and SRAMs, and these markets did not decline as fast as they did China/Hong Kong.

Figure 4-5
China/Hong Kong 1997 Top 10 MOS Memory Suppliers' Revenue and Percentage Growth (Millions of U.S. Dollars)



Source: Dataquest (July 1998)

Figure 4-6
China/Hong Kong MOS Memory Market Share, 1997 (Percentage of Revenue)



Source: Dataquest (July 1998)

No. 3, Samsung Electronics Company Ltd.

Approximately 19 percent of Samsung's Asia/Pacific revenue came from sales to China/Hong Kong in 1996, which climbed to 21 percent in 1997. Only 20 percent of Samsung's China/Hong Kong business was generated by memory in 1997. The memory shipments declined 16 percent in 1996 and grew 2 percent in 1997. Samsung was able to increase its memory market share for the second consecutive year. Its market share ranking for memories increased from No. 6 to No. 4 as a result. Yet, China/Hong Kong has not been a high-priority market for Samsung's memory division because only 9 percent of Asia/Pacific MOS memory sales are shipped to China/Hong Kong. Because of Samsung's size and the company's sizable volume in microcomponents, analog, and discrete, it jumped from No. 7 to No. 4 in overall semiconductor ranking.

No. 4, NEC Corporation

China/Hong Kong is NEC Corporation's most important Asia/Pacific market, constituting 27 percent of its total regional revenue in 1997. This number was 1 percent less than 1996's share. In recent years, increasing memory market share was an important factor behind NEC's overall success in the China/Hong Kong market (moving in total ranking from sixth to fourth). Approximately 44 percent of NEC's total semiconductor sales in China/Hong Kong came from memory products in 1996. This number declined to 29 percent in 1997. NEC's relative success in DRAM enabled it to increase memory market share from 13.8 percent in 1995 to 14.1 in 1996, thereby ranking third in memories after LG and Samsung, respectively. In 1997, the company lost significant market share because of its 35 percent decline in memory shipments, compared to only 16 percent for the overall market. But the company did not lose its third-ranking position as a result.

No. 5, Hitachi Ltd.

China/Hong Kong increased in importance to Hitachi's Asia/Pacific revenue from 14 percent to 17 percent in 1997. Hitachi has been losing memory market share in China/Hong Kong for several years and almost exited the market completely in 1997. In 1996, Hitachi moved from fourth rank to fifth rank, and its memory revenue declined from $136 million to $57 million in 1996. Market share decreased from 8.6 to 5.0 percent. Hitachi's memory shipments to China/Hong Kong represented 12 percent of all Asia/Pacific memory shipments. Within its China/Hong Kong sales, memories were 35 percent of total sales. Nevertheless, memory shipments declined 67 percent in 1997 to a meager $19 million. As a result, Hitachi's memory ranking slid from No. 8 to No. 10. Hitachi's total semiconductor ranking grew only 1.2 percent, and its ranking declined from No. 12 to No. 13.

Microcomponent Market Share Rankings

Microcomponent shipments increased 17 percent in 1996 to $1.6 billion and another 36 percent in 1997. Microcomponents' share of the semiconductor market in China/Hong Kong increased substantially, from 29 percent in 1996 to 33 percent in 1997. MPUs and microperipherals (MPRs) led the growth, with 31 percent and 40 percent growth, respectively, while MCUs expanded by 27 percent. Intel's dominance of the MPU market distorts this ranking, but a further analysis is discussed later.

 ©1998 Dataquest

Microprocessors

Intel's revenue from MPU shipments to China/Hong Kong as a percentage share of Asia/Pacific decreased from 17.5 percent in 1996 to 17 percent in 1997. In 1996, more than 85 percent of Intel's semiconductor business came from MPUs, totaling $477 million, compared with $558 million for the company's semiconductor shipments as a whole. In 1997, MPU sales increased 25 percent to $599 million, a slowdown from 1996's growth. Intel's next largest segment was MPRs, which totaled approximately $34 million in 1996 and only $36 million in 1997. Dataquest estimates Intel's MCU sales at approximately $31 million, experiencing a flat growth.

Intel dominates this sector, but if one deducts its $599 million in MPU sales, then only $67 million remains, which is split equally between MCUs and MPRs. Intel's 22.9 percent growth is attributed to a 25.6 percent growth in MPRs, rather than to MCUs and MPRs, which were relatively flat products.

The overall MPU market expanded 31.2 percent, and Intel lost market share, with non-Intel parts expanding by 75 percent. Non-Intel x86 MPU vendors, including AMD, National Semiconductor, STMicroelectronics BV (formerly SGS-Thomson), and IBM, accounted for 14.1 percent of x86 MPU shipments to China in 1997. However, this 14.1 percent share is having a significant impact on Intel's pricing and product strategy in China. In 1998, tightened budgets in business and home result in a price-conscious buying behavior that has benefited the non-Intel camp. Additional challenges lie ahead for Intel, as the market's move to the sub-$1,000 PC is diminishing brand association, which is likely to benefit non-Intel vendors. At the same time, diminished margins make retail-level marketing all the more expensive and difficult to rationalize—but perhaps, all the more necessary. Figure 4-7 illustrates China/Hong Kong's top 10 MOS microcomponent suppliers' revenue and growth in 1997. Figure 4-8 shows MOS microcomponent vendors' market share in China/Hong Kong for the same year.

Microperipherals

The MPR market was bolstered by VCDs, communications, and a continued strength in PC production. The market growth accelerated from 22.7 percent to 40 percent in 1997. S3 Incorporated moved from insignificant sales to a 15 percent market share within one year, ranking No. 2 behind United Microelectronics Corporation (UMC) in 1997. UMC remained the dominant MPR vendor because of its dominance in the PC motherboard segment. Only a few major PC vendors rely on Intel core logic chipsets, and Intel's MPR revenue is only one-third of UMC's.

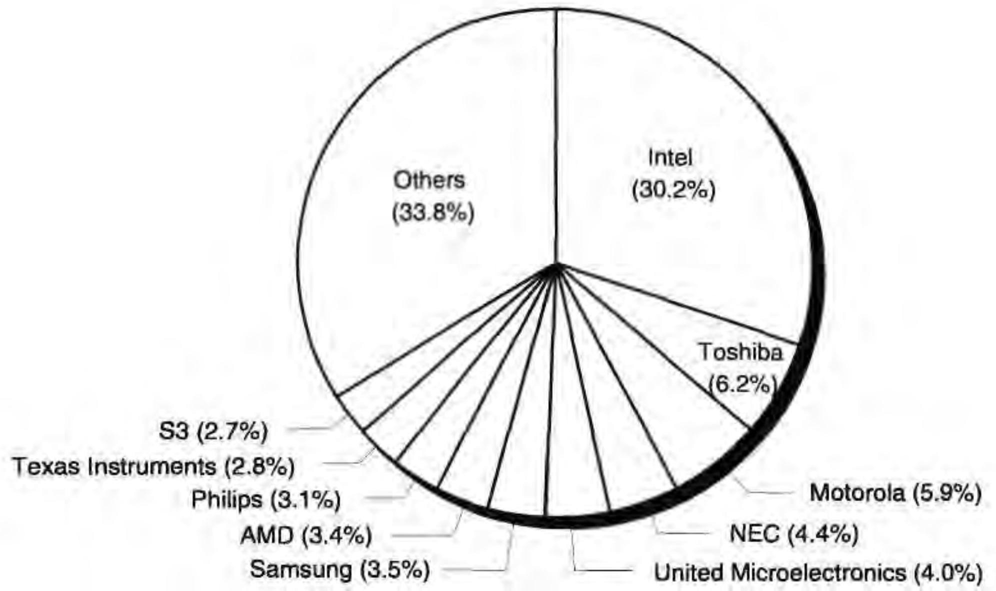
Source: Dataquest (July 1998)

Figure 4-8
China/Hong Kong MOS Microcomponent Vendors' Market Share, 1997 (Percentage of Revenue)



Source: Dataquest (July 1998)

Microcontrollers

The MCU market also accelerated, recovering with a 27.7 percent growth after experiencing a decline in 1996. The primary growth areas were communications and home appliance markets. As previously discussed, Samsung aggressively and successful tackled this market. Because of the diversity of applications, the success stories vary. Companies in the communications sector generally outperformed those in the consumer sector. Toshiba had made strong gains in the home appliance sector, but the low average selling prices (ASPs) resulted in a below-average market performance.

Motorola, which ranked second overall in the microcomponents market (because of its high revenue levels in MCUs), trailed far behind Intel in MPU revenue. More than 23 percent of Motorola's Asia/Pacific microcomponent revenue came from China/Hong Kong in 1996. In 1997, this number declined to 19 percent. About 33 percent of Motorola's China/Hong Kong semiconductor revenue came from microcomponents in 1996. In 1997, similarly, 32 percent of revenue came from microcomponents. MCUs occupied 20 percent of China/Hong Kong's semicon-ductor business in 1996. But this figure dropped to 14 percent, and the company lost significant market share at the same time. MCUs were the slowest sector of microcomponents in 1996, growing at just 6 percent (this slow growth was attributed, in part, to a market slowdown). The MCU market recovered with a 28 percent growth, yet Motorola's revenue was flat.

 ©1998 Dataquest

Digital Signal Processors

The fourth segment in microcomponent is digital signal processors (DSPs), which doubled from $81 million to $162 million in 1997. Lucent Technologies usurped the No. 1 position from TI by doubling its sales, while TI experienced a flat growth. Philips Electronics NV's market presence was felt as its sales rose from zero to $8 million in 1997, securing a top five position. Toshiba promoted its DSPs in the communications markets and expanded revenue nearly sixfold to approximately $40 million.

MOS Digital Logic Market Share Rankings

Dataquest's estimates indicate that China/Hong Kong's MOS digital logic market grew from $650 million in 1996 to $895 million in 1997, with an annual growth rate of 40 percent. In 1996, the demand for MOS digital logic comprised mainly ASICs (43 percent), and standard logic products (15 percent), while another 38 percent of MOS logic consumption in China consisted of other logic devices. In 1997, the market makeup was ASICs (28 percent), standard logic products (22 percent), and other logic devices (41 percent). MOS custom ICs increased from 5 percent to 9 percent of MOS digital logic revenue in this period.

Toshiba became the No. 1 supplier with 16 percent of this market. Its 1997 sales increased 107 percent to $143 million (see Figure 4-9).

In 1997, the overall market growth of MOS digital logic was 37.8 percent from negative 9.3 percent a year earlier, which was a sharp turnaround in the MOS logic market. However, the range of vendor performance was more dramatic than in most years. The main reason for these variances is the volatility within various end markets. Although ASIC consumption declined 8.6 percent in 1997, standard logic kept pace with the broad-based growth within communication, consumer, and computer sectors in China. Lucent, NEC, Motorola, and Fujitsu are exceptions among the top 10 in that they generated a positive revenue growth in ASICs. The rest, Samsung, TI, Matsushita Electric Industrial Company Ltd., IBM, Toshiba, and LG Semicon, suffered declines. The MOS logic market was helped by a strengthening in standard logic and other MOS logic, which grew by 103 percent and 50 percent, respectively. Figure 4-10 illustrates China/Hong Kong's MOS digital logic market share in 1997.

Analog IC Market Share Rankings

The $1.4 billion analog-monolithic market has a diverse supplier base with minor differences among the companies' market share but a wide variance in the 1997 growth rates (see Figures 4-11 and 4-12).

The total analog market in China expanded 28.6 percent in 1997 because of a surprisingly strong growth in China's communication markets. The large, dispersed monolithic-analog IC market represents a formidable 21 percent of China's total semiconductor consumption. The 32 companies surveyed increased sales by 32.7 percent and, therefore, gained market share. TI jumped from No. 8 to No. 2 because of an impressive 149 percent revenue growth. Market leader Toshiba maintained its lead with an above-average growth of 31.6 percent. The consumer analog market also performed well in 1997, and vendors—such as SANYO and Rohm—expanded their market share.

©1998 Dataquest

Discrete Market Share Rankings

Dataquest estimates that in 1997, the value of China/Hong Kong's discrete devices reached $859 million. The discrete market represents a 12.7 percent share of China's total semiconductor consumption, but it continues to undergo steady growth year after year. In 1997, the market expanded 22.1 percent. The surveyed companies increased shipments to China by 25.8 percent and gained market share over less competitive domestic manufacturers. This segment's consumer applications are relatively close to discrete devices, as Dataquest observes the vendors' shipment performance. Toshiba, SANYO, Rohm, and Philips are able to leverage their consumer market presence to ship analog and discrete products to the same customers. Among the top 10 discrete suppliers to China, only NEC, Korea Electronic Company Ltd., and Hitachi are not among the top 10 analog suppliers (see Figures 4-13 and 4-14).

Chapter 5
Drivers of Future Semiconductor Demand

Forecast Synopsis

Global overcapacity—particularly in MOS memories—in the Asia/Pacific and China semiconductor markets will result in a lower overall revenue growth than forecast in May 1998.

The financial crises and economic recessions across Asia/Pacific are expected to recover in the next two to three years. Despite China's mammoth economic challenges, its management of the economy, thus far, has allowed it to avoid Southeast Asia's fate. As always, there is a on-going balance between the divergent forces. The electronics industry is helped by its product and market diversity, foreign investors' continued confidence, long-term market prospects, strong government support in communications and computer infrastructure projects, and rising equipment exports to the United States and Europe, which accounted for more than 31 percent of China's total production.

Dataquest's economic assumptions for this forecast are described in Chapter 2. The key assumptions for 1998 are as follows:

- The growth of China's GDP has been revised down to 6.5 percent by several economists. Hong Kong's economic growth is expected to contract by 1 percent to 2 percent in 1998.
- The effect of the Asian financial crisis and Japan's economic quagmire on China's economy is not apparent.
- Dataquest has lowered its electronic equipment production forecast from 20 percent to 16 percent in 1998. Some of the key high-level assumptions behind this change are as follows:
    - A slowdown in domestic consumption, including the following:
        - Weaker consumer spending attributed to slower economic growth and rising unemployment
        - A delay in purchases by state-owned enterprises (SOEs)
        - Conservative fiscal policy and lending to businesses
        - Restructuring of SOEs
    - A slowdown in electronics exports, which represent more than 50 percent of electronic equipment production, including the following:
        - China's exports to Japan, Korea, and Southeast Asia represent 25 percent of total exports and will be drastically affected.
        - Continued strength in exports to Europe and the Americas, which represent more than 65 percent of total exports, will help counter the effect of Asia's economic slowdown.
        - Foreign investment in production capacity has slowed somewhat but not dramatically.

©1998 Dataquest

- Semiconductor consumption will have difficulty achieving a 15.5 percent growth because of the following factors:
  - DRAM revenue could decline by 27 percent.
  - The memory market shows a widespread weakness.
  - Nonmemory market forecasts in this report have not changed.

A Long-Term Forecast Overview

Table 5-1 shows that Asia/Pacific will grow by an estimated 15.7 percent CAGR from 1997 to 2002, which is slower than Dataquest's 1996-to-2001 forecast of 19 percent. This projected growth is only 2 percentage points faster than the worldwide forecast of 14 percent in this period. Dataquest expects a worsening of the current semiconductor slowdown in Asia/Pacific. The long-term growth is likely to be slower than in North America.

The Asia/Pacific market consumed 21 percent of all semiconductors shipped worldwide in 1996, which rose to 22.1 percent in 1997. China/Hong Kong consumed 19 percent of shipments to the Asia/Pacific region in 1996, or 4 percent of the worldwide market. This share rose to a 21 percent share of Asia/Pacific and 5 percent of the worldwide market in 1997. Dataquest expects that share to reach 26 percent of Asia/Pacific and 7 percent of worldwide consumption by 2002, representing a $17.6 billion semiconductor opportunity.

Table 5-1
Worldwide Semiconductor Consumption Forecast by Region, 1997 to 2002
(Millions of U.S. Dollars)

	1997	1998	1999	2000	2001	2002	CAGR (%) 1997 to 2002
North America	48,086	53,326	64,133	78,388	95,782	99,906	15.7
Japan	36,499	37,397	42,943	49,988	58,610	61,093	10.9
Europe	30,046	32,627	38,425	46,927	56,152	59,335	14.6
Asia/Pacific	32,534	35,899	42,754	51,751	64,483	67,561	15.7
Worldwide	147,165	159,249	188,255	227,054	275,027	287,895	14.4

China/Hong Kong: The Largest and Fastest-Growing Market in Asia/Pacific

Dataquest believes that China/Hong Kong will continue to expand its manufacturing scope capabilities faster than any other region in Asia/Pacific. This is because of strong government support for numerous large manufacturers and significant foreign investments, which have showed no signs of slowing. China is learning and improving its manufacturing capabilities at a faster rate than its Asian predecessors. Dataquest continues to observe quality and efficiency rising across consumer, communications, and data processing industries. For this reason, foreign investment confidence continues to rise, although China has long way to go to improve its investment environment. Semiconductor content will consequently rise as production quality and capacity expand to suit overseas market and China's quality-conscious consumers. The shift of factories to China/Hong Kong from Japan, Europe, America, and Taiwan makes China of central importance to semiconductor suppliers' strategies in the region.

Figure 5-1 shows that China/Hong Kong is expected to remain the fastest-growing country in the Asia/Pacific region from 1997 to 2002. Dataquest believes that the China/Hong Kong market will expand about 7 percentage points faster than the rest of the region and 4 percentage points faster than Taiwan. It is noteworthy that China/Hong Kong was only the third-fastest-growing market in this region from 1991 to 1995, at a 31.3 percent CAGR, after Singapore and Southeast Asia. As explained in Chapter 3, Dataquest asserts that structural changes in China's electronics industries and end markets from 1995 to 1997—in addition to Korea's and Southeast Asia's economic troubles—will result in China's long-term growth leadership in the region. For sure, China and Hong Kong have challenges of their own, but not nearly to the extent of most of the region (see Chapter 2).

Semiconductor Market Forecast Drivers

The China/Hong Kong semiconductor market is positioned for accelerating growth in the next five years, but it is not immune from the prolonged worldwide slowdown. Dataquest has lowered its long-term electronic equipment production forecast because of the weaker worldwide consumption forecast by GartnerGroup and Dataquest systems market research divisions. Because China exports about half of its semiconductor production, global consumption trends play an important part in Dataquest's forecast assumptions. Additionally, Dataquest believes that domestic consumption will slow because of massive restructuring and rising unemployment. However, the overall disposable income and domestic consumption will show significant gains, thereby boosting local production.

Time to market has become the fundamental competitive advantage of electronics companies in all major markets in the world. Production will accelerate in China as companies seeking growth markets in an increasingly competitive global marketplace attempt to steal or protect market share from competitors.

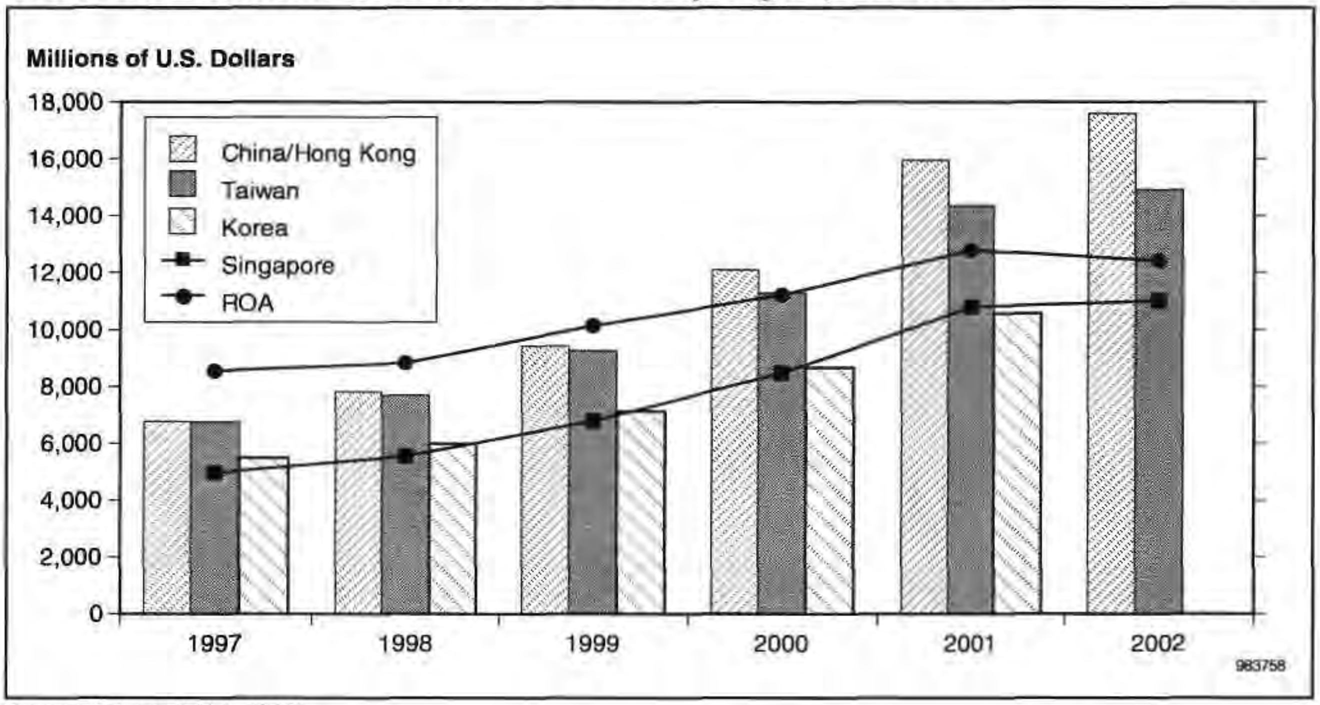
Figure 5-1
Asia/Pacific Semiconductor Market Forecast by Region, 1997 to 2002



Source: Dataquest (July 1998)

Dataquest expects a worldwide electronic equipment market upturn in 2000, which will be driven by digital consumer electronics and convergent computer-communication technologies. At the same time, the worldwide semiconductor industry will have recovered by 2000 because of two years of slow capital spending.

In this scenario, Dataquest's forecast shows that China/Hong Kong will achieve electronic production growth of 16 percent CAGR from 1997 to 2002. Dataquest foresees the immature PC and communications industries in China as leading the broad-based growth in the next silicon cycle. Growth in China during the past two years has been led by computers and communications. Now the American and European companies, rather than the Japanese, are the most aggressive investors in China's IT industries. With leadership from China's newly formed Ministry of Information Industry, computers and communications have moved to the center of China's industrial development policy. Furthermore, business applications for computers and communications are swelling in an economy with a GDP that will expand by 7 percent in the next five years.

Market Forecast by End Equipment

Table 5-2 shows China/Hong Kong's electronic equipment production forecast and semiconductor consumption by application from 1997 to 2002. Dataquest publishes information on detailed electronic equipment production and semiconductor consumption by device in other reports. The intent of this section is to provide a top-line summary of these production and consumption databases. Dataquest publishes detailed unit and company-level production forecasts, which provide the quantitative basis of these figures.

Data Processing: To Become the Application Leader in Size and Growth

Data processing was the fastest-growing equipment and market segment in 1997. Dataquest has not changed its views from 1997 that data processing will be the fastest-growing electronics production and semiconductor consumption segment from 1997 to 2002. Production is expected to grow at a 24 percent CAGR, engendering a semiconductor market growth of 28 percent—driven by strong domestic demand and continued export prowess. Data processing did not achieve the No. 1 ranking in production in 1998 as Dataquest forecast because of a strong year for VCDs. But Dataquest expects it to become the largest industry by the end of 1998. Data processing was the largest semiconductor market in China/Hong Kong in 1997, despite the memory market, decline because of its volume growth. With data processing equipment production forecast to grow by a 24 percent CAGR, data processing semiconductors will grow by 28 percent from 1997 to 2002. Data processing was and will continue to be the fastest-growing application of the China/Hong Kong semiconductor market for the decade (see Table 5-3).

Table 5-3

Consumer: Benefiting from Strong Domestic Consumption

Consumer electronics production will be the slowest segment with a 12 percent CAGR from 1997 to 2002. The year 1997 was a good year because of VCDs' phenomenal growth. Semiconductor shipments to this segment will grow by 18 percent because of digitally enhanced products that are expected to be introduced worldwide in this period. Dataquest expects digital television broadcasting to begin after 2000, and the Chinese government is formulating policies and plans to keep pace with the world in this arena. Chinese and Hong Kong consumer electronics manufacturers are moving into set-top boxes, and Dataquest expects a strong OEM production growth in 1999 (see Table 5-4).

Communications: Large Markets with a Steady Growth

Communications is the third-largest electronics equipment industry and the second-largest semiconductor market in China/Hong Kong. Dataquest forecasts communications equipment production and semiconductor consumption to grow at a 12 percent CAGR. Because communications production consisted predominantly of price-sensitive retail products—such as handsets, pagers, cordless phones, and answering machines—production revenue growth will lag communication systems' market expansion (see Table 5-5). These products are exported and shipped locally. Dataquest believes that the majority of China's purchases of public infrastructure and premises equipment, which are semiconductor-rich equipment, will continue to be imported rather than produced locally for the next few years. But there, the government is achieving increased localization of production by encouraging multinationals in the market to invest in production or by supporting local Chinese companies.

Semiconductor Device Forecast Trends

The DRAM market growth from 1991 to 1995 was a remarkable 50 percent CAGR. But these good days are gone. Dataquest's five-year projection of 16 percent represents a dramatically slower cycle that is pulling down the overall semiconductor forecast. As shown in Table 5-3, the total China/Hong Kong semiconductor market will decelerate to 21 percent CAGR from 1997 to 2002. The severe price drop of MOS memory that began in 1996 will hamper the market growth in 1998 and part of 1999. MOS memory growth will experience an 18 percent CAGR from the contraction year of 1997 to the next contraction beginning in 2002. This is a much lower forecast than expected in 1997 because of the delayed DRAM recovery. Table 5-6 presents China/Hong Kong's semiconductor forecast by device type in the 1997-to-2002 forecast period.

Figures 5-2 and 5-3 illustrate China/Hong Kong's semiconductor consumption forecast by device type in revenue and percentage, respectively. Figure 5-4 depicts China/Hong Kong's semiconductor forecast by main application market.

Source: Dataquest (July 1998)

Leading this 21 percent CAGR from 1997 to 2002 are MOS microcomponents, growing by a 23 percent CAGR. The next growth category is expected to be MOS microcomponents in terms of size and growth. This growth is enabled by strong MPU demand that will carry the microcomponent market to $5.3 billion in 2002. MOS logic devices lost relative share in this period, but expanded in absolute terms to $1.8 billion. Dataquest expects a stronger growth toward the end of the forecast period because ASIC capabilities will increase after three years. Similarly, analog, discrete, and optoelectronics devices will occupy 38 percent of China/Hong Kong's market by 2002, compared to 37 percent in 1996. Nevertheless, these will grow from $2.4 billion in 1997 to $6.6 billion to 2002. Much of this growth is the result of continued economic expansion into China's new regions. That is, demand for appliances, radios, color televisions, and communications equipment has slowed in coastal provinces, but it is increasing in the second-tier markets of inland provinces (such as Henan, Hubei, Shanxi, and Hunan).

 ©1998 Dataquest

Overall Memory Forecast

Dataquest expects MOS memories to lag the market expansion in China/Hong Kong in the next five years. The problem of falling memory average selling prices is ameliorated by rapid bit growth resulting in an 18 percent CAGR. Demand is coming from a strong electronic sector, which thrives on exports, but is being further bolstered by local demand. Dataquest's five-year CAGR for electronic equipment production is forecast to be more than 16 percent. PC production, forecast to expand at a 40 percent CAGR, is expected to generate a growth in semiconductor consumption at about an 18 percent CAGR. This result is very achievable. Dataquest expects China to accelerate is migration to high-content systems that are already mainstream or mature in Europe, Japan, and North America, but just starting to be manufactured in volume in China. These mainstream products—such as PCs, peripherals, and mobile and premise communications equipment—will represent high-growth opportunities because they are much richer in semiconductor content than China's current production base. In addition to existing high-content products, Dataquest sees new products already emerging in the Chinese market. The case in point is the DVDs that will be rapidly introduced in the China market as an extension of the current VCD craze.

As discussed in greater detail in later sections, Dataquest expects the market to be further supported by nonmemory parts that will experience more steady but accelerated growth in the next five years. Nonmemory products are forecast to grow at a 22 percent CAGR from 1997 to 2002 in China/Hong Kong.

DRAMs

Memory pricing will continue to be the most volatile and pivotal segment of the market. A sluggish growth in 1998 is expected to give way to greater growth in 2000. The CAGR for the next five years is 48 percent, which is more than double the worldwide growth rate. This forecast is consistent with Dataquest's view that PC production will grow by more than 40 percent in this period, which is more than double worldwide production growth.

Microcomponent Market Forecast

MOS microcomponents will be the fastest-growing market in China/Hong Kong from 1997 to 2002. The microcomponent market surpassed memories in 1996 to become the largest market segment in China/Hong Kong, reaching $1.6 billion. In 1997, the market experienced growth across MPU, MCU, MPR, and DSP products, enabling a 36 percent growth to $2.2 billion. In the next five years, Dataquest does not expect memories to surpass microcomponents again. By 2002, microcomponents will represent a $6.5 billion market, which will constitute a 37 percent share of China/Hong Kong's semiconductor consumption, compared to only a 15 percent share for MOS memories.

©1998 Dataquest

Microprocessors

MPUs are the largest and fastest-growing microcomponent market in China/Hong Kong. MPUs sustained market dominance with a 39 percent market share in 1997. After MPU shipments rose by 48 percent in 1996 to $0.7 billion, they decelerated to 31 percent in 1997, as competitors entered the China market and ASPs declined. The 32-bit-and-above CISC processors occupy more than 80 percent of the China/Hong Kong MPU market. The 8- and 16-bit processors and below represent less than 10 percent of the market, while the 32-bit-and-above RISC processors represent about 10 percent of the total China/Hong Kong MPU market.

If not for a near monopoly in MPUs, Dataquest might even see a decline in semiconductor content per system. Table 5-2 presents Dataquest's estimates of PC production by MPU type in each quarter of 1997. Pentium II and AMD's K6 were the only other non-Pentium, x86 products to experience growth in the fourth quarter of 1997. The success of China's domestic manufacturers is attributed to their ability to introduce next-generation products before technically superior foreign brands could import and distribute their products in China. Their proximity to their channels and ability to source locally buy critical time to market.

Chinese companies are accelerating their rate of technology adoption and surpassing their foreign counterparts in Pentium II consumption in the fourth quarter of 1997, as illustrated in Figure 5-6. For the year, foreign-versus-local Pentium-class processor consumption was proportional to total PC production. In short, there was no marked difference between foreign and local manufacturers' technology level relative to the Chinese market.

Microperipherals

MPRs were the fastest-growing microcomponent segment in 1997, with a 40 percent growth. MPRs will almost keep pace with MPU revenue growth in the next five years with a 22 percent CAGR, compared to a 27 percent CAGR for MPUs. As always, there will be more competition and pricing pressure in this sector. However, the broad range of audio/video, graphics, core logic, communication controllers, and mass storage, which are in high demand in China/Hong Kong, will support growth. The year 1997 was a recovery year with 40 percent growth. Dataquest believes that two high-growth sectors include communication controllers and mass-storage controllers. Because of the pricing pressure, the MPR segment will experience a revenue decline from a 22 percent to 20 percent share of the microcomponent revenue from 1997 to 2002.

 ©1998 Dataquest

Microcontrollers

The MCU market represented 31 percent of the microcomponent market in China/Hong Kong in 1997. The overall share has been declining as the consumer segment represents a smaller and smaller share of overall applications. After a sluggish 5 percent growth in 1996, MCUs improved in 1997 as Dataquest forecast. Dataquest saw a firming of worldwide prices and a recovery in consumer electronics production in China, fueled by new applications, expanding demand, and a healthy communications sector growth. Dataquest's five-year forecast calls for approximately 20 percent CAGR from 1997 to 2002, which is about 3 percentage points faster than for Asia/Pacific.

Digital Signal Processors

The digital signal processor market is a small but rapidly developing market in China. Current DSP consumption is predominantly in systems that are designed in Europe, North America, or Japan, and shipped to China. The largest market in 1997 was rigid disk drives. TI's DSP strategy focuses on delivering solutions, and its DSP part of the solution includes analog ICs such as drivers. As shown in Chapter 4, TI's market share increased in both DSPs and analog ICs.

DSP shipments to assemblers and manufacturers was only about $20 million in 1996, but jumped to $165 million in 1997. From a local design standpoint, the DSP market will not develop for another two years when local manufacturers have the capabilities to utilize DSP technology to differentiate or enhance the performance of a wide range of mobile and base-station communication equipment. TI is leading the way in China by setting up design centers that will play a role in providing turnkey solutions and support to local manufacturers. Dataquest has raised its market forecast to exceed $683 million by 2002, growing at a 33 percent CAGR.

MOS Digital Logic Market Forecast

The MOS digital logic market in China/Hong Kong comprised four segments, including ASICs, standard logic, custom ICs, and other digital logic ICs. The largest logic market, the other MOS digital logic device market, was approximately $368 million in 1997, sharing 41 percent of the MOS digital logic market.

Asia/Pacific's 17 percent growth and China/Hong Kong's 38 percent growth exceeded worldwide consumption of 9.2 percent significantly. Dataquest expects China/Hong Kong to decelerate to 9 percent in 1998 but maintain a five-year 16 percent CAGR. The main opportunity for ASIC vendors to emerge will be to provide ASIC solutions and reference designs to China's local electronic equipment industry that competes for local market share against multinational companies. The most lucrative opportunity for ASIC growth will be in systems-level integration (SLI), which will be prominent in low-power, portable computing and communication devices. Currently, mobile computing is not a high-growth PC market in China.

©1998 Dataquest

Standard logic consumption doubled in 1997 to $197 million after expanding only about 5 percent in 1996. Dataquest expects standard logic devices to reach $300 million in 2002, but to decline in share of the MOS logic market from 22 percent to 16 percent. This is a 9 percent CAGR, compared to MOS logic's 16 percent. Dataquest's other logic category is forecast to grow faster than standard logic from 1997 to 2002, with a 13 percent CAGR. Total other MOS logic will still decline in overall share from 41 percent to 36 percent because of the rising market share of ASICs.

Analog Market Forecast

The analog market (including monolithic and hybrid analog) in China/Hong Kong maintained its 21 percent of total semiconductor consumption in 1996 and 1997. Dataquest forecasts that analog will become increasingly important from 1997 to 2002, rising in overall share to 25 percent of total semiconductor consumption. China's communications markets have been booming in the past five years, but Dataquest did not see comparable growth in communications equipment production. Dataquest saw the same phenomenon with PCs—PC production has only surged in the past three years but still lags the rate of PC market growth. In the next two years, Dataquest expects computer applications to outpace consumer and communications electronics significantly as production capacity comes online. Analog is benefiting from its wide applications in these sectors and will, therefore, grow by 25 percent CAGR from 1997 to 2002. The introduction of several new major consumer electronics products will bolster consumer electronic production in the next few years. However, it will require a wider application of digital consumer devices in China before consumer will be able to keep pace with computer production.

Discrete and Optoelectronic

Discrete semiconductors and optoelectronic semiconductors have an even wider base of applications than analog, but they are more price sensitive—especially because local companies supply the Chinese market. In revenue terms, these markets are smaller than analog, however. These devices are also linked primarily to China's consumer applications market growth, as described previously. Dataquest's forecast for discrete shows a healthy growth of 17 percent CAGR, but this market will decline slightly in overall revenue share from 13 percent to 11 percent of total semiconductor consumption.

China/Hong Kong's Increased Share of Asia/Pacific Device Markets

Dataquest's forecast of China/Hong Kong's share of the Asia/Pacific semiconductor market is shown in Tables 5-7 and 5-8. All devices will increase their total share of the Asia/Pacific market. China/Hong Kong will account for 26 percent of the total Asia/Pacific semiconductor market in 2002, from 19 percent in 1996. China/Hong Kong's analog market will grow from 20 percent to 31 percent of Asia/Pacific consumption, discrete will expand from 21 percent to 30 percent, and optoelectronic will increase from 23 percent to 28 percent share of Asia/Pacific consumption. China/Hong Kong's MOS digital market, which is driven mainly by data processing and accounted for only 18 percent of the total Asia/Pacific market in 1996, is less than analog, discrete, or optoelectronic.

However, the China/Hong Kong MOS digital market's share of Asia/Pacific consumption will increase at a faster rate, rising to 21 percent by 2002. Specifically, the MOS microcomponents' segment will be the key driver as it increases its share from 19 percent to 26 percent. Table 5-9 presents China/Hong Kong's share of Asia/Pacific semicon-ductor consumption by semiconductor product from 1997 to 2002. Tables 5-10 and 5-11 show the dollar and percentage value of China/Hong Kong's semiconductor consumption by application subsegment in this forecast period.

Table 5-7
China/Hong Kong Semiconductor Consumption Forecast by Device Type, 1997 to 2002 (Percentage Growth)

Chapter 1
Market Share Survey Overview

Each year, Dataquest surveys semiconductor vendors to estimate their annual sales. The survey currently covers more than 150 semiconductor vendors worldwide (this varies according to mergers, acquisitions, liquidations, start-ups, and so on) by 61 individual semiconductor product categories (excluding subtotals), six application segments, and four world regions (Europe is split into further subregions). This exercise helps Dataquest maintain its dynamic database of semiconductor supply by company and semiconductor vendor revenue by world region and product. The information gained is supplemented by, and cross-checked with, Dataquest's various other information sources.

The semiconductor market share survey process starts during the fourth quarter of each calendar year. The first-phase, top-level estimates for large companies are completed by the end of the calendar year under review, and the results are summarized in several Dataquest reports.

The final detailed survey of all companies starts just after the end of the calendar year under review. These estimates are published in the second quarter of the year following the calendar year under review.

The categories for which semiconductor revenue is reported are defined comprehensively for the purpose of clarity and guidance to survey participants. These definitions may occasionally be revised, altered, or expanded to reflect changes in the industry. To support these definitions, Dataquest will issue an annual survey guide to all participants in its semiconductor market share survey program. This document is the 1997 survey guide.

Chapter 2
Semiconductor Companies Surveyed Worldwide

In gathering market share data we contact semiconductor companies worldwide.

Americas Companies Surveyed

The following Americas companies were surveyed during 1997:

- ACC Microelectronics
- Actel
- Adaptec
- Advanced Micro Devices
- Allegro MicroSystems
- Altera
- Analog Devices
- Applied Micro Circuits
- AT&T
- Atmel
- Brooktree
- Burr-Brown
- C-Cube Microsystems
- California Micro Devices
- Catalyst
- Cherry Semiconductor
- Chips & Technologies
- Cirrus Logic
- Cypress Semiconductor
- Cyrix
- Dallas Semiconductor
- DSP Semiconductor
- Elantec
- Electronic Designs
- ETEQ Microsystems
- Exar
- General Instrument
- Gennum
- Gould AMI
- Harris
- Hewlett-Packard
- Honeywell
- Hughes

- IBM
- IMI
- Integrated Circuit Systems
- Integrated Device Technology
- Integrated Information Technology
- Integrated Silicon Solution
- Intel
- International CMOS Technology
- International Microelectronic Products
- International Rectifier
- Kulite
- Lattice
- Linear Technology
- Linfinity
- Logic Devices
- LSI Logic
- Maxim
- Micrel
- Micro Linear
- Micro Power Systems
- Microchip Technology
- Micron Technology
- Microsemi
- Mitel
- Motorola
- National Semiconductor
- NCR
- Optek
- OPTi
- Paradigm
- Performance Semiconductor
- Powerex
- Q Logic
- Quality Semiconductor
- Quality Technologies
- QuickLogic
- Ramtron
- Raytheon
- Rockwell

- S3
- Seeq Technology
- Semtech
- Sierra Semiconductor
- Silicon General
- Silicon Systems
- Sipex
- Solitron
- Standard Microsystems
- Supertex
- Symphony Laboratories
- Tektronix
- Telcom
- Texas Instruments
- Trident Microsystems
- TriQuint Semiconductor
- Tseng Labs
- Unitrode
- Universal
- Vitesse
- VLSI Technology
- VTC
- WaferScale Integration
- Weitek
- Western Digital
- Xicor
- Xilinx
- Zilog

 ©1998 Dataquest

Japanese Companies Surveyed

The following Japanese companies were surveyed in 1997:

- Fuji Electric
- Fujitsu
- Hitachi
- Matsushita Electronics
- Mitsubishi Electric
- NEC
- New Japan Radio
- Nippon Steel
- Oki Electric Industry
- Ricoh
- Rohm
- Sanken Electric
- SANYO Electric
- Seiko Epson
- Sharp
- Shindengen Electric Manufacturing
- Sony
- Toko
- Toshiba
- Yamaha

European Companies Surveyed

The following European companies were surveyed in 1997:

- ABB-Hafo
- ABB-Ixys
- Austria Mikro Systeme
- Elex
- Elmos
- EM Microelectronic
- Ericsson
- Eupec
- European Silicon Structures
- Fagor
- GEC Plessey Semiconductors
- ITT
- Micronas
- Mietec
- Philips Semiconductors

- Semikron
- STMicroelectronics
- Siemens
- TCS (Thomson Composants Spatiaux)
- TEMIC
- Thesys
- Westcode Semiconductors
- Zetex

Asia/Pacific Companies Surveyed

The following Asia/Pacific companies were surveyed in 1997:

- Acer
- Daewoo
- LG Semicon
- Hualon Microelectronics
- Hyundai
- Korean Electronics
- Macronix
- Mosel Vitelic
- Samsung
- Silicon Integrated Systems
- United Microelectronics
- Vanguard
- Winbond Electronics

Summary

The following summarizes the semiconductor companies surveyed in 1997:

- 100 Americas companies
- 20 Japanese companies
- 23 European companies
- 13 Asia/Pacific companies
- 156 companies worldwide

Chapter 3
General Sales Definitions

Dataquest tracks semiconductor vendors' revenue as defined in the following paragraphs.

Revenue

Revenue is the gross sales generated by a vendor or manufacturer, measured in unit currency.

Semiconductor Vendor

A vendor is the last entity in the chain that brands a product and sells it either directly to end users or through a channel. A semiconductor vendor may design and manufacture its own products, in which case it is also an original component manufacturer, or the vendor may procure semiconductors from a component contract manufacturer.

Vendor Revenue

Vendor revenue is defined as the average selling price of a semiconductor product multiplied by the vendor's unit shipments of that product.

Revenue Based on Customer Location

All revenue from sales is reported according to customer location, that is, the shipping destination. The four regions that Dataquest uses for the purpose of this survey are the Americas; Japan; Europe, Africa, and Middle East; and Asia/Pacific.

Manufacturer

A manufacturer is a producer of branded or unbranded finished products. A semiconductor manufacturer could be a contract manufacturer, an original manufacturer, or both.

Original Component Manufacturer

This is a manufacturer that designs and produces components such as semiconductors and design tools either for sale under its brand name or for use internally. An original component manufacturer is also a vendor.

Contract Component Manufacturer

This is a manufacturer that produces components such as semiconductors under an original manufacturer's brand name or that produces components for a semiconductor vendor that brands them. In the semiconductor industry, a contract component manufacturer is sometimes referred to as a "foundry."

Any business done by a semiconductor manufacturer on a contract manufacturing basis is *excluded* as vendor revenue regarding that manufacturer.

Companies that produce exclusively on a contract manufacturing basis are excluded from the list of semiconductor vendors.

 ©1998 Dataquest

Finished Semiconductor Products

Finished products are assembled and tested semiconductor products. Count only sales of finished semiconductor products to equipment manufacturers and through channels (that is, distributors). Do not include sales of finished semiconductors to other semiconductor vendors for value-added resale. Resale revenue is counted as revenue of the semiconductor vendor to which it is sold. Also, count only sales made by an overseas subsidiary to a equipment manufacturer or distributor, as opposed to counting sales from headquarters to an overseas subsidiary.

Unfinished Semiconductor Products

These are wafer and die foundry products. Count only sales of unfinished semiconductor products to equipment manufacturers or channels (that is, distributors). Do not include sales of unfinished semiconductors to other semiconductor vendors for resale. Resale revenue will be estimated separately for these companies. Also, count only sales made by an overseas subsidiary to equipment manufacturers or distributors, as opposed to counting sales from headquarters to an overseas subsidiary.

Internal Semiconductor Sales

This is defined as revenue from finished or unfinished semiconductor products from intracompany (internal) transfers to divisions of that company or subsidiaries of the parent company that manufactures end equipment. Internal semiconductor sales are classified as in-house sales or captive sales, depending on whether the company sells semiconductors on the merchant market.

In-House Semiconductor Sales

This is defined as internal semiconductor sales if the company also sells semiconductors on the merchant market. Count all in-house semiconductor sales at market prices. Market price is defined as the price at which the same or equivalent product is sold to equipment manufacturers.

Captive Semiconductor Sales

This is defined as internal semiconductor sales if your company does not sell semiconductors on the merchant market. We do not include any captive semiconductor sales.

Multichip Modules

Multichip modules (MCMs) are semiconductor-based functions that include more than one semiconductor device. The multiple dies are arranged either on a thin-film deposited (MCM-D) substrate, a ceramic (MCM-C) substrate, or a polyimide or laminate (MCM-L) substrate. Count only sales of MCM products and board-level products that conform with the definitions for "finished semiconductor products" or "unfinished semiconductor products." MCMs are not considered hybrids or monolithic ICs. MCMs are an advanced form of package interconnect.

System-Level Products

These are products that comprise a number of module or board-level products amounting to a single system or subsystem. Examples include development systems, hardware platforms, and box-level products. Do not include any sales from such system-level products. By contrast, do include application-specific ICs (ASICs) that provide system-level integration into silicon.

 ©1998 Dataquest

Nonrecurring Engineering Charges

Nonrecurring engineering (NRE) charges are charges made to customers as the result of costs incurred during the design or customizing of a semiconductor device for that customer. Count NRE charges only when they occur in the following product areas:

- Design charges for ASICs, including gate arrays, cell-based ICs, and full-custom ICs
- Mask charges that result from the customizing of a programmable array logic (PAL), when the customer's fuse pattern is masked into it to produce a hard-wired array logic (HAL)
- Mask charges that result from the customizing of ROMs
- Mask charges that result from the storage of the customer's program in a microcontroller

Count revenue from NRE charges only on active semiconductor products that conform with the definitions for "finished semiconductor products" or "unfinished semiconductor products." Include these NRE charges as part of the revenue received from associated semiconductor product. Do not include revenue from NRE charges incurred during research, feasibility studies, or facility rental to third parties.

Electronic Design Automation Software

Electronic design automation (EDA) software is used to automate the design of semiconductors. Dataquest includes revenue from ASIC semiconductor vendors that also sell their own EDA software. Include any revenue derived from EDA software in the appropriate ASIC product category. The applicable categories are programmable logic device (PLD), gate array, and cell-based IC.

Intellectual Property Rights Income

This includes intellectual property rights (IPR) income from royalties, licensing agreements, technology transfers, and dispute settlements. Do not include any IPR income.

Chapter 4
Exchange Rate Definitions

When converting a company's local currency sales into U.S. dollars, or vice versa, it is important to use the 1998 exchange rates provided by Dataquest. This will prevent inconsistencies in the conversion of offshore sales between each company.

Chapter 5
Semiconductor Product Category Hierarchy

The semiconductor product category hierarchy in Table 5-1 begins with total semiconductor, and indents each subcategory in the left-hand column according to its position in the hierarchy. At each level in the hierarchy, all subcategories that contribute to this level are shown as a subcategory summation in the right-hand column. Any level in the hierarchy that does not depend on any subcategory is marked as a "Data Point."

Chapter 6
Semiconductor Product Category Definitions

The semiconductor product category definitions in Table 6-1 begin with total semiconductor and continue through each subcategory in the same order as shown in the preceding semiconductor product category hierarchy. At each level in the hierarchy, all subcategories that contribute to this level are shown as a subcategory summation in the right-hand column. Comprehensive definitions are given at every level. Table 6-2 shows microcomponent word widths.

Table 6-1
Semiconductor Product Category Definitions

Category	Definition
Total Semiconductor	**(Total Monolithic Integrated Circuit + Total Discrete + Total Optical Semiconductor)** Defined as an active semiconductor product that contains semiconducting material (such as silicon, germanium, or gallium arsenide but excluding ceramics) and reacts dynamically to an input signal, either by modifying its shape or adding energy to it. This definition excludes standalone passive components, such as capacitors, resistors, inductors, oscillators, crystals, transformers, and relays.
Total Monolithic Integrated Circuit	(Digital Monolithic Bipolar IC + Digital Monolithic MOS IC + Analog IC) A monolithic IC is one that is formed on a single chip of semiconducting material. This designation has been applied more broadly to mean any device, even multiple-chip packaged devices, that does not contain other, nonsemiconductor, components. This differentiates monolithic ICs from hybrid ICs that may also be multiple chip, but represent a "hybrid" in the sense of mixing other technologies within the IC package, such as film resistors or chip capacitors.
Digital Bipolar IC	(Bipolar Digital Memory IC + Bipolar Digital Logic IC) A bipolar digital IC is defined as a monolithic semiconductor product in which 100 percent of the die area performs digital functions, and, concurrently, 100 percent of the die area is manufactured using bipolar semiconductor technology. A digital function is one in which data is carried as numerical values, usually in a binary code.
Bipolar Digital Memory IC	A bipolar digital semiconductor product in which binary data is stored and electronically retrieved. Includes emitter-coupled logic (ECL) random-access memory (RAM), read-only memory (ROM), programmable ROM (PROM), last-in/first-out (LIFO) memory, and first-in/first-out (FIFO) memory. Not included are products made with mixed bipolar CMOS (that is, BiCMOS) with transistor-transistor logic (TTL) or ECL outputs, which are classified as Other Bipolar Digital Logic.
Bipolar Digital Logic IC	(Bipolar Digital Logic Application-Specific IC + Bipolar Digital Standard Logic IC + Other Bipolar Digital Logic IC) A bipolar semiconductor product that serves a general-purpose function using bit-processing technology. This bit processing is defined by hardwiring, mask programming, or field programming. Logic ICs also include customer-specific logic ICs.
Bipolar Digital Logic ASIC	(Bipolar Digital Gate Array + Bipolar Digital Programmable Logic Device + Bipolar Digital Cell-Based IC/Bipolar Digital Full-Custom IC) A single-user bipolar digital logic IC that is manufactured using vendor-supplied tools or libraries. Does not include bipolar digital ASICs incorporating microprocessor cells or microcontroller cells; these should be reported in the Other Bipolar Digital Logic IC category.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Bipolar Digital Gate Array	A bipolar digital gate array is defined as an ASIC device that is customized by the vendor to end-user specification using layers of interconnect. Included in this category are generic or base wafers with embedded functions, such as static RAM (SRAM) and electrically erasable PROM (EEPROM).
Bipolar Digital Programmable Logic Device	An ASIC device that is customized by the end user after assembly. Included in this category are bipolar field-programmable logic (bipolar FPL), bipolar field-programmable gate array (bipolar FPGA), bipolar programmable array logic (bipolar PAL), bipolar programmable logic array (bipolar PLA), bipolar electrically programmable logic devices (bipolar EPLDs), and bipolar complex PLDs.
Bipolar Digital Cell-Based IC/ Full-Custom IC	A bipolar digital cell-based IC is an ASIC device that is produced from a library of standard circuits/cells to a single-user specification. This process involves automatic routing and placement of cells using a full mask set. Included in this definition are bipolar standard cell ICs. Excluded from this definition are cell-based ICs with processor cores. These should be reported under Other Bipolar Digital Logic IC.
	A full-custom IC is an ASIC device that is produced for a single user using a full set of masks. This manufacturing process involves manual routing and placement of cells.
Bipolar Digital Standard Logic IC	A commodity bipolar family logic with fewer than 150 gates. Sometimes referred to as glue logic. Examples include TTL, ECL, and the following other family logic: TTL-compatible SSI, MSI, and LSI; standard, AS, FAST, LS, and ALS lines; and ECL-compatible SSI, MSI, and LSI. Also included are RTL and DTL.
Other Bipolar Digital Logic IC	All other bipolar digital logic ICs not accounted for in the preceding categories. Includes bipolar commodity family logic with 150 or more gates, bipolar digital general-purpose logic not belonging to any families, and bipolar digital microcomponent ICs.
MOS Digital IC	(MOS Digital Memory IC + MOS Digital Microcomponent IC + MOS Digital Logic IC)
	A monolithic semiconductor product in which 100 percent of the die area performs digital functions, and, concurrently, any portion of the die area that is manufactured using metal-oxide semiconductor (MOS) technology. A digital function is one in which data is carried as numerical values, usually in a binary code. Includes mixed-technology manufacturing, such as BiMOS and BiCMOS, where there is some MOS technology employed.
MOS Digital Memory IC	(DRAM + SRAM + EPROM + EEPROM + Flash Memory + Mask ROM + Other MOS Digital Memory IC)
	A MOS digital IC in which binary data is stored and electronically retrieved.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
DRAM	Dynamic RAM, multiport-DRAM (M-DRAM), video RAM (V RAM), synchronous DRAM (SDRAM), cached DRAM (CDRAM), and self-refreshed DRAM. DRAMs have memory cells consisting of a single transistor and require regular memory cell refreshes. These are volatile memories, and addressing is multiplexed.
SRAM	Static RAM, multiport-SRAM (M-SRAM), battery backed-up SRAM (BB-SRAM), and pseudo SRAM (PSRAM). SRAMs have memory cells consisting of a minimum of four transistors, except PSRAM, which has a memory cell consisting of a single transistor and is similar to a DRAM with non-multiplexed addresses. SRAMs do not require memory cell refreshes (except in the case of PSRAM). These are volatile memories and addressing is not multiplexed. Note that color palette digital-to-analog converters (DACs) are included in the Data Converter/Switch/Multiplexer IC category of analog ICs.
EPROM	Erasable programmable read-only memory. This product classification includes ultraviolet EPROM (UV EPROM) and one-time programmable read-only memory (OTP ROM). EPROMs have nonvolatile memory cells consisting of a single transistor and do not require any memory cell refreshes. These devices are considered nonvolatile memories.
EEPROM	Electrically erasable programmable read-only memory. Includes serial EEPROM (S-EEPROM), parallel EEPROM (P-EEPROM), and electrically alterable read-only memory (EAROM). EEPROMs have memory cells consisting of a minimum of two transistors and do not require memory cell refreshes. Also includes nonvolatile RAM (NV-RAM), also known as shadow RAM. These semiconductor products are a combination of SRAM and EEPROM technologies in each memory cell. The EEPROM functions as a shadow backup for the SRAM when power is lost. These devices are considered nonvolatile memories.
Flash Memory	Nonvolatile products designed as flash EPROM/EEPROM that incorporate either 5V or 12V programming supplies and one-transistor (1T) or two-transistor (2T) memory cells with electrical programming and fast bulk/block erase. Flash memory can erase data only by bulk/block, not by byte.
Mask ROM	Mask-programmable read-only memory. Mask ROM is a form of memory that is programmed by the manufacturer to a user specification using a mask step. Mask ROM is programmed in hardware rather than software. These devices are considered nonvolatile memories.
Other MOS Digital Memory IC	All other MOS digital memory not already accounted for in the preceding categories. Includes MOS digital content addressable memory (CAM), MOS digital cache-tag RAM, MOS digital first-in/first-out memory (FIFO), MOS digital last-in/first-out (LIFO) memory, and ferroelectric memory.
Microcomponent IC	(Microprocessor + Microcontroller + Digital Signal Processor + Microperipheral) Microcomponents are a category of metal oxide semiconductor (MOS) integrated circuits (ICs), which are mostly digital, made up of the microprocessor (MPU), microcontroller (MCU), programmable digital signal processor (DSP), and microperipheral (MPR) product subcategories.
Microprocessor	(8-Bit MPU +16-Bit MPU + 32-Bit and Greater Computational MPU + 32-Bit and Greater Embedded MPU)

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
	Microprocessor (MPU): An MPU is a MOS digital integrated circuit that includes an instruction decoder, arithmetic logic unit (ALU), registers, and additional logic. It may contain instruction, data, or unified caches, memory management systems, and auxiliary ALUs for floating-point and other special data types. An MPU's functions are determined by fetching and executing instructions and manipulating data held in registers, internal cache, or external memory. MPUs operate out of external memory systems typically ranging from 1MB to 64MB of RAM and often backed by secondary memory systems (such as disks). More highly integrated versions of MPUs may contain on-chip peripherals, interface, and support circuits. The MPU category includes MPUs incorporating or originating from an ASIC design. MPUs are subdivided into 8-bit, 16-bit, or 32-bit and up word width. Beginning in 1997, 32-bit and larger MPUs are further divided into computational and embedded according to the applications into which they are designed. MPUs can be complex-instruction-set-computer (CISC) or reduced-instruction-set computer (RISC) implementations, although Dataquest no longer divides RISC and CISC in favor of architectural family distinctions (68000, x86, MIPS, and SPARC, among others). Similar terms are processor, central processor unit (CPU), and integrated processor.
Microcontroller	(4-Bit MCU + 8-Bit MCU + 16-Bit MCU + 32-Bit and Greater MCU)
	An MCU is a MOS digital integrated circuit designed for standalone operation that includes a programmable processing unit, program memory, read/write data memory, and some input/output capability. The processing unit contains an instruction decoder, arithmetic logic unit, registers, and additional logic. The MCU's functions are determined by fetching and executing instructions and manipulating data held in on-chip program and data memory (not including cache memories). MCU devices must be available with on-chip program store (ROM, EPROM, and flash, among others), typically ranging from 1KB to 64KB. As an option, some MCU devices can be purchased without on-chip memory for use during the debug and development phase of the system. Peripheral circuits are typically included on chip to assist in sophisticated input, output, and control functions. The MCU category includes MCUs incorporating, or originating from, an ASIC design. Standalone digital signal processors are not included with MCUs. MCUs are subdivided into 4-bit, 8-bit, 16-bit, or 32-bit word width. In 1996, Dataquest began separating 32-bit MCUs from 16-bit MCUs. All MCUs are designed into embedded applications. A similar term is microcomputer.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Digital Signal Processor	A digital signal processor (DSP) is a programmable MOS digital integrated circuit (IC) designed for standalone operation, constituting a high-speed arithmetic unit (typically a multiplier-accumulator unit) designed to perform complex mathematical operations such as Fourier transforms in real time to generate, manipulate, or interpret digital representations of analog signals. Modern DSPs typically access multiple pieces of data in different locations of on-chip memory over separate data paths using specialized addressing modes. Most DSP functions, such as the multiply-and-accumulate function, complete in a single instruction clock. DSPs usually include peripherals, which may include analog circuits like analog-to-digital converters. DSPs typically operate on 16 or 24 bits of fixed-point data or 32 bits of floating-point data, although Dataquest does not currently subdivide DSPs into these categories. DSPs that have no version that can be reprogrammed by the user in assembly or a higher-level language are not included but are classified as fixed-function application-specific standard products (ASSPs) or microperipherals. DSPs integrated on-chip with an independent microprocessor or microcontroller are classified as either an MPU or an MCU, respectively. All DSPs are designed into embedded applications. A similar term is programmable DSP (pDSP).
Microperipheral	(System Core Logic Chipsets + Graphics and Imaging Controllers + Communications Controllers + Mass Storage Controllers + Audio/Other Controllers) A microperipheral is a MOS digital integrated circuit that serves as a dedicated logical support function to a microprocessor or microcontroller in a system, performing sophisticated input, output, and control functions. Microperipherals are not programmable from assembly language, although they are often highly configurable by software or electrical signals. This definition includes MPRs comprising more than one device, such as PC or core logic chipsets. The MPR category includes MPRs incorporating, or originating from, an ASIC design. MPRs might be implemented using microprocessor, microcontroller, or digital signal processing elements, although this is generally not evident to the user. A similar term is peripheral. Note that this definition may change radically for 1999.
System Core Logic Chipset	Devices dedicated to a particular microprocessor interface that perform some of the basic interface functions such as memory management, DRAM control, cache control, bus interface control, DMA control, and interrupt control.
Graphics and Imaging Controller	Devices that typically interface to some form of systems bus to interpret, control, and display the visual output systems (computer-generated graphics, live video, and other images).
Communications Controller	Devices that control, format, and perform handshaking for the serial transmission and reception of information between systems or intelligent devices, including network controllers, integrated fax/modem chips, serial UARTs, and other communications interfaces.
Mass Storage Controller	Devices that are used to control data storage into and retrieval from all forms of mass storage media (magnetic, optical, and others), which include controllers used within host computers (host-side) and within mass storage drives (device-side).
Audio/Other Controller	Devices used to input or output information through other forms, including audio input/output controllers, keyboard controllers, pen input controllers, parallel port controllers, and various other devices.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Word Width	A programmable device's word width is the width, in bits, of one of the inputs to the primary on-chip integer arithmetic and logic unit. This measurement is independent of the data bus width or any other bus associated with the device. Wider and narrower data types might be operated on by the processor, with multiple passes through the ALU or special hardware. The word width classification is not influenced by the existence of additional integer units or of floating point and other special data type processors. A similar term is bit size.
Logic IC	(Total ASIC + MOS Digital Standard Logic IC + Other MOS Digital Logic IC) A MOS semiconductor product that serves a general-purpose function using bit-processing technology. This bit processing is defined by hardwiring, mask programming, or field programming. MOS microcomponents and MOS memory ICs are MOS logic ICs, but are either dedicated to a function (such as MOS microperipherals or MOS memory ICs) or are software programmable (such as MOS microprocessors and MOS microcontrollers). MOS logic ICs also include customer-specific MOS logic ICs.
Total ASIC	(Traditional Digital Gate Array + Embedded Gate Array + Digital Programmable Logic Device + Digital Cell-Based IC + Digital Full-Custom IC + Mixed ASIC + Linear Array) Defined as a single-user digital logic IC that is manufactured using vendor-supplied tools or libraries. Does not include digital ASICs incorporating microprocessor cells or microcontroller cells; these should be reported in the microprocessor IC or microcontroller IC category, respectively.
Traditional Digital Gate Array	Traditional gate arrays are ASICs that contain a configuration of uncommitted elements in a prefabricated base wafer. They are customized by interconnecting these elements with one or more metal routing layers. Included in this category are channeled and sea-of-gates architectures.
Embedded Gate Array	Embedded gate arrays are ASICs with a portion of the chip having traditional gate array architecture (channeled or sea-of-gates) and with megacells such as SRAM diffused into the gate array base wafer.
Digital Programmable Logic Device	An ASIC device that is customized by the end user after assembly. Included in this category are MOS field-programmable logic (MOS FPL), MOS field-programmable gate array (MOS FPGA), MOS programmable array logic (MOS PAL), MOS programmable logic array (MOS PLA), MOS electrically programmable logic device (MOS EPLD), and MOS complex PLDs.
Digital Cell-Based IC	An ASIC device that is produced from a library of standard circuits or cells to a single-user specification. This process involves automatic routing and placement of cells utilizing a full mask set. Included in this definition is MOS standard cell IC.
Digital Full-Custom IC	An ASIC device that is produced for a single user using a full set of masks. This process involves manual routing and placement of cells.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Linear Array ASIC	A single-user linear IC that is manufactured using vendor-supplied tools or libraries. Linear arrays fall into one of three types, as follows: 1. Arrays of discrete-level cells such as transistors and diodes 2. Arrays of discrete device combinations, referred to as tiles 3. Arrays of higher-level functional macro cells such as operational amplifiers, comparators, voltage-controlled oscillators (VCOs), references, and other analog functions These arrays are interconnected with a metal mask or by means of some user-programmable interconnect scheme. Unlike cell-based designs, they do not have a unique set of masks for all layers.
Mixed-Signal ASIC	A mixed-signal ASIC that is manufactured for a single user, using vendor-supplied tools or libraries and containing analog in more than 50 percent of the die area. ASICs with analog making up less than 50 percent of the die area should be counted in the appropriate category under digital ASIC.
MOS Digital Standard Logic IC	Commodity MOS family logic with fewer than 150 gates. Sometimes referred to as glue logic. Examples include: HC/HCT, AC/ACT, FACT, and 74BC/BCT BiCMOS family logic.
LCD Driver	Display driver IC designed to control and drive liquid crystal display (LCD) panels. LCD drivers convert digital inputs into the multilevel signals needed to drive liquid crystal displays. Excluded from this category are microperipheral controller/driver ICs that include the LCD drive function and TV LCD drivers that accept analog video inputs. These devices are counted as part of the microcomponent category or analog IC category, respectively.
Other MOS Digital Logic IC	All other MOS digital logic ICs not accounted for in the preceding categories. Includes MOS commodity family logic with 150 or more gates and MOS digital general-purpose logic not belonging to any families.
Total Analog IC	(Amplifier/Comparator IC + Voltage Regulator/Reference IC + Data Converter/Switch/Multiplexer IC + Interface IC + Telecom IC + Disk Drive IC + Other Special-Function IC + Linear Array/ASIC + Mixed-Signal ASIC + Total Special Consumer IC + Special Automotive IC + Smart Power IC) An analog IC is a semiconductor product that deals in the realm of electrical signal processing, power control, or electrical drive capability. It is one in which some of the inputs or outputs can be defined in terms of continuously or linearly variable voltages, currents, or frequencies. Includes only monolithic analog ICs manufactured using bipolar, MOS, or BiCMOS technologies. Includes monolithic linear IC and monolithic mixed-signal IC. A monolithic linear IC is characterized by having 100 percent analog input/output, while a mixed-signal IC carries information in both digital (numeric) and signal/power forms.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Amplifier/Comparator IC	An amplifier is a general-purpose linear IC that provides a voltage or current gain to an input signal. Includes operational amplifiers (mono, dual, and quad, among others), instrumentation amplifiers, buffer amplifiers, and power amplifiers. Consumer-dedicated amplifier ICs are counted in special consumer IC. Amplifier ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC. A comparator IC is defined as a general-purpose linear IC that compares two analog signal inputs and provides a single logic bit output. Although the output could be considered digital, these products are classed as linear ICs because they are specialty high-gain amplifiers, used in an open-loop mode, for which the output is constrained to only two states. By using a comparator, an unknown voltage can be compared with a known reference voltage. Comparator ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
Voltage Regulator/Reference IC	A voltage regulator IC is defined as a general-purpose linear IC that outputs a variable current at a regulated DC voltage to other circuits from a variable current and voltage input. Regulator ICs are either linear regulators, in which the device provides an input-to-output voltage drop, or switching regulators, in which the device provides switched quantities of power to a smoothing circuit to gain higher efficiency and reduce power dissipation. Voltage regulator ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC. A voltage reference IC is defined as a general-purpose linear IC that outputs a precise reference voltage to other circuits from a variable voltage input. A reference IC differs from a regulator IC in that it is not expected to power other circuits. In fact, voltage regulator ICs incorporate a voltage reference circuit. Voltage reference ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Data Converter/Switch/Multiplexer IC	A data converter IC is defined as a general-purpose mixed-signal IC that converts an analog signal into a digital signal or vice versa. Includes analog-to-digital converters (ADCs), digital-to-analog converters (DACs), sample-and-hold circuits (SHCs), voltage-to-frequency circuits (VFCs), frequency-to-voltage circuits (FVCs), synchro-to-digital circuits (SDCs), and digital-to-synchro circuits (DSCs). All these are general-purpose data ICs. Also included in this category are color-palette DACs. Consumer-dedicated data converter ICs are counted in special consumer IC, under monolithic linear ICs. Data converter ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC. A switch/multiplexer IC is defined as a mixed-signal IC that digitally controls analog transmission gates. These products connect or disconnect the analog signal path in analog circuits. Analog switches operate in a mode where each switch is operated independently by a single logic bit. Multiplexers are multiple analog switches that are connected in a dependent manner, where only one signal path is connected through to the output, depending on the state of a digital address word (greater than one bit). Thus, analog multiplexers are really addressable signal selector switches that select one of many signals for further analog processing. Because these addressable analog switches were the key element in time-division multiplexing, the term "multiplexer" has remained. They are an important part of the data conversion product family in that they are used to provide time-division multiplexing of signal inputs to a fast analog-to-digital converter. Switch/multiplexer ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Interface IC	A general-purpose mixed-signal IC that serves as an interface between a digital system and other external nonsemiconductor systems. Includes line drivers, peripherals drivers, receivers, transmitters, and transceivers. Interface ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Telecom IC	A general-purpose mixed-signal IC that is used for voice band communication or data communication over voice band media. This category includes codecs, combos and SLACs, subscriber line interface circuits (SLICs), modem and fax/modem ICs, dialer and ringer ICs, repeaters, cellular communications ICs, ISDN ICs, telecom filter ICs, and other telecom-specific circuits. Telecom ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Disk Drive IC	A mixed-signal IC that is designed specifically for the rotating mass storage market. Applications include the read/write path from preamplifier up to the ENDEC, head-positioning controller, and spindle motor control. Disk drive ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in mixed-signal ASIC.
Other Special-Function IC	An IC that is either a general-purpose IC that does not fit into the other categories or market or application specific ICs for which a category does not yet exist. The main products that fall into this category include timers, phase-locked loops (PLLs), voltage-controlled oscillators, signal- or function-generator ICs, and analog multipliers. Other special-function ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in the linear array/ASIC IC category.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Total Special Consumer IC	(Video Special Consumer IC + Audio Special Consumer IC + Other Special Consumer IC) A general-purpose IC that is dedicated to general consumer applications but is not application-specific. Consumer ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
Video Special Consumer IC	An IC implemented for video applications.
Audio Special Consumer IC	An IC implemented for audio applications, including radio and speech synthesis and recognition.
Other Special Consumer IC	An IC implemented in other consumer applications such as electronic games, personal and home appliances, and electronic cameras.
Special Automotive IC	An IC that is used in the following automotive applications: entertainment, engine control, safety, traction, or in-car electrical and suspension systems. Special automotive ICs designed specifically for one customer using vendor-supplied tools or libraries are counted in linear array ASIC.
Total Discrete	(Transistor + Diode + Thyristor + Other Discrete) A discrete semiconductor is defined as a single semiconductor component such as a transistor, diode or thyristor. Although multiple devices may be present in a package, they are still considered discretes if they have no internal functional interconnection and are applied in the same manner as other discrete devices.
Transistor	(Small-Signal Transistor + Power Transistor)
Small-Signal Transistor	Signal transistors, RF microwave transistors, dual transistors, MOS field-effect transistors (MOSFETs), conductivity modulated field-effect transistors (COMFETs), insulated gate bipolar transistors (IGBTs), and MOS-bipolar transistors (MBTs). All rated below 1W power dissipation.
Power Transistor	(Bipolar Power Transistor + MOS Power Transistor + Power IGBT) All are rated at 1W power dissipation and above.
Bipolar Power Transistor	Bipolar Darlington transistor, bipolar microwave transistor, and bipolar radio frequency (RF) transistor.
MOS Power Transistor	MOS field-effect transistor (MOSFET), MOS microwave transistor, and MOS radio frequency (RF) transistor.
IGBT Power Transistor	Insulated gate bipolar transistor (IGBT). Also includes conductivity modulated field-effect transistor (COMFET), MOS-bipolar transistor (MBT), and GEMFET.
Diode	(Small-Signal/Reference Diode + Power Diode/Rectifier)
Small-Signal/Reference Diode	Signal diodes, Schottky diodes, zener diodes, switching diodes, voltage reference diodes, voltage regulator diodes, and rectifier diodes. All are rated below 0.5A.
Power Diode/Rectifier	Zener diodes and rectifier diodes. All are rated 0.5A and above.
Thyristor	Thyristors, silicon-controlled rectifiers (SCRs), diacs, and triacs. Also includes solid-state relays (SSRs) incorporating triacs, thyristors, resistors, and capacitors.
Other Discrete	All other discrete semiconductor products not accounted for in the preceding categories. Includes microwave diodes, varactors, tuning diodes, tunnel effect diodes, and selenium rectifiers. Does not include thermistors and varistors.

(continued)

Table 6-1 (Continued)
Semiconductor Product Category Definitions

Category	Definition
Total Optical Semiconductor	(Total LED Lamp/Display + Optocoupler + CCD + Laser Diode + Photosensor + Other Optical Semiconductor) A semiconductor product in which photons induce the flow of electrons or vice versa. Other functions may also be integrated onto the product. This category does not include LCDs, incandescent displays, fluorescent displays, cathode ray tubes (CRTs), or plasma displays.
Total LED Lamp/Display	(Infrared LED Lamp/Display + Other LED Lamp/Display)
Infrared LED Lamp/Display	Infrared LED lamps/displays are single light-emitting diodes (LEDs) or an array of LEDs consisting of more than one die (in the case of displays) functioning in the invisible infrared range.
Other LED Lamp/Display	Includes visible LEDs and other LED products not included elsewhere. A visible LED lamp is defined as a light-emitting diode for which the light is visible: a semiconductor product consisting of a single die in which photons are emitted at frequencies dependent upon the semiconductor material employed. An LED display is defined as an array of LEDs: a semiconductor product consisting of more than one die in which photons are emitted at frequencies dependent upon the semiconductor material employed and where the light transmission is visible.
Optocoupler	An optocoupler or optoisolator. A semiconductor product consisting of an LED separated from a photosensor by a transparent, insulating, dielectric layer. These are mounted inside an opaque package. Includes optointerrupters, in which the separation between LED and photosensor is large enough to allow external physical systems to influence the device.
Charge-Coupled Device	A charge-coupled device (CCD) is a semiconductor product consisting of an array of photodiodes, an analog CCD shift register, and an output circuit. Includes linear array CCDs with serial shift registers and area array CCDs with parallel shift registers. Includes charge injection device (CID), charge-coupled photodiode (CCP), charge-priming device (CPD), and self-scanning photodiode (SSP).
Laser Diode	A diode that produces coherent light. A semiconductor product in which the heterojunction structure stimulates light amplification by stimulated emission of radiation (laser), resulting in coherent light. Includes Fabrey-Perot laser diodes, pulsed laser diodes, and phase-shifted laser diodes.
Photosensor	(Photodiode + Phototransistor) A diode or transistor in which photons are used to affect current flow or electric potential.
Other Optical Semiconductor	All other optical semiconductor devices not accounted for in the preceding categories. Includes solar cells and optical thermal piles.

Chapter 7
Worldwide Geographic Region Definitions and Regional Roll-Ups

Americas

Includes countries of North America, Central America, and South America.

Dataquest officially treats the countries of South America, Central America, Mexico, and Puerto Rico as the Latin America region.

Japan

Japan is the only single-country region.

Europe, Africa, and Middle East

Europe

Western Europe

Includes Austria, Belgium, Denmark, Finland, France, Germany (including the former East Germany), Greece, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom, and Rest of Western Europe

Rest of Western Europe: Includes Andorra, Cyprus, Faroe Islands, Gibraltar, Greenland, Guernsey, Iceland, Isle of Man, Jersey, Liechtenstein, Luxembourg, Malta, Monaco, San Marino, and Svalbard

Eastern Europe

Includes Belarus, Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Russia, Slovakia, Ukraine, and Rest of Eastern Europe

Rest of Eastern Europe: Includes Albania, Armenia, Azerbaijan, Bosnia and Herzegovina, Croatia, Georgia, Kazakhstan, Kyrgyzstan, Macedonia, Moldova, Romania, Slovenia, Tajikistan, Turkmenistan, Uzbekistan, and Yugoslavia (Serbia and Montenegro)

Africa

Middle East

Asia/Pacific

Includes Australia, China, Hong Kong, India, Indonesia, South Korea, Malaysia, Singapore, Taiwan, Thailand, and Rest of Asia/Pacific

Rest of Asia/Pacific: American Samoa, Ashmore and Cartier Islands, Baker Island, Bangladesh, Bhutan, Bouvet Island, Brunei, Cambodia, Christmas Island, Cocos (Keeling) Islands, Cook Islands, Coral Sea Islands, Federated States of Micronesia, Fiji, French Polynesia, Guam, Howland Island, Jarvis Island, Johnston Atoll, Kingman Reef, Kiribati, Laos, Macau, Maldives, Marshall Islands, Midway Islands, Mongolia, Myanmar (Burma), Nauru, Nepal, New Caledonia, New Zealand, Niue, Norfolk Island, Northern Mariana Islands, North Korea, Pakistan, Palau, Palmyra Atoll, Papua New Guinea, Paracel Islands, Philippines, Pitcairn Islands, Solomon Islands, Spratly Islands, Sri Lanka, Tokelau, Tonga, Tuvalu, Vanuatu, Vietnam, Wake Island, Wallis and Futuna, and Western Samoa.

Chapter 8
Semiconductor Application Segment Definitions

Data Processing

Defined as computer systems, data storage, input/output devices, dedicated systems, and other data processing equipment:

- Computer systems: The computer estimate does not include the value of the following systems: rigid disk drive, flexible disk drive, keyboards, and displays. The computer estimate does include the value of aftermarket sales of the following: graphics boards, motherboards, memory cards or single in-line memory modules (SIMMs), storage host adapters, and serial and parallel I/O boards. Worldwide computer systems production has been re-estimated and revalued to equal the value of worldwide (factory) revenue and shipments of computer systems as estimated by the Dataquest Computer Systems and Peripherals Worldwide group and to eliminate double-counting of system sales of storage devices, keyboards, and displays. Computer systems include supercomputers, mainframe computers, midrange computers (also known as superminicomputers and minicomputers), workstations, and personal computers (including portable computers). This includes the value of central processing units (that is, boxes) only.
- Data storage includes rigid disk drives, flexible disk drives, optical disk drives, and tape drives.
- Input/output devices include alphanumeric terminals and graphics terminals (for example, X terminals), monitors, and funds-transfer terminals; and printers, media-to-media data conversion, magnetic ink character recognition, optical scanning equipment, plotters, mice, keyboards, and digitizers.
- Dedicated systems include electronic copiers, electronic calculators and personal organizers, smart cards (IC cards), dictation and transcribing equipment, electronic typewriters and dedicated word processors, point-of-sale terminals and electronic cash registers, and mailing, letter-handling, and addressing equipment.
- Other data processing includes sound and audio boards, digital video boards, accelerator boards, and embedded CPU boards.

Communications

Defined as premise telecom equipment, public telecom equipment, mobile communications equipment, broadcast and studio equipment, and other telecom equipment:

- Premise telecom equipment includes image and text communication, such as facsimile and facsimile cards, and video teleconferencing; data communications equipment such as modems and modem cards, statistical multiplexers, T1 multiplexers, front-end processors, data service unit/channel service unit (DSU/CSU), protocol converters, (local area) network interface cards, LAN hubs and internetworking equipment, packet data switching systems; premise switching equipment, such as PBX telephone equipment, and key telephone systems; call-processing equipment, such as voice messaging, interactive voice response systems, and automatic call distributors; and desktop terminal equipment, such as telephone sets/pay telephones and cordless telephones, and teleprinters.
- Public telecom equipment includes transmission equipment, such as multiplexers, carrier systems, microwave radio, laser and infrared transmission equipment, and satellite communications equipment; and central office switching equipment.

©1998 Dataquest

- Mobile communications equipment includes mobile radio systems such as cellular telephones, microcellular telephones, mobile radios, mobile radio base station equipment and pagers; portable radio receivers and transmitters; and radio checkout equipment.
- Broadcast and studio equipment includes audio equipment, video equipment, transmitters and RF power amplifiers, studio transmitter links, cable TV (head-end) equipment, closed-circuit TV equipment, and other equipment, such as studio and theater equipment.
- Other telecom equipment includes intercom equipment and electrical amplifiers; and communications equipment not elsewhere classified.

Industrial

Defined as security/energy management systems, manufacturing systems/instruments, medical equipment, and other industrial equipment:

- Security/energy management includes alarm systems, such as intrusion-detection and fire-detection systems, and energy management systems.
- Manufacturing systems/instruments include semiconductor production equipment, controls, process controls, control and processing displays and robots and test and measuring equipment such as semiconductor-dedicated automatic test equipment (ATE), other test and measurement equipment, and nuclear electronics.
- Medical equipment includes diagnostic equipment, therapeutic equipment, patient monitoring equipment, surgical support systems, and irradiation equipment.
- Other industrial equipment includes vending machines, power supplies, traffic-control equipment, and industrial equipment not elsewhere classified.

Consumer

Defined as audio equipment, video equipment, personal electronics, appliances, and other consumer equipment:

- Audio equipment includes compact disc players, radios, stereo components, musical instruments, and tape recorders.
- Video equipment includes VCRs and VTRs, video cameras and camcorders, videodisc players, color and monochrome TVs, and cable/satellite set-top decoders.
- Personal electronics includes electronic games and toys (systems and cartridges), cameras, watches, and clocks.
- Appliances includes air conditioners, microwave ovens, washers and dryers, refrigerators, dishwashers, and ranges and ovens.
- Other consumer equipment includes automatic garage door openers and consumer equipment not elsewhere classified.

©1998 Dataquest

Military and Civil Aerospace

Defined as military electronic equipment and civil aerospace.

- Military/civil aerospace: North American military/civil aerospace production has been re-estimated and revalued to reflect U.S. Department of Commerce estimates of U.S. defense and civil (aerospace) electronics. Military/civil aerospace includes radar/sonar/reconnaissance systems, missile/space-related electronics, navigation equipment, electronic warfare, aircraft flight systems, and command and control systems.

Transportation

Defined as in-car entertainment, body control electronics, power train systems, and safety and convenience systems.

- In-car entertainment includes systems such as AM/FM radios, cassette and compact disc players, and radio/cassette combination systems.
- Body control electronics includes four-wheel steering control, two-wheel drive/four-wheel drive (2WD/4WD) control; multiplex systems such as driver's door console, door locks, windshield wipers, heated rear windows, memory seats, memory steering wheel, remote security systems, and suspension control and traction control systems; lighting controls including automatic headlight systems, timers, reminders, and sequential signal controls; and other body control electronics including aerodynamic aid control and power roof/window controls; driver information systems including electronic dashboard/instrument clusters, analog or digital clusters, electronic analog/digital clocks and compasses, electronic thermometers, head-up displays, navigation and location systems, signal and warning lights, and trip computers.
- Power train systems include engine management systems, power train sensors, ignition control, fuel injection systems, fuel flow, engine temperature, air temperature, coolant level, wheel speed sensors, and transmission control.
- Safety and convenience systems include climate control systems (air conditioning/heating), air purifier systems, air bag control systems, antilock braking systems, collision warning systems, and cruise control.

Perspectives

Semiconductors Europe

Market Analysis

Water, Water, Everywhere, nor any Drop to Drink

Abstract: *The DRAM market is poised for recovery as demand for PC100 SDRAM increases sharply and vendors struggle to keep up. This Market Analysis updates Dataquest's Europe, Middle East and Africa DRAM forecast, detailing annual unit shipments, average selling prices and revenues from 1992 to 2002.*

By Richard Gordon

Come on in, the Water's Lovely!

It might seem strange that, in a world awash with DRAM production capacity, the market has moved on and is now demanding a type of DRAM that cannot be manufactured in high enough volume. However, this is undoubtedly the case. The industry has moved away from producing asynchronous FPM and EDO DRAM, which are now relegated to the specialist and upgrade sectors of the market, and is struggling to meet demand for DRAM utilizing synchronous interfaces.

As the fundamental demand driver for the DRAM market, the dynamics of the PC market are critical in determining the outlook for the DRAM market. Europe, Middle East and Africa (EMEA) PC production is expected to reach almost 25 million units in 1998 and is forecast to rise to about 41 million units in 2002. With this level of production, together with an increase in the average main memory factory fit from 55MB per system in 1998 to 245MB per system in 2002, the demand-side assumptions in terms of bit shipments are understood. However, bearing in mind that the PC industry is gearing up to fit 100 MHz synchronous DRAM (PC100 SDRAM) to mainstream PCs as a standard, it is by no means certain that the DRAM industry will be able to satisfy this demand for high-performance devices, especially in the short term.

The DRAM industry has entered a new phase based on a shift in demand towards increasingly higher-performance DRAM, driven by a widening gap between microprocessor speed and memory access time. As 1998 draws to a close, demand is firmly established for PC100 SDRAM at densities of 64Mb as minimum. However, although there remains too much DRAM production

FILE COPY: MARIA VALENZUELA

Dataquest

Product Code: SEMI-EU-DP-9811
Publication Date: October 30, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

capacity globally, to be able to manufacture this leading-edge product competitively requires 0.25-micron process technology (or better). It is the lack of this leading-edge process technology that is already beginning to constrain the supply of 64Mb or 128Mb PC100 SDRAM and which will fuel the next DRAM market boom.

Short-Term Forecast Highlights and Assumptions

The following are Dataquest's highlights and assumptions for 1998:

- Bit growth of 86 percent, resulting in shipments of more a 900 million 16Mb equivalents into the EMEA region
- Average selling price (ASP) for 1998 of less than $1.50 per megabyte
- Revenues decline by 30 percent over 1997 levels to $2.8 billion

The following are Dataquest's highlights and assumptions for 1999:

- Bit growth at 68 percent returns to a level more consistent with the historic average
- ASPs stabilize at fourth quarter 1998 levels and remain above $1 per megabyte throughout the year
- Revenues increase by 30 percent over 1998 to reach $3.7 billion

Long-Term Forecast Highlights and Assumptions

The following are Dataquest's highlights and assumptions for the long term:

- The current forecast period encompasses the remnants of the last DRAM market downturn, a DRAM boom in 1999 through to 2001 and the start of the next cyclical downturn in 2002.
- Following the return to growth of DRAM revenues in 1999, strong revenue growth of 81 percent in 2000 will be followed by healthy revenue growth of 54 percent in 2001.
- The three growth years of 1999, 2000 and 2001 will be followed by an ASP crash and the next cyclical market downturn in 2002.
- Bit growth is expected to continue at close to 70 percent per annum throughout the forecast period.
- ASPs are expected to remain stable during 1999, 2000 and 2001 at more than $1 per megabyte.
- Continuous developments in DRAM technology are expected during the forecast period. Although PC133 specification DRAM will supersede PC100 and initiatives such as double data rate DRAM and NEC's Virtual Channel DRAM will emerge, by 2002 Dataquest expects Direct Rambus to be firmly established as the DRAM technology of choice in mainstream applications.

Forecast Detail

Table 1 shows the annual history and forecast detail for the EMEA DRAM market for the period 1992 to 2002.

A rapid transition in shipment volume from the 16Mb device density to the 64Mb device density is expected to occur in 1999, so that almost 80 percent of all DRAM bits shipped in the EMEA region will be in the form of 64Mb devices. At this stage, it is expected that the 64Mb device will remain the largest volume shipment device density throughout the forecast period, although it is possible that some cannibalization of 64Mb unit shipments may occur if 128Mb devices gain in popularity. As an "intermediate" device density, there are two schools of thought about 128Mb devices: that they will be restricted to high-end servers and workstations that require a large amount of memory, but have limited space for expansion modules, or, alternatively, that it will actually be more profitable for DRAM vendors to produce a single-chip 128Mb device rather than a pair of 64Mb devices. Dataquest remains to be convinced about the latter argument and the forecast for 128Mb unit shipments reflects our skepticism. Towards the end of the forecast period, shipments of 64Mb devices are expected to begin to reduce in favor of 256Mb devices, as shown in Figure 1.

A period of price stability is forecast for 1999, 2000 and 2001, with the ASP of 64Mb devices remaining above $8 (or $1 per megabyte). At the end of the forecast period, in 2002, the return of DRAM overcapacity is forecast, resulting in a price crash and the next cyclical market downturn. At that time, price parity between 64Mb and 256Mb device densities is expected.

Forecast bit growth of almost 70 percent per annum in parallel with the absence of a decline in ASPs means that spectacular revenue annual growth rates is inevitable during the period from 1999 to 2001, bringing the EMEA DRAM market size to more than $10 billion in 2001. A revenue decline of 10 percent is forecast for 2002, induced by the next cyclical downturn in the DRAM market.

Dataquest Perspective

While many DRAM industry watchers cannot see an end to the era of doom and gloom that has beset the market since 1996, a few, Dataquest included, are convinced that an upturn is just round the corner. There are very good reasons for this optimism, not least of which is a firm belief that the DRAM market will continue to behave as a "closed loop system": the output stage (DRAM revenues) feeding back and influencing the input stage (capital investment), which ultimately dictates the result at the output stage, and so on. This "feedback loop" behavior results in a DRAM market characterized by a cyclicity that, if left unchecked, can result in extreme peaks and troughs.

The last time an end to cyclicity was mooted was in 1995, at the end of a prolonged growth cycle, when it seemed impossible that the market could crash ever again. But crash it did, principally because of a huge buildup of DRAM capacity. Today, many are convinced that something new is going on because the current DRAM recession has resulted in an unprecedented third consecutive year of negative revenue growth in the EMEA region: approximately minus 41 percent in 1996 and minus 13 percent in 1997, with a further decline of 30 percent forecast for 1998. However, it is precisely because the latest trough has been more severe and prolonged than any in the past that the nature of the closed loop system suggests that the corrective action taken to pull the market out of recession (that is, cutbacks in capital investment) is the very action that will cause the next DRAM boom. Aggressive investment in 0.25-micron technology during 1997 exacerbated existing overcapacity in the industry and added another unwelcome pressure to prices already in decline as a result of the currency devaluation caused by the Asian financial crisis. The industry is witnessing very deep capital spending cuts in 1998 caused by overcapacity and financial uncertainty, and it is these cutbacks that ultimately will lead to the return of undersupply and stable prices.

Assuming that the number of DRAM bits shipped continues to increase at a rate consistent with history (about 70 percent for the sake of argument) then it is the level of the right kind of production capacity that will determine whether the DRAM market is over- or undersupplied and whether prices, revenues and margins are low or high respectively. The continuous increase in DRAM bit demand sits uneasily with short, but intensive, bursts of periodic investment and it is this relationship that causes DRAM market cyclicity. As with all commodities, today's investment affects tomorrow's market, and the recent slowdown in DRAM capital investment is already having its effect.

Following the oversupplied DRAM market of the past three years, it is all too easy to continue to predict a gloomy outlook. However, prices have stabilized, demand remains strong and supply is tightening. So, forget all the rational arguments and all the reasons why a recovery may not happen—trust in the industry cycles and look forward to a DRAM boom.

European Inward Investment Opportunities

In this Market Analysis Dataquest examines what the key factors are in attracting inward investment from the semiconductor industry, and analyzes eight major locations. Funding is no longer the critical factor it once was, while educational infrastructure is playing an increasingly significant role.

Table of Contents

List of Tables

Executive Summary

Most countries in Europe are interested in, and are actively seeking, inward investment from semiconductor manufacturers. With most countries offering broadly similar incentives by way of capital grants and taxation benefits, the battleground to win high-quality inward investment is shifting to skills management. The future winners in this battle will be those that offer a combination of the correct skills in the right numbers, as well as attractive financial packages. This calls for an integrated response by each country to the demands of the semiconductor industry.

Some countries have recognized this and are rising to the challenge of developing methods to meet these demands. These will be the countries that attract the added-value inward investment projects. Some countries or regions will continue to offer large grants, but as this becomes more expensive, and as their competitors become more differentiated, the quality of inward investment that these regions or countries attract will suffer. While the focus of this *Market Analysis* is the semiconductor industry, many of the financial and fiscal incentives described are equally applicable to other industries.

Introduction

The location of a wafer fabrication plant or assembly and test plant is a key decision taken by semiconductor vendors when considering capital expenditure programs. Identifying where sufficient staffing, reliable infrastructure and suitable land can be found is becoming increasingly important. At the same time, many countries within the European Union (EU) have realized the potential benefits of having semiconductor plants located within their borders, in terms of direct employment, indirect employment, enterprise creation and regional regeneration. It is no surprise, therefore, that many countries, and specific regions within countries, are positioning themselves as high-technology centers and competing vigorously for new inward investment proposals. This *Market Analysis* analyzes some of the regions that a semiconductor manufacturer might consider when deciding upon a location within the EU. This *Market Analysis* also provides details of appropriate staffing availability, as well as training infrastructure and an overview of the financial incentives and support available in each location.

The locations covered in this *Market Analysis* are as follows:

- Flanders, Belgium
- Southeast France
- Western France
- Eastern Germany (Saxony)
- Ireland
- Northern England
- Central Scotland
- Central and eastern Spain

Table 1 shows the regions which have been most successful in promoting themselves to the semiconductor vendor community.

Table 1
Semiconductor Inward Investment Projects in Europe Since 1990

Year	Investment Location	Company
1990	Scotland	Motorola
	Scotland	Motorola
	Italy	Texas Instruments
1991	Northern England	Fujitsu
	Sweden	Mitel
	Northern Germany	Philips
	Northern Italy	SGS-Thomson
1993	Southern Germany	Hitachi
	Southern France	SGS-Thomson
1994	Ireland	Intel
1995	Western France	Philips
	Ireland	Analog Devices
1996	Scotland	NEC
	Northern England	Philips
	Netherlands	Philips
	Southern Italy	SGS-Thomson
	Southern France	SGS-Thomson
	Eastern Germany	Siemens
	Italy	Texas Instruments
1997	Southern France	Atmel
	Corbielle-Essomes, France	IBM
	Ireland	Intel
	Northern Italy	International Rectifier
	Germany	Mitsubishi
	Southern Italy	SGS-Thomson
	Northern England	Siemens
1998	Israel	Intel
1999	Eastern Germany	AMD
	Northern England	Fujitsu
	Scotland	Hyundai
	Wales	LG Semicon

Flanders

Recently, Flanders has been one of the more proactive regions in Europe trying to attract inward investment. The main focus of activity has been in attempting to attract a semiconductor wafer fabrication facility into the region, which, it is hoped, will act as a catalyst for the further development of the semiconductor industry within the region.

One of the most interesting ideas being investigated by the Flanders Foreign Investment Office (FFIO) is the concept of building its own wafer fabrication plant and leasing this out to semiconductor vendors on a long-term basis. The model would have the Flanders government consortium managing the plant and issues such as chemical, gas and waste handling, while the tenant vendor would be responsible for manufacturing development and core competencies. This business model is still being developed by the

FFIO and Meissner and Wurst, a wafer fab design company.

Flanders is home to two semiconductor fabrication facilities. Alcatel Microelectronics, which is based in Oudenaarde, near Gent and IMEC, which has a smaller-scale facility in the region. IMEC is the largest independent microelectronics R&D center in Europe. IMEC's R&D activities are concentrated on the development of novel design methodologies, the development of processing technologies for the next generation of ULSI chips and the support of the training of VLSI design engineers on behalf of both educational institutes and industry. IMEC also provides training facilities for industrial partners upon request.

However, there are approximately ten other fabrication modules located within 150 km of Brussels. In addition to the semiconductor wafer fabrication plants and IMEC, Flanders has two other universities with specialist electronics faculties. The Flanders region also has 15 industrial engineering colleges which provide four-year electronics courses to degree standard.

The principal financial incentive offered by the Flanders government to inward investors is a series of cumulative direct subsidies. The first is a basic subsidy of 4 percent of total investment, which is available to qualifying investments that are the first operational unit by the company in Flanders. The second is a direct subsidy of up to 8 percent of the total investment, depending on the economic importance of the investment into the region. Given Flanders' eagerness to attract a semiconductor fabrication plant, it would be fair to assume that such an investment would be considered as being of great economic importance and, thus, would attract a significant part of this 8 percent. The third subsidy is based on employment growth, and can be up to 9 percent of the total investment. The combination of these three subsidies means a total direct subsidy of 21 percent of total investments is available to any qualifying inward investment project.

In addition to the direct subsidies that are available as incentives, Flanders also offer several fiscal measures to increase the value of inward investment support packages. These measures include an exemption of real estate tax for the investment site for five years and accelerated depreciation schemes. The FFIO will also participate in site acquisition and preparation.

The Flanders employment agency also participates in the sourcing of staff for any inward investment project. The Flanders employment agency, as part of an incentive package, will meet the expenses of new staff's first six to eight weeks of employment, when they usually will be in training.

France

Within France, the regions of western France and Marseilles-Provence in the southeast are two of France's primary high-technology and IT conurbations. Consequentially, both regions are being given a lot of support from the Invest in France Agency. Philips, Temic Matra (now part of Atmel) and SGS-Thomson have all located wafer fabrication plants within western France. Marseilles-Provence hosts wafer fabrication plants belonging to SGS-Thomson and Atmel. In addition, Motorola is nearby in Toulouse, and SGS-Thomson has more plants close by in Grenoble.

The importance of this high level of wafer fabrication plants is that both regions have been acclimatized to the high levels of service that wafer fabrication investments need in terms of ground preparation requirements, planning permission, waste material management, traffic and customs infrastructure, and supply infrastructure. In addition, the regions also have an existing skill base and orientation towards high-technology industries.

Western France

As well as the wafer fabrication plants located in western France, the region also has a high concentration of R&D facilities, including CNET (applied telecommunications research organization), CCETT (applied audiovisual research) and the microelectronics center for the west of France (CCMO), which is a collaboration between three electronics educational establishments in Rennes together with

SGS-Thomson, Matra and SOREP. CCMO provides R&D facilities as well as further training facilities and courses for workers in the electronics industry.

Western France is also home to more than 50 university- or engineering-school-based laboratories or departments with a high-technology orientation. These laboratories and departments are in 13 universities or engineering schools specializing in electronics, data processing and telecommunications.

The primary financial incentive available to companies investing in western France is the regional development grant (PAT). Most areas within western France qualify for a subsidy of up to FF 50,000 (approximately $8,250) per job created, although some areas within the region qualify for up to FF 70,000 (approximately $11,500) per job created. PAT is available to all companies investing at least FF 20 million (approximately $3.3 million) and creating 20 permanent jobs over three years. Neither of these restrictions would pose much of a problem for a semiconductor vendor considering investing in a new operation. The PAT incentive is limited to 17 percent of total investment. Some exceptional levels of financial assistance are available from PAT in western France, however, because of the restructuring of the French defense industry.

In addition to PAT, other assistance schemes are available for training programs and ensuring that manufacturing facilities are environmentally friendly. Full or partial exemption from business tax (a local tax) is also negotiable for up to five years for inward investment projects. In PAT-qualifying areas, local authorities are also prepared to become involved in land acquisition and preparation, and may provide a discount of up to 25 percent on purchase or lease costs.

Marseilles-Provence

The Marseilles-Provence region in the southeast of France has, as stated earlier, many wafer fabrication plants either in the region or close by. Additionally, the region has several technology parks serving the electronics industry, including Rousset, Aixles-Milles industrial development park, the Chateau-Gombert science park and the Arbois Europole project.

Within these parks and the region's universities there are 30 laboratories carrying out research in various fields of microelectronics. These laboratories are based around the four universities in the Bouches du Rhone region. In addition, Marseilles-Provence is home to the Microelectronics Regional Study Center on Silicon (CREMSI), which has some 40 members, including SGS-Thomson, Atmel, Gemplus and DuPont Photomasks, and 10 R&D laboratories. CREMSI is focused on furthering microelectronics in the Marseilles-Provence region and undertakes joint research for those companies involved. The Marseilles-Provence region also provides training programs and facilities for the technicians and senior technicians required to populate semiconductor fabrication plants.

Financial incentives in the Marseilles-Provence region are structured as those for western France. Marseilles-Provence is one of the few regions in the southeast of France which qualifies for PAT. The PAT rate for Marseilles-Provence is FF 70,000 per job created, subject to a maximum of 25 percent of total investment.

Ireland

Analog Devices' investment in Limerick in 1976 was the catalyst for Ireland's interest in attracting electronics-related investment. Since then, in addition to attracting a prestigious investment from Intel, Ireland has attracted several other semiconductor-related inward investments in the form of design houses.

Ireland has focused its efforts to attract future inward investment by building an infrastructure to supply the key staff for future technology. In addition to the National Microelectronics Research Centre base at University College Cork, which has a 3-inch foundry, IC design group, and interconnect and packaging laboratory, Ireland has eight universities with electronic engineering faculties, which produce between 600 and 700 electronics engineering graduates per year. Also, the Irish government has put in place an

Ir£50 million ($68 million) program aimed at developing additional engineering courses.

As well as its higher education establishments, Ireland also has 12 regional technical colleges offering electronics-related courses. Included in these courses is one codesigned by Hewlett-Packard and Intel to develop a suitably educated pool of technician-level staff.

One of the major financial attractions for investing in Ireland is the level of corporation tax levied against companies. The standard corporate tax rate is set at 10 percent until 2010. From 2010 until 2025 the rate will be 12.5 percent, which is significantly lower than that of most other countries. Surprisingly, other financial incentives aimed at attracting investment are significantly lower than those that some other regions are offering. The Irish Development Agency (IDA) offered Intel approximately IR£30,000 ($40,000) per job, which was significantly below some other offers, for a total commitment of 2,800 jobs, yet it still won the bid. This speaks volumes for the quality of staff on offer.

The IDA tends to work on an investment incentive per job created basis. However, once an amount per job has been fixed, it is broken down into three constituent parts: a capital grant based on the value of fixed assets; an employment grant, which, typically, would not exceed Ir£10,000 ($14,000) per job; and a training grant, which would cover up to 100 percent of agreed training costs.

Saxony, Germany

The former East German state, now one of the new German *Länder*, is positioning itself as the microelectronics center of eastern Germany. Since the reunification of Germany, Siemens has built a new DRAM wafer facility, in which it is planning its new 300-mm pilot line, and AMD is close to completing a new wafer fabrication plant for the manufacture of microprocessors. These developments are on top of the semiconductor infrastructure which existed when Saxony was part of East Germany. Zentrum Mikroelektronik Dresden (ZMD), which produces primarily memory products, has been located in Dresden since 1987. Prereunification, ZMD employed more than 3,000 staff in the microelectronics industry. Today it employs approximately 500, but the supply base for skilled employees, many of which worked in high-technology industries prior to reunification, remains.

Saxony, and Dresden in particular, offers a significant R&D and university infrastructure; Dresden has more than 30 educational and research institutes. Included in this number are the Institute for Semiconductor and Microsystems Technology, the Institute for Communications Systems, the Institute for Information Systems and the Institute for Technical Informatics, all at the Technical University (TU) Dresden, which has 21,000 students. In addition to TU Dresden, TU Chemnitz, FHS Mittweida, FHS Zwickau and FHS Zittau-Goerlitz all have IC design courses. Dresden is also home to the Fraunhofer Institutes for Microelectronic Circuits and Systems, the Fraunhofer Institute for Material Physics and Layer Technology and the Fraunhofer Institute for Integrated Circuits.

The financial incentives offered to inward investors in Saxony, and the new *Länder* of eastern Germany in general, are quite significant. Both Siemens and AMD received funding of approximately DM 800 million (approximately $450 million) to assist in their fabrication plant location decision.

Start up grants can reach 28 percent for large inward investment firms in the surrounding areas of Dresden and Leipzig. In other regions of the new federal states, grants can reach 35 percent of total inward investment. These grants are from the Improvement of Regional Economic Structures Program, which is funded by the Saxony Government, the federal government of Germany and the EU.

In addition to grants, several tax incentives are available to inward investors. Included in these are an investment allowance and a special accelerated depreciation allowance. The investment allowance returns 5 percent of any investment in movable depreciable equipment. Given that the cost of facilitizing a state-of-the-art wafer fabrication plant is now in the region of $1 billion, this allowance on its own is worth approximately $50 million. The special accelerated depreciation allowance allows companies to depreciate their capital equipment by between 20 percent and 40 percent above the normal depreciation rates.

United Kingdom

The United Kingdom has three regions that are focusing their attention on attracting semiconductor inward investment. These regions are the central belt of Scotland, stretching from the east coast around Edinburgh to the west coast around Glasgow, northern England and South Wales.

In 1996, semiconductor companies with manufacturing locations in the United Kingdom, along with the UK government, founded the National Microelectronics Institute (NMI). The NMI's role is to coordinate and enhance the activities of all parts of the UK semiconductor industry's support infrastructure. Included in this is the development of supporting industries and the coordination of further- and higher-education activities related to the microelectronics industry, as well as facilitating cooperation between companies in noncompetitive areas.

The NMI treats the three geographic areas as a single cluster, given their relative geographical proximity, coordinating all its activities to assist each area equally. The NMI has, with semiconductor vendors, developed two further-education courses designed to supply the semiconductor industry with appropriately qualified operators and technicians. To date, four further-education colleges in Scotland, and ten in the United Kingdom, offer these courses. In addition, the NMI has also created and had accredited a microelectronics MSc qualification for the development of engineer-level staff.

The main financial incentives provided to those considering investing in any of the three regions are, in principle, the same, although in the last round of inward investment, which involved Hyundai, the peculiar situation of two regions within the cluster trying to outbid each other occurred. Regional Selective Assistance (RSA) is the main financial incentive and applies to all three regions. Locate in Scotland, the inward investment agency, and the Northern Development Agency say only that RSA is negotiable on an individual basis, but is based on levels of capital expenditure and jobs created. In addition to RSA, all three regions have enterprise zones, which attract additional benefits of exemption from property taxes for 10 years and 100 percent depreciation allowance for buildings in the first year of operation.

Investors into the three regions will also be eligible for training and employment grants. Typically, these grants cover up to 50 percent of training costs, with a maximum of £4,000 ($6,500) per eligible employee.

An example which shows other potential benefits for investors is available in Scotland, where other substantial benefits including site acquisition and preparation, as well as considerable assistance with site management costs have been made available. An example of these is Hyundai's ongoing (and delayed) investment in Dunfermline, where it was reported that in an assistance package which totaled £151 million ($250 million) for a total maximum investment of £2.3 billion ($3.8 billion), amounts of £9.6 million ($16 million) for site acquisition, £23.4 million ($39 million) for site preparation (including new road infrastructure) and £9 million ($15 million) for waste treatment facilities were included.

Central Scotland

Since the mid 1970s, when National Semiconductor opened its first fabrication plant in Greenock, Scotland has recognized the increasing importance of high-technology manufacturing as a driver of national growth and large-scale provider of jobs. Since the 1970s, central Scotland has tried to reposition itself as the high-technology center of Europe, going so far as to coin the term "Silicon Glen."

The central belt of Scotland is home to six semiconductor companies, which have a total of ten wafer fabrication plants between them, and a further two plants are in planning or under construction. Central Scotland is therefore very adept at dealing with the requirements of semiconductor wafer fabrication plants.

In addition to the NMI infrastructure, central Scotland also houses 11 institutes and research centers related to the microelectronic industry. These are based at eight universities throughout the central belt region. Four of these universities are participating in a project with Cadence Design Systems to establish the world's first system-level integration institute. There are also 46 further education colleges, in and around the central belt, offering two-year electronic or electronic engineering courses.

Northern England

In addition to the regions' participation in the NMI, northern England also has a significant electronics-oriented training infrastructure, which produces more than 800 electronics-related graduates per year. In early 1998 the North of England Microelectronics Institute, a joint venture between the region's universities, Siemens and Fujitsu, opened in North Tyneside. The £16.5 million ($26 million) site includes laboratories for testing post-wafer processing reliability and design fault analysis, together with a new interconnection research project.

The region also has two universities: the University of Newcastle upon Tyne and Durham University, which both have a number of research groups related to the microelectronics industry. The University of Newcastle upon Tyne includes the Semiconductor Technology Group, the Microelectronic Systems Design Group and the DSP Group. Durham University includes the Centre for Molecular Electronics and the Centre for Electronic Systems. Durham University also manages a course developed by Fujitsu and continued by Siemens to fulfil the educational needs of both companies.

Spain

Spain appears to be something of an enigma in the field of attracting inward investment from the semiconductor industry. Since attracting Lucent Technologies to Madrid in the late 1980s it has not attracted any other major semiconductor fabrication investment.

Spain has set up two scientific parks focusing on the semiconductor industry. The first is Valles Technology Park located just outside Barcelona, and the second is Tres Cantos Technology park in Madrid, where Lucent Technologies has its wafer fabrication plant. In and around Valles Technology Park are the Spanish National Microelectronics Center, the Regional General Testing and Research Laboratory, and the New Materials Center, which is part of the Higher Center for Scientific Research. The National Microelectronics Center also has a site in the Tres Cantos Technology Park.

The principal financial incentive offered in Spain is for investment in certain regions. This is offered by the state, and varies from 20 percent to 60 percent of a project's capital expenditure. However, neither of the scientific parks mentioned above fall into one of the qualifying regions and, thus, they receive no regional incentive from the Spanish central government. In addition to the central government regional aid, each autonomous region also offers its own smaller-scale investment packages.

Spain has also created a $420 million high-technology fund called the ATYCA initiative, which will run until the end of 1999. The program is financed by the Ministry of Industry and Energy, and can provide funding for the improvement of the technology infrastructure and training.

Dataquest Perspective

Potentially useful manufacturing locations are essentially products for which there is a very small, but valuable, customer base. When Europe started attracting semiconductor inward investment, each country's offerings were essentially commodities, where, typically for commodities, price played the pivotal role in deciding which country won the inward investment. Price in this marketplace was represented by the amount of cash a region or country would pay to convince the prospecting company to move to their location.

However, the market has moved on; in the marketplace of inward investment the emerging key differentiator is the supply chain for appropriate human resources. Those regions or countries that develop a coherent and integrated road map to supply sufficient numbers of appropriate graduates and other technical staff will be the winners in attracting the quality inward investment projects in most cases.

For some, though, location will remain a commodity product and price (in the form of capital grants) will still have a key role to play. It could be argued that AMD's investment in Dresden, Germany was an example where "price" was the determinant factor whereas Intel's investment in Ireland was an occurrence where the differentiator won out over the highest bidder–the differentiating factor being the availability of staff at all levels of engineering expertise.

Some regions are further along the differentiation curve than others. For those lagging behind, price, in the form of subsidies, will continue to be their major attraction. For some companies this may be enough, although the dynamic is changing. Companies are beginning to want more than just a massive cash handout at the beginning of a project. They now want to ensure the long-term future of their plants and maximize the value they add to the company. Equally, countries want more than a cash for jobs equation, especially as the amount of cash required to win becomes unaffordable. They want investment in their communities and participation in their educational infrastructure. We may not have seen the last of the bidding wars that occurred in the fight to attract inward investment in the 1980s and early 1990s, but they will be fewer, as will be the participants involved in the fight. The next step for the inward investment market may well be its segmentation, on both the part of the semiconductor vendor and the regions.

Vendor Analysis

ARM: Embraced as a De Facto Standard

Abstract: *Clear winners are emerging as a result of the boom in semiconductor intellectual property. One of these is ARM, a microprocessor architecture that is fast becoming a de facto industry standard in several key volume application areas. This Vendor Analysis examines the UK company behind ARM and why it has been successful.*

By Joe D'Elia

Introduction

In the mid 1980s, when Acorn Computers was looking for a microprocessor to replace the 6502 that had been the basis of its BBC and Electron computers, a group of Acorn engineers were not happy about the available contenders. Dissatisfied with the price/performance of systems built using merchant market products, they decided they could come up with a cheaper, simpler and more elegant solution—luckily their management believed them. Since then, ARM has become one of the leading microprocessor architectures for the embedded environment.

For the first few years of its existence, ARM was used by Acorn primarily as the engine for its RISC PCs. In 1990 Apple Computer was looking for a new processor to power its new Newton PDA product and ARM was a leading contender. ARM Holdings plc was set up as a separate company so that Apple could be serviced and to ensure the development of the architecture on a commercial basis.

FILE COPY:
MARIA VALENZUELA

Acorn transferred the ARM design team to the new company and took an equity share, as did Apple and VLSI Technology. VLSI Technology was the semiconductor company that provided the original ARM devices; it was looking to ARM to provide it with a RISC core that it could incorporate in its ASIC libraries. In 1993 these initial investors were joined by Nippon Investment and Finance.

Like other leading third-party IP vendors, such as MIPS Technologies, DSP Group and Rambus Corporation, ARM has found that success in the intellectual property (IP) business takes time. The company was unable to go public until April 1998, its IPO being oversubscribed with shares offered at £5.75 each and selling at £8.38 at the end of the first day of trading.

Dataquest

Program: Semiconductors Europe

Publication Date: September 14, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Table 1 shows revenue for ARM from 1991 to the first half of 1998; while the company generated revenue from the start, profits did not appear until the third year of its existence. Since then, both revenue and profits have been increasing and, in pound terms, the company has achieved a CAGR of 86.4 percent in revenue over the period 1992 to 1997. This growth rate is slowing down and has been in the region of 60 percent for the past two years. If growth was to continue at 60 percent, 1998 revenue would be in the low £40 millions. However, first-half revenue of £18.6 million would indicate that a more likely number will be in the high £30 millions.

In setting out to be a leading IP provider, ARM realized that it had to supply more than the basic IP. While ARM architecture offered many advantages regarding code density, performance, die size and flexibility in system implementation, this was not enough. The company had to ensure that its cores were supported by all the major EDA vendors, that comprehensive tools were available, that application software was written and that consulting support was on offer.

Through a combination of internal efforts and external partnering the company has successfully built up a comprehensive support network that covers all these items. At any stage, a potential ARM user has a wide choice as to what is available to assist in the project implementation process. In mid 1998 there were more than 20 tools and EDA vendors, almost 50 OS and applications vendors and 20 design services providers. ARM's own participation in these areas has also resulted in a services-based revenue stream for the company to supplement its primary licensing and royalties revenue.

Table 1
Revenue and Profit for ARM, 1991-First Half 1998
(Pounds and Dollars)

	1991	1992	1993	1994	1995	1996	1997	1H 1998	CAGR 1992-1997

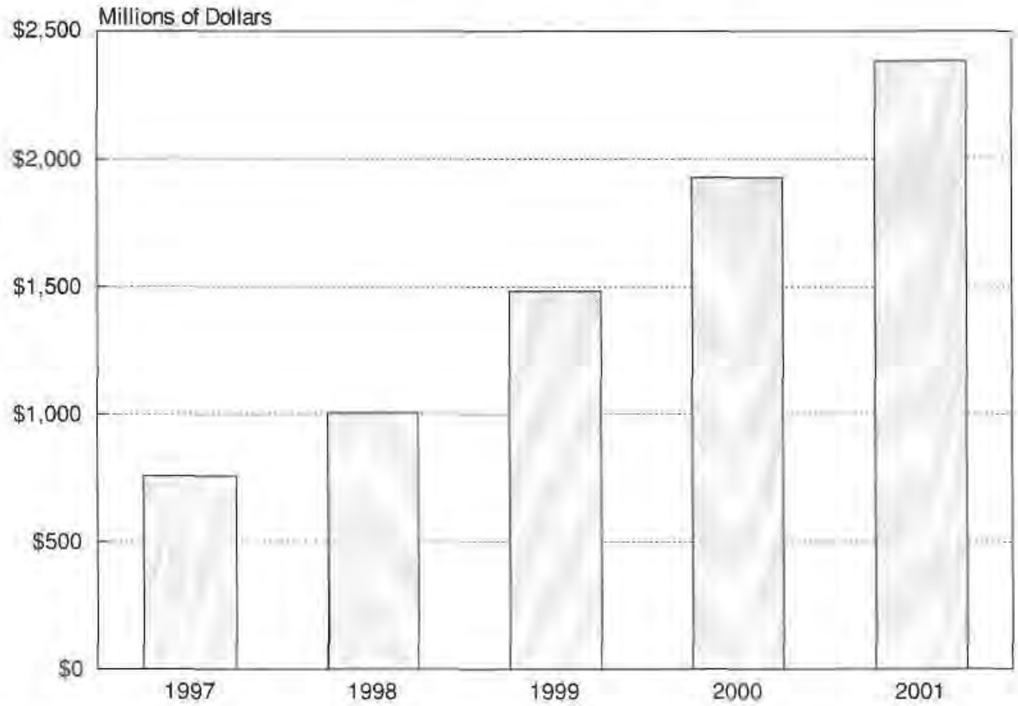
Intellectual Property Market

The supply of semiconductor IP is one of the fastest-developing markets in the world. Dataquest's estimates of how IP value in ASICs will develop is shown in Figure 1, which contains estimates for the period 1997 to 2001. Revenue is estimated at $757 million in 1997 and is expected to exceed $2.3 billion in 2001. For an explanation of how this value was derived, please refer to the *Dataquest Perspective* titled "Evaluating the Market for ASIC Intellectual Property." A comparison of ARM's results for its last financial year against other major third-party IP players shows that its revenue of $43.9 million is lower than MIPS Technologies' result of $56.8 million, but much higher than Rambus' $26 million and DSP Group's $10.7 million. These companies all have different fiscal years, so the results are not directly comparable but do give an indication of scale.

The numerous market players have many different business models, but these can be split into two major categories: direct and indirect. In the direct model, the IP provider designs and supplies cores direct to the end user.

Figure 1
Worldwide Intellectual Property Revenue, 1997-2001



Source: Dataquest (September 1998 Estimates)

Most semiconductor IP is supplied through the direct channel by semiconductor ASIC vendors through their extensive macrocell libraries. These cores are usually proprietary and therefore available from only one vendor; however, this is changing as vendors recognize the need to proliferate their architectures and are therefore slowly starting to cross-license each others' cores.

The drive behind this is the increasing complexity of semiconductor cores, and therefore the cost and effort required to generate and maintain them, together with the need to offer a comprehensive selection. The advance in semiconductor process technology is having as much of an impact on the ability of semiconductor vendors to deliver products to market on time as it is impacting their customers. Tied to the time-to-market issue is the ability to provide comprehensive support on all the complex cores in their libraries. These issues, coupled with customer demands for multisourcing, are driving the trend to cross-licensing and, even more so, the move to providing third-party IP.

In the third-party model, one company designs the IP and licenses it to a second (normally the semiconductor vendor), which sells it on to the end user, usually as a component part of a larger IP group. The licenser derives its revenue from several sources as follows:

- The first source is the license fee paid by the licensee company when it licenses the IP.
- The second is from providing training, engineering resources and tools to the second company during the exercise of porting the IP to that company's process technology.
- The third is through providing training, software and tools to the end user when he incorporates the IP into his design.
- The fourth is the per-unit royalties that the end user will pay indirectly through the silicon vendor.

Ultimately, the whole process starts again as further generations of the IP are introduced. The third-party market is growing because it enables all parties in the "food chain" to focus on what they do best: the silicon vendor provides silicon, the IP vendor provides the IP and the end user can focus on adding differentiation to his product through his knowledge of the end market.

ARM is tapping all four sources of income and is going through a transition period as the relative importance of these revenue streams changes. In its few years, ARM survived on licensing and providing porting support services to its licensees. As those licensees grew in number and the architecture started to become accepted by end users, ARM was able to tap into supporting end users' design efforts. Finally, in the past two years, ARM has been starting to tap into the fourth component, the royalty stream, as ARM-based products finally hit volume production.

As well as an increase in royalty streams, ARM is seeing an acceleration in licensees licensing newer cores and therefore starting the process again; to date, 18 of its licensees have already licensed subsequent IP. Figure 2 compares revenue with number of primary licenses, and shows the cumulative effect of these various revenue streams. Clearly, the rate of licenses increasing alone does not explain the revenue increase, even though ARM licenses will have become more expensive as the architecture became more established.

ARM is not alone in providing microprocessor cores, there are many other players, both third-party vendors—for example, MIPS Technologies, ARC, Hyperstone and Lexra—and direct vendors. However, Dataquest research shows that ARM is the architecture with the most design wins and we expect it to maintain this record. Figure 3 shows respondents' replies to Dataquest's 1997 ASIC user survey regarding the use of system-level functions in ASICs. In 1997 ARM was being used in 13 percent of these devices; in 1999 this figure should double to 26 percent.

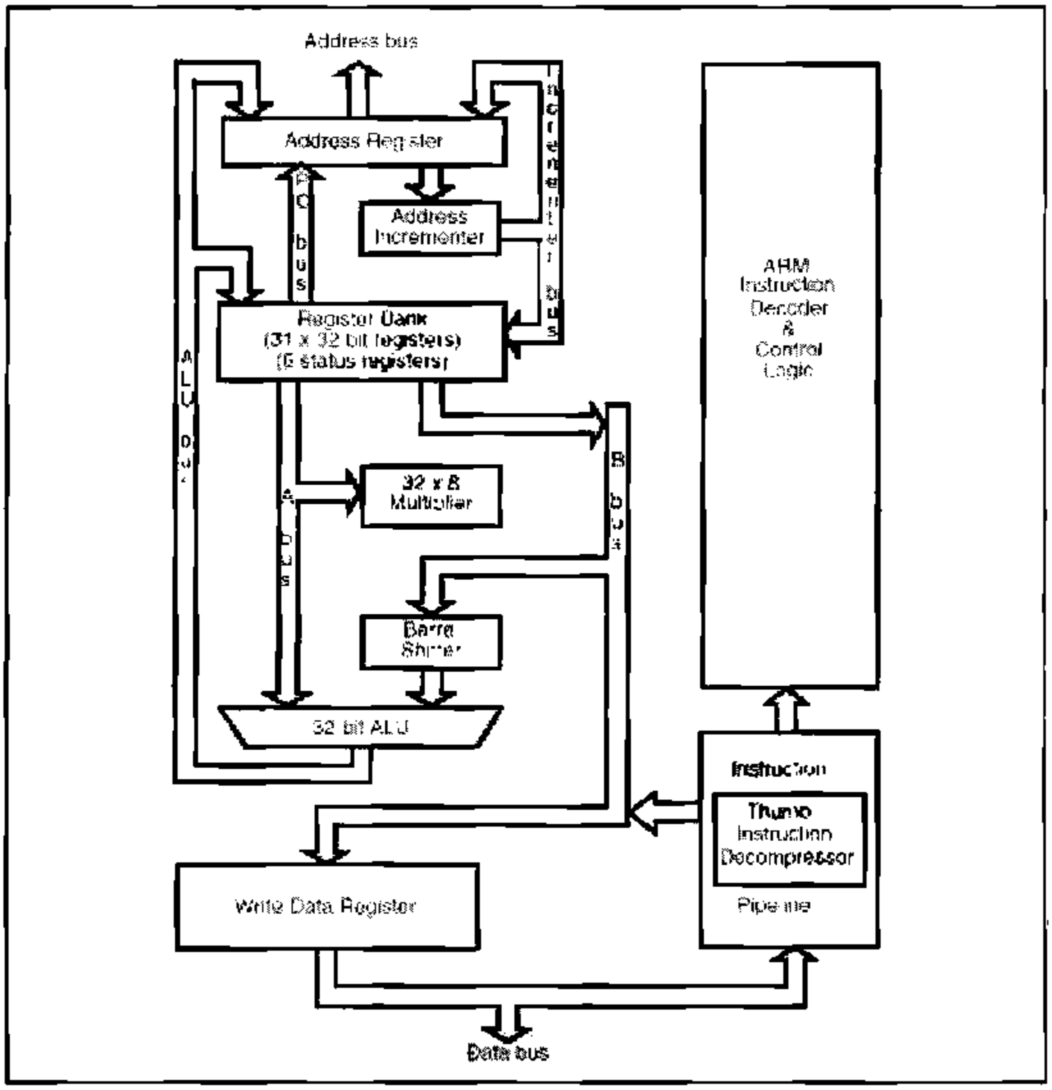
Products

ARM has had several generations of architecture. The one that started its current success is the ARM7D, introduced in 1993. More important is the ATM7TDMI core, introduced in 1995. The difference between the two is that ARM7D is a full 32-bit architecture with 32-bit code and data, while the ARM7TDMI inserts a 32-bit to 16-bit instruction decompression engine between the MPU and memory. This enables the device also to execute with a 16-bit reduced instruction set with only minimal performance degradation, while saving overall silicon area and memory costs in cost-sensitive applications. This "Thumb" extension to the ARM7 has proved so successful that the ARM7TDMI is now the only ARM7 core offered by ARM.

As well as the basic core, three preconfigured macrocells match the core with various peripherals such as cache, write buffers and memory-management functions to offer preconfigured options optimized for different applications. Figure 4 is a block diagram of the ARM7TDMI. It shows that, from an architectural perspective, there is nothing unusual in the RISC architectural implementation of the device; it is the combination of the whole package of products and services that makes ARM successful. The Thumb Instruction Decoder is shown as an integral part of the Instruction Pipeline and Read Data Register block.

In late 1997, ARM announced the ARM9TDMI, a five-stage pipelined core with Harvard buses that provides twice the performance of the ARM7TDMI. Also offered are two preconfigured Cached Processor Macrocells targeted at different applications.

Figure 4
ARM7TDMI Block Diagram



Source: ARM

Table 2 shows ARM's list of licensable cores, macrocells and various architectural extensions. The most interesting of these is the Piccolo DSP coprocessor, which integrates a second DSP-oriented data path and instruction set into a standard ARM system; both the DSP and CPU share the same system bus and memory, thereby minimizing silicon area. The Piccolo core addresses the growing number of applications where there is a need for general purpose processing and DSP functionality. These applications include hard disks, GSM telephony, GPS mapping systems and most of the high-volume digital consumer applications whose growth is just starting. The one disadvantage of this solution is that, as the system bus and memory are shared, only one of the units can be active at a time.

Another component of ARM architecture is StrongARM; this is not offered directly by ARM but by Intel, which acquired it as a result of the settlement of its litigation with Digital Equipment Corporation. With StrongARM, the objective was to offer the best possible performance with the lowest possible power consumption—this StrongARM achieved. Having found application in Apple's Newton resurrection, StrongARM's general acceptance was stalled by the Digital/Intel litigation and the uncertainty about its future after this was resolved. Late July saw Intel give an extremely strong message to the industry: that StrongARM was an integral part of its strategic thrust to obtain market share in those high-volume consumer and communications applications where its x86 architecture had been woefully unsuccessful. To this end, Intel has rebuilt and expanded the StrongARM design teams and is actively pushing to design StrongARM 2 and 3, together with ASSPs targeted at specific applications. This is extremely significant for ARM's overall market acceptance as it brings to the architecture the weight of the world's largest semiconductor manufacturer and microprocessor vendor.

Table 2
Licensable ARM Products

Product Code	Product Type	Product Description
ARM7TDMI	Core	ARM7 32-bit CPU core with Thumb extension
ARM7TDMI S	Core	Synthesizable ARM7 32-bit CPU core with Thumb extension
ARM740T	Macrocell	ARM7TDMI with 8KB cache, write buffer and MPU
ARM710T	Macrocell	ARM7TDMI with 8KB cache, write buffer and full MMU
ARM720T	Macrocell	ARM7TDMI with 8KB cache, write buffer and MMU for Windows CE
ARM9TDMI	Core	5-stage pipelined 32-bit CPU with integral Thumb extensions, giving twice performance of ARM7
ARM910T	Macrocell	ARM9TDMI with peripheral set for deeply embedded applications requiring simple memory management
ARM940T	Macrocell	ARM9TDMI with peripheral set for embedded applications requiring full virtual memory management
Thumb	Architecture Extension	Provides memory compression capibility, enabling 32-bit CPU to run from 16-bit memory
Multiplier	Architecture Extension	DSP-enhanced multiplier
EmbeddedICE debug	Architecture Extension	Provides integral ICE-like debug for CPU cores integrated into ASICs
Piccolo	Architecture Extension	High-performance ARM DSP coprocessor

Partnerships

Aside from the core products, the single most important factor contributing to ARM's success is the range of partners that it has built up since its inception. While the main interest of this *Vendor Analysis* is the semiconductor partners, the list that ARM has developed in the areas of development tools and services, EDA vendors, RTOS and application software is equally impressive and not to be discounted in the success of the architecture.

Table 3 lists the 27 public semiconductor partners; apart from this list there are two or three other partners that have not made their status public. Examining the participants shows that their regional origin is a good match to the overall semiconductor industry: 13 in the United States, 9 in Japan, 3 in Asia/Pacific and 2 in Europe. Three of the companies—Atmel, Intel and Mitel Semiconductors—were not the original licensees, but inherited their licenses through their acquisition of the original licensees. In all three cases they have maintained the license as a strategic contributor to their product plans.

The range of ARM usage is primarily in three product areas: as cores offered in ASIC vendors' libraries; as standalone microprocessors and microcontrollers, both general purpose and for very targeted applications such as PDAs; and as ASSPs for specific applications. Table 3 lists the application areas for which

©1998 Dataquest

ARM-based ASSPs have been marketed. This gives a good idea of the broad coverage available and indicates where the real volumes of ASIC ARM applications lie. Today, the main areas are electronic data processing and communications, over the next year these will be joined by various major digital consumer applications and within two years by important automotive applications.

ARM's ASIC partners are using the architecture diligently as their path into these major application areas and in certain key areas, such as digital cellular handsets, have established the architecture as the de facto standard. This latter occurrence is important enough to be considered a major reason why companies like LSI Logic and IBM Microelectronics, which have their own competitive offerings in the form of MIPS-based TinyRISC from the former and PowerPC from the latter, have taken on an ARM license. The message they were getting from the major players in the digital cellular market was "Don't call if you can't supply ARM!"

Table 3
Public Semiconductor Partners

Company	Year First Licensed	ARM Offerings	ASSP Application Area
AKM Semiconductor	1994	ASSP	Mobile Communications

The sheer number of ASIC licensees provides evidence of one of ARM's strengths: by using ARM an ASIC customer can choose from a variety of vendors and, if the volumes justify it, can get his product multisourced. While customers increasingly can get this benefit from several other architectures, there is not the same guarantee that what they get will be exactly the same. ARM's use of hard macros has resulted in a guaranteed product that works in exactly the same way and that has well-specified guaranteed parameters, irrespective of which vendor supplies it. A major factor in this strength is that ARM itself is closely involved in each porting effort and has ported the cores so many times and to such a range of processes that it is a well-practiced routine.

Future Directions

With ARM's current penetration of semiconductor vendors, the company has to look both for new products that will enable it to sell more to its existing customers and for products with which to expand its customer base. One initiative addressing the latter issue is the offering of soft macro versions of the architecture. Two of the most recent licensees, IBM Microelectronics and LSI Logic, are offering their own soft versions of the ARM7TDMI core, and now ARM is offering its own version in the form of the ARM7TDMI S. These soft macros will enable those ASIC customers and future licensees whose design flow cannot encompass a hard macro to employ the architecture.

The advantage of ARM's soft macro is that it enables a licensee to use a semiconductor vendor or foundry that is not an ARM licensee, although the downside is that the performance/size of the resulting implementation is entirely the licensee's responsibility. A soft macro will also be of interest to FPGA vendors as the increasing complexity of their devices increasingly demands ASIC-like design methodologies. To be successful, this latter usage would require a radically different business model, as controlling the use of the core would be much more difficult with off-the-shelf FPGAs.

Another initiative that indicates future directions for the company is the recent agreement with Lucent Technologies and Cirrus Logic to codevelop an open ARM-based architecture for hard disk drives. This kind of application-oriented development applied to other vertical markets would enable ARM to sell more to its existing customer base by facilitating its entry into new markets.

Beyond ARM9, the company's design center in Austin, Texas is working on ARM10, which will be introduced at this year's Microprocessor Forum. This shows an obvious acceleration in the introduction of new products: ARM7 was introduced in 1993 and ARM9 was introduced at the same forum in 1997. ARM10 will integrate a floating point unit and take the company into new areas of high-end performance. This combination of the three cores will give ARM a wide spectrum of performance to offer its licensees. The two questions that arise from this product strategy are ARM's ability to support all its customers should they choose to migrate, and the product positioning versus StrongARM, current and future. Figure 5 shows the roadmap for ARM and StrongARM, and shows that there is an overlap of performance as both move forward. However, other factors, such as power dissipation and process technology, will clearly dictate which is the best candidate for a particular application.

Speculation that ARM would extend its product offerings by taking ARM architecture to different word lengths to address areas such as the 8-bit embedded market should be discounted. This avenue was explored and found wanting; the investment required to make ARM successful would not bring the returns necessary to justify it.

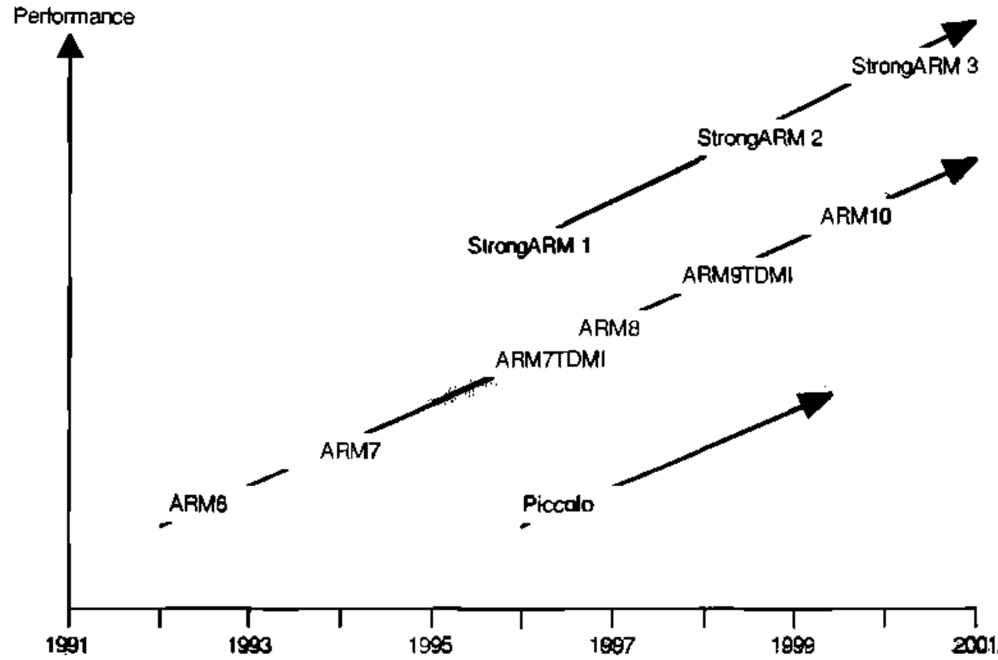
Figure 5
ARM Core Roadmap, 1991-2001



Source: ARM, Dataquest (September 1998)

Dataquest Perspective

The third-party IP market has been a long time coming. ARM has been at the forefront of the campaign and is now enjoying the rewards. It has been able to satisfy the four major issues facing customers looking to implement third-party IP today. These four issues and the ways in which ARM addresses them are listed in Table 4.

With success come new challenges and it is important that the company addresses these to ensure that it continues to grow. ARM's success has encouraged others to enter the third-party microprocessor IP market. The most significant of these new entrants is the revamped MIPS Technologies, which is now refocusing on this market. Beyond MIPS, there are companies like ARC, which has achieved reasonable success in its short existence, and other start-ups such as Lexra with its MIPS clone. These companies are small and flexible, and can use ARM's perceived weaknesses to their advantage. For example, ARC supplies a synthesizable macro and has a business model that minimizes the up-front license fee. Also, its architecture allows customers the flexibility of creating application-specific instructions that can keep code compact and help to minimize peripheral silicon. These three points address some of the major criticisms leveled at ARM; however, they are also cited by other customers as some of the key reasons for ARM's success.

On the same microprocessor IP front, the semiconductor vendors and their proprietary architectures constitute a threat to ARM; again, these competitors are adjusting to make their offerings more competitive. In particular, they are making their architectures more accessible by cross-licensing IP so that a particular architecture is available from several sources. Hitachi is ahead in this respect, having cross-licensed its Super H to four other vendors.

Table 4
Major Issues in the Implementation of Third-Party Intellectual Property

Issue	Resolution
Ease of implementation	Tools, services, software, training, partner programs
Multisourcing	Number of licensees, soft macro
Cost of license and royalty	Flexible business model, transparent end-user royalties
Manufacturability	Proven hard macros

Source: Dataquest (September 1998)

Another major factor for the company is the management of its growth rate, keeping resources in line with revenue. Over the next two years, ARM is due to introduce two major incremental products that require considerable resources to manage all the ports required by its customer base. Coupled with this will be all the necessary internal development for the actual products and tools (for example) needed to support them. ARM is now a public company and no longer has its previous flexibility; it has to meet its forecasts and keep its stockholders happy by maintaining growth in the stock price. ARM's management is aware of this and is learning to manage its revenue flow. If ARM adopts a relentless policy of killing old products, the company should be able to manage its growth successfully into the next millennium.

ARM is in a strong position. The architecture is established, the support infrastructure is in place and well-supported and its revenue streams are starting to be supplemented by royalties generated by the explosive growth of ARM-enabled unit shipments. This makes ARM the target for current and future entries into the microprocessor IP market. Fortunately, the market is growing so fast that there is room for several players. The key for ARM is to maintain its momentum and establish the architecture as a standard across a broad spectrum of applications such that when the market settles it is still in the leading position.

Chapter 1
Total MOS Memory Market Statistics and Analysis

Important Information

When reading this *Market Statistics* report, please bear in mind the contents of the chapter titled "Important Information," which refers specifically to the DRAM market.

Overview

Dataquest's latest market share survey, completed in April 1998, resulted in an estimated market size of $6 billion for Europe, Middle East and Africa (EMEA) MOS memory in 1997. When compared with the market's value of $7 billion in 1996, as shown in Table 1-1, this figure represents a decline of 13 percent. The 1996 figure, represented a 31 percent reduction in revenue from the high of $10 billion in 1995. This continued revenue decline of the MOS memory market further impacted the proportion of the total EMEA semiconductor market accounted for by MOS memory as a product category. The total MOS memory category, which includes DRAM, SRAM and nonvolatile memory, accounted for just 20 percent of the total EMEA semiconductor market last year—down from 24 percent in 1996 and 36 percent in 1995. The MOS microcomponent product category, which includes microprocessors, microcontrollers, microperipherals and digital signal processors, increased its share to 36 percent, while the MOS digital logic product category, which comprises mainly ASICs, grew its share to 14 percent. The share of the three main categories, namely MOS memory, MOS microcomponent and MOS digital logic, which together constitute the MOS digital product category, remained constant at 70 percent of the total EMEA semiconductor market.

The decrease in MOS memory revenue from 1996 to 1997 was driven by a decline in ASPs across all product categories. The only crumb of comfort was that this decline would have been much worse had it not been for healthy increases in bit demand, particularly in DRAM and flash memory. Consequently, the shares of the markets within the total MOS memory market remained largely unchanged. The DRAM market still dominates, retaining 67 percent of 1997 revenue. Similarly, the nonvolatile market held its one-fifth share of the total. However, the significant decline in SRAM revenue resulted in a slight loss of share at less than 11 percent. Making up the total, the other MOS memory market doubled its share from 1 percent to 2 percent, but this was more because a reclassification of revenue by one vendor during the market share reporting process resulted in an artificial fillip rather than a result of any real upsurge in the market.

Dataquest's segmentation for the MOS memory market is shown in Figure 1-1, and a full definition for each device family is included at the end of this document.

Table 1-2 illustrates all of the memory device markets and their relative size in the EMEA region and worldwide in 1997. Overall, the EMEA MOS memory market marginally increased its share of the worldwide total to more than 19 percent compared to the 1996 level of slightly less than 19 percent. This increase in share was driven by the flash and EPROM markets, which each increased worldwide share to 24 percent, along with the DRAM market, which increased its worldwide share to more than 19 percent. The EMEA SRAM market and the ROM market remained pegged at 16 percent and 5 percent respectively worldwide. The sharp decline in the worldwide share of the EMEA EEPROM, as with the apparent increase in the fortunes of the other MOS memory market, owes more to a reclassification of revenue by a vendor during the market share reporting process and is not a true reflection of the market situation.

©1998 Dataquest

Dataquest estimates that the EMEA market for MOS memory will grow at a compound annual growth rate (CAGR) of 15 percent from 1997 to 2002. As expected, MOS memory revenue declined in 1997 compared to the 1996 level, and the hoped-for strong upturn in the market in 1998 is looking less likely as revenue could struggle to maintain the $6 billion level of 1997. This prolonged period without positive market growth has meant that the expected three-year DRAM boom has been pushed out by a year, resulting in a strong growth outlook for 1999, 2000 and 2001. The next capacity-driven downturn is expected in 2002, leading to negative growth which will hold back the CAGR to 15 percent.

1997 Review

The EMEA semiconductor market grew by a modest 6 percent in 1997—a feat made all the more impressive considering the gloom hanging over MOS memory revenue. With the markets for DRAM, SRAM, EPROM, EEPROM and ROM all declining, the only bright spot was the flash memory market, which managed 5 percent growth in spite of severe ASP erosion.

DRAM prices continued to fall throughout 1997 as demand failed to mop up the glut of 16Mb EDO devices that swamped the market. DRAM manufacturing capacity was simply not reigned in, despite public announcements to the contrary. DRAM vendors continued to chase market share by improving production efficiencies and reducing costs to enable further price cuts. For example, the 16Mb contract ASP, which began the year at less than $10, declined by 50 percent to less than $5 by December as vendors shaved margins to the bone and flirted with the specter of antidumping legislation. However, DRAM prices—averaging at $3 to $4 per megabyte—did have a positive effect on the PC market during 1997. By the end of the year, 32MB was a standard PC factory fit and, with EMEA PC production topping 21 million units, a DRAM "bit boom" resulted in more than 100 percent bit growth in 1997 over 1996, compared with the typical level of 70 percent. A year of flat growth is predicted for DRAM revenue in 1998 as prices remain low while the industry is in a lull between DRAM density and technology generations. A very strong growth cycle is expected for the following three years before the cyclical downturn again in 2002.

Weakness in the SRAM market continued throughout 1997, although there were a few "false dawns" for the vendors when prices on selected devices were raised in anticipation of future shortages. These shortages failed to materialize, however, and the market declined by a hefty 19 percent to just $650 million. This decline in revenue meant that the SRAM market was relegated to third place behind the flash memory market, confirming that flash memory has come of age as a memory technology. Dataquest expects the SRAM market to return to low, single-digit growth in 1998 as it continues to shake down following the overcapacity of the past three years. The wide range of SRAM applications is expected to continue to fuel growth throughout the forecast period—especially in the telecommunications area, which is a lucrative market for slow SRAM.

The nonvolatile memory market continues to shape up as expected. The relative strength of the flash market in 1997, albeit at a less spectacular level than in the early 1990s, was achieved at the expense of the EPROM market, where revenue declined by more than 30 percent to less than $200 million. In addition, the removal of a large chunk of EEPROM revenue from the market in 1997 because of a definition change in the reporting of one vendor's memory sales and a residual ROM market that remained stubbornly low meant that the total nonvolatile market declined by 14 percent.

Other MOS memory will continue to be a niche and specialist market, but revenue in the EMEA region is expected to grow at a CAGR of 11 percent for the period 1997 to 2002, putting the market size ahead of that of EPROM and ROM by the end of the forecast period.

 ©1998 Dataquest

Long-Term Forecast

Table 1-3 shows the complete EMEA MOS memory consumption history and forecast for the period from 1992 to 2002. Included in this table are forecasts for units, ASPs, revenue, bit growth and costs per megabit. The DRAM market is expected to remain the most significant element of the EMEA memory market, rising from 67 percent of the total MOS memory market in 1997 to 76 percent in 2001 before falling back to a 67 percent share in 2002. The SRAM contribution will be maintained at about 10 percent to 12 percent throughout the forecast period, leaving the nonvolatile memory market to account for the remaining portion, a maximum of 20 percent. The dollar value of each of the memory families is illustrated in Figures 1-2 and 1-3. Notably, the flash memory market outgrew the SRAM market in 1997—much earlier than forecast—and these two markets look set to track each other in terms of size over the coming years. Much of this contention is dependent on the PC cache SRAM market, which may disappear in the EMEA region as PC microprocessor solutions migrate to an integrated L2 SRAM cache. Also noteworthy is that the decline in the EPROM market was more aggressive than forecast, primarily because of the emergence of flash technology as a cost-effective, higher-performance alternative. The EPROM market is expected to reach a residual market level of $50 million by the end of the five-year forecast period, and compete with ROM as the smallest EMEA memory market. Steady growth is expected in the EEPROM market following the glitch in 1997, which was caused by the removal of a large portion of "phantom" EEPROM revenue previously attributed to smart cards.

The top ten suppliers of MOS memory to the EMEA region for 1997 are shown in Table 1-4. Samsung retained number-one position by virtue of a steady performance in the declining DRAM market, where it actually managed to post a modest increase in revenue. This growth was coupled with a very good consolidation of its dominant position in SRAM, where the company gained significant market share, especially in the GSM handset arena. Siemens gained one position in the ranking at the expense of NEC; the latter's DRAM revenue declined by almost 20 percent, while the German vendor managed to hold its DRAM revenue reduction to a modest 6 percent. Texas Instruments (TI) and Hyundai both performed well, maintaining their memory revenues at just above 1996 levels. In contrast, heavy declines in DRAM sales pulled Fujitsu and Hitachi down the ranking, although LG Semicon, whose revenue fell at a similar rate, actually climbed a place. Micron Technology made it into the ranking, climbing five places to number seven—a vindication of its strategy of applying aggressive geometry shrinks to the aging 16Mb DRAM density generation to cut costs and prices. Finally, Advanced Micro Devices (AMD), whose flash products are gaining wide acceptance in the EMEA region, entered the top ten at number nine.

Total MOS memory units sold in 1997 grew by 13 percent over 1996. Figure 1-4 shows the forecast unit shipments for each memory family. DRAM unit consumption growth jumped to 35 percent in 1997 as the industry crammed more and more 16Mb devices into the PC. This growth will slow and level off later in the forecast period as the DRAM industry transitions from the 16Mb to the 64Mb device density; similarly, a shift to higher-density devices will result in a stabilization of SRAM unit consumption at about 150 million units per annum. Continued increased bit demand and cannibalization of the EPROM market will ensure that flash unit consumption increases at a CAGR of about 20 percent through 2002, even allowing for a move to higher-density devices. The blip in the EEPROM trend is an anomaly caused by the removal of a significant amount of prepaid telephone card units from the EEPROM category as a result of a definition change by one of the vendors. Unit shipments in this category will therefore be driven by the wide array of applications that use standard EEPROM devices. ROM unit consumption is expected to remain flat at a maximum of 20 million units per year.

 ©1998 Dataquest

The outlook for MOS memory ASPs is shown in Figure 1-5. The single most notable effect is the across-the-board reduction in ASPs seen in 1997 that affected all memory technologies. Looking ahead, volatile memory ASPs are expected to increase as supply-and-demand dynamics combine with a move to higher-density devices, while those for nonvolatile memories are expected to remain subdued because of the more stable nature of these markets.

The MOS memory application split is shown in Table 1-5. The dominance of DRAM within the memory market and the fact that most DRAM sales are made to the PC industry mean that the electronic data processing (EDP) sector accounted for 67 percent of the MOS memory market in 1997. The next most significant application segments are flash and SRAM; again, this is reflected in the application split where sales of memory chips into communications equipment represented 19 percent of the MOS memory total available market (TAM) in 1997. The EMEA region has a strong market for SRAM and flash in communications end equipment owing to the existence of large OEMs producing both fixed and mobile telephony equipment for the global marketplace. The remaining 14 percent of the EMEA MOS memory market is split between industrial (6 percent), automotive (3 percent), consumer (3 percent), and military and civil aerospace (2 percent).

The largest region for memory continues to be United Kingdom/Ireland with Germany in second place, as illustrated by Table 1-6. The dominance of the EDP and communications markets for MOS memory products in the EMEA region mean that the United Kingdom/Ireland and Germany account for more than 60 percent of the MOS memory TAM. Communications equipment production and strong industrial and automotive sectors mean that France is the third-largest country market for MOS memory in the EMEA region. It is ahead of Italy, where the troubles at Olivetti continue to affect the semiconductor TAM, and the Nordic countries, which are heavily reliant on the communications sector alone.

Figures 1-6, 1-7 and 1-8 show the terabit consumption by all memory products. DRAM bit consumption swamps all other memory types and continues to increase year on year. In spite of wild fluctuations in DRAM ASPs, historical and forecast bit growth remains largely unaffected at about 65 percent per annum on average. This will lead to DRAM bit consumption of 100,000 terabits in 2002. Flash memory is firmly established as the second-largest memory device family in bit terms and is forecast to reach almost 8,000 terabits in 2002, compared with an SRAM bit-consumption forecast of about 1,000 terabits in the same timescale.

Figure 1-9 shows costs per megabit of the various memory technologies. The ASP declines for DRAM in 1996 and 1997 are evident; this trend is expected to continue in 1998 before a leveling in 1999 through 2001, followed by another DRAM ASP crash in 2002. Following the plateau of the early 1990s when flash demand exceeded supply, flash cost per megabit is expected to decline at a steady rate as the technology matures and benefits from economies in manufacture in line with the other more mature memory technologies.

Chapter 2
Total DRAM Market Statistics and Analysis

Important Overview

Please refer to the chapter titled "Important Information," which relates specifically to the DRAM market.

Overview

The long-term forecast for the EMEA DRAM market is shown in Table 2-1. The year 1997 saw a 13 percent fall in EMEA DRAM revenue following the 40 percent revenue decline of 1996. Again, the cause was ASP erosion and it left the EMEA DRAM market worth a fraction above $4 billion in 1997. The outlook for 1998 is just as pessimistic with the most optimistic forecast for revenue growth in the low single digits. Realistically, another decline in revenue is far more likely in 1998, although Dataquest's forecast is for flat revenue growth. Whatever happens in 1998, Dataquest believes that the market will return to strong growth in 1999 through 2001 before falling back in 2002. The long-term outlook forecasts a CAGR of 15 percent for the period 1997 to 2002.

In addition to the long-term forecast, downside and upside forecasts for 1998 are presented in Tables 2-2 and 2-3 respectively. The assumptions behind these upside and downside scenarios are presented later in the text.

1997 Review

Following the DRAM market correction in 1996, ASPs continued to decline throughout 1997, albeit at a less spectacular rate. Overcapacity remained a feature of the global DRAM market and production of the high-volume 16Mb EDO reached new peaks. Vendors produced this device more and more efficiently as they tried to remain ahead of the competition and maintain market share. Talk of regulating production to cut back supply came to nothing and vendors resigned themselves to "slugging it out" while they waited for supply and demand to come back into balance.

The continued and unrelenting reduction in DRAM ASPs finally filtered through to the PC end user as the standard main-memory fit rapidly moved to 32MB in 1997. This, together with growth in PC production to 21 million units, drove unprecedented bit growth of more than 100 percent in 1997 over 1996.

The domination of the 16Mb device density is shown in Figure 2-1. Shipments of the 16Mb density were more than double that of the 4Mb in 1997 as the market switched wholesale to higher-density devices. In revenue terms, the 16Mb density accounted for six times more in sales than the 4Mb. Even sales revenue for the low volume 64Mb was twice that of the 4Mb.

The top ten DRAM suppliers to the EMEA region are shown in Table 2-4. Samsung consolidated its number-one position in the EMEA DRAM market and managed to grow revenue by 7 percent to achieve 25 percent revenue market share with slightly more than $1 billion in DRAM sales. Siemens faired better than most and jumped a place in the ranking to number two with revenue declining by 6 percent. Just behind Siemens, Hyundai also had a good year, growing revenue to almost $400 million to grab third position. The number two in 1996, NEC, suffered a 19 percent DRAM revenue drop which was enough to cause it to fall to number four in 1997. TI and Micron Technology grew their DRAM revenues at a similar rate and both vendors jumped three places in the rankings to fifth and sixth respectively. LG Semicon and Fujitsu both had a poor year with about a 30 percent decline in DRAM revenue, causing both vendors to drop one position in the ranking table. However, the worst performance came from Hitachi: the company's revenue was cut in half in 1997 causing it to drop from number four in 1996 to number nine in 1997. Finally, IBM made up the top ten at number ten.

The application split for DRAM is shown in Table 2-5. Unsurprisingly, a huge proportion of the DRAM shipped in the EMEA region is consumed by EDP applications. The PC accounts for the vast majority of these shipments, taking about three-quarters of the DRAM shipments into the EDP sector. Other compute applications such as workstations and mainframes, together with printers and disk drives among others, account for the remaining 25 percent of the EDP DRAM market. Outside the EDP segment, the communications sector, which is particularly strong in the EMEA region, accounts for a further 8 percent of DRAM sales. The same amount again is split between the application areas of consumer, automotive, industrial, and military and civil aerospace.

Table 2-6 shows the regional split for DRAM in the EMEA region. About two-thirds of DRAM sales are to the main EDP equipment-producing countries of the United Kingdom/Ireland and Germany. France, with its broad applications base, accounts for a further 10 percent of the EMEA DRAM market, with Scandinavia, Benelux and Italy together with the rest of the EMEA region making up the remaining quarter of the market.

Long-Term Forecast

Dataquest's forecast for 1998 assumes an ASP of slightly less than $2 per megabyte for the 16Mb and 64Mb device densities which are expected to account for 80 percent of the units shipped. In addition, a bit growth of 99 percent is forecast—much higher than the historic norm of 65 percent to 70 percent per annum. This high bit-growth assumption is more a recognition of demand elasticity because of continued low prices, rather than the existence of any new software application driver. The upshot of these assumptions is a market size in 1998 comparable to that in 1997.

Dataquest believes that there is plenty of downside opportunity in the DRAM forecast for 1998, as shown in Table 2-2. Because of continued overcapacity in the global DRAM industry—exacerbated by prolonged cost cutting on the aging 16Mb generation of devices—ASPs have declined and are likely to continue to do so. ASPs are forecast to fall month on month throughout the first half of the year, so that by mid 1998 the contract price for a 64Mb device is about the $10 mark. The average ASP assumption factored into the forecast is significantly higher than this figure. Moreover, to anticipate another year of bit growth of about 100 percent would be optimistic to say the least, especially in the absence of any real software application driver. Therefore, Dataquest's downside scenario factors in lower ASPs and lower bit growth to arrive at a DRAM market that could decline by 22 percent in 1998. This would be unprecedented in the history of the DRAM market, but the indications are that it is quite a likely scenario.

If there is any upside, as shown in Table 2-3—Dataquest believes that this scenario is extremely unlikely—it is just possible that an early move to 64Mb synchronous devices could result in device specific shortages and a stabilization in prices. If this ASP stability had a minimal effect on bit growth, there is a remote possibility that single-digit positive growth could return to the DRAM market in 1998.

The downturn in the DRAM market that began in 1996 is likely to continue for longer than any previous DRAM bust. The effect of the Asian financial crisis and currency devaluation against the dollar in the short term, particularly in South Korea, has been to reduce manufacturing costs, thus prolonging the lifetime of 16Mb device-density generation by enabling lower prices. Longer term, there is likely to be a supply crisis as the effects of reduced or canceled capital spending ripple through.

The prospects for the recovery of the DRAM market are entirely dependent on the removal of overcapacity from the industry. DRAM capital spending continued to increase during the first half of 1997, fueling the industry's overcapacity. Capital spending has now been reigned in, but Dataquest's projections on the DRAM supply-and-demand situation suggest that a balance between the two will not occur until late 1999 or early 2000, thus keeping prices low. Therefore, individual DRAM vendors are likely to try to persuade their customers to make the switch sooner rather than later from 16Mb EDO devices to 64Mb synchronous devices, believing that there is an edge to be gained in higher market share at the 64Mb density. Although it is currently more profitable for DRAM vendors to manufacture the 16Mb density device, they will be motivated to sacrifice short-term profitability and will attempt to move the market to the 64Mb density device to enable them eventually to reduce cost per bit over time and to achieve higher margins. However, the desire of the DRAM industry to move the PC industry to the 64Mb device density is not enough on its own; there needs to be a demand pull as well and PC vendors will not make the move to the 64Mb device until it reaches bit price parity with the 16Mb. This crossover is unlikely to occur until late 1998 or early 1999.

Longer term, the DRAM market is expected to return to healthy revenue growth in 1999, 2000 and 2001 as prices stabilize. There will be a move to the synchronous DRAM PC100 specification that will gather momentum towards the end of 1998 and, by 1999, it will have become the mainstream DRAM technology for the forthcoming forecast period. The much-talked-about Rambus technology is unlikely to make an appearance in the mainstream DRAM market until early in the next century. As shrinks in process geometry move the industry to feature sizes below 0.25 micron for volume production, the 64Mb device density will become the standard for the PC market and drive the next DRAM upswing. On the demand side, the outlook for PC production in the EMEA region is for continued unit growth at the mid-teens level. PC main-memory fit is expected to continue to increase from an average of 50MB per system in 1998 to an average of 188MB per PC in 2002.

Towards the end of the forecast period, Dataquest expects another DRAM market downturn driven by overcapacity and falling ASPs. Although the exact timing of this downturn is difficult to call, there is no doubt that it will occur unless some new DRAM market dynamics come into play.

Chapter 3
Total SRAM Market Statistics and Analysis

Overview

As shown in Table 3-1, Dataquest's latest forecast estimates that the SRAM market will exceed $1.5 billion by 2002. From a level of $646 million in 1997, the market is forecast to grow at a CAGR of 19 percent during the period 1997 through 2002. Maintaining the proportion seen in 1997 throughout the forecast period, the EMEA SRAM market is expected to continue to represent about 10 percent to 12 percent of the total EMEA MOS memory market.

1997 Review

The EMEA SRAM market declined more sharply than expected in 1997, revenue declining by 19 percent over 1996 levels to $646 million. The decline in 1997 followed a 14 percent decline in 1996 from the high point of $921 million in 1995. The market size is now comparable to that in 1994 in revenue terms, although the number of bits shipped in 1997 was double the number shipped in 1994.

Total unit shipments in 1997 were on a par with those in 1996, as shown in Table 3-1, although there was a 30 percent growth in the number of bits shipped. The average cost per chip declined as prices for higher-density devices such as the 2Mb and 4Mb fell. The attractiveness of these higher-density devices is reflected in the fact that this segment of the market was the only one to show revenue growth in 1997. Revenues in both the 1Mb and the 256Kb market segments declined in 1997 over 1996. From a unit shipment perspective, as shown in Figure 3-1, shipments of the 2Mb and 4Mb device densities increased sharply in 1997, and these higher-density devices are expected to become the highest volume shipment density by 2001.

Table 3-2 illustrates the top ten suppliers of SRAM in the EMEA region. In a difficult year, Samsung consolidated its number-one position and now accounts for 26 percent of the EMEA SRAM market. If the level of Samsung's EMEA SRAM revenue stands head and shoulders above its competition, in a graphic demonstration of the inherent fragmentation of the SRAM market, the companies ranked from number two to number ten in revenue terms each had market shares ranging from about 5 percent to 8 percent in 1997. This increase in Samsung's market share came at the expense of Mitsubishi, Toshiba, Motorola, Sony and Hitachi, all of whose revenues declined by more than 30 percent, resulting in market share losses. NEC and Integrated Device Technology both increased market share and moved up the ranking table in 1997 by limiting their revenue declines to single digits and Cypress Semiconductor held on to 5 percent of the market, even though its revenue declined by almost 20 percent. Surprisingly IBM entered the top ten in 1997, but this can be explained by an improved visibility in the company's reporting of the level of its SRAM sales in the EMEA region.

Table 3-3 shows the application split for SRAM in Europe. Although the SRAM market is fragmented among a multitude of applications, the core markets are in EDP, communications and, to a lesser extent, industrial applications. The EDP sector accounts for about half of SRAM revenue, while the use of SRAM in communications equipment adds another third of the revenue total.

Since half of SRAM revenue comes from the EDP segment, it is not surprising that the key EDP production regions of the United Kingdom/Ireland and Germany together account for more than 50 percent of the SRAM market (see Table 3-4). Communications and industrial equipment production mean that France and the Nordic countries account for about a quarter of SRAM sales by revenue.

Long-Term Forecast

Although Dataquest forecasts steady growth in the EMEA SRAM market throughout the forecast period—driven by existing EDP, communications and industrial markets as well as emerging markets such as digital consumer applications and automotive navigation—there are threats to some of the major SRAM markets that could adversely affect the forecast.

The SRAM market remains fragmented and multifarious applications continue to consume all kinds of device speed and density, but there are common threats to the steady growth forecast for the EMEA SRAM. The trend towards higher integration to reduce costs in high volume consumer-oriented products, such as the PC and the mobile telephone, is leading to a demand for embedded memory in System Level Integration devices. A particular area of concern for SRAM vendors in the short term must be the fate of fast SRAM for the PC L2 cache application. Indeed, many vendors have already exited this market, ostensibly because of the fierce competition but also, no doubt, because of the uncertain future longer term.

The long-term forecast for the EMEA market is heavily dependent on the fortunes of the cache market for fast SRAM. The market for sub-20-ns access time devices accounted for more than one third of EMEA SRAM revenue in 1997, but a large part of this market is expected to disappear over the forecast period because of the accelerating trend towards modular PC microprocessor solutions. The integration of PC SRAM cache memory, either onto the microprocessor module or into the microprocessor device itself, is already underway spearheaded by Intel and its competitors. Intel has chosen a limited number of SRAM vendors as partners to supply cache SRAM for its modular microprocessors so the size and location of the TAM in this segment will be predetermined by the microprocessor vendor. The trend towards modular microprocessors has implications for the EMEA fast SRAM TAM in particular because it is likely that Intel will place its purchase orders for cache SRAM in other global regions such as the Americas. Longer term, the global market for PC cache is likely to disappear altogether as cache becomes incorporated into the microprocessor silicon.

In cellular telephony—a buoyant market for slow SRAM in the EMEA region in recent years—there are emerging threats for the slow SRAM market. Although healthy handset unit growth is expected over the forecast period, it is unlikely to match the 100 percent growth seen in 1997. This is partly because of a growing trend by the major OEMs to shift production to the lower cost manufacturing regions of the Far East and partly because of a slowing in the growth of end-user demand. In addition, there is strong pressure from the OEMs to reduce the handset chip count and this has already resulted in the development of single package multichip flash and SRAM solutions for the handset memory market. Over time, it is likely that the flash and SRAM functions will become truly integrated onto a single piece of silicon, reducing the number of vendors capable of competing in this market.

Chapter 4
Total Nonvolatile Memory Market Statistics and Analysis

Overview

Table 4-1 shows Dataquest's latest revenue forecast for the total nonvolatile memory market in Europe up to 2002, broken down into the four constituent product categories of EPROM, flash, EEPROM and ROM. For nonvolatile memory as a whole, a modest CAGR of 12 percent for the period 1997 to 2002 is expected, held back by the declining EPROM market, the static ROM market and the anticipation of continued pressure on flash and EEPROM ASPs.

1997 Review

The decline in the nonvolatile memory market of 14 percent in 1997 over 1996 occurred because of a real decline in the EPROM market and a virtual decline in the EEPROM market. The EPROM market declined much more severely than expected because ASPs were driven down in line with a continued reduction in flash ASPs. In fact, some flash devices were actually priced lower than equivalent density EPROM devices during 1997, which meant that any reason for choosing EPROM over flash disappeared. This effect was a "double whammy" for the nonvolatile market as marginal growth in the flash market failed to compensate for a 32 percent decline in the EPROM market. This real effect was exacerbated by the artificial removal of more than $100 million of EEPROM revenue because of a redefinition of one vendor's smart card sales. Although the ROM market declined by 11 percent in 1997 over 1996, the fact that it continues to account for only about $50 million of revenue meant that it had little effect on the overall growth in EMEA nonvolatile sales.

Long-Term Forecast

The outlook for the EMEA nonvolatile market remains subdued in 1998. No revenue growth is anticipated as the EPROM market continues its slide and low ASPs hold back flash market growth in the short term. Longer term, however, a return to mid-teens growth in both the flash and EEPROM markets will drive a CAGR of 12 percent through 2002. The decline in the EPROM market is expected to continue apace so that by 2002 it will rival ROM as the smallest nonvolatile market in the EMEA region.

Figure 4-1 shows share of the nonvolatile memory market accounted for by EPROM, flash, EEPROM and ROM. In 1997, the flash and EEPROM markets already accounted for 80 percent of the EMEA market. The decline in the EPROM market will mean that, by 2002, 95 percent of nonvolatile sales will be either flash with 67 percent or EEPROM with 28 percent. The remaining 5 percent of the market will comprise either EPROM or ROM sales.

Chapter 5
Total EPROM Market Statistics and Analysis

Overview

Table 5-1 shows the long-term forecast for EPROM in the EMEA region. The market declined by more than 30 percent in 1997 and the outlook is for more of the same. Declining unit sales will lead to an average bit-growth decline of 13 percent per annum over the forecast period. Although ASPs may stabilize as the market transitions towards becoming little more than a residual one, revenue is still expected to decline by a CAGR of 22 percent over the course of the forecast period, leaving the market at the $50 million level by 2002.

1997 Review

The only surprise in the EPROM market in 1997 was the rate at which the market declined. This decline can now be said to be terminal, following a 32 percent drop in revenue in 1997. There no longer appears to be any compelling reason to buy EPROM, other than for products reaching the end of their life cycle. Any new product requiring a nonvolatile code storage device will be using flash now that it is competitively priced and unlikely to be in short supply.

Table 5-2 shows the top ten suppliers of EPROM to the EMEA market in 1997. The top four accounted for more than 90 percent of the EPROM market in 1997. Although it might be a dubious honor, SGS-Thomson continues to dominate the market and accounted for as much EPROM revenue as all the other vendors combined in 1997. Bizarrely, TI jumped to number two in the ranking, growing its EPROM revenue by 10 percent and leapfrogging both AMD and Atmel, whose revenues declined by more than 40 percent. Clearly, these two vendors were concentrating on their flash business in 1997. Judging by the level of sales, the remaining vendors in the ranking had other things on their minds as well.

Figure 5-1 shows the unit volume shipment forecast for all densities of EPROM. The market is concentrated in the lower-density 256Kb to 4Mb range, confirming that EPROMs are now used purely in legacy systems. For this reason, decline in EPROM unit shipments is expected across all these densities.

Traditionally EPROM devices find sockets in a wide range of applications as shown in Table 5-3. The EDP and communications sectors each account for about a third of the EPROM market, the remaining third being dominated by the industrial sector.

Since the United Kingdom/Ireland and Germany are the major EDP and communications electronics equipment producers in the EMEA region, more than half of EPROM revenue is derived in these countries, as shown in Table 5-4. France is the next-largest country market for EPROM at 15 percent of the TAM.

Long-Term Forecast

The maturing flash market will push the EPROM market towards an early death. As vendors concentrate investment on flash technology, EPROM devices will become less competitive and relegated to fewer and fewer application areas. With more and more leading-edge flash capacity planned for the coming years, there is no reason to expect a return to the days of flash shortages which may have provided an opportunity for a resurgence in demand for EPROM. With that prospect in mind, Dataquest expects the market level to fall to about $50 million by 2002.

Chapter 6
Total EEPROM Market Statistics and Analysis

Overview

The long-term forecast for EEPROM is shown in Table 6-1. The market size in 1997 suffered an anomalous decline because of a reclassification of its smart card revenue by SGS-Thomson. Although its memory smart card revenue remains included in its EEPROM business, the company now correctly reports its "true" smart card revenue as part of its microcontroller business rather than as part of its memory business, as was previously the case. Although it is difficult to extricate a true EEPROM market growth rate for 1997 because of this definition change by SGS-Thomson, as a rough estimate it appears that the market would have been more or less flat. Removing the effect of SGS-Thomson's true smart card business from the forecast, Dataquest expects a CAGR of 15 percent for the period 1997 to 2002 growing the market to $600 million.

1997 Review

EEPROM continues to be pervasive in all types of electronics equipment, especially in application areas such as communications, automotive and consumer. However, price pressure was again a feature of the market in 1997, as competition for sockets remained intense, so any growth in the non-smart card EEPROM market would have been driven by increased unit volumes. Because of the removal of SGS-Thomson's microcontroller-based smart cards from the EEPROM market, there is a step-function decline in the ASP of 256b EEPROMs to reflect the fact that this category now contains primarily 192b and 272b EEPROM memory-based smart cards.

Table 6-2 shows the 1997 EMEA market share ranking for EEPROM. Siemens is the number-one vendor, overtaking SGS-Thomson, now without the artificial benefit of its microcontroller-based smart card revenue. Atmel, traditionally a stalwart in the EEPROM market, suffered a 19 percent revenue decline in 1997, but managed to retain third spot in the ranking. There was a strong performance by Microchip Technology, which swapped positions with TI and moved into fifth position by increasing revenue by 68 percent. Xicor remained in sixth position, growing revenue slightly, but Fairchild's revenue declined by 41 percent causing it to lose seventh place to Catalyst. Rohm and NEC make up the top ten, but cannot be considered serious EEPROM players.

The unit shipment detail, as illustrated in Figure 6-1, shows the high proportion of unit shipments in the 256b density line which reflects the high volume shipments of 192b and 272b memory-based smart cards. Although there are higher density EEPROM-based smart cards, the 1Kb to 64Kb density range is principally the domain of the standard EEPROM device. A general shift in shipments of standard EEPROM devices is expected towards the higher end of this density range over the forecast period but, in parallel with this shift, EEPROM will face a cannibalization of its market by flash products.

Table 6-3 shows the application split for the EEPROM family. The removal of a significant amount of smart card revenue from the EEPROM market has reduced the proportion of the market accounted for by the EDP sector. It has also left the application split more representative of the traditional EEPROM application areas such as communications, automotive and consumer, each of which accounts for about 15 percent of the overall EEPROM TAM.

The country split, shown in Table 6-4, confirms the wide usage of EEPROM in many application segments. The importance of Germany, the United Kingdom/Ireland and France as electronics equipment producers is evident, as they take almost 75 percent of the available EEPROM market.

Long-Term Forecast

The restatement of the smart card contribution to the EEPROM market TAM has resulted in a more conservative forecast. Dataquest expects the EEPROM family to grow with a CAGR of 15 percent in revenue terms between 1997 and 2002.

EEPROM will continue to be in demand across a wide range of applications and the market will receive an injection of momentum through the use of EEPROM in synchronous DRAM DIMM modules. However, there are signs that some applications, such as digital cellular handsets, are integrating the EEPROM function into the flash device through the use of EEPROM emulation software techniques. This is a cause for concern for vendors reliant on the EEPROM market, especially as emerging applications such a digital set-top boxes move towards higher levels of integration even before high levels of unit production get underway.

Chapter 7
Total Flash Memory Market Statistics and Analysis

Overview

The long-term forecast for flash memory is shown in Table 7-1. The outlook is for continued growth, although the expectation for 2002 has been reduced to $1.4 billion courtesy of a CAGR of 17 percent for the period 1997 to 2002.

1997 Review

The EMEA market for flash memory was ravaged by fierce competition and heavy ASP erosion. Particularly affected was the price of the 8Mb device, which suffered as the major OEMs played one flash supplier off against another in the face of abundant supply. The 8Mb device ended the year at less than $7 with the ASP slide expected to continue through 1998.

Figure 7-1 shows the unit life cycles for flash memory for the forecast period. The market is expected to be driven by the 1Mb, 4Mb and 8Mb densities in the EMEA region in 1997 and 1998 before the 16Mb takes over in 1999 and 2000 when applications such as digital cellular and digital set-top boxes migrate to the higher density.

Table 7-2 shows the flash market shares for 1997. Here the most notable point is the change in top-ranked vendor in 1997. Following several years of Intel domination, AMD finally gained top spot. This occurrence is particular to the EMEA region because of the importance of two flash application markets: the digital cellular handset market and the automotive market. The technology offered by Fujitsu AMD Semiconductor Ltd. continued to increase its penetration and benefited because of a huge increase in GSM handset production. Because of this and because of its strength in automotive powertrain applications, AMD deposed Intel as the flash market leader in the EMEA region. These two vendors held two-thirds of the EMEA flash market in 1997, although Intel lost market share not only to AMD but also to its partner, Sharp, which entered the ranking at number four. AMD's partner, Fujitsu, the fourth member of the "NOR four" maintained its solid number-three position. The NOR four increased their dominance to account for 89 percent of the market in 1997, up from 81 percent in 1996. Intel was not the only casualty in the market share battle between the top four vendors. Both SGS-Thomson and Atmel, as the only other credible players in the EMEA flash market, lost market share to account for only 7 percent between them, compared with 15 percent the previous year.

Table 7-3 confirms that the dominant flash application area is the communications market, which accounts for 71 percent of the EMEA flash market. The other main application areas are the EDP sector driven by flash PC BIOS, and the automotive electronics sector driven by powertrain applications such as engine control and the emerging application of in-car entertainment and information systems. The consumer segment is set to become an important area for flash memory, particularly as the digital set-top box looks likely to take off during the forecast period.

The regional split for flash is contained in Table 7-4. Surprisingly, although it accounts for a quarter of the flash market, the Nordic region, with its high concentration of digital cellular handset and base station manufacturing, is not the single-largest country market for flash. This honor goes to Germany with its large EDP, telecommunications and automotive industries.

©1998 Dataquest

Long-Term Forecast

The low revenue growth seen in 1997 is expected to be repeated in 1998 as the EMEA market remains dominated by the digital cellular handset and its requirement for the 8Mb device density. Higher unit shipments of the 8Mb device will be offset by lower ASPs, and it is not until demand switches to the higher-density 16Mb in 1999 and beyond that healthy growth will return to the EMEA flash market. A more conservative CAGR forecast of 17 percent revenue growth for the period 1997 to 2002 is driven by increased revenue from the 16Mb-and-above device densities later in the forecast window.

ASPs for the 32Mb-and-above device densities are influenced by the fact that NAND-based devices are cheaper on a bit basis than NOR-based devices. In the five-year period, the program code storage market for NOR-based flash will generally require a maximum device density of 32Mb, while the market for the 64Mb and 128Mb will be centered around NAND-based flash and restricted to a limited number of data storage applications.

The flash market has moved into a period of maturity and is showing signs of becoming a commodity market, albeit on a much smaller scale than in the case of DRAM. There are certainly plenty of applications emerging to drive demand, particularly in the digital consumer and automotive segments, but such is the competitive nature of the market that die shrinks and additional fab capacity mean that no supply shortages are on the cards. It remains to be seen whether the NOR four can hold onto their dominant position, but the constant drive to win market share means that they are very lean competitors. Any potential challenger would have to be able to compete at the leading edge of flash technology; it would take a serious commitment to develop a competitive NOR-based flash offering. It is more likely that the NAND-based flash vendors will concentrate on the emerging data storage applications of the Far East markets rather than attempting to enter the EMEA market with its heavy NOR-based technology bias.

Chapter 8
Total ROM Market Statistics and Analysis

Overview

Dataquest's latest long-term outlook for ROM is contained in Table 8-1. The market as a whole is so insignificant in the EMEA region, comprising only 5 percent of global sales, that any growth—positive or negative—fails to have much of an impact in absolute terms. Within the margin of forecasting error, Dataquest expects that the market will neither grow nor shrink significantly but will continue at its present level of about $50 million. A CAGR of minus 3 percent is forecast between 1997 and 2002, resulting in ROM accounting for less and less of a percentage of the total nonvolatile market.

1997 Review

The ROM market is dominated by the printer application and, in the absence of new application drivers, falling ASPs led to a market decline in 1997 of 12 percent over 1996.

The main suppliers of ROM to the EMEA region are illustrated in Table 8-2. Again, this year Dataquest's market share figures have identified only nine vendors active in ROM in this region, reflecting the lack of interest in this area. However, there were some ranking changes compared with the 1996 lineup. The market fell to $53 million with NEC and Toshiba maintaining their top two positions. Samsung and Sharp share third place with Harris, which added $5 million to its sales. The top five vendors in 1997 accounted for 79 percent of the EMEA ROM market compared with 80 percent in 1996. LG Semicon, OKI, Macronix and Hitachi completed the lineup.

As shown in Figure 8-1, unit shipments were concentrated around the 4Mb, 8Mb and 16Mb densities in 1997 with little sign of demand for higher densities even later in the forecast period.

The printer industry is the overriding ROM market in the EMEA region. For this reason, the EDP segment, which contains printers, accounts for about 70 percent of the ROM market, as shown in Table 8-3.

Table 8-4 shows the country split for the EMEA ROM market. The main EDP production regions of the United Kingdom/Ireland and Germany make up 60 percent of the market with another 12 percent going to France.

Long-Term Forecast

The usage of ROM in the EMEA region is limited to applications such as printers which account for approximately half of the market. The possibility that ROM will start to be used more widely as a low-cost alternative to flash, in applications such as budget digital cellular, looks less likely now that flash is so cost competitive. Indeed, the prospect of flash devices replacing ROM in the printer applications seems a more likely scenario.

Chapter 9
Total Other MOS Memory Market Statistics and Analysis

1997 Review

The EMEA market for other MOS memory devices benefited in 1997 from a windfall gain in the form of additional revenue as a result of a definition change by Philips during the market share reporting process. The market size was $147 million in 1997—a growth of 73 percent—but, if Philips' sales are removed, the growth in the residual market was minus 4 percent. The top suppliers to the EMEA region are shown in Table 9-1. Dataquest's market share figures have managed to identify only six vendors active in the EMEA other MOS memory market in 1997, even after the inclusion of Philips. The introduction of Philips to the category displaced long-term market leader Integrated Device Technology, which now occupies number-two spot. Cypress Semiconductor's revenue in this category increased by 140 percent to $24 million to put it ahead of SGS-Thomson whose revenue declined slightly. NEC and OKI each recorded $5 million in sales, while Xicor and Motorola recorded no sales for this category in 1997.

Long-Term Forecast

For the other MOS memory category, Dataquest expects a modest CAGR of 11 percent for the period 1997 to 2002.

Table 9-1
EMEA Other MOS Memory Market Share Rankings, 1997

Chapter 10
Important Information

DRAM Section

As well as a "most likely" DRAM market forecast for the EMEA region, this *Market Statistics* report contains upside and downside DRAM forecast scenarios. The purpose of this approach was to acknowledge and make clients aware that there was significant risk associated with any set of DRAM forecast numbers published in 1998—such has been the unprecedented volatility in the global DRAM market in recent months.

Two factors have compounded the usual vagaries of the commodity DRAM market. These have led to a reduction in confidence levels in a single DRAM forecast, and the certainty that any forecast is likely to be out of date as soon as it is published. Firstly, the global DRAM oversupply shows no signs of alleviation because of a reluctance on the part of DRAM vendors to reduce production capacity and hence jeopardize their market share position. Secondly, the continuing financial crisis that is affecting the economies of Southeast Asia, particularly that of South Korea (which is heavily dependent on the DRAM market), has made forecasting the DRAM market like "trying to hit a moving target." The most important ramification of this financial crisis for the DRAM market has been the ability of the South Korean vendors to continue to reduce costs because of local currency devaluation. This, in parallel with the continued global DRAM oversupply, has continued to force DRAM ASPs down to levels which are universally acknowledged as below cost throughout the first half of 1998.

When this report was compiled in April 1998, Dataquest was unwilling to forecast that ASPs could be sustained at levels below cost for an extended period. However, as the July publication date loomed, it became clear that this was indeed the case. Therefore, Dataquest believes that the downside forecast for the DRAM market is now the more credible scenario and would advise clients to be guided by it. We are already working on a comprehensive update to the DRAM forecast reflecting this view, and a *Dataquest Perspective* on this subject will be published in the next few weeks.

©1998 Dataquest

Appendix A
Definitions

Devices

Dataquest classifies memory devices in the following categories:

- **DRAM**: Includes dynamic RAM, multiport-DRAM (M-DRAM) and video DRAM (VRAM). DRAMs have memory cells consisting of a single transistor, and require regular externally cycled memory-cell refreshes. This category also includes new-architecture DRAMs (NADs) such as Rambus, cache, enhanced and synchronous DRAMs. These are volatile memories and addressing is multiplexed.
- **SRAM**: Includes static RAM, multiport-SRAM (M-SRAM), battery backed-up SRAM (BB-SRAM), and pseudo SRAM (PSRAM). SRAMs have memory cells consisting of at least four transistors, except a PSRAM, which has a memory cell comprising a single transistor and is similar to a DRAM. SRAMs do not require externally cycled memory-cell refreshes. These are volatile memories and addressing is not multiplexed (except in the case of PSRAM). Note that color-palette DACs are included in the mixed-signal data converter category.
- **EPROM**: Includes erasable programmable read-only memory. This product classification includes ultraviolet EPROM (UV EPROM) and one-time programmable read-only memory (OTPROM). EPROMs have memory cells consisting of a single transistor, and do not require any memory-cell refreshes. These devices are considered nonvolatile memories.
- **EEPROM**: Includes electronically erasable programmable read-only memory, encompassing serial EEPROM (S-EEPROM), parallel EEPROM (P-EEPROM) and electrically alterable read-only memory (EAROM). EEPROMs have memory cells consisting of at least two transistors, and do not require memory-cell refreshes. This category also includes nonvolatile RAM (NV-RAM), alternatively known as shadow RAM, which is a combination of SRAM and EEPROM technologies in each memory cell; the EEPROM acts as a shadow backup for the SRAM when power is lost. These devices are considered nonvolatile memories.
- **Flash Memory**: Includes nonvolatile products designed as flash EPROM/EEPROM that incorporate either 5V or 12V programming supplies and one-transistor (1T) or two-transistor (2T) memory cells with electrical programming and fast chip or sector erase. Flash memory can erase data only by chip or sector, not by byte. These devices are considered nonvolatile memories.
- **ROM**: Defined as mask-programmable read-only memory. ROM is a form of memory that is programmed by the manufacturer to a user specification using a mask step. ROM is programmed in hardware rather than software. These devices are considered nonvolatile memories.
- **Other MOS Digital Memory ICs**: Defined as all other MOS digital memory not already accounted for in the preceding categories. Includes MOS digital content addressable memory (CAM), MOS digital cache-tag RAM, MOS digital first-in/first-out (FIFO) memory, MOS digital last-in/first-out (LIFO) memory and ferroelectric memory.

EMEA Region

Dataquest defines the EMEA region as follows:

- Benelux: Belgium, the Netherlands and Luxembourg
- France
- Italy
- Nordic Region: Denmark, Norway, Sweden and Finland
- United Kingdom/Ireland
- Germany
- Rest of EMEA region
    - Rest of Western Europe: Andorra, Austria, Cyprus, Faroe Islands, Gibraltar, Greece, Greenland, Guernsey, Iceland, Isle of Man, Jersey, Liechtenstein, Malta, Monaco, Portugal, San Marino, Spain, Svalbard and Switzerland
    - Central/Eastern Europe: Albania, Armenia, Azerbaijan, Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, the Czech Republic, Estonia, Georgia, Hungary, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Macedonia, Moldova, Poland, Romania, Russia, Slovakia, Tajikistan, Turkmenistan, Ukraine, Uzbekistan and Yugoslavia (Serbia and Montenegro)
    - Middle East/Africa: Afghanistan, Algeria, Angola, Bahrain, Bassas da India, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Cape Verde, Central African Republic, Chad, Comoros, Congo, Cote d'Ivoire, Djibouti, Egypt, Equatorial Guinea, Eritrea, Ethiopia, Europa Island, Gabon, Gambia, Ghana, Glorioso Islands, Guinea, Guinea-Bissau, Iran, Iraq, Israel, Jordan, Juan de Nova Island, Kenya, Kuwait, Lebanon, Lesotho, Liberia, Libya, Madagascar, Malawi, Mali, Mauritania, Mauritius, Mayotte, Morocco, Mozambique, Namibia, Niger, Nigeria, Oman, Qatar, Reunion, Rwanda, Saint Helena, Sao Tome and Principe, Saudi Arabia, Senegal, Seychelles, Sierra Leone, Somalia, South Africa, Sudan, Swaziland, Syria, Tanzania, Togo, Tromelin Island, Tunisia, Turkey, Uganda, United Arab Emirates, Western Sahara, Yemen, Zaire, Zambia and Zimbabwe

Rounding

Please note that some tables might not add up to totals because of rounding.

Final 1997 EMEA Semiconductor Market Share Rankings

Executive Summary

- In 1997 there was a return to growth in the EMEA semiconductor market, with revenue 5.9 percent higher than in 1996, which was 2.4 percent more growth than that of the worldwide market. EMEA companies grew their share of the worldwide market by 0.5 percent, raising it to 10.1 percent.
- The EMEA market still had the lowest worldwide semiconductor total available market (TAM) despite increasing by 0.4 percent to 20.4 percent of worldwide semiconductor TAM in 1997.
- DRAM continued to be the major price driver in 1997, and DRAM revenue continued to shrink even though the market experienced 107 percent DRAM bit growth.
- Intel continued to dominate the rankings at 2.7 times the size of its nearest contender in EMEA. The company accounted for 19.4 percent of the market, a rise of 1.6 percent over 1996.

Project Analysts: Joe D'Elia and Ellie Babaie

Introduction

This *Market Statistics* report contains Dataquest's final estimates of semiconductor vendor market shares in EMEA for 1997.

EMEA semiconductor sales by vendor base region over the past 17 years are shown in Table 1. Some of these figures are plotted in Figure 1, which shows that EMEA companies' share of their home market showed a slight upturn of 0.5 percent in 1997. This follows several years of negative or static growth and may be the precursor of future growth as the market moves to higher integration differentiated products. Japanese companies' share of the market continued the decline started in 1996, as did Asia/Pacific companies, and the Americas companies' continued to grow their share of the market, again a trend started in 1996. These trends are mirrored at the worldwide level, as is shown in Figure 2, where the dramatic reversal of fortunes for Japan and Asia/Pacific companies is evident.

EMEA's diverse mix of applications stood it in good stead in 1997, with the decline of the DRAM market being counteracted by unit growth in the PC market and, therefore, higher sales of microprocessors. The incredible growth in digital cellular handsets also made significant contributions to the microcontroller, ASIC and flash memory segments. The contribution made by these applications resulted in EMEA increasing its share of the worldwide market by 0.4 percent, significantly lower than in 1996 when its share grew by 1.2 percent. However, it should be borne in mind that EMEA's performance relative to worldwide performance in 1996 was much better, as the EMEA market grew when the worldwide market shrank.

Although the EMEA market grew in 1997, this must be put in perspective, it was still the smallest of the four regions comprising the worldwide semiconductor market, with 20.4 percent of the world semiconductor TAM. The Asia/Pacific market, which still grew during 1997, had 22.1 percent share, the declining Japanese market had a 24.8 percent share, and the Americas market had 32.7 percent, having experienced modest growth (see Figure 3).

Products

The 1997 product categories are not absolutely in line with those of previous years; observant readers will have noticed the omission of the word hybrids in all our product category titles. Because of the decline of this category, the residual hybrids have been absorbed into the appropriate functional category, and will no longer be a category tracked by Dataquest. The 1996 numbers have been restated where necessary to allow comparison with the current year. Other changes have occurred in MOS digital logic and analog, where the mixed-signal ASIC and linear array categories have been switched from analog to MOS digital logic; therefore, the 1997 growth rates for these categories are somewhat artificial.

Table 2 shows the EMEA market split by product category. The largest percentage decline is in bipolar digital, which fell by 31.7 percent; the surprise here is more that the category continues to exist rather than the rate of decline. Compared with the previous year, the decline is accelerating, and by the end of the decade the category will in all probability have disappeared as per hybrid above. The most significant decline is in memory, which declined 12.7 percent, here the guilty party was, as in 1996, DRAM, which declined 12.8 percent. The other category that declined was optoelectronics, which suffered severe erosion of ASPs throughout the year.

Looking at the positive side, MOS microcomponents grew 17.1 percent, making this category by far the largest in EMEA. MOS logic also grew, although the rate is raised artificially by the shift of the two categories discussed above. This correspondingly lowers the increase in analog, with a growth of 3.7 percent, which would have been higher without the reassignment; discretes also grew by 9.6 percent. All these categories are listed in Table 2, and growth is shown in Figure 4. Figure 5 shows EMEA semiconductor product share of revenue for 1997 by region.

©1998 Dataquest

The different regions are prime sources for different product categories, this is illustrated in Figure 5, which shows that the bulk of Asia/Pacific shipments were memory, while the majority of Americas-sourced shipments were micro-components. Japanese shipments used to be more than 50 percent memory, in 1997 that figure dropped to 38 percent of total shipments to EMEA.

EMEA's strongest product category traditionally has been analog, and this remains the case in 1997, with 34 percent of shipments into EMEA from EMEA companies falling into this category.

Table 2
EMEA Total Available Market by Product Category, 1996 and 1997

Product Category	1996 ($M)	1997 ($M)	Growth (%)	Share (%)
Total Semiconductor	**28,379**	**30,046**	**5.9%**	**100.0%**
Hybrids	126	-	NA	NA
Total Integrated Circuit	24,606	26,195	6.5%	87.2%
Bipolar Digital	246	168	-31.7%	0.6%

Growth of Intel

Intel remains unique, the gap between Intel and the second-place contender, Siemens, grew to $3.6 billion in 1997. Intel's EMEA revenue was $5.8 billion, while Siemens, in second place, had revenue of $2.2 billion. This gap has been growing over the past few years, and Table 3 shows that over the period 1992 to 1997 the ratio grew from 1.2 to 2.7. Also, during this period Intel's share of the EMEA market grew dramatically from 9.3 percent to 19.4 percent of all EMEA shipments. Intel's CAGR for the period 1992 to 1997 was 38.6 percent, while the CAGR for Siemens was 17.5 percent, which was even less than the CAGR of 19.7 percent for the total EMEA market during this period.

Table 3
Intel: Market Share and Ratio to Nearest Contender, 1992 to 1997

	1992	1993	1994	1995	1996	1997	1997/1992 CAGR (%)
Intel Revenue ($M)	1,136	2,056	2,605	3,240	5,044	5,811	38.6%
Second-Place Revenue ($M)	975	1,260	1,380	2,058	2,068	2,182	17.5%
Total Market Revenue ($M)	12,218	15,486	20,900	28,410	28,379	30,002	19.7%
Ratio: Intel/Second Place	1.2	1.6	1.9	1.6	2.4	2.7	
Intel Share of Total Market	9.3%	13.3%	12.5%	11.4%	17.8%	19.4%

EMEA Companies' Performance Worldwide

EMEA companies are active on the world stage, and are not supplying just to an EMEA customer base. Table 4 shows how they performed on a global basis in 1996 and 1997. Of the big three EMEA players, only Siemens showed any improvement in its ranking, having moved up one place to 12th position. TEMIC, in its last year of existence, remained static, and GEC Plessey, similarly in its last year of existence, dropped seven places, as the uncertainty about its future influenced customers' decisions about whether or not to buy the company's products.

Outside the five top-placed EMEA companies, Micronas was the entity that resulted from the merging of Micronas OY and ITT Intermetall, and, for the first time, we have the commercial market sales of Robert Bosch appearing in the semiconductor rankings. Mietec metamorphosed into Alcatel Microelectronics and lost two places, even though its sales actually increased above the worldwide growth norm of 3.5 percent. Ericsson also grew its sales but remained static in 75th place, while Austrian Mikro Systeme's revenue decreased, resulting in a four-place drop to 89th position.

The single, most significant improvement in rankings was achieved by TCS, which grew its sales by more than 48 percent and jumped 13 places to 93rd position. Further down the rankings are two new names: Power Innovations, which is the management buyout of Texas Instruments' power devices group in the United Kingdom, and Elex, which has been transformed into Melexis.

EMEA's Top Ten Companies

Intel

Intel's growth was driven once again by its dominance in the PC processor market. Of its $5.8 billion total revenue, $4.9 billion was from x86 processors in compute applications. The total compute microprocessor category was $5.5 billion and encompassed Intel's x86 competitors and the use of PowerPCs by Apple in Ireland. Intel lost its flash crown in EMEA during 1997, as not only did its revenue drop, but it also lost the first-place ranking that it had maintained since the creation of this category. Intel's other main product category was microperipherals, where its sales grew from $386 million to $432 million in 1997, thereby strengthening its number-one position in the category.

Siemens

Despite being EMEA's only indigenous DRAM vendor, Siemens managed to increase its worldwide revenue by 13.6 percent and its EMEA revenue by 5.5 percent in 1997. In EMEA the company's DRAM revenue shrank by 9.4 percent, less than the industry average; worldwide, the company managed to grow its DRAM revenue by 12.7 percent—no mean feat when the market was shrinking. Analog products, in particular those for telecommunications and automotive, drove Siemens' success in EMEA, where the company leveraged the systems expertise available in the Siemens equipment manufacturing groups to consolidate its grip on these categories. Also adding to the company's growth were successes in the discrete and microcomponents categories, which benefited from new product acceptance in volume applications.

Motorola

Motorola had a relatively flat year in EMEA, growing semiconductor revenue only 2.2 percent. Memory revenue was clearly down as Motorola exited the DRAM market, but SRAM revenue was also down as fast cache SRAM ASPs collapsed. The areas of growth that counterbalanced declines in logic and memory were microprocessors and DSP, where the company experienced major growth as Apple migrated to higher-performance PowerPC products. DSP revenue was boosted by the huge surge in digital cellular handset production in EMEA. The drop in microcontroller revenue gives cause for concern, as, historically, this has been one of Motorola's strengths.

Philips

Philips grew in line with the industry average in EMEA, and this resulted in it gaining one place in the rankings, moving to fourth position. While microcomponents appear to have declined and analog to have grown, the changes in these categories are more a result of reclassification of some products into more appropriate categories. The area that showed real growth was discretes, where Philips made significant gains on the power transistor front, with increases in both bipolar and MOS devices; being particularly successful in the automotive sector with these latter devices.

SGS-Thomson

Following growth in 1996, 1977 was disappointing for SGS-Thomson, as several markets that were poised to provide good growth for the company either collapsed, as in the form of the hard disk drive market, or failed to materialize because of regulatory interference by the European Union. This regulatory interference impacted the takeoff of digital set-top boxes, an application area in which SGS-Thomson is well placed. Comparison of 1997's numbers with those of previous years will show significant changes in several product categories, as SGS-Thomson moved some product lines to synchronize them with the industry norm.

©1998 Dataquest

Texas Instruments

Texas Instruments managed to grow its EMEA business well above the industry average, and achieved 16.4 percent growth. Significant gains were made in the DSP, MOS digital logic and analog categories in 1997. Some of these gains were as a result of product reclassification, but most were because of the advances that the company has made in supplying products incorporating a high level of system integration to markets such as digital cellular handsets. Aggressive pursuit of available business even allowed the company to grow its DRAM business marginally in the region. The jump in DSP was particularly impressive and heralds the success of the decision to base the company's future on this technology.

Samsung

While successful in growing its business and increasing market share in 1997, Samsung was able to do this only in its traditional product areas of DRAM and SRAM. The strategy to diversify out of these areas has not succeeded yet and took a step backwards in 1997 as memory increased its share of Samsung's EMEA revenue to 95.5 percent, having dropped to 94.0 percent in 1996.

NEC

NEC's revenue in EMEA was flat, with the company showing 0.4 percent growth for the year. The drop in DRAM revenue was compensated for by rises in ASIC, discrete and optoelectronics, while microcomponents remained steady. This result is a vindication of NEC's diversification strategy, as nonmemory products accounted for 59.1 percent of its EMEA revenue in 1997, having been 50.7 percent in 1996.

Hitachi

Hitachi's DRAM revenue dropped significantly from $393 million to $236 million in 1997. Some of this loss was offset by growth in other products; however, this was not enough to stop the company's revenue declining by 13.0 percent. The "star" in Hitachi's nonmemory revenue in previous years had been 16-bit microcontrollers, but this segment showed zero growth in 1997, indicating that the company had failed to find any further significant design wins. The product group with the highest growth proved to be discretes, an area which Hitachi has not been noted for in the past.

National Semiconductor

National Semiconductor's figures are not a direct comparison with any that have been published before; only comparisons between the 1996 and 1997 figures published in this document are valid. The reason for this is that during 1997 the company divested itself of the Fairchild division and acquired Cyrix. This has altered the product mix radically, thus making comparison with past years difficult. National Semiconductor is fast becoming synonymous with the PC through its indigenous peripherals business and the acquisition of Cyrix. These areas were strong for the company in 1997, as it supplied its multi-I/O devices to the remaining EMEA PC motherboard manufacturers, its Ethernet devices to major networking companies and Cyrix processors to the second- and third-tier players in EMEA.

 ©1998 Dataquest

Product Classification Tables

Tables 5 to 23 show the rankings in all the major product groups together with some subsidiary groups. These subsidiary groups are included where they had a significant impact and where there have been definition changes. By including these extra tables those customers wishing to compare the figures with previous years can extract the data in the format that they desire.

As Dataquest is not publishing a separate ASIC market share report this year, we have also included some of the detail tables that would have appeared in that document.

The hierarchy of the product categories used in the tables included is as follows:

- All Semiconductor
  - Digital Bipolar
  - Memory
    - DRAM
    - Flash
  - Microcomponents
  - Logic
    - ASIC
      - Gate Array
      - Cell Based
        - Linear Arrays
        - Mixed Signal
      - PLD
    - Custom
    - Standard Logic
    - Other Logic
  - Analog
  - Discretes
  - Optoelectronic

Chapter 1
European Fab Database

Background and Methodology

This report contains the European portion of Dataquest's wafer fab database. The records in these tables are fabs located in the Europe, Africa, and Middle East region. The Semiconductor Equipment, Materials, and Manufacturing Worldwide (SEMM) program conducts extensive annual surveys, complemented with quarterly secondary research to maintain this database. Published once a year, this document represents Dataquest's best insights and estimates into the end-market of semiconductor equipment.

The tables in this report cover planned and existing merchant, captive, and foundry fab lines. A fab line is a series of equipment to do front-end (from initial oxide through wafer probe) semiconductor manufacturing. Occasionally, two or more separate product-specific fab lines or wafer sizes operate in a single clean room or physical plant. In this situation, Dataquest divides the clean room as separate fab lines if the company dedicates equipment to each wafer size or product line. If a company installs substantially different equipment during an expansion (for example, equipment to increase its maximum wafer diameter), again Dataquest divides the clean room and creates two entries into the database. Therefore, a company may operate many fab lines at one location.

Worldwide Geographic Region Definitions and Regional Roll-Ups

Americas
Includes Central America (all nations), Canada, Mexico, United States, Puerto Rico, and South America (all nations).

Japan
Japan is the only single-country region.

Europe, Africa, and Middle East
Includes Africa (all nations), Albania, Andorra, Armenia, Azerbaijan, Belarus, Belgium, Bulgaria, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Georgia, Germany, Gibraltar, Hungary, Iceland, Israel, Italy, Kazakhstan, Kyrgyzstan, Latvia, Liechtenstein, Lithuania, Luxembourg, Malta, Middle East (all nations), Moldova, Monaco, Netherlands, Norway, Poland, Romania, Russia, San Marino, Scandinavia, Slovakia, Spain, Sweden, Sweden, Switzerland, Tajikistan, Turkey, Turkmenistan, Ukraine, United Kingdom, Uzbekistan, Vatican City, and all nations within the former Yugoslavia.

Asia/Pacific
Includes Australia, Bangladesh, Cambodia, China, Hong Kong, India, Indonesia, Laos, Malaysia, Maldives, Myanmar, Nepal, New Zealand, Pakistan, Philippines, Singapore, South Korea, Sri Lanka, Taiwan, Thailand, and Vietnam.

Field Definitions

The Company field indicates the operator of the fab line. For contract manufacturers that trade capacity for capital investment in the fab, Dataquest lists the contract manufacturer. For incorporated joint ventures, Dataquest lists either the incorporated entity or the major investors, separated with slashes.

The Fab Name field provides a reference to a particular fab or fab line to distinguish it from other fabs or lines owned by that company. Although Dataquest makes every attempt to match the nomenclature used by the company, occasionally some additional qualifiers (for example, "Phase 1") will appear to provide insight to the facility's history or organization.

The City field displays the most detailed location information. This reference is usually a city or town, but could be an often-used district name (for example, Science Park in the city of Hsinchu, Taiwan). If this field lists a district, Dataquest will list the city in the State or Province field. In some cases, a reference to a state or province will be included in the City or District field to create a unique identifier for this location.

The State, Province, or Prefecture fields denote the second most detailed location. This reference is usually a state (for the United States), province (for Canada and many European and Asian countries), or a prefecture (for Japan). For countries within the United Kingdom, Dataquest lists the country name (for example, "Scotland") in this field so Dataquest can list the descriptor "U.K." in the Country field.

The Country field indicates the broadest location identifier in this report. This reference is usually a country, except in the case of the United Kingdom (see "State or Province" above). Because Japan is a single-country region, there is no regional qualifier for fabs in Japan.

The Devices Produced field lists the products manufactured at this site. The listings generally fall into five product groups, with the following nomenclature and definitions (when warranted):

- MOS memory
  - DRAM: Dynamic RAM
  - EEPROM: Electrically erasable PROM
  - EPROM: Ultraviolet erasable PROM
  - FERRAM: Ferroelectric RAM
  - FIFO: First-in/first-out memory
  - Flash: Flash memory
  - Mem: Memory
  - NV Mem: Nonvolatile memory (ROM, PROM, EPROM, EEPROM, and FERRAM)
  - PROM: Programmable ROM
  - RAM: Random-access memory
  - ROM: Read-only memory
  - SGRAM: Synchronous graphics RAM
  - Sp Mem: Other specialty memory (such as dual-port, shift-register, or color lookup)
  - SRAM: Static RAM
  - VRAM: Video RAM

©1998 Dataquest

- MOS microcomponent/digital logic
  - Array: Gate array
  - ASIC: Application-specific IC
  - ASSP: Application-specific standard product
  - Bit: Bit slice (subset of MPU functions)
  - CBIC: Cell-based IC
  - Custom: Full-custom IC (single user)
  - DSP: Digital signal processor
  - FPGA: Field-programmable gate array
  - LISP: 32-bit list instruction set processor for AI
  - Logic: Standard logic
  - LSI: Large-scale integration
  - MCU: Microcontroller unit
  - MixSig ASIC: Mixed-signal ASIC
  - MPR: Microperipheral
  - MPRCom: MPR digital communication (ISDN, LAN, UART, or modem)
  - MPU: Microprocessor unit
  - PLD: Programmable logic device
  - RISC: Reduced-instruction-set computation 32-bit MPU
  - Telecom: Telecommunications chip
- Power/discrete/analog (including bipolar power)
  - A/D D/A: Analog-to-digital, digital-to-analog converter
  - Automotive: Dedicated to automobile applications
  - CODEC: Coder/decoder
  - Diode
  - Discrete
  - FET: Field-effect transistor
  - GTO: Gate turn-off thyristor
  - HEMT: High-electron-mobility transistor
  - IGBT: Insulated-gate bipolar transistor
  - Interface: Interface IC
  - Linear: Linear/analog device
  - MDiode: Microwave diode
  - MESFET: Metal semiconductor field-effect transistor
  - MFET: Microwave field-effect transistor
  - Modem: Modulator/demodulator
  - MMIC: Monolithic Microwave IC
  - MOSFET: MOS-based field-effect transistor
  - Op Amp: Operational amplifier
  - Pwr IC: Power IC

 ©1998 Dataquest

- Pwr Tran: Power transistor
- Rectifier
- Reg: Voltage regulator
- RF: Radio frequency
- SCR: Schottky rectifier
- Sensor
- Smart Pwr: Smart power
- SST: Small-signal transistor
- Switches: Switching device
- Thyristor
- Tran: Transistor
- Zener Diode

- Optoelectronic
  - CCD: Charge-coupled device (imaging)
  - Coupler: Photocoupler
  - IED: Infrared-emitting diode
  - Image Sensor
  - Laser: Semiconductor laser or laser IC
  - LED: Light-emitting diode
  - Opto: Optoelectronic
  - PDiode: Photo diode
  - PTran: Photo transistor
  - SAW: Surface acoustic wave device
  - SIT Image Sensor: Static induction transistor image sensor
- Bipolar Digital and Other Devices (includes all digital ICs using a bipolar process)
  - Darlington
  - Micromachining Sensors
  - MilStd: Military Standard Logic
  - RadHard: Radiation hardened

©1998 Dataquest

The Activities field shows the types of semiconductor manufacturing performed at this location. The activities include:

- "Frnt" means this location performs front-end wafer processing. Front-end wafer processing includes the manufacturing steps from initial oxide through wafer probe test.
- "Rsrch" means the location performs product or process research. Research differs from pilot manufacturing in that research wafers are nonsalable.
- "Dsgn" means this location has a design center.
- "Pilot" means this location performs pilot production. Pilot production means the location produces in small volumes while "debugging" new products or process technologies. The main difference between Research and Pilot is that, unlike Research, Pilot wafers are a salable product.
- "Fndry" means this location performs contract manufacturing. Contract manufacturing is the production, under contract, of another company's branded product. This is also known as foundry production.
- "A/T" means this location performs assembly or testing. Assembly and testing includes the manufacturing steps from E-test through final assembly into a package and final test.
- "Cptiv" means that the company consumes some portion of the fab's output internally.

The Processes field indicates each fab's use of five major types of process. The process groupings are as follows:

- P/CMOS: P-channel metal-oxide semiconductor (PMOS) or complementary metal-oxide semiconductor (CMOS)
- NMOS: N-channel metal-oxide semiconductor (NMOS)
- BiCMOS: Bipolar and CMOS combined on a chip
- Bipolar
- III-V: Gallium arsenide and other compound semiconductor processes

The Year and Quarter of Initial Production displays the year (and quarter, if available) in which this line, having completed all qualifications, began manufacturing in production volumes. The format for this reference is "year.quarter" (for example, 1994.3 translates to the third calendar quarter of 1994).

The Initial Monthly Wafer Starts field indicates the initial monthly volume of production wafer throughput.

The Estimated Maximum Monthly Wafer Starts field contains the equipment-limited wafer start capacity per four-week period. Only the throughput of the installed equipment and the process complexity limits the maximum starts. Dataquest does not consider current staffing or the number of shifts operating in determining this metric.

 ©1998 Dataquest

The Maximum (Wafer) Diameter represents the maximum wafer size that the fab or fab line can process. Wafer diameters, although expressed colloquially in inches, conform to metric specifications. For wafers greater than 3 inches in diameter, expression in inches becomes inaccurate. When calculating square inches, Dataquest uses the following approximations:

- Stated diameter of 4 inches (100 mm) = Approximate diameter of 3.938 inches
- Stated diameter of 5 inches (125 mm) = Approximate diameter of 4.922 inches
- Stated diameter of 6 inches (150 mm) = Approximate diameter of 5.906 inches
- Stated diameter of 8 inches (200 mm) = Approximate diameter of 7.87 inches

The Minimum Line Width is the smallest feature size, measured in microns, attainable in production volumes.

Chapter 1
Executive Summary

Key findings of this *Focus Report* include the following:

- The European PC industry is enjoying an excellent year in 1998, with 21.4 shipment growth and 18.2 percent unit production growth.
- The industry is continuing to consolidate, with a greater market share in the hands of large multinationals, the top five of which produced 38.6 percent of all units in Europe in 1997. This figure is forecast to increase to 44.5 percent in 1998.
- Central and Eastern Europe (CEE) will continue to grow faster than Europe as a whole, even though parts of CEE continue to experience economic and social unrest.
- The industry is dominated by transplant manufacturers, which controlled 54.6 percent of regional manufacturing capacity in 1997.
- Growth is forecast at 14.6 percent compound annual growth rate (CAGR) for production and 14.2 percent CAGR for shipments from 1998 to 2002.
- PC workstations will experience strong growth, helping to maintain semiconductor content and unit average selling prices (ASPs).
- Component sourcing decisions are controlled increasingly outside Europe, minimizing design-win opportunities for local semiconductor vendors.
- Intel's dominance as a processor vendor is continuing, although its competitors are beginning to make inroads, finally aided by an increase in sales of sub-$1,000 PCs.
- PC price points are declining, with sub-$1,500 units accounting for 44.5 percent of shipments in the second quarter of 1998.
- The DRAM market is expected to return to strong revenue growth from 1999 to 2001.
- Starting in 1999, a shortage of sub-0.25 micron manufacturing capacity is expected to lead to a tightening of supply of 64Mb PC100 devices.
- 64Mb PC100 pricing levels are expected to stabilize in the fourth quarter of 1998.
- Average PC DRAM fit is expected to be 55MB per system in 1998 and 246MB per system in 2002.
- DRAM fit continues to increase at a historical norm of 65 percent to 70 percent bit growth per annum.
- Worldwide component purchasing agreements are bypassing local vendor offices, establishing virtual total area markets (TAMs) for semiconductor devices.
- Non-DRAM or processor sales of PC-related semiconductors have a minimal impact on the semiconductor design TAM.
- The PC semiconductor TAM over the forecast period will remain about 35 percent of the overall European semiconductor TAM.
- The manufacturing growth rate of motherboards is continuing to decline as the number of locally manufactured motherboards lessens.

©1998 Dataquest

Overview

In contrast with the rest of the world, the PC industry in Europe is set to have another year of strong growth. Following 17.3 percent growth in shipments and 18.4 percent growth in production in 1997 over 1996, Dataquest forecasts 21.4 percent growth in shipments and 18.2 percent growth in production for 1998. This *Focus Report* evaluates the European PC industry, analyzing trends in the market, companies and components and presenting the latest forecasts for the 1998 to 2002 period. The PC manufacturing industry in Western Europe is undergoing a period of major restructuring, and has been transformed almost completely into a production-based industry that focuses on the manufacture and assembly of PCs, with very little product design being undertaken in the region. The serious implications of this change for the semiconductor industry are evaluated, together with recommendations for participating companies. DRAM and microprocessors continue to be the main contributors to the semiconductor TAM in PCs. Accordingly, they are evaluated in detail, together with an overview of other, less important contributors.

Chapter 2
European PC Manufacturing

Overview

PC manufacturing in Europe is undergoing major restructuring; some companies have been sold, others have shut down capacity. More notably, some major companies are adding significant manufacturing capacity. Certain restructuring efforts have been thwarted, primarily Siemens Nixdorf Informationssysteme's (SNI's) attempt to sell its facility in Augsburg, Bavaria, Germany, to Acer; others, such as Olivetti PCs' attempts to divest itself of capacity at its facility in Scarmango, Italy, seem finally to be coming to fruition. Table 1 shows the most significant activities of the past twelve months as regards local PC production capacity. The overall impact is positive as the major PC manufacturers are continuing to increase their transplant manufacturing capacity in Western Europe. It is, however, only manufacturing capacity, and therefore is vulnerable in times of market downturn when foreign-located facilities are politically easier targets to shut down—a lesson that the UK government is learning the hard way.

The extent of some of the transplant manufacturing expansion is astounding. In particular, Dell has, in the space of a few months, announced two expansions to its Irish facility that will triple the number of employees and its manufacturing space by 1999. Packard Bell NEC's plans to build a new plant in Scotland to double its European capacity causes concern, especially as the company is not experiencing growth comparable with that of Dell. Table 2 shows the final PC production figures for 1997 together with Dataquest's latest estimates for 1998 production. The numbers included in the tables and figures in this *Focus Report* incorporate both PCs and PC workstations (that is, workstations that generally will run Windows NT and that are based on x86 processor architecture). The split between these products is identified in the section titled "Production and Shipment Forecasts" later in this report.

Looking at the current forecast, it becomes apparent that the table will look very different next year—names such as Digital Equipment Corporation and Unisys will have disappeared, and there will be a significant reordering of the ranking positions. New names will creep in to replace those companies that no longer exist and those whose production has shrunk. One immediate result will be that the differential between top and bottom will increase greatly. An increased share of the market will be concentrated in the hands of the top 15 companies: Dataquest forecasts 22.8 percent growth for these companies compared with 18.2 percent growth for the whole sector. The unit ratio between the top company and the bottom company in the top 30 in 1997 was 32.5; in 1998 it is likely to be about 90. Also significant will be the increase in the top 5 companies' market share, which will grow from 38.6 percent to 44.5 percent. Capping it all will be the increase in Compaq's share from 13.1 percent to 16.7 percent. Of this, slightly less than 2 percent will result from the incorporation of Digital's share.

The forecast takes into account the financial and political turmoil that surfaced in Russia in the third quarter of 1997, and the relevant manufacturers' numbers have been reduced to reflect Dataquest's estimation of the impact on the Russian market. Other factors taken into consideration are the impact of Ingram Micro's takeover of the Tulip facility, the sale of Vobis to CHS Electronics and the adoption of Vobis as the exclusive channel for IBM's Aptiva brand in the German market.

Table 1
Major PC Manufacturing Announcements—Europe, Second Half 1997 to Second Half 1998

Company	Action	Comments
Apple	Ceased motherboard assembly in Ireland.	
AST	Ceased Irish assembly activities, except for portables.	Capacity reduction.
Compaq/Digital	Consolidating all production into its facility at Erskine, United Kingdom.	
Dell	Announced that a second Irish assembly plant would start in mid 1998, and a third in late 1999.	Triples Dell's capacity to more than 1 million ft^2 in Europe.
FIC	Opened an assembly facility in the Czech Republic.	OEM build capacity increased.
Fujitsu	Stopped PCB manufacture in Kilo, Finland, and has built up assembly in Germany.	Fujitsu increases screwdriver assembly.
Hewlett-Packard	Started consumer PC production with SCI in the Netherlands.	
IBM	Increased server build in Scotland.	
Packard Bell NEC	Announced major build-to-order assembly facility in Scotland.	To double the company's European capacity by 2002.
Olivetti PCs	Downsizing facility at Scarmango, Italy.	
SNI/Acer	Canceled Acer's takeover of SNI's Augsburg facility.	
Toshiba	Started desktop assembly in Regensburg, Germany.	
Tulip	Sold manufacturing plant to Ingram Micro.	Ingram Micro to channel build.
Unisys	Stopped making PCs and outsourced from a third party.	
Vobis	Sold to CHS Electronics.	Future of Vobis stores uncertain.

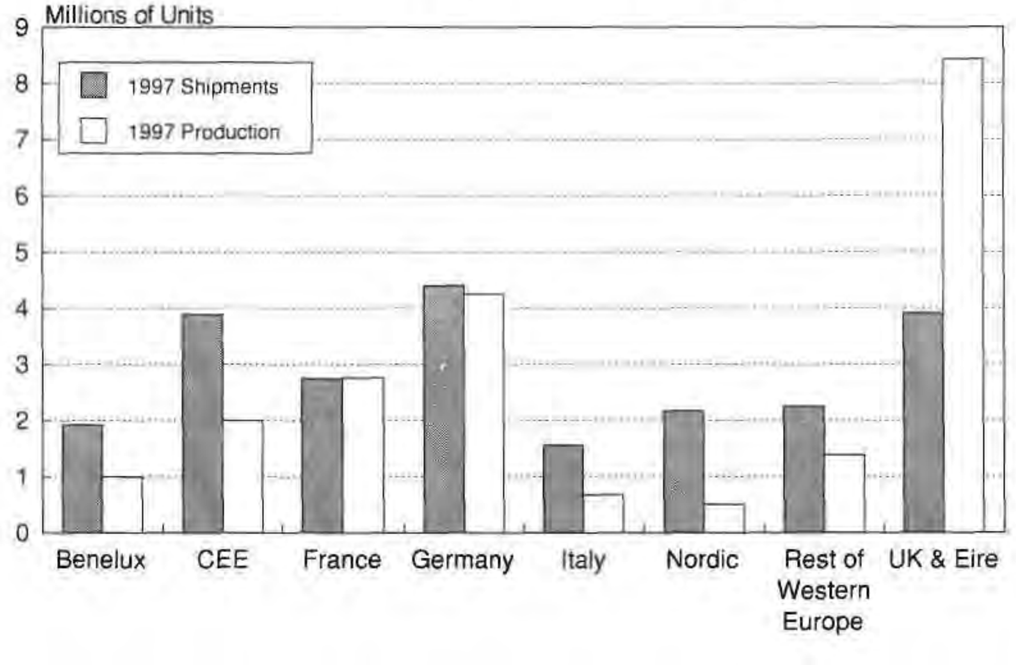
Market Factors

Both the products manufactured and shipped in Europe and their markets are evolving continuously. This section examines various aspects of these products and markets.

The first point to consider is the regional aspect of the total European market—people talk glibly about the "European market," but this market actually comprises many individual markets. For the purpose of data acquisition, Dataquest divides Europe into 20 country markets for PC shipments and 8 regional markets for PC production. For the sake of consistency, this report considers 8 regional markets for both production and shipments. Also for the sake of consistency, this report refers to Europe when talking about the whole market, but uses Western Europe or CEE when referring to these subdivisions. Figure 1 compares PC shipments and PC production by region in 1997, showing that most of the regions were net importers. Only France and the United Kingdom and Eire were net importers: France produced slightly more PCs than were shipped; the United Kingdom and Eire manufactured 2.2 PCs for each PC shipped in the region. This situation will continue, and the dominance of the United Kingdom and Eire region will become even greater as the planned increase in capacity for the major transplant factories is fulfilled.

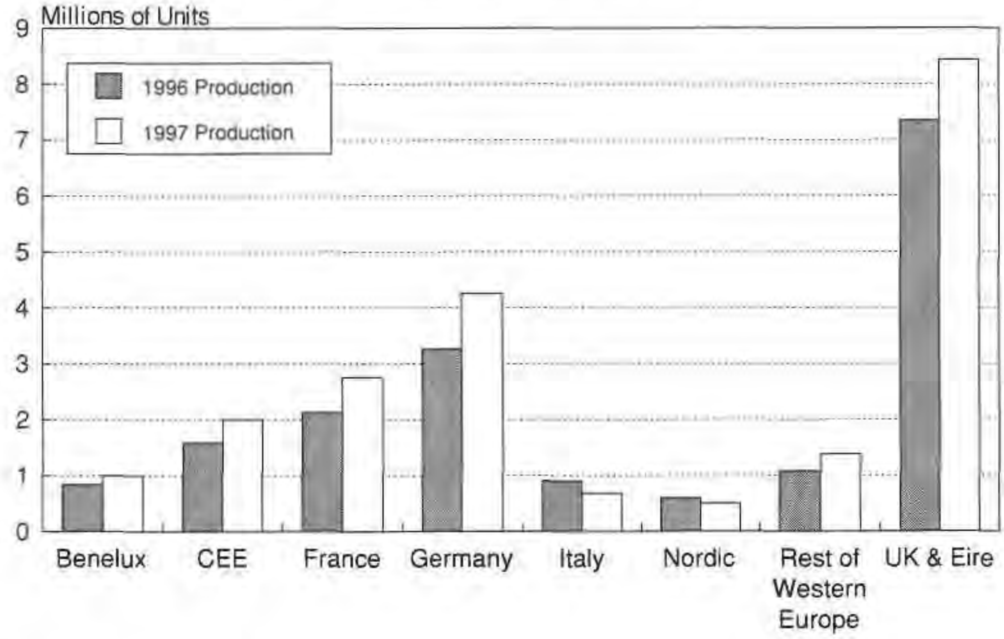
Figure 1
PC Shipments and Production by Region—Europe, 1997



Source: Dataquest (October 1998 Estimates)

Figure 2 shows European PC production by region in 1996 and 1997. All regions increased production during this period with the exception of Italy and the Nordic region. In these two regions the dependence on a single prime player—Olivetti PCs and Fujitsu respectively—reduced the overall regional number as Olivetti PCs continued to shrink and Fujitsu redistributed its production between the Nordic and German regions. CEE continues to grow, and over the five-year period 1997 to 2002 is forecast to have a shipment CAGR of 21.1 percent, compared with 14.2 percent for Europe as a whole. This growth will result in CEE constituting 21.6 percent of the European TAM in 2002.

Figure 2
PC Production by Region—Europe, 1996 and 1997



Source: Dataquest (October 1998 Estimates)

Considerable excitement was generated in 1997 by the advent of the sub-$1,000 PC. Unfortunately, locally, this was nothing but "hot air," as the products in this price band continued to be excess old inventory or local garage shop offerings. Those products designed by major vendors such as Compaq and HP to sell in this price band continued to suffer the inflationary malaise involved in translating dollars into local currencies—in Europe these companies' PCs were priced at well above $1,000. Figure 3 tracks PC price bands in Europe by quarter from 1997 to the second quarter of 1998, showing that only in 1998 has the sub-$1,000 segment begun to be significant. Total 1997 shipments in the sub-$1,000 bracket amounted to only 3.8 percent of the total. The first half of 1998 saw that number jump to 14.2 percent, and the expectation is that by the fourth quarter of 1998 the number will be in the low 20s.

Another clear conclusion to be drawn from Figure 3 is that there is an overall downward migration of price points. The $1,000 to $1,499 bracket is becoming a significantly greater portion of the total—a trend that is apparent over the six quarters—and the higher price brackets are becoming correspondingly smaller. This reduction is very important to the industry because it means that unit growth has to keep increasing to maintain revenue. The magnitude of this shift is evident from the following statistic: in the first quarter of 1997 shipments of units that were priced at less than $1,499 amounted to 18.6 percent of the total, while by the second quarter of 1998 that figure had grown to 44.5 percent.

The split between professional users and home users is closely monitored in the PC industry. Over the past five years this split has averaged 78 percent for professional users to 22 percent for home users—see Figure 4, which tracks the percentage split from the first quarter of 1993 to the second quarter of 1998. Over this period the range has been from 80.5 percent for professional users and 19.5 percent for home users in the first quarter of 1997 to 73.3 percent for professional users and 26.7 percent for home users in the fourth quarter of 1995. This ratio gives a good indication of whether a year is good or bad—the higher the ratio of home users to professional users the better the year is likely to be for shipments. Different dynamics drive the two sectors. The professional market is steadier and driven by fiscally motivated replacement cycles and business growth. Consumer cycles are more volatile, being driven by consumer confidence and local market conditions. Figure 5 shows the growth rates of the two markets, with the home-user rate showing much wider swings (both positive and negative) compared with the professional sector. This comparison of growth rates also shows that the slowdown from the latter half of 1996 to the first half of 1997 was caused primarily by a lessening of demand from home users. Although European production and consumption in the first half of 1998 was very high (and the second half is showing signs of remaining good), the fact that all three of the growth rates tracked in Figure 5 have begun a downward trend since first quarter of 1998 gives cause for concern for growth in 1999.

Like many industries, the PC industry is very seasonal. That the ratio of professional users to home users is seasonal is shown clearly in Figure 4, with an average year showing a gradual buildup of home-user sales from the first quarter to the third quarter. This is followed by a major spurt in the fourth quarter, typically adding several percentage points to the home-user segment's share. The overall PC market is also very seasonal—its profile can be seen in the sawtooth line that tracks quarterly shipments in Figure 4. This line shows that the fourth quarter is again the largest quarter for shipments in any year. What is surprising is that the first quarter is the second-biggest quarter, followed by a decline in the second quarter. The third quarter declines again before a huge fourth quarter starts the cycle again. This pattern is sufficiently consistent that a model of quarterly shipment behavior has been built on this basis.

European PC Semiconductor Applications

The restructuring that occurred in 1997, and which has continued this year, has reinforced a trend in the European market for semiconductors used in PCs. While overall consumption has increased in line with PC production, the decision-making process involved in component vendor selection has gone increasingly offshore. That 54.6 percent of Europe's PC production was foreign-controlled in 1997—a figure that will continue to rise with the increase in capacity planned by Dell and other companies—means that, increasingly, all sourcing decisions are made elsewhere. That only 5.9 percent of the remaining 45.4 percent was designed in Europe by European-controlled companies means that only 5.9 percent of the non-DRAM and microprocessor TAM was controlled by European decision makers. The remaining 39.6 percent of locally controlled assemblers are merely screwdriver operations and therefore purchase only DRAM and processors locally. This means that, on the DRAM and microprocessor front, European buyers determined all of the 45.4 percent build controlled by European companies. This percentage will continue to decline as foreign-owned companies increase their share of the European market.

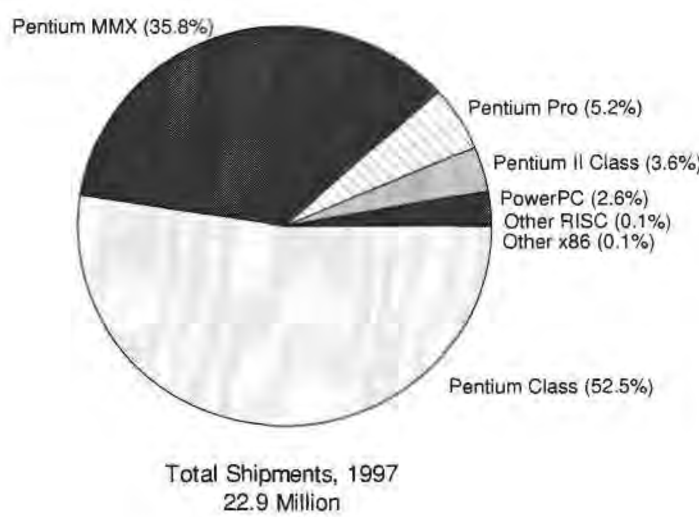
PC design in Europe has been in terminal decline for some years. Since the early 1990s, only a handful of companies has indulged in the luxury of PC design: SNI, Hewlett-Packard (HP), Olivetti PCs, Tulip, Mitsubishi and Fujitsu have held the line, but this is now left to SNI, HP and (for high-end systems only) to Mitsubishi and Fujitsu. The commoditization of the PC has made it uneconomic to design motherboards, especially for budget and mainstream desktops. Portables are brought in from the Far East for local configuration, apart from some transplant builds. SNI and HP are the only companies designing desktop products in Europe. The main difference between these two companies and most other vendors is that SNI and HP have worldwide design centers in Europe. Looking beyond 1998, Dataquest believes that, ultimately, SNI will stop European design and source its PCs from outside Europe. The deal with Acer would have enabled SNI to do this, but, with Acer pulling out, SNI will still be sourcing PCs from within Siemens. The question is: how long before the company stops designing? HP will continue to design in Europe because its facility in Grenoble, France, is its worldwide desktop design center, with products subsequently being manufactured for local markets by contract equipment manufacturers (CEMs) around the world. Although the company's design is undertaken in Europe, HP's centrally organized purchasing is done in the United States—consequently, major sourcing decisions are not controlled locally.

With this discussion in mind, the main focus here will be microprocessors, DRAM and cache SRAM. This *Focus Report* will identify the key players and their market shares, and determine market and product trends. Other products will be touched upon, but only to give an overview of significant trends in any sector.

Microprocessor Trends

The PC microprocessor market was in a state of transition in 1997. On the x86 front, not only was Intel moving forward on two parallel migrations—Pentium to Pentium MMX and Pentium to Pentium II—but Intel's competitors also finally managed to ship competitive products. On the PowerPC front, Apple was completing its migration from first-generation to second-generation products. Figure 6 shows the unit processor split for 1997 and confirms that x86 architectures took all bar 2.7 percent of shipments in Europe. Again on the x86 front, Pentium class devices (that is Pentium, M1 from Cyrix/IBM and K6 from Advanced Micro Devices [AMD]), took the lion's share of the market with 52 percent, followed by Pentium MMX with 36 percent. The rest was taken up by Pentium II (4 percent) and Pentium Pro (5 percent), the bulk of the latter being used in server and PC workstation applications.

Figure 6
PC Market Processor Shares by Architecture—Europe, 1997



Source: Dataquest (October 1998 Estimates)

Figure 7 shows the migration of major processor families from the first quarter of 1995 to the second quarter of 1998. It shows that the tail end of the 486 generation has been superseded by the Pentium, which is the dominant architecture over the period. The Pentium is shown to have given way to Pentium MMX, which in mid 1998 is already declining rapidly as Pentium II climbs quickly to replace it. Over the whole period all other processors apart from the PowerPC barely registered, and even the PowerPC was barely able to lift itself off the baseline.

 ©1998 Dataquest

The market revenue shares of the various processor vendors in 1997 are shown in Table 3. Computer processor revenue in the European PC market grew by 18.8 percent in 1997, with total shipments of $5.5 billion. The lion's share of this revenue went to Intel, which shipped $4.9 billion—an increase of 15.6 percent over 1996. Second place went to Motorola, whose revenue rose to $262 million from $120 million in 1996. The main reason for Motorola's 118.3 percent revenue growth was the complete migration of Apple PC production to the PowerPC. The only other non-x86 vendor in the list is VLSI Technology, which continued to supply ARM devices to Acorn for its RISC PC. AMD managed to increase its revenue by 74.8 percent, while National Semiconductor (formerly Cyrix) and IBM made slight gains.

A comparison of Intel's share of the European market in 1997 with its share in 1996 shows that in 1996 Intel had 91.9 percent of the total PC processor market and 94.4 percent of the x86 market, while in 1997 these numbers had dropped to 89.4 percent and 93.9 percent respectively. Evidently, competitive products like AMD's K6 processor can impact Intel. Although AMD's 1997 revenue share was only 3.5 percent, the expectation is that this figure will be considerably higher in 1998—the rise of sub-$1,000 PC shipments shown in Figure 3 is firm evidence to this effect.

Table 3
PC Processor Vendor Revenue Shares—Europe, 1997

Rank 1996	Rank 1997	Company	Revenue 1996 ($M)	Revenue 1997 ($M)	AGR 1996-1997 (%)	Share 1997 (%)
1	1	Intel	4,282	4,948	15.6%	89.4%
2	2	Motorola	120	262	118.3%	4.7%

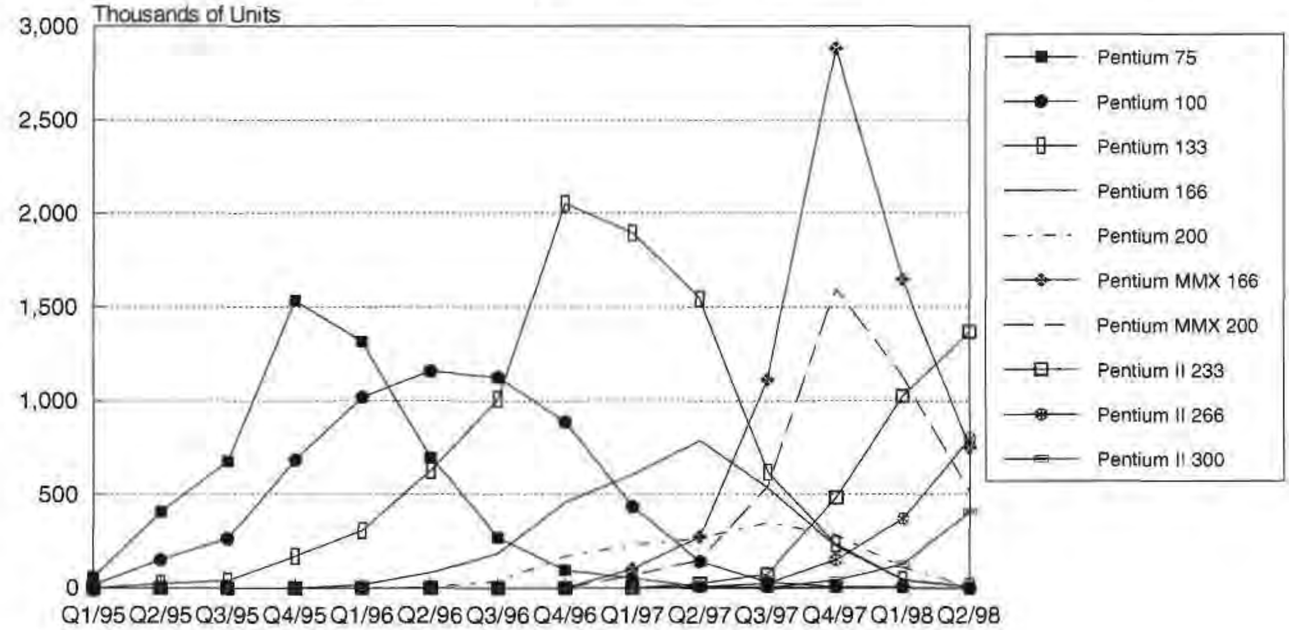
Source: Dataquest (October 1998 Estimates)

From a situation in 1996 where Intel had almost no competition, 1997 saw the company reacting to the changed situation in two ways, both of which led to a faster acceptance of new processor speeds and architectures. Firstly, Intel announced new products at an increasing rate. Secondly, Intel manipulated its regular price announcements in such a way as to ensure that the market moved to the newer products more quickly than it had in the past. Figure 8 shows how the average time taken for an Intel processor to reach its maximum level of adoption has shortened from six quarters to four quarters. In the period covered by Figure 8, Intel announced 30 speed grades spread over five device families, not counting products specific to portable PCs. For the sake of readability, only the most significant Intel speed/device combinations are plotted.

Figure 8
Intel Processor Speed Adoption—Europe, First Quarter 1995 to Second Quarter 1998



Source: Dataquest (October 1998 Estimates)

Although this abundance of processors might appear to give users more choice, there is a considerable backlash from users against the rapid change because products have increasingly short life cycles. This is felt particularly by corporate IT departments where the decision-making process is long and where it is expected that the products purchased should last for a reasonable period of time. The fast introduction rate of processors and associated technology has meant that customers have had to accept products of entirely different specifications during the life span of their projects. The resulting backlash has induced major PC vendors to introduce product ranges that have life cycles and specifications guaranteed specifically to meet the needs of IT departments.

In 1997, Intel x86 microprocessor pricing was impacted by the arrival of competitive devices. As already noted, Intel was forced to increase the speed with which it reduced its prices, and as a result saw its ASP drop in comparison with that of 1996. Processor ASPs are relatively uniform throughout the world because of the tight control that Intel has over the market. Table 4 shows the worldwide ASPs of Intel and its competitors in 1997 and so far in 1998. The release of 350-MHz and 400-MHz Pentium II products in the first half of 1998 enabled Intel to increase its ASP in the second quarter. This will not continue, however, because the release of Celeron products at a price point that is guaranteed to compete with AMD (among others) will bring down prices in the second half of 1998. Intel plans to maintain its overall ASP by means of Pentium II Xeon products. Pentium II Xeon shipments will start to increase in the second half of 1998, but their full impact will not be felt until 1999.

AMD has suffered the worst ASP fall. This company has publicly tied its pricing at 25 percent less than the nearest comparable-speed Intel product. For the first half of 1998 this meant that AMD's pricing was tied to the Pentium MMX, comparable Intel speeds being available only on this product. With the launch of 300-MHz (and faster) versions of the K6-2, AMD is realigning its pricing at 12.5 percent less than the most comparable Pentium II device. In so doing, AMD hopes to raise its ASP. However, this will only happen if customers accept the resulting price/performance combination when offered an AMD-powered PC.

PC Memory Applications

Flash BIOS

Since the advent of the Pentium class PC, all BIOS chips have been of the flash memory type. Although in-system reprogrammability is seldom, if ever, required, the decline in the price of flash memory in recent years has meant that there is now little or no premium over EPROM. In 1997, the vast majority of PC BIOS applications required 1Mb of flash memory, but a rapid shift to 2Mb is underway, and 4Mb will be the norm in coming years.

The European market for flash BIOS is limited by the number of PC and PC workstation motherboards that are manufactured locally. Typically, about 50 percent of the PCs and PC workstations produced in Europe have had locally produced motherboards. In 1997, therefore, about 10 million flash BIOS chips were consumed by the European PC industry. At an ASP of $2.30 per megabit, the TAM was at most $23 million (or less than 3.5 percent of the total flash market). And ASPs have continued to fall, so that the average price of a 1Mb flash device in 1998 is expected to be less than $2, further reducing the attractiveness of this market. In practice, Dataquest has found that the market for flash BIOS in the European region is much smaller than the theoretical maximum because of the number of motherboards produced by CEMs, which to reduce costs procure components centrally, elsewhere in the world.

In Europe, such is the dominance of the GSM handset as an application for flash memory, both in terms of units and of the flash megabits per system requirement, that the major flash vendors—AMD, Intel, Fujitsu and Sharp—have tended to ignore the flash BIOS market, leaving it to emerging vendors such as Macronix and Silicon Storage Technology.

Cache SRAM

By far the most important factor holding back current-generation PC performance is the amount of time taken to store data in, or to retrieve data from, the system main memory. Such has been the acceleration of improvement in microprocessor speed in recent years that system performance remains predominantly limited by the time taken to access the main memory. Although continual progress has been made in developing higher-performance DRAM for system main memory over the years—from asynchronous technologies such as page mode, fast page mode and extended data out (EDO) to the new synchronous DRAM (SDRAM) technologies—a PC's performance can be enhanced greatly by the addition of a relatively small amount of high-speed cache SRAM.

Cache SRAM sits close to the microprocessor and provides high-speed local memory space for recently accessed data, the theory being that the microprocessor is likely to continue to need access to data that it has used recently. The more often the microprocessor achieves a successful "cache hit" the higher the PC system performance will be because the number of times the main memory has to be accessed is reduced.

In fact, there are two levels of cache SRAM. Level 1 cache is located within the microprocessor itself and typically provides 32KB of on-chip memory. Here, memory access time is reduced to a minimum because of the absence of the capacitive loading associated with printed circuit board tracks and chip packages. Historically, level 2 cache has been located off the microprocessor chip, either directly soldered onto, or fitted as a module on, the PC motherboard, or included as part of a microprocessor daughterboard. It is level 2 cache SRAM that this *Focus Report* is concerned with because it utilizes commodity SRAM devices and has therefore been considered a viable end market for semiconductor vendors.

Market Background and Outlook: In the early 1990s the fast SRAM market was buoyant, driven by the PC cache application's demand for the 1Mb (32Kb x 32) synchronous device. Although the product specification required a sub-12 ns access time, the lucrative market attracted many SRAM vendors (particularly new players from Taiwan), which led to a market crash in 1995 as supply exceeded demand.

The market remained competitive up to and including 1997, with demand switching to the 2Mb (64Kb x 32) synchronous device, and access time specifications moving toward sub-5 ns performance. However, 1997 marked a watershed in the PC cache SRAM market—the market situation has changed in 1998. Contemporary PCs are moving rapidly to Pentium II microprocessor technology with SRAM cache incorporated on the microprocessor daughterboard by Intel during assembly. Intel has qualified only a few well-established SRAM vendors, and to date, in Europe, only four vendors (Samsung, NEC, Mitsubishi and Toshiba) are known to be supplying Intel's module assembly plant in Ireland. So, given Intel's dominant position in the microprocessor market, its key fast SRAM suppliers effectively have the European TAM to themselves. Samsung is believed to be the favored supplier with up to 45 percent share, while NEC, Mitsubishi and Toshiba have up to 20 percent each.

More recently, however, as process technology has developed, there has been a move by microprocessor manufacturers to eliminate level 2 cache altogether by increasing the size of the level 1 cache. When this happens—and it is inevitable—the merchant PC cache SRAM market will all but disappear. By the end of 1999, it is expected that the PC cache SRAM market will be restricted to a requirement for sub-5 ns synchronous SRAM in high-end servers and workstations. These machines will be based on Intel's Xeon microprocessor, and it is already clear that Intel will produce the high-speed SRAM for the Xeon's level 2 cache.

Market Statistics: Dataquest estimates that 21 million PCs and PC workstations were manufactured in Europe in 1997. However, only about 10 million motherboards were manufactured locally, and it was the level of motherboard production that effectively determined the size of the European cache SRAM market in 1997. Table 5 gives a breakdown of PC and motherboard production by microprocessor type, with a corresponding estimate of the number of megabits of fast SRAM.

Dataquest estimates that about 28 million cache SRAM 1Mb equivalents were shipped in the European region in 1997, comprising about 14 million 1Mb devices and about 7 million 2Mb devices. At an ASP of $2.50 this puts the 1997 TAM at about $71 million.

The leading PC cache SRAM vendors were Samsung, Mitsubishi, NEC and Toshiba, which shared about half the market equally between them. The remaining half was fought over by multifarious SRAM vendors.

 ©1998 Dataquest

Dataquest's estimate for PC and PC workstation production in 1998 is almost 25 million units, about 15 million of which will be Pentium II-based machines. Intel will manufacture the Pentium II modules with a fixed 512KB of PC cache SRAM on board at its facility in Ireland. It follows that the cache SRAM TAM at Intel will amount to about 60 million 1Mb equivalents in 1998. As the year progresses, the mix of processor speed will shift from 200/233 MHz to between 300 MHz and 450 MHz; together with this shift will go a requirement for faster specification SRAM devices. Since 1Mb devices are typically specified at 133/150 MHz and 2Mb devices at 183/200 MHz, there will be a corresponding shift in shipments to Intel from 1Mb to 2Mb devices.

Because of this move by Intel to a modular microprocessor with on-board cache, much of the cache SRAM TAM will be "virtual," with only four SRAM vendors qualified by Intel able to participate in this business. This means that the bulk of the cache SRAM market will be shared between the qualified vendors—Samsung, NEC, Mitsubishi and Toshiba—to the exclusion of all others. In addition, the contracts are such that cache SRAM shipments to Intel, although made in Europe, are not necessarily recorded as sales in the region.

Of the remaining 9.4 million machines expected to be produced in Europe, only about 5 million will have their motherboards manufactured locally. These 5 million motherboards effectively determine the size of the PC cache SRAM market available to all SRAM vendors. With an average PC cache SRAM fit of about 600KB, it follows that the maximum available TAM will be about $50 million, comprising 25 million 1Mb equivalent devices at an ASP of $2 each.

Table 5
PC Cache SRAM Consumption—Europe, 1997 and 1998

	PC Production (Units, M)	Local Motherboard Production (Units, M)	Average Cache (KB)	1Mb Equivalents TAM (Units, M)	ASP ($)	TAM ($M)

DRAM

PC system main memory uses DRAM because it is the semiconductor memory technology that offers the optimum price/performance trade-off in this application. The memory performance requirements of the PC are tempered by price-per-megabyte considerations and DRAM offers the lowest price per megabyte of any semiconductor memory technology (excluding mask ROM and EPROM), as shown in Table 6.

Table 6
Semiconductor Average Memory Price Comparison—Europe, 1997

	DRAM	Flash	SRAM	EEPROM
Price per Megabyte ($)	3.68	8.16	32.32	464.00

Source: Dataquest (October 1998 Estimates)

 ©1998 Dataquest

Although flash memory may be compared with DRAM on a price per megabyte basis, as programmable memory flash memory cannot offer the write-time performance to be viable as PC main memory. SRAM, on the other hand, can offer access times ten times faster than DRAM—but at almost ten times the price. Consequently, DRAM and PC main memory go hand-in-hand—about 73 percent of all DRAM consumption is accounted for by PCs and PC workstations. DRAM's dependence on the PC for its end market means that all drivers of the DRAM industry—cost-per-megabyte reduction, density transitions and bit price crossover, input/output (I/O) configuration and architecture, and cell design—relate directly to the PC. Therefore, generic DRAM technology and trends in the DRAM market automatically apply in the context of the PC more than in any other application.

Market Background and Outlook: DRAM is a true commodity product and, as such, the market is notoriously cyclical and dependent on the precarious balance between supply and demand. From a peak of more than $40 billion in 1995, the global DRAM market declined to about $25 billion in 1996 and to about $20 billion in 1997 as prices crashed because of a glut of products. Overinvestment in DRAM capacity during the early 1990s finally affected the market in 1996 as existing players and new entrants fought for market share.

Although this DRAM market crash was a disaster for the semiconductor industry, it was good news for PC vendors, which were able to increase margins during 1996 by maintaining PC price levels while reducing memory costs. It was not until 1997 that PC end users began to see the benefits, typically in the form of higher-specification machines offered by PC vendors at no additional cost to customers. By 1998, the PC industry was able to offer the so-called "$1,000 PC," which gave the consumer acceptable performance when running contemporaneous software. Continuing DRAM price declines went a long way to making this possible.

The cost of DRAM per megabyte declines by 32 percent per year on average, but imbalances between supply and demand mean that prices do not necessarily follow. While demand for DRAM bits has increased at a relatively predictable 65 percent to 70 percent for more than a decade, fluctuations in the price per megabyte have caused the DRAM market's legendary booms and busts. Contrary to popular belief, DRAM booms are caused by periods of stable rather then increasing prices, while DRAM busts result from a price-per-megabyte correction to the long-term price decline trend. Although the demand side of the DRAM industry equation might be well understood in terms of PC production and main memory fit expectations, it is the supply side—where the timing of the capital investment cycle is critical—that determines future market conditions. Investing in next-generation process technology is fundamental to success in the DRAM market, and the ability to ensure that the right level of capacity is available at the right time in the industry cycle is what distinguishes winners from losers.

Table 7 shows European DRAM vendor market share rankings for 1996 and 1997.

Source: Dataquest (October 1998 Estimates)

To the uninitiated, DRAM vendors can be placed in five groups, as follows:

- Committed: Samsung and NEC
- Ambitious: Siemens Semiconductor, Micron Technology and Hyundai/LG Semicon
- Reluctant: Hitachi, Fujitsu, Matsushita, Mitsubishi and Toshiba
- Strategic: IBM, Oki, Sanyo, Sharp and Nippon Steel Semiconductor
- Emerging: Vanguard International Semiconductor, Mosel Vitelic, Alliance Semiconductor and G-Link

The prolonged market downturn has caused many vendors to reappraise their involvement in DRAM. Many names that appeared in the 1997 ranking will disappear in 1998. Motorola pulled out of the DRAM market in late 1997, Micron bought Texas Instruments' DRAM business earlier this year and, at the time of writing, it appears likely that LG Semicon and Hyundai will merge their semiconductor businesses.

Samsung and NEC—long-time DRAM technology and market leaders—are in the unenviable position of having to defend their market shares against aggressive competitors, such as Siemens Semiconductor, Micron Technology and Hyundai/LG Semicon, that are equally committed to the DRAM market. It is interesting to note a geographic trend in the level of commitment to the DRAM market based largely on the maturity of companies as semiconductor vendors. Investing in DRAM has often been the means used by nonsemiconductor companies to enter the semiconductor industry before diversifying into other semiconductor product areas, such as microcontrollers or application-specific ICs (ASICs). This was true of Japanese companies in the 1980s and of South Korean companies in the 1990s. In general, the wider a company's product portfolio the less committed that company will be to any one product. This is especially true of DRAM because of the unpredictable nature of the market. Broadly speaking, Japanese tier-two DRAM vendors (that is, Hitachi, Fujitsu, Matsushita, Mitsubishi and Toshiba) appear to be losing patience with the DRAM market, preferring to concentrate on their wider product portfolios; in contrast, South Korean vendors' product portfolios are not sufficiently diversified for the companies to be anything other than committed to the DRAM market. Continuing this geographic trend, the emergence in recent years of the Taiwanese vendors, Vanguard International Semiconductor and Mosel Vitelic, is noteworthy. It would not be a surprise to see companies from other emerging economies, such as China, follow the same strategy.

The involvement in DRAM of some semiconductor companies, such as IBM, Oki, Sanyo, Sharp and Nippon Steel Semiconductor, is more for strategic business reasons than for a desire to be major DRAM merchant market players. DRAM process technology is often seen as a technology driver for the semiconductor industry as a whole and, with the emergence of system-level integration and embedded memory, many semiconductor companies continue to believe that DRAM capability is important.

Market Statistics: Dataquest's European PC unit production history and forecast data is shown in Table 8.

Although growth in PC unit production is expected to decline from a CAGR of 21 percent for the period 1992 to 1997 to 15 percent for the period 1997 to 2002, growth in main memory fit for the same two periods is expected to be maintained at a CAGR of slightly less than 50 percent, resulting in a decline in the bit growth rate for the European PC DRAM market from a CAGR of 79 percent to 69 percent for the same periods. However, this reduction in the bit growth rate is not a cause for concern, but merely a return to historical levels following the "bit boom" of 1997. PC main memory fit (including aftermarket fit) is still expected to increase from an average 35MB in 1997 to an average 246MB in 2002 (see Figure 9).

Source: Dataquest (October 1998 Estimates)

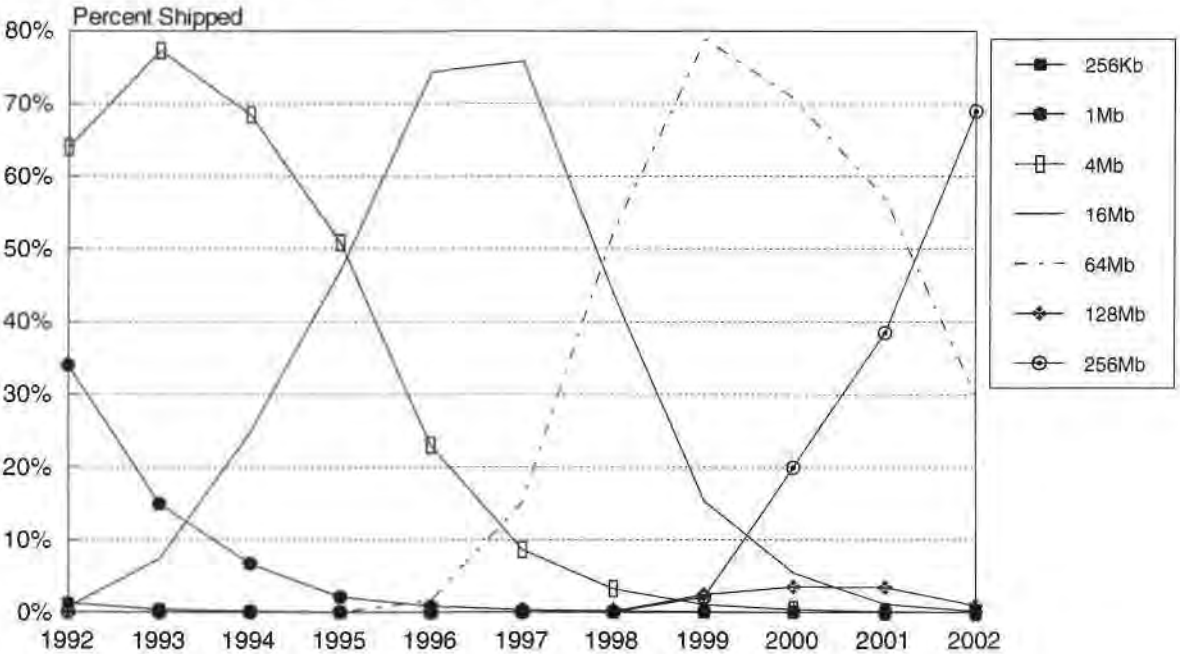
PC DRAM revenue in 1998 is expected to total about $2 billion—about the same level as in 1993 even though the number of megabytes per system is expected to be almost ten times greater this year! With a shortage of PC100 64Mb devices expected because of a lack of sub-0.25 micron fab capacity, the DRAM market is poised to enter an era of price stability. A return to strong growth in DRAM revenue is expected in the period 1999 to 2001 on the assumption that during this time ASPs will stabilize at about the levels of the fourth quarter of 1998.

The period 1999 to 2001 will coincide with the demise of the 16Mb device density in favor of the 64Mb density (see Figure 10). There is a strong body of opinion that advocates the introduction of the 128Mb density as an intermediate density between the 64Mb and 256Mb densities on the grounds that, given the process technologies available, the 128Mb density can be manufactured more cost effectively.

Figure 10
Bits Shipped by Device Density—Europe, 1992-2002



Source: Dataquest (October 1998 Estimates)

Technology transitions will remain as important as density transitions to the development of the DRAM market. Figure 11 shows the rapid shift from EDO technology to synchronous technology that occurred during 1998, when PC66 enjoyed brief popularity. By the first quarter of 1999 about 90 percent of 64Mb DRAM shipments will be SDRAM, and the vast majority of these will be PC100 specification. By the end of 2000, the next generation of DRAM—almost certainly based on proprietary Rambus technology—will have begun to appear, providing yet another quantum leap in DRAM performance.

Other Devices

The remaining semiconductor components (that is, in addition to microprocessor and DRAM) found on a motherboard fall into several categories (see Table 10), and, of these, SRAM for level 2 cache and flash nonvolatile memory for the BIOS are dealt with in the section titled "PC Memory Applications." These remaining devices are universal to most motherboards and the greatest value is in the chipset, an area where Intel had a virtual monopoly in 1997 as all the transplant fabricators and the European manufacturers used Intel products. Of a market worth $270 million, Intel accounted for $268 million, with the remainder spread between various other companies. In fact, in 1997, more companies left this market than remained. Intel's competitors should gain market share in 1998 because the acceptance of AMD's K6-2 and Cyrix's MII by the major PC vendors will necessitate the use of non-Intel chipsets to get maximum performance from these processors.

The multi-I/O device is the next-largest value item, with European revenue of about $80 million. National Semiconductor has the bulk of this business; Winbond and SMC share about $5 million between them. As we move down the list of devices revenue gets increasingly less and is spread between more players. Because of the small values involved, Dataquest has not done further analysis on these products.

Compaq Deskpro EN Motherboard Analysis

Analysis of a Compaq motherboard for a Deskpro EN as an example of a current high-volume mainstream production unit shows that it has all of the various components previously described. It also has on-board audio, which is increasingly becoming a standard function on motherboards designed by the major PC vendors. Surprisingly, few other functions are migrating to the motherboard—areas like networking are still served mainly by network adapter cards rather than by LAN-on-motherboard (LOM). LOM migration is starting to happen, but the almost religious devotion of network administrators to particular brands of network adapters prevents PC vendors from integrating this function. On the graphics front, the fast rate of innovation plus the targeting of graphics adapters to particular markets (such as games players, electronic design automation and mainstream office users), is also discouraging migration to the motherboard.

Table 11 gives a breakdown by function of the devices on the Compaq Deskpro EN motherboard. A Mitsubishi ASIC M65444 is included on the motherboard. It is believed to carry out functions tied in with administrative security settings and the various interlocks connected to the software-controlled lock that is incorporated inside the chassis. The sound system on this board is based on the ESS1869F, which provides adequate 16-bit stereo sound reproduction. Surprisingly, as well as using a Philips amplifier to drive the internal loudspeaker, Compaq has included a separate headphone driver device.

A device that is beginning to become a standard is the CY2318, which provides clock signal to the SDRAM dual in-line memory modules (DIMMs). Because of 100-MHz DRAM's tight timing, it is necessary to use such a device to ensure the minimum amount of skew between the clock signals applied to each DIMM. The BIOS device on this board is a Fujitsu 2Mb product; this size is fast becoming the standard, having been at 1Mb for several years.

Like so many new-generation motherboards, this one is based on the NLX standard and as such has no slots on it other than an accelerated graphics port slot and a connector for the riser board onto which all expansion boards are plugged. Furthermore, the processor is not fitted vertically on the board, but plugged into a slot 1 socket that is at 90 degrees to the vertical, thereby allowing the processor to lie flat. This keeps down the height of the motherboard and processor combination and allows the board to be used in enclosures of various heights.

Table 11

Production and Shipment Forecasts

The future for PC manufacturing in Europe appears relatively secure. The nature of the market will change over the next few years as Western Europe becomes saturated and goes into a replacement mode. However, CEE will continue to grow, albeit with temporary stalls caused by events such as the crisis in Russia. Table 12 gives Dataquest's latest shipment forecast. It shows that from 1998 to 2002 the overall European market will grow at a CAGR of 14.2 percent, with Western Europe growing at 12.4 percent and CEE at 21.1 percent. PC workstations will be the highest-growth format, growing at a CAGR of 32.5 percent. Although PC workstation units are relatively few, they are important because of the impact of their higher ASP on revenue.

Table 12
PC Shipments—Europe, 1996-2002 (Thousands of Units)

	1996	1997	1998	1999	2000	2001	2002	CAGR 1998-2002
Western Europe (PCs)	16,323	18,914	22,860	25,772	29,024	32,685	36,452	12.4%

©1998 Dataquest

European PC and PC workstation production is forecast to have a CAGR of 14.6 percent from 1998 to 2002 (see Table 13). Again, the highest growth will be in PC workstations, which will have a CAGR of 41.9 percent over the forecast period. However, when the semiconductor content of ordinary PCs is analyzed, a negative CAGR of 0.7 percent is forecast. This is because Dataquest believes the next DRAM downturn induced by overcapacity will start in 2002 and that DRAM prices will be main factor reducing semiconductor content in 2002. However, the higher semiconductor content of PC workstations will result in a positive (albeit only just) CAGR of 0.6 percent for the total number of PCs manufactured.

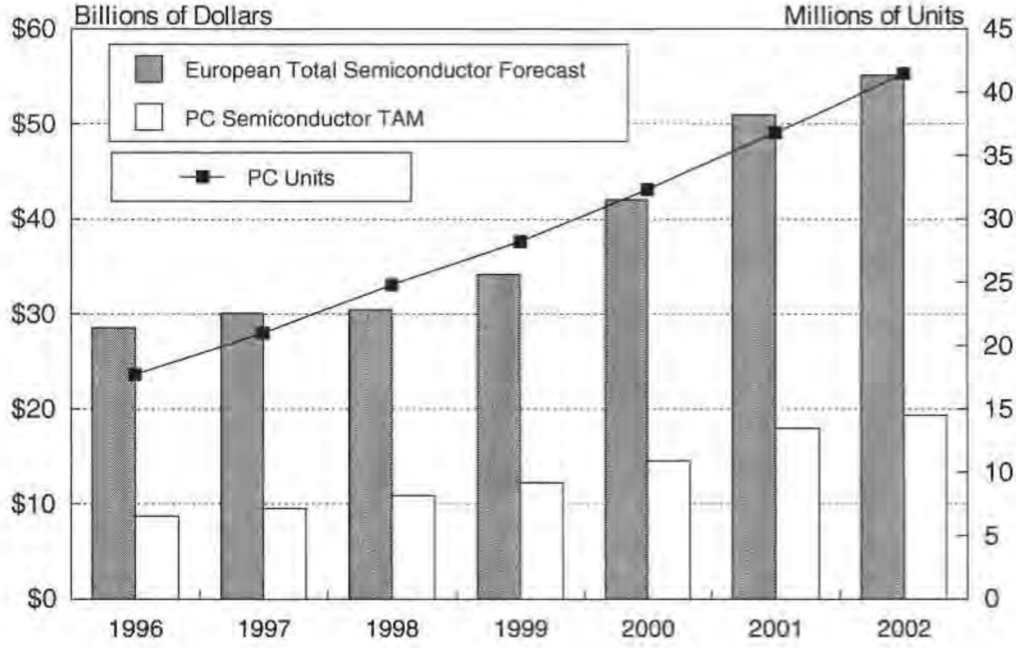
Factory ASPs for both PCs and PC workstations are forecast to decline during the period 1998 to 2002 at minus 5.7 percent CAGR and minus 2.7 percent CAGR respectively, resulting in a negative 4.3 percent CAGR for the total PC ASP. Unit growth is forecast to compensate for the decline in ASP, and therefore we see a total factory revenue CAGR of 9.6 percent. Again, this figure will be achieved because of the higher revenue growth rate of PC workstations—38.0 percent CAGR compared with 7.6 percent CAGR for ordinary PCs.

Examination of the PC semiconductor TAM as a percentage of the whole European semiconductor market reveals that over the forecast period this percentage remains relatively constant, being 35.7 percent in 1998 and falling to 35.1 percent in 2002. Interestingly, in 1996 the ratio was 30.5 percent. This increase in value between 1996 and 1998 is attributable primarily to the rise in processor ASP. As the Pentium became the dominant processor family, the corresponding rise in ASP offset the decline in DRAM ASP over the same period and increased the overall PC semiconductor TAM. Figure 12 shows this comparison as well as PC unit growth over the forecast period.

Figure 12
PC Production Units and Semiconductor TAM—Europe, 1996-2002



Source: Dataquest (October 1998 Estimates)

PC motherboard manufacturing in Europe is dominated totally by the transplant manufacturers that continue to produce foreign-designed products in Europe. Table 14 gives Dataquest's forecast for local manufacturing, which is forecast to have a CAGR of 10.2 percent from 1997 to 2002. With the recently accelerating rate at which motherboard production is being transferred to centralized locations in the Far East, this figure may prove to be optimistic in the long term.

Table 14
PC Motherboard Production Forecast—Europe, 1996-2002

	1996	1997	1998	1999	2000	2001	2002	CAGR 1997-2002
Units (K)	9,523	10,650	11,834	12,650	14,150	15,200	17,290	10.2%
Factory ASP ($)	135	125	120	117	116	114	114	-1.8%
Factory Revenue ($M)	1,286	1,331	1,420	1,480	1,641	1,733	1,971	8.2%
Semiconductor Content ($)	66	60	62	66	69	71	78	5.4%
Semiconductor TAM ($M)	629	639	734	835	976	1,079	1,349	16.1%
I/O Ratio	48.9%	48.0%	51.7%	56.4%	59.5%	62.3%	68.4%	7.3%

Conclusions

The European PC industry is shoring up growth in the worldwide PC industry in 1998—forecast worldwide shipment growth of 15.6 percent compares badly with the European forecast of 21.1 percent this year. Although the Asian financial crisis is impacting shipments in the Far East, it is having a beneficial impact in Europe because prices for Asian-sourced components are continuing to fall as a result of declining local currency costs, thereby helping to lower PC prices in Europe. Although short-term conditions look good, several issues cloud the future of the European PC industry. The most profound of these is the continuing decline in local ownership and the lack of local intellectual property. The European semiconductor industry is experiencing the impact of being in a similar situation, with local DRAM factories being closed because of worldwide overcapacity, while home region facilities that include research functions and product design centers remain immune.

From the perspective of semiconductor vendors, the key to the European PC manufacturing market is ensuring that they are diligently getting products "designed in" where PCs are being designed, especially in the United States, where most of the multinationals are based. They then have only to service the business on a local basis when production switches to Europe. However, even this is becoming a precarious position because so many deals are being negotiated on a worldwide basis and because products are being drop-shipped into manufacturing facilities around the world without involving semiconductor vendors' local offices. As a result, companies with headquarters in Europe that sell to this market must have strong sales and support presence in the United States and the Far East (especially Taiwan) if they want to be successful.

Processor and memory technology migrations over the next few years will ensure that the PC market remains turbulent. PC prices will continue to decline and most PCs sold will be in the sub-$1,499 price band. This situation will remain as long as the current hiatus in software development continues. There is no convincing candidate on the horizon for the "killer application" that will necessitate much more powerful processors and more memory. Therefore, industry demand for these products will continue to grow at historical growth rates. Various candidates for the killer application have been advocated, but none has yet stood the test of time. The current candidate is speech I/O, but this seems to be making slow progress.

Intel continues to dominate the computer processor arena and has increased its influence further by becoming the dominant player in PC chipsets. The company is also expanding its involvement in networking and graphics. Although Intel's ASPs have declined over the past year, Dataquest expects them to recover as the PC workstation becomes an increasingly important part of the PC market. Pentium II Xeon devices that are targeted specifically at the workstation and server markets are priced at many times the price of a Celeron or Pentium II device. Their cost, however, is only fractionally greater than that of a Pentium II, so their contribution to margins and ASPs will be significant.

Overall, the European market looks healthy. However, analysis of growth rates shows that both the consumer and professional sectors—and therefore the whole market—are slowing. This gives concern for 1999 and beyond. The increase in assembly capacity at such a time means that PC vendors need to keep a close eye on the trend, and ensure that they do not overinvest in production facilities that will become expensive if not running at full capacity.

EMEA Semiconductor Market Forecast and Country Analysis, 1990-2002

Executive Summary

Total EMEA

- The market was worth $30.0 billion in 1997—a revenue growth of 5.9 percent over 1996.
- Growth will slow to 2.9 percent in 1998, putting revenue at about $31.0 billion.
- A compound annual growth rate (CAGR) of 15.6 percent is forecast for the period 1997 to 2002.
- Revenue in 2002 is forecast to exceed $62 billion.

Benelux

- Revenue in 1997 was $1.2 billion, up by 4 percent over 1996.
- Benelux is the smallest regional market, accounting for less than 4 percent of total EMEA revenue.
- Growth of about 2 percent is expected in 1998.
- No dramatic change in regional share is anticipated over the forecast period.
- Almost unnoticed, the region is developing as a center of PC production.
- Non-PC markets are declining, holding back the 1997 to 2002 CAGR to 14.5 percent.
- Revenue will exceed $2 billion in 2002.

France

- Average growth of approximately 5.5 percent in 1997 puts revenue at almost $4 billion.
- Above-average growth of 5.8 percent is forecast for 1998.
- A 13 percent share of the total EMEA market is expected to continue through to the end of the forecast period.
- The country has probably the best balance in semiconductor application markets, encompassing healthy communications, automotive, industrial, and military and civil aerospace sectors.
- The wide range of application markets will drive an above-average CAGR of 16.1 percent for the period 1997 to 2002.
- The market will exceed $8 billion in 2002.

Germany

- The market declined by almost 5 percent to $7.5 billion in 1997.
- Germany is no longer the largest single market within the EMEA region in revenue terms, but remains the most important in terms of design-in activity.
- A recovery to 7 percent growth is forecast for 1998.
- Germany has the most broad-based electronics sector of all the EMEA regional markets, so long-term growth goes hand in hand with the EMEA average.
- A CAGR of 15.9 percent is forecast for the period 1997 to 2002.
- Market revenue in excess of $15 billion is forecast for 2002.

©1998 Dataquest

Italy

- Revenue declined by 5.0 percent to $1.7 billion in 1997.
- Revenue of $1.6 billion is forecast for 1998—a further decline.
- Ongoing troubles at Olivetti, the region's most significant OEM, continue to depress the semiconductor total available market (TAM).
- A lack of investment in electronics over many years means that there is no salvation on the horizon.
- Long-term growth at 11.1 percent will continue to lag significantly behind the EMEA average.
- At almost $3 billion in 2002, the market size will be barely above that of Benelux, the smallest EMEA regional market.

Nordic

- Revenue grew by 7.7 percent to $2.7 billion in 1997.
- Forecast growth is 12 percent in 1998, putting the market at $3.0 billion.
- The market has a unique makeup, dominated as it is by Ericsson and Nokia—world leaders in digital cellular handset and infrastructure manufacturing.
- In spite of a move by the major OEMs towards contract electronics manufacturing in low-cost regions and continued pressure to reduce component costs, the region will remain the strongest in growth terms.
- A CAGR of 16.5 percent for the forecast period will drive the market towards $6 billion in 2002.

United Kingdom/Ireland

- At 15.0 percent, the region experienced the highest growth in 1997, putting the market at almost $9 billion.
- The market is now the single largest, ahead of Germany—a situation that will continue throughout the forecast period.
- The large multinational PC companies based in the region have continued to corner the market, providing increased sales for semiconductor vendors.
- The region will benefit most from the anticipated upswing in the DRAM market, which is expected to occur during the forecast period.
- The boom in mobile telephony equipment manufacturing is not restricted to the Nordic region: United Kingdom/Ireland has a lucrative semiconductor market in the sector as well.
- An above-average CAGR of 16.3 percent for the period 1997 to 2002 will put the market at $19 billion by the end of the forecast period.

Rest of EMEA

- Revenue grew by 14.6 percent to $4.1 billion in 1997.
- Many of these countries are still very much immature markets, with much of the electronics equipment manufacturing utilizing subassemblies brought in from outside.
- There are bright spots, such as the Czech Republic and Turkey, but these are the exception.
- Dataquest expects the Rest of EMEA to grow at a slower rate than the industry average over the forecast period to reach $8 billion in 2002.

Scope

This *Market Trends* report analyzes the semiconductor markets that comprise the EMEA region for the period 1990 to 2002. Product level detail is included for the major EMEA market regions: Benelux, France, Germany, Italy, Nordic, United Kingdom/Ireland and Rest of EMEA. Additional breakdown of this latter region gives top-level country market shares and forecasts for Central and Eastern Europe, the Middle East and Africa.

Introduction and Definitions

This *Market Trends* report analyzes the market sizes and outlooks for the major EMEA regions from 1990 to 2002. Dataquest's forecast details the following regional and market definitions.

EMEA

Dataquest defines the EMEA region as follows:

- Benelux: Belgium, the Netherlands and Luxembourg
- France
- Germany
- Italy
- Nordic: Denmark, Finland, Norway and Sweden
- United Kingdom/Ireland
- Rest of Europe, Middle East and Africa: For market analysis purposes, this region is further broken down as follows:
    - Rest of Western Europe: Andorra, Austria, Cyprus, Faroe Islands, Gibraltar, Greece, Greenland, Guernsey, Iceland, Isle of Man, Jersey, Liechtenstein, Malta, Monaco, Portugal, San Marino, Spain, Svalbard and Switzerland
    - Central/Eastern Europe: Albania, Armenia, Azerbaijan, Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, the Czech Republic, Estonia, Georgia, Hungary, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Macedonia, Moldova, Poland, Romania, Russia, Slovakia, Slovenia, Tajikistan, Turkmenistan, Ukraine, Uzbekistan and Yugoslavia (Serbia and Montenegro)
    - Middle East/Africa: Afghanistan, Algeria, Angola, Bahrain, Bassas da India, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Cape Verde, Central African Republic, Chad, Comoros, Congo, Cote d'Ivoire, Djibouti, Egypt, Equatorial Guinea, Eritrea, Ethiopia, Europa Island, Gabon, Gambia, Ghana, Glorioso Islands, Guinea, Guinea-Bissau, Iran, Iraq, Israel, Jordan, Juan de Nova Island, Kenya, Kuwait, Lebanon, Lesotho, Liberia, Libya, Madagascar, Malawi, Mali, Mauritania, Mauritius, Mayotte, Morocco, Mozambique, Namibia, Niger, Nigeria, Oman, Qatar, Reunion, Rwanda, Saint Helena, Sao Tome and Principe, Saudi Arabia, Senegal, Seychelles, Sierra Leone, Somalia, South Africa, Sudan, Swaziland, Syria, Tanzania, Togo, Tromelin Island, Tunisia, Turkey, Uganda, United Arab Emirates, Western Sahara, Yemen, Zaire, Zambia and Zimbabwe

Semiconductor Market Definition

Dataquest defines the semiconductor market as representing all merchant market business together with in-house business that exists for those semiconductor manufacturers that also participate in the merchant market. This element of in-house business between a manufacturer and its equipment divisions or subsidiaries is valued at merchant market prices. This gives a true reflection of the TAM to merchant semiconductor suppliers. Figure 1 shows the shipment model used by Dataquest in the definition of the total semiconductor market in EMEA. Table 1 shows, for 1996 and 1997, the market sizes for the seven major EMEA regions, broken down into individual country markets.

©1998 Dataquest

Note that the TAM estimates shown for Central and Eastern Europe, the Middle East and Africa markets are for true end-market consumption and are not the same as for the other regional markets. Dataquest estimates of market sizes are normally based on sales made by semiconductor vendors, that is first-invoice sales. These include sales made to distributors and agents that then sell on to the true end users. In the case of markets such as the Czech Republic or South Africa, the industry chooses to consider their TAM based on surveying the true end users. So, the sales opportunity visible to semiconductor vendors in these new and emerging markets is somewhat smaller than the TAM shown in the particular tables.

Assumptions

The following are some key assumptions that were used in the forecast model. Significant changes in these assumptions will therefore affect the forecast outlook.

Production Capacity

The global semiconductor industry has been in oversupply since early 1996 and this situation has continued throughout 1997 and into 1998. Dataquest does not see a return to a balance in supply and demand until well into 1999, so prices are expected to continue to decline in the short term. Longer term, the slowdown in capital expenditure witnessed in the later part of 1997 and into 1998 will ripple through, resulting in undercapacity later in the forecast period. For these reasons, Dataquest's forecast semiconductor industry growth rates are below the long-term average of about 15 percent in 1998 and 1999, but higher than the average in 2000, 2001 and 2002. The next cyclical downturn has been pushed out to 2003, outside the current forecast window, because of the effect of reduced capital spending in 1997 and 1998.

Exchange Rates

Actual exchange rates for the EMEA regions covered in this *Market Trends* report are contained in Table 2. Dataquest does not forecast currency fluctuations; therefore, the rate used for 1998 is the average of 1998 year-to-date combined with the latest available month's rates at the time of writing (April) used for the rest of the year. The rate for 1999 onwards is simply the latest rate available for 1998. Figure 2 shows the relative performance of the currencies since 1990.

Changes from 1997 Forecast

In a third year of dismal revenue growth in the semiconductor industry, the forecast growth rate for the EMEA region in 1998 has been reduced to less than 3 percent largely because of a continued reduction in DRAM average selling prices (ASPs). The ability of DRAM vendors to continue to reduce costs has been aided by the effects of currency devaluation in the economies of Southeast Asia and Japan and by more aggressive application of leading-edge process technologies on trailing-edge device densities. The constant battle for DRAM market share has ensured that these cost reductions have been passed on to end customers, resulting in reduced revenue for the DRAM industry.

Product Analysis

Tables 3 and 4 detail the overall history and forecast for EMEA by product family. For the period 1997 to 2002, a CAGR of 16 percent is expected, influenced greatly by the MOS memory (22 percent CAGR), MOS microcomponent (14 percent CAGR) and MOS logic (16 percent CAGR) categories. Figures 3 and 4 illustrate the relationship between the MOS memory, MOS microcomponent and MOS logic categories, and their effect on the total semiconductor market in EMEA.

Bipolar Digital

There is no sign of an end to the continuing demise of the bipolar digital market. The bipolar digital category is forecast, at about $50 million, to become the smallest single-product category by 2002, accounting for less than 0.1 percent of the total market. However, such is the insignificance of this market segment, it is highly unlikely that the category will survive for analysis until the end of the forecast period.

MOS Digital

Comprising MOS memory, MOS microcomponent and MOS logic, the MOS digital category traditionally accounts for about 70 percent of the total semiconductor market in EMEA. From a low of 69 percent in 1996 this proportion is forecast to rise to 73 percent in 2002 driven by growth in the memory market as a result of a DRAM boom. In spite of the healthy CAGR expected for the memory category, Dataquest is still forecasting that MOS microcomponent will remain the largest of the three MOS digital categories until 2002.

MOS Memory

Following a decline of 13 percent in 1997, the MOS memory market is forecast to decline by a further 21 percent in 1998. Overcapacity and continued device cost reductions continue to suppress DRAM ASPs. Price pressure is also a feature of the SRAM and flash memory markets; it is caused by abundant supply and fierce competition. Longer term, the DRAM market is expected to boom again as continued bit growth combined with a slowdown in capital investment bring supply and demand back into balance during 1999. A DRAM boom is therefore forecast for 2000, 2001 and 2002 with a bust anticipated in 2003. Prospects for SRAM are not so bright. It now looks likely that the fast SRAM market in the EMEA region will disappear because of the move to modular microprocessor solutions for the PC market. The slow SRAM market is buoyed by demand from EMEA's communications sector, but price pressure means that spectacular market growth is unlikely. In the nonvolatile arena, the EPROM market demise is accelerating as flash becomes more and more competitive because of continued ASP declines.

MOS Microcomponent

The MOS microcomponent sector is dominated by the microprocessor, which, in turn, is dominated by Intel's X86 architecture. The accelerated pace of product introduction has resulted in Intel's ASPs being maintained, although fierce competition in the low-end and midrange segments of the X86 market will result in entry-level and midrange ASPs (including Intel's) declining over the forecast period. Intel will recoup these losses in the high end of the market—that is, servers and workstations—which it will continue to expand. PC production is forecast to remain healthy, thereby continuing to make microprocessors a lucrative sector.

Microcontroller unit shipments continue to grow and, while the 8-bit market will still suffer from ASP attrition, the 16-bit-and-above arena is growing in importance as volume applications in automotive and consumer segments come onstream. These devices are becoming increasingly application specific and Europe has become a focal point of design for devices aimed at these high-volume applications. The higher ASPs of these application-specific products combined with the continuing unit growth of the 8-bit devices will result in continuous revenue growth for this product category over the forecast period.

Digital signal processors (DSPs) are the glamour product within the microcomponents portfolio, with the highest growth of any product over the forecast period. Increasingly, these devices are finding new applications in high-volume consumer products. The ongoing digital revolution in consumer products would not be possible without affordable DSP products. During the forecast period, standalone DSPs will continue to grow based on their use in digital cellular infrastructure and other applications such as motor control. The bulk of the DSP market will become increasingly IP based, with DSP cores being embedded into application specific standard products targeted at specific products such as single-chip baseband devices for cellular phones or single-chip solutions for the various digital broadcast delivery systems.

MOS Logic

Downward pressure on pricing is likely to continue through 1998 and into 1999. This will not be as marked as in other areas of the semiconductor market, but will still impact growth significantly.

Cell-based ICs (CBICs), the main vehicle for system-level integration products, will continue to be the fastest-growing logic product. Gate arrays, however, are under serious pricing pressure and are entering the decline phase of the life cycle. CBICs are displacing gate arrays from high-end applications as programmable logic devices (PLDs) displace gate arrays from low-end applications. This translates into higher long-term growth in the CBIC and PLD segments, and lower growth for gate arrays, which are squeezed between the two.

PLDs are suffering from more rapid price erosion than the other ASIC categories. However, price reduction is necessary in order for PLDs to penetrate the widest possible range of market sectors. The difficulty for the vendors is one of slowing down these price falls at the right levels.

The major applications driving the logic market in EMEA over the forecast period are set-top boxes, automotive navigation systems, cellular handsets, LAN adapter boards and MPEG-based multimedia engines for digital video applications.

In spite of the increased digitization of many applications, mixed-signal devices will continue to be a significant factor in the EMEA ASIC market, driven largely by requirements in the telecommunications and automotive sectors. We forecast that this technology will increase its share of the cell-based market over the forecast period.

The use of cores or large functional blocks that are pretested is clearly on the rise. According to Dataquest's latest analysis of design starts, cores are taking up a larger portion of the die area at the expense of random logic. Trade in these cores—the so-called intellectual property (IP) market—will begin to be a major factor in the ASIC market during the forecast period.

Analog, Discrete and Optical Semiconductors

In the EMEA region the analog category is, in fact, larger than that of MOS logic. Europe's standing as a center of excellence for telecommunications and automotive electronics design assures continued equipment production and demand for analog semiconductors.

The discrete category accounts for about 10 percent of semiconductor revenue in the EMEA region, which is not an insignificant TAM. However, this category will do well if it manages to hold its share of the total semiconductor market as, in spite of healthy growth products such as IGBTs, it faces the threat of higher integration.

The optical semiconductor market is expected to experience a modest CAGR of 8 percent for the period 1997 to 2002, allowing the market to break through the $1 billion barrier by the end of the forecast period.

EMEA Outlook by Country/Region

The trends in the semiconductor market in EMEA are dependent on semiconductor consumption by the major electronics equipment manufacturers. Therefore, there tends to be a concentration of the majority of the market in regions where there is a strong electronics production base, such as in Germany and United Kingdom/Ireland, together with regions characterized by a particular expertise, such as mobile communications in Scandinavia.

The history and forecast for each of the EMEA regions is contained in Table 5 and Figure 5. In 1997, the United Kingdom/Ireland region became the largest single market for semiconductors, ahead of Germany, and this situation is expected to continue throughout the forecast period. The Benelux region is the smallest, and will continue to lose share gradually. The Italian market is expected to lose share at the fastest rate, because of the absence of any new electronics production investment to compensate for the demise of Olivetti. Growth in the Nordic region is the highest in the EMEA region as it continues to benefit from communications equipment production. Semiconductor market growth in France is on a par with the EMEA average—a reflection of the wide applications base in the country. Spectacular growth is not expected in Rest of EMEA, as many of the constituent countries have yet to develop any significant electronics manufacturing capability.

Table 6 shows the overall top 10 semiconductor market share ranking by revenue for the EMEA region in 1997. Intel retained number-one spot with double the revenue of its nearest competitor, Siemens, which was in second place. Unsurprisingly, broadliners Motorola, Philips, STMicroelectronics and Texas Instruments feature in ranked positions three to six, while Samsung, NEC and Hitachi, companies with a narrower product focus, are in positions seven through nine. Lucent Technologies makes up the top 10 ranking at number 10.

Benelux

The Benelux semiconductor market history and forecast is shown in Tables 7 and 8. Dataquest estimates that the Benelux region, defined as Belgium, the Netherlands and Luxembourg, was worth about $1.2 billion in semiconductor revenue in 1997, a growth in dollar terms of 4.1 percent over 1996. However, growth of 20 percent in local currency is hidden by a significant devaluation of 15 percent against the dollar between 1996 and 1997. In dollar terms, the region accounted for 3.8 percent of the EMEA semiconductor TAM in 1997, 0.1 percent less than in 1996.

Historically, the Benelux region has relied upon the communications and consumer segments for its semiconductor markets. This reliance has tended to restrict the growth prospects of the semiconductor TAM, but there is increasing activity in the region from Europe's PC manufacturers that will help to slow the decline in the Benelux region semiconductor TAM. Although a market size in excess of $2 billion by 2002 is forecast, a marginal decline in share over the forecast period is expected, which will reduce the Benelux region share to 3.6 percent of the EMEA semiconductor TAM.

Table 9 shows the top 10 semiconductor vendors in the Benelux region, ranked by sales revenue in 1997. Intel's position at number one is testimony to the existence in the region of a healthy PC industry that consumes appreciable quantities of the microprocessor vendors' high-value products. The fact that Philips and STMicroelectronics are ranked second and third is no surprise and confirms the region's semiconductor market profile as heavily consumer-segment oriented, because both companies have a strong consumer electronics focus. Further down the ranking, broadliners such as Texas Instruments, Siemens and Motorola feature, as well as more specialist vendors such as Lucent Technologies and Alcatel Microelectronics, attracted by the telecommunications sector. The presence of AMD and NEC in the rankings is further evidence of an increasing PC manufacturing sector.

In 1998 the Benelux region is expected to show marginally positive dollar growth of about 2 percent, which equates to some 7 percent growth in gulden. Over the next five years, the semiconductor market in the Benelux region is forecast to grow at a CAGR of 14.5 percent, which is below the average for the EMEA region as a whole. A graphical representation of the Benelux semiconductor market history and forecast by product category is shown in Figures 6 and 7.

France

The French semiconductor market history and forecast is shown in Tables 10 and 11. The semiconductor market in France was estimated to be worth almost $4 billion in 1997, about 13 percent of the EMEA semiconductor TAM. Growth of 5.4 percent in dollar terms in 1997 over 1996 was on a par with the EMEA average, but again a devaluation of 14 percent by the franc against the dollar meant that 20 percent growth in local currency was masked.

The French electronics sector is well-balanced between the six traditional application segments. As well as significant EDP and telecommunications equipment manufacturing, often the mainstay of any region's semiconductor marketplace, the semiconductor TAM in France also benefits from strong consumer, automotive, industrial, and military and civil aerospace sectors.

Table 12 shows the top 10 semiconductor vendors in France ranked by sales revenue in 1997. Intel retained its number-one position, growing sales by 22 percent to more than $600 million, while STMicroelectronics held on to second spot in spite of relatively flat sales in 1997 over 1996. Philips, whose electronics arm manufactures cellular handsets in France, gained one place in the ranking at the expense of Motorola. Siemens gained three positions in the ranking as a result of a product portfolio well-suited to the applications profile of the French market. Siemens is traditionally strong in communications and automotive, and is also one of the leading vendors of silicon for the booming French chip card market. NEC and Samsung, two vendors with a heavy DRAM bias, suffered revenue loss in France in 1997, and each fell one place in the ranking, as did Texas Instruments, although revenue for the American company was up by 9 percent. National Semiconductor, another broadliner, entered the top 10 at the expense of Toshiba, while Analog Devices held on to a top 10 ranking, growing revenue as a result of the continued strength of the mobile telecommunications sector.

 ©1998 Dataquest

In 1998 Dataquest expects the French semiconductor market to show dollar growth of nearly 6 percent, which equates to a franc growth rate of 10 percent. The outlook for the French semiconductor market remains healthy because of its wide applications base, although the region will fail to benefit significantly from the anticipated recovery in the DRAM market. Nevertheless, France is well-placed in almost all non-PC sectors, and it will benefit from a continued boom in chip card production. This broad applications spectrum means that the French semiconductor market ought to grow at a CAGR of about 16 percent over the forecast period, in line with the EMEA average, holding a share of about 13 percent and putting the TAM at more than $8 billion by 2002. A graphical representation of the product breakdown for the French semiconductor market history and forecast is shown in Figures 8 and 9.

Germany

The German semiconductor market history and forecast is shown in Tables 13 and 14. Dataquest estimates that the German semiconductor market declined by 5 percent in dollar terms last year to less than $7.5 billion, putting the TAM significantly lower than the United Kingdom/Ireland region for the first time since 1988. However, growth in local currency did return in 1997, signifying that a recovery in the semiconductor market in the region is being hidden by the relative strength of the dollar against the deutsche mark.

Although the EDP sector has suffered in Germany relative to the United Kingdom/Ireland region, late 1997 saw the start of a recovery as consumer PC demand was rekindled. The German telecommunications and automotive sectors remain the strongest in the EMEA region, and there are signs of an upturn in the industrial sector. The consumer segment remains weak, although it may benefit from increased white goods semiconductor content during the coming years.

Table 15 shows the top 10 semiconductor vendors in Germany ranked by sales revenue in 1997. There is a change at the top of the revenue rankings, in that Intel has now added the German market to its "collection of top spots" by displacing Siemens. The mid-ranked vendors, Motorola, STMicroelectronics, Texas Instruments and Philips, all posted a revenue decline in Germany in 1997, but the two European companies declined most in the ranking, reflecting the poor state of the consumer electronics industry in the region. NEC and Samsung represented the memory vendors in the rankings, but both companies' revenues remained in the doldrums as the DRAM market failed to recover. AMD held both ranking and revenue steady as it continued to chip away at Intel's dominant position in microprocessors, while Fujitsu entered the ranking at number 10, displacing Toshiba.

 ©1998 Dataquest

In 1998 Dataquest forecasts that the German semiconductor market will grow by 7 percent in dollar terms, double the EMEA average. In the longer term, Germany's broad electronics manufacturing base means that its semiconductor market fortunes mirror the wider EMEA marketplace. A CAGR of about 16 percent for the period 1997 to 2002 is therefore no surprise, and will put the German semiconductor market at $15.5 billion by the end of the forecast period.

Graphs of the product split for the German semiconductor market history and forecast are shown in Figures 10 and 11.

Italy

The Italian semiconductor market history and forecast is shown in Tables 16 and 17. At $1.7 billion, Italy's semiconductor market declined by 5 percent in dollar terms in 1997 over 1996, and accounted for less than 6 percent of the semiconductor billings in the EMEA region. Only the Benelux region is a smaller semiconductor market. Growth in lire terms was a modest 5 percent, as semiconductor sales continue to suffer from a lack of semiconductor-rich electronics manufacturing in the country.

Apart from some ongoing telecommunications equipment manufacturing by Italtel, the production of midrange cars and low-semiconductor-content white goods epitomizes the weakness of the Italian electronics sector for semiconductor vendors. Olivetti, once a significant PC manufacturer, shows no sign of emerging revitalized from is protracted restructuring, so prospects for the Italian semiconductor market are bleak.

Table 18 shows the top 10 semiconductor vendors in Italy ranked by sales revenue in 1997. The same 10 vendors appear in the ranking table as in 1996, although there were mixed fortunes. Siemens' performance in gaining three places to reach number seven in the ranking by growing sales almost 30 percent stands out in a year when seven of the top 10 ranked vendors saw sales decline. STMicroelectronics now ranks as the number-one vendor in Italy, because Intel's sales declined significantly as a result of Olivetti's continued demise. The lack of any PC manufacturing powerhouse in the country affected the sales of Samsung, Toshiba and Hitachi, which all experienced a decline, with NEC being the only memory vendor to hold revenue level. Recent progress by Motorola and Philips in Italy was reversed in 1997, while Texas Instruments bounced back from a significant decline in 1996.

 ©1998 Dataquest

Dataquest does not see any sign of an improvement in the Italian semiconductor market on the horizon. In 1998, the market is expected to decline by a further 6 percent in dollar terms, or 2 percent in local currency terms. Longer term, the outlook is for a continued decline in regional market share. A CAGR of 11 percent in dollar terms is expected, resulting in a 5 percent share of the EMEA semiconductor market in 2002. This CAGR is well below the European average, and will result in a market size that fails to reach $3 billion by the end of the forecast period. A graphical representation of the product split for the Italian semiconductor market history and forecast split is shown in Figures 12 and 13.

Nordic

The Nordic semiconductor market history and forecast is shown in Tables 19 and 20. Dataquest estimates that the market in the Nordic region grew by almost 8 percent to reach $2.7 billion in 1997. Local currency growth was an impressive 22 percent.

The Nordic semiconductor market is dominated by Nokia and Ericsson, which continue to gain in standing in the field of global telecommunications equipment manufacturing. As an indication of how mobile telephony has now reached a mass market, in 1997 GSM handset unit production grew by more than 100 percent, and the two Scandinavian companies are the leading manufacturers. However, in the light of a global overcapacity of all types of semiconductor products, severe price pressure has tempered the semiconductor TAM despite the phenomenal unit demand. There is also a continuing trend towards contract electronics manufacturing by Nokia and Ericsson that is in danger of shifting the semiconductor TAM progressively towards the Baltic states, although the majority of semiconductors are still procured centrally by the two OEM giants. As well as telecommunications, the region also has significant automotive production and some declining EDP activity generating additional demand for semiconductors.

Table 21 shows the top 10 semiconductor vendors in the Nordic region ranked by sales revenue in 1997. As expected, the ranking is populated by vendors that serve the mobile telecommunications sector, so those that have strong ASIC, mixed signal and power product offerings feature. Of the companies strong in mixed signal and power semiconductors, STMicroelectronics consolidated its number-one position, growing revenue by 21 percent, while Philips suffered a revenue decline of 25 percent, dropping to number four in the rankings. Texas Instruments, through a series of GSM design wins, grew revenue by almost a third, but failed to improve on its second place in the ranking.

©1998 Dataquest

Declining PC production, coupled with severe ASP erosion on flash products, hit Intel and it fell one place to third in the rankings even though growth was a healthy 36 percent. Lucent Technologies, on the other hand, was able to jump two places in the ranking as a result of a 27 percent increase in revenue. Another GSM design win beneficiary was VLSI Technology, which entered the rankings at number six. Another new entrant was National Semiconductor, which increased revenue by 22 percent to displace Toshiba in ninth spot. Along with Toshiba, the other memory vendor in the rankings is Hitachi. Both companies' SRAM products feature in GSM handsets, but this failed to prevent single-digit slides in revenue for the two Japanese vendors. Siemens also suffered a single-digit decline in revenue with its focus on fixed-line telephony infrastructure preventing it benefiting from the boom in mobile communications.

The outlook for 1998 is for growth of 12 percent in dollars, or 17 percent in local currency, as unit demand continues to boom. Dataquest is still forecasting growth in the Nordic region as the strongest within the EMEA semiconductor market, although abundant supply and OEM pressure will continue to mean severe price erosion. Therefore, the CAGR for the period 1997 to 2002 has been trimmed back to 16.5 percent in dollar terms, putting the Nordic semiconductor TAM at about $5.7 billion by the end of the forecast period. Graphs of the product split for the Nordic region semiconductor market history and forecast are shown in Figures 14 and 15.

United Kingdom/Ireland

The United Kingdom/Ireland semiconductor market size history and forecast is shown in Tables 22 and 23. In 1997, Dataquest estimates that the semiconductor TAM grew by 15 percent to almost $9 billion, ahead of Germany in second place at about $7.5 billion. In contrast with all the other regions within the greater EMEA region, the United Kingdom/Ireland local currency actually grew stronger against the dollar, which added to the dollar growth in the United Kingdom/Ireland semiconductor market. Sterling growth is estimated at about 10 percent.

The United Kingdom/Ireland region's semiconductor market is dominated by PCs. Although the DRAM market remains in decline, strong PC unit growth together with increased main memory fit meant that any adverse effect on the semiconductor market size was limited. The consolidation of PC production among the large vendors, such as Compaq and IBM, benefited the United Kingdom/Ireland region, especially in the microprocessor market, where increased units and continued healthy microprocessor ASPs fueled growth. In addition to the PC sector, the United Kingdom/Ireland region has significant mobile telephony infrastructure and handset manufacture, a sizable automotive electronics sector and a fast-growing consumer electronics segment.

Table 24 shows the top 10 semiconductor vendors in the United Kingdom/Ireland region ranked by sales revenue in 1997. While the top eight vendors maintained their ranking positions, it is interesting to note that some consolidation of market share occurred in the market. The top four vendors grew revenue sharply, while vendors ranked in positions five to eight lost market share. Of course Intel, as the dominant microprocessor vendor, remains atop the ranking with 25 percent market share and semiconductor revenue four times greater than its nearest rival Samsung, which was in second place. The South Korean company posted a revenue increase as a result of increased DRAM bit shipments and in spite of continued DRAM price erosion. Motorola and Texas Instruments were the other vendors to do particularly well, benefiting from the United Kingdom/Ireland region's non-PC electronics segments. Apart from

 ©1998 Dataquest

Samsung, the memory vendors did not fair so well. Although Hitachi's revenues were flat, the semiconductor revenues of NEC, Siemens and Toshiba all declined by a modest amount, as did those of Philips in eighth position. Finally, National Semiconductor entered the ranking at number 10 displacing IBM Microelectronics.

Although 1997 was a good year for the United Kingdom/Ireland region, the outlook for 1998 is more gloomy, with more or less flat revenue growth expected. However, longer term, the region will ride the anticipated DRAM boom cycle. A CAGR of more than 16 percent is forecast for the period 1997 to 2002, which will grow the United Kingdom/Ireland semiconductor TAM to $19.0 billion by the end of the forecast period. Graphs of the product split for the United Kingdom/Ireland region semiconductor market history and forecast are shown in Figures 16 and 17.

Rest of EMEA

Note that the TAM estimates shown for the Central and Eastern Europe and Middle East and Africa regions are for true end-market consumption and are not the same as for the other regional markets. Dataquest estimates of market sizes are normally based on sales made by semiconductor vendors, that is, first-invoice sales. These include sales made to distributors and agents that then sell on to the true end users. In the case of markets such as the Czech Republic or South Africa, the industry chooses to consider their TAM based on surveying the true end users. So, the sales opportunity visible to semiconductor vendors in these new and emerging markets is somewhat smaller than the TAM we have shown in the tables pertaining to these regions.

Dataquest expects the regions encompassed within the Rest of EMEA to grow at a rate marginally below the industry average over the forecast period. Despite a high degree of interest, particularly in the developing economies of Eastern Europe, many of these countries are still very much immature markets, with much of the electronics equipment production utilizing subassemblies coming in from outside the region.

A CAGR of 15 percent is forecast for the region as a whole for the period 1997 to 2002. Detailed forecasts are shown in Tables 25 and 26 and Figures 18 and 19. Table 27 shows the market forecast regional breakdown detail within the Rest of EMEA region.

Source: Dataquest (August 1998 Estimates)

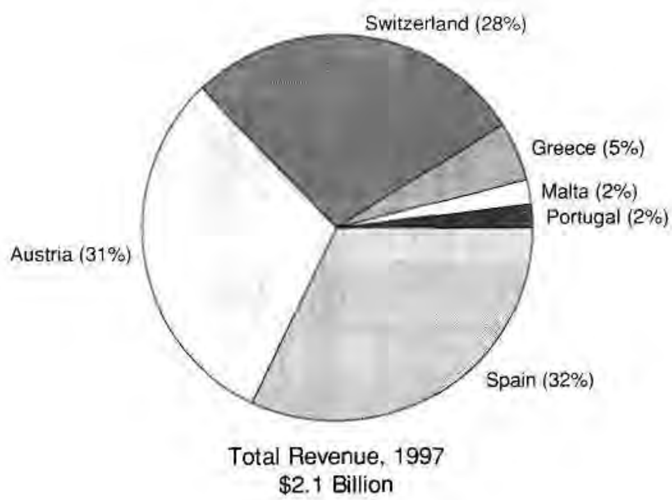
Rest of Western Europe

Within the Rest of Western Europe region there are three major countries—Austria, Spain and Switzerland—each accounting for about 30 percent of the Rest of Western Europe TAM. The remaining 10 percent or so is split between Greece, Portugal and Malta. In a definition change, Turkey is now included in the Middle East and Africa region, and the market size numbers have been retrospectively adjusted to take account of this change. A breakdown of the Rest of Western Europe TAM in 1997 is shown in Figure 20. A semiconductor market CAGR of about 15 percent is forecast for the region as a whole in the period 1997 to 2002.

Figure 20
Rest of Western Europe Total Available Market Shares, 1997

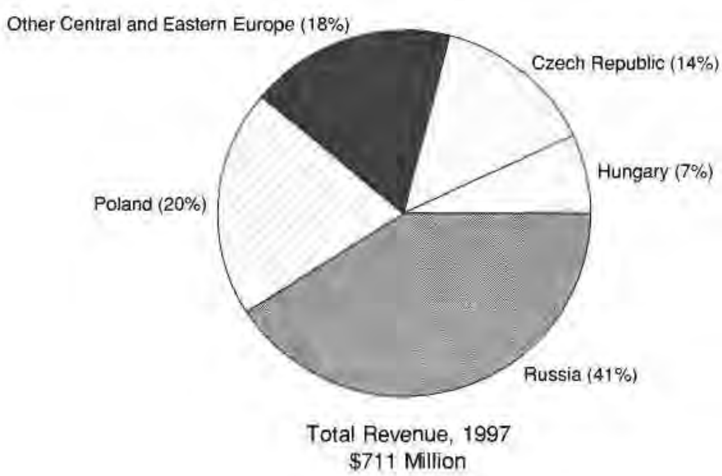


Source: Dataquest (August 1998 Estimates)

Central and Eastern Europe

A breakdown of the Central and Eastern Europe TAM in 1997 is shown in Figure 21. Of the three most developed economies in the region, namely the Czech Republic, Hungary and Poland, it is the Czech Republic that is attracting most interest from the semiconductor vendor community because of a recent increase in electronics equipment manufacturing activity. The Russian market, although full of promise for the future, has scared many semiconductor vendors away for the time being because of the unstable political situation. A semiconductor market CAGR of 14.5 percent is forecast for the region as a whole in the period 1997 to 2002.

Figure 21
Central and Eastern Europe Total Available Market Shares, 1997



Source: Dataquest (August 1998 Estimates)

Middle East and Africa

A breakdown of the Middle East and Africa region TAM in 1997 is shown in Figure 22. There are three countries within the region with measurable semiconductor markets. Israel is the largest of the three, and South Africa the smallest. In both cases, market growth has slowed because of a lack of new electronics production. The booming market in the region is Turkey, which is now included in the Middle East and Africa region rather than in the Rest of Western Europe region. Here production of consumer goods, especially televisions, has taken off in parallel with increased CEM activity in the country. An above-average semiconductor market CAGR of almost 17 percent is forecast for the region as a whole in the period 1997 to 2002.

Chapter 1
Executive Summary

Overview of Results and Key Findings

One of the most valuable insights provided by market research is that of determining customer requirements and the short-term expectations of customers. Attention paid to this information benefits both vendor and customer alike. The Dataquest European semiconductor procurement survey seeks semiconductor buyer positions and requirements, then analyzes this information to allow appropriate actions to be taken. This year, the electronic data processing (EDP) segment regained its lead as the largest purchaser of semiconductors in Europe. The use of distributors rose, together with the average number of vendors used by buyers. Unusually, inventory fell over 1997; pricing again heads the list of major issues facing buyers. However, these overall findings mask the significantly different perspectives in individual segments, reflecting the varying dynamics of each segment. The key findings are summarized as follows:

- The companies surveyed provided insight into their semiconductor purchasing needs, trends and favored suppliers. The survey sample was chosen to represent the views of the market in each segment of interest. The semiconductor spend of the 93 companies that responded was 42 percent of the entire European semiconductor market estimated spend for 1998.
- The companies estimate their spend for 1998 at $13.5 billion. This will rise to $16.5 billion in 1999.
- Unsurprisingly, the EDP segment regained the lead in the purchasing league, with $5.3 billion spent by the survey respondents in 1998. EDP respondents forecast that their semiconductor spend would increase by 32 percent in the next 12 months.
- The EDP and communications segments dominate European semiconductor procurement, together taking three-quarters of the total spend. Automotive was the third-largest group, responsible for $1.3 billion in 1998, followed by industrial at $1.2 billion. The consumer segment reported a spend of $793 million, while the military and civil aerospace segment reported $107 million.
- The five most important purchasing criteria of 1998 are the same as those of 1997, with pricing remaining the most important issue. Despite the fact that semiconductor pricing has been very attractive in 1998, buyers are facing pressure as price competition in their end markets forces them to maintain margins by reducing manufacturing costs.
- On-time delivery remains the second most important issue to survey respondents, only marginally behind pricing. This is because companies are demanding that suppliers become an integrated part of the manufacturing process—a fact that is further illustrated by the significant increase in importance of just-in-time (JIT) delivery in 1998 over 1997.
- Flexibility, lead times and availability were third, fourth and fifth in importance respectively. Again, these issues are indicative of buyers' desires to secure their supply lines and integrate delivery into the manufacturing process.
- Technical support and design-in issues were rated much higher than last year, indicating a strong demand for more support from suppliers.
- Inventory levels have fallen in 1998. The average target inventory in 1998 is 20.5 days—a decrease of 23 percent over 1997.
- Distributors accounted for $821 million of respondents' semiconductor spend. This figure amounts to 7.6 percent of the total spend.

©1998 Dataquest

- Surprisingly, the trend of decreasing the number of suppliers with which respondents do business has been reversed this year. The average number rose to levels similar to those in 1996. The average number of suppliers of all components that equipment manufacturers do business with was 73—an increase of 47 percent over 1997.
- The most common factors that cause a semiconductor supplier to lose business with the end-equipment producer are: pricing, followed by quality and delivery problems.
- The Dataquest vendor of the year awards for outstanding performances in serving customers in Europe were made to the following companies:
  - European overall vendor of the year: Texas Instruments
  - European vendor of the year for responsiveness and flexibility: Philips
  - European vendor of the year for technical support: Siemens Semiconductor
  - European medium-sized vendor of the year (European sales of less than $600 million): Fairchild Semiconductor
  - European niche vendor of the year (European sales of less than $50 million): Sharp
  - European distributor of the year: Arrow

Project Analysts: Jim Tully and Edmund Gemmell

Chapter 2
Methodology, Demographic Overview and Significance of Results

This report summarizes the results of the 1998 European procurement survey conducted by Dataquest's European Semiconductor group from March to May 1998. This section of the report describes the methodology and survey demographics and discusses the significance of the results.

This year, 93 companies took part in the survey, providing insight into their purchasing needs, trends and favored semiconductor suppliers. The survey sample was chosen to represent the views of the market in each of the segments of interest. Of this year's surveyed buyers, the semiconductor spends totaled 42 percent of the expected market of $35.6 billion in Europe, as shown in Figure 2-1. Because of this, the actions and opinions of this sample of companies closely mirror the overall market and are a sound basis on which to make decisions.

Figure 2-2 shows the dollar values of purchases made by each segment for 1997 to 1999. Forecast growth in spending by segment is shown in Figure 2-3. Growth rates for 1998 vary considerably, with 1999 having a higher growth outlook across all segments.

This year, EDP has overtaken the communications segment to head the purchasing responses, with $5.3 billion projected to be spent in 1998—in spite of flat or falling DRAM prices. This figure is 39 percent of total respondents' semiconductor spend. EDP respondents forecast that the segment's semiconductor spend will increase by one third in 1999, bringing it to slightly more than $7 billion worth of purchases.

Along with EDP, the communications segment contributed greatly to respondents' semiconductor spend. This segment was responsible for 35 percent of semiconductor spend or $4.8 billion, although growth this year is a relatively flat 1.6 percent. EDP and communications dominated the responses, jointly accounting for three-quarters of the overall semiconductor spend.

©1998 Dataquest

The automotive segment accounted for $1.3 billion with virtually no growth projected for 1998, while the consumer segment accounted for little more than half of this figure at $790 million.

The industrial segment showed the most disappointing performance of all the segments in 1998 with a fall of 12.6 percent to $1.2 billion, accounting for 8.9 percent of respondents' semiconductor spend. Military and civil aerospace also declined in reported spending in 1998 to $107 million or just 0.8 percent of respondents' semiconductor spend.

This pattern of purchases is different from the actual market distribution. Yet, these responses of spending outlook reveal more than market forecast figures. These are the *perceptions* of the respondents, based on knowledge of their own production requirements, and on their goals and expectations in terms of device prices. This means they will be second-guessing price changes in the market. In EDP a sharp increase is expected next year, presumably in anticipation of sharp rises in DRAM prices at that time. Smart cards are another major factor in the EDP segment, generating strong growth in 1998 and 1999.

In the communications segment, mobile telephony is now a significant part of the European end-equipment market and digital cellular accounts for most of the growth. Digital enhanced cordless telephony (DECT) and computer networking applications are also significant semiconductor sectors. However, in spite of the increase in production volume, price erosion has been severe and is shaping the perceptions and responses of the survey participants.

The industrial segment is powered by some large companies in Europe, and is linked to the macroeconomic conditions in the main industrialized countries of Europe. As such, growth next year (1998 to 1999) is forecast to be higher as Germany and France emerge from their relative downturns.

As digital devices creep further into consumer electronics, there are certain to be higher semiconductor purchases in the consumer segment, although this may happen beyond the scope of this report. Nevertheless, consumer companies are forecasting growth rates of about 23 percent in 1999. Digital set-top boxes are a major factor in the consumer segment; this equipment will have some impact in 1998 but the effect will be felt most strongly in 1999.

Another notable segment is military and civil aerospace. Defense budgets continue to be attractive targets for spending cuts, but as the Eurofighter 2000 program moves into full production defense electronics will rise as a percentage of the total. This, together with increased spending on military communications, helps to explain the 53 percent anticipated growth in 1999.

In the automotive segment we draw two conclusions:

- That automotive companies have prices on their minds this year, so vendors should expect some tough negotiations.
- Much of the sharp growth next year comes from car entertainment companies rather than engine control, safety or other applications. This can mean only one thing: they expect strong growth in DAB. This is a similar pattern to last year's survey, suggesting that the rise in DAB expected by the industry is delayed by one year.

Chapter 3
Procurement and Inventory Trends and Issues

This chapter considers procurement and inventory trends and issues. Where possible, the 1998 results for purchasing issues have been compared with last year's to check for changes and trends.

Procurement Issues

Each company that returned a survey was allocated to one or more end applications, then weighted to produce the results.

Each respondent was asked to rate the importance of 24 different purchasing criteria (Table 3-1). Each criterion was marked out of 10, with 1 being the least important issue and 10 the most important.

The overall survey results can be seen in Table 3-2. In Tables 3-3 to 3-8, data is analyzed by application segment. These statistics are shown graphically in Figures 3-1 to 3-7. Last year's results are included in the tables and figures to allow comparisons to be made.

Table 3-1
European Semiconductor Purchasing Trends
Semiconductor Procurement Issues, 1998

Availability of products	On-time delivery
Design-in issues	Pricing
EDI	Quality/reliability
Environmental issues	Reducing vendor base
Flexibility of vendor	Responsiveness of vendor
Fluctuating currency exchange	Second sourcing
Forecasting internal demand	Speed of bringing new products to market
IC packaging	Supplier certification/accreditation status (for example, ISO 9000)
Inventory control (for example, JIT)	Technical support
Lead times	Total cost of ownership
Long-term agreements/partnerships	Vendor local manufacturing capabilities
Obsolescence risks

The ratings given by respondents do not measure the absolute importance of each criterion. Rather they indicate those issues that occupied a greater share of mind at the time of each survey. The responses can therefore provide valuable insight into current issues from a buyer's perspective. Pricing, unsurprisingly, has remained the number-one criterion for buyers. With continued price erosion over the past year, buyers are used to the concept of a deflationary marketplace and are looking for opportunities to drive prices as low as possible.

Overall, the top five purchasing criteria have remained the same as in last year's report. On-time delivery has remained the second most important criterion, with availability of products moving down to fifth from third most important and flexibility of vendors and lead times moving up one place each.

The continued importance of on-time delivery confirms last year's observation that vendors are being increasingly integrated into the manufacturing process, and that manufacturers are expanding their expectations of vendors (while expecting continually lower pricing). In this year's survey these growing expectations are borne out by several other criteria responses. Inventory control methods (such as JIT) increased its importance rating to 7.2, an increase of 22 percent over the result in 1997. Total cost of ownership also became significantly more important to buyers, increasing to 8.2 on the buyers' importance scale.

Responsiveness of vendor and design-in issues also increased their importance significantly, suggesting that buyers are becoming much more strategic in their approach to sourcing manufacturing inputs and are expecting more added value from suppliers. Contrary to this, EDI is marginally less important this year when compared to last year's response. Lead times also remained very important to buyers this year—a strange response considering that for most products lead times generally are not an issue, although as manufacturers require more specialized components the situation is starting to change.

Segment Issues

In the EDP segment, all criteria except "other" increased their importance rating significantly. This may indicate that purchasing managers within the EDP segment are coming under more pressure from their organizations to provide a better or wider service.

Availability was the most important issue for EDP buyers, up from number five in 1997. Given the current DRAM market environment, this seems to be an unusual result; however, with noncontract pricing falling below contract pricing, it could be indicative of buyers having to take a more active role in sourcing DRAM and other components to ensure that they get the best possible price consistently. In addition, it could reflect buyer discomfort at relying on a sole vendor for key microprocessor purchasing. It could also be explained by the increasing use of PC technology in dedicated systems such as point-of-sale terminals and ATM machines. There is a life cycle incompatibility issue here that concerns a lot of people. Devices are being rendered obsolete too soon for some of these non-PC EDP applications which have a longer life cycle than PCs.

Other factors within the EDP segment are consistent with the key overall trends. Namely, integrating suppliers into the manufacturing process to reduce manufacturing costs as much as possible in order both to offset the ASP squeeze being felt throughout the PC market and to further ensure the supply chain is free of uncertainty.

In the communications segment, on-time delivery and lead times are given the highest weightings in the list. Pricing and flexibility of vendor are third and fourth in importance respectively, while total cost of ownership moved up to number five at the expense of availability of products.

 ©1998 Dataquest

The overriding importance placed on on-time delivery and lead times is likely to be a reaction to the changing customer base of the market. Before liberalization, PTTs were the dominant customers in the communications segment. Now, each country has several operators, all expanding at different rates, promoting their services at different times and requiring new products from manufacturers on a much less orderly basis than previously known.

The speed of bringing new products to market increased its importance significantly this year—a consistent trend over the past few years. Companies in this segment have tackled the issue by forming closer strategic partnerships with fewer vendors. One of the disadvantages of this approach is the problem of securing second-sourcing arrangements, particularly in ASICs—hence the 55 percent increase in importance in second sourcing this year.

The importance of most purchasing criteria within the consumer application segment grew substantially in 1998, which seems to indicate that the life of a buyer in the consumer market is becoming more difficult and which would be consistent with a market segment overcoming the issues associated with the process of digitization. Buyers in the consumer segment report an increase in importance of technical support of more than 70 percent, second sourcing more than 135 percent, quality and reliability more than 60 percent, obsolescence risks more than 85 percent and design-in issues more than 75 percent. All these issues are critical during the implementation of new technologies and new designs, the mid stages of which the consumer market is currently undergoing. In addition, the rise in importance of other issues such as responsiveness of vendor, pricing and EDI shows that buyers in the consumer segment are dealing with issues faced by the rest of the industry, such as integrating the supply chain into the manufacturing process.

Industrial segment companies are often small and are rarely viewed as strategic partners by semiconductor companies. Also, specialized components are often needed. For both of these reasons, availability of products remains the number-one concern for industrial segment companies. Unlike in all other segments, pricing is not rated highly. However, long-term agreements and reducing the vendor base have risen sharply in importance. Many industrial products are particularly affected by economic conditions in the major industrialized countries of Europe. These turbulent market conditions raise concerns about availability, lead times and on-time delivery; as such, they require special arrangements with a limited number of vendors.

As in previous years, the pricing issue was the major concern in the automotive segment, retaining its average rating of 9.8 out of 10—higher than in any other segment. Quality/reliability retained second place. Six purchasing criteria became significantly more important to buyers: second sourcing, responsiveness of vendor, on-time delivery, inventory control, EDI and supplier certification/accreditation. Most of those categories relate to the issue of guaranteeing supply. Car manufacturers are focusing heavily on reducing their cost bases in order to achieve greater margins in a more price-competitive market; they are using initiatives like creating common vehicle platforms and reducing suppliers. For those companies that have maintained their supplier status, guaranteeing delivery performance is the only way to retain their position.

Inventory

Inventory levels have consistently proved an important issue to buyer companies. In the questionnaire, respondents were asked about their present and anticipated inventory levels based on the first six months of 1998.

Overall, inventory levels have fallen since last year. The target inventory in 1998 is 20.5 days—lower than in 1997 and 1996. Curiously, Figure 3-8 shows that the average inventory level for the EDP segment has increased from 14.8 days to 18.7 days, despite the favorable pricing and availability of products in the marketplace just now. Inventory levels have fallen in all other segments except automotive.

Figure 3-9 illustrates the attitude of respondents to current inventory levels. It shows that a majority of respondents consider inventory levels to be still too high, despite the general decrease over 1997 levels. Almost 50 percent of EDP respondents feel that inventory levels are too high. Given that inventory levels in this segment have increased over 1997, this figure appears to be a little low in view of the favorable conditions for the EDP market. A clear majority of respondents in each of the other segments think that inventory levels are still too high.

Overall, looking forward to next year, companies expect to reduce inventory levels—see Figure 3-10. However, previous surveys suggest that companies often state this but rarely actually achieve it. So this should be viewed as a wish rather than a firm intention. Nevertheless, there could be major benefits for vendors that help these companies make the wish come true.

Chapter 4
Distribution Factors

This chapter focuses on issues relating to sourcing via distributors. The amount purchased via distributors varied considerably by company size and by segment.

Figure 4-1 shows both the total and distributor spend of each company surveyed, ranked in order of decreasing total spend. For example, company number 1 at the left-hand side spent approximately $2.6 billion, 10 percent of which was through distributors. By contrast, company number 93 at the right-hand side was a much lower spender and 95 percent of its spend was through distributors.

There is a general trend to increase the use of distributors as overall spend falls, although this is by no means true for every company. Even quite low-spending companies buy all their semiconductors directly. But these low-spending/low-distributor companies tend to be in the following categories:

- Divisions of larger companies, able to leverage off the purchasing muscle of their parent companies
- Specialized or focused companies whose semiconductor purchases are of a small set of components, such as memory-board companies

Overall, distributors accounted for a relatively small percentage of the total spend at almost 7.6 percent—up significantly on last year's figure of 4 percent. The distributor spend of the sample amounted to $821 million of semiconductor purchases.

Figure 4-2 shows that EDP accounted for almost $400 million of distributor spending, while communications also accounted for a significant percentage with a distribution spend of more than $200 million. Figure 4-3 illustrates that, although the EDP segment is the major distributor spender in dollar terms, it is in line with most other application segments at between 5 percent and 10 percent of total spend. Military and civil aerospace is the largest distributor spender as a percentage of total spend, with more than 30 percent of sales originating through this channel. This is consistent with the relatively low-volume, infrequent purchases made by military and civil aerospace companies, as well as with a recent trend of using standard semiconductor products rather than specially qualified parts.

Chapter 5
Supplier Assessment

This chapter focuses on the issues relating to supplier assessment—how customers view and evaluate their suppliers.

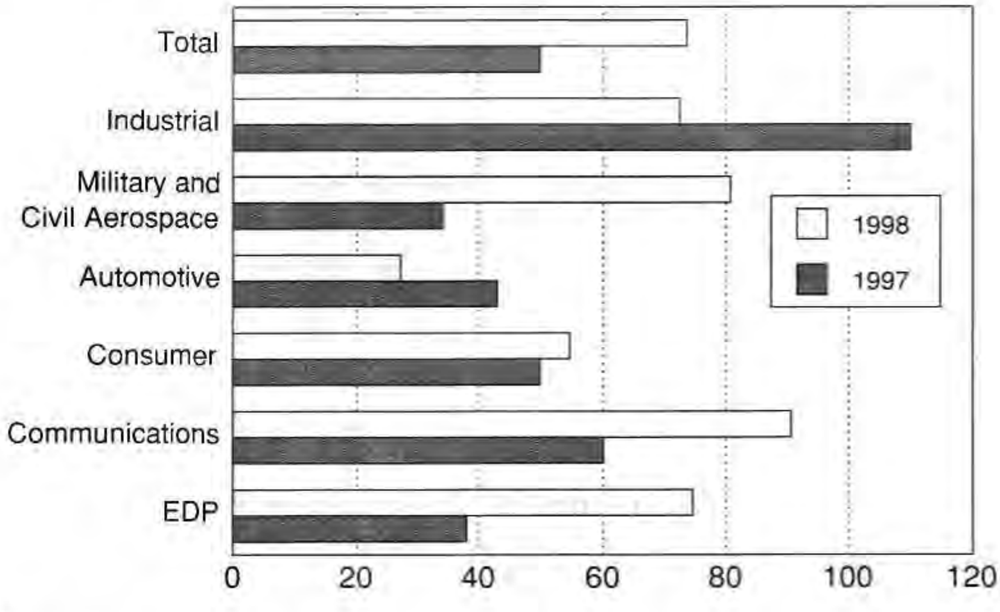
Supplier Base

Part of the survey tracks changes in the number of component vendors that respondents do business with. The key finding is that the trend has reversed and that the average number of suppliers has gone up in 1998. The only application segments that have not shown an increase in vendors are industrial and automotive. The efforts being made in the automotive industry to consolidate supply chains are mentioned earlier.

Figure 5-1 shows the number of suppliers of all semiconductor components that equipment manufacturers do business with. The average number of suppliers has grown from 50 in 1997 to 73 in 1998—an increase of 47 percent. However, this figure was skewed by a number of very high responses in the industrial and military and civil aerospace segments. Nonetheless, increases have also been registered in the number of suppliers used in the consumer and communications segments, which grew 10 percent and 50 percent respectively. In addition, there was a near doubling of suppliers in the EDP segment, which appears to have grown its supplier base by 96 percent.

Interestingly, supplier numbers in all segments except automotive have returned to levels close to those of 1996. This could mean that, having undergone supplier-reduction programs, manufacturers have found operating conditions to be unsatisfactory or supply chains too volatile, or—and perhaps more likely—that respondents are including component suppliers (rather than solely semiconductor suppliers) in their responses.

Figure 5-1
European Semiconductor Purchasing Trends
Number of Semiconductor Suppliers, 1997 and 1998



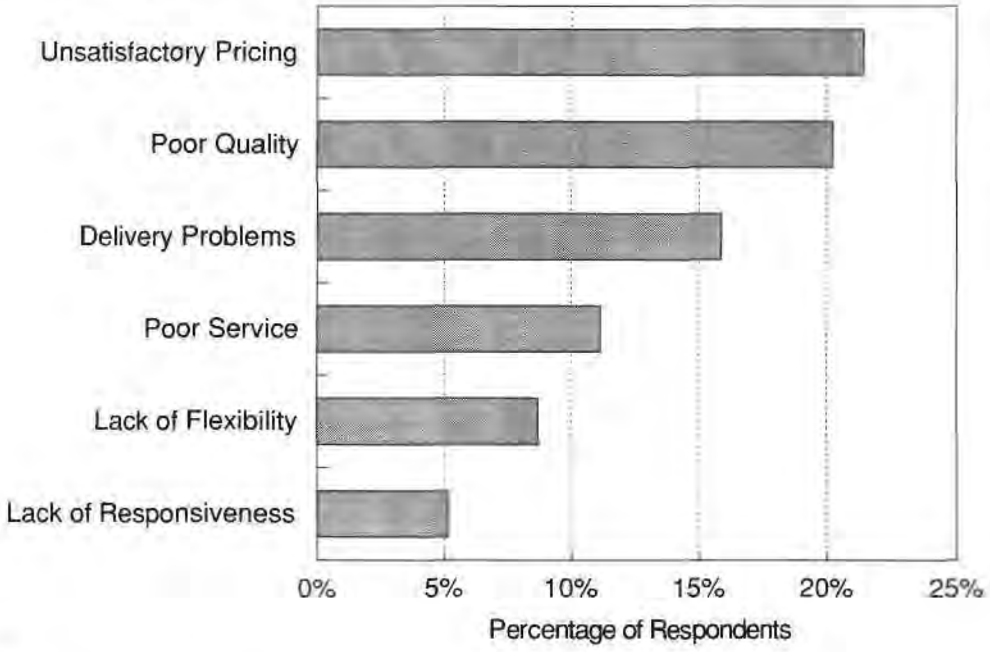
n = 93
Source: Dataquest (July 1998)

©1998 Dataquest

Figure 5-2 illustrates respondents' reasons for canceling business with semiconductor suppliers. In line with last year's responses, unsatisfactory pricing and poor quality remain the two most commonly cited reasons why suppliers lose business; both issues are mentioned by more than 20 percent of respondents.

Proof of manufacturers' desire to integrate suppliers more closely into their manufacturing process is underlined by the fact that the next four most mentioned reasons refer to unsatisfactory levels of value added by semiconductor suppliers. Delivery problems was the third most mentioned reason for losing business, followed by poor service, lack of flexibility and lack of responsiveness. To reinforce the validity of these reasons, all six appear in the ten most important criteria shown in Figure 3-1.

Figure 5-2
European Semiconductor Purchasing Trends
Reasons Why Semiconductor Suppliers Lose Business, 1998



n = 93
Source: Dataquest (July 1998)

Vendor of the Year

One of the sections in the procurement survey asks buyers to nominate their "best" vendors in a number of categories. The results are aggregated and result in a ranking of vendors in these categories. Dataquest presents the leading vendor in each category with an award in recognition of this achievement.

This year, Dataquest made awards to five companies for their outstanding performance in serving their customers in Europe. There were 77 companies nominated and these are shown in alphabetical order in Table 5-1. This was a significant increase on the 50 companies nominated in 1997.

Table 5-1

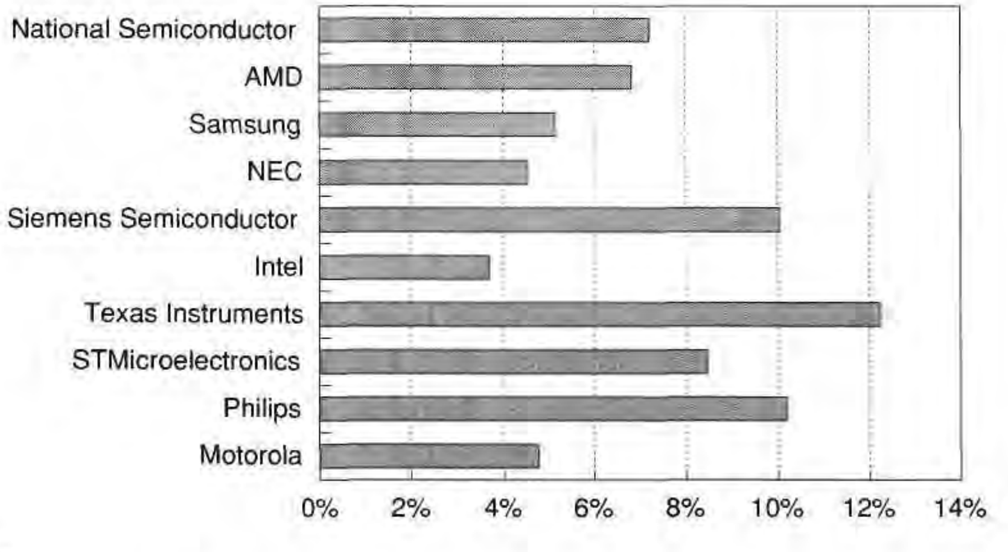
In 1998, the categories and winners are as follows:

- European overall vendor of the year: Texas Instruments
- European vendor of the year for responsiveness and flexibility: Philips
- European vendor of the year for technical support: Siemens Semiconductor
- European medium-sized vendor of the year (European sales between $50 million and $500 million): Fairchild Semiconductor
- European niche vendor of the year (European sales of less than $50 million): Sharp
- European distributor of the year: Arrow

This year's top prize was again awarded to Texas Instruments, which continued its outstanding performance of the past three years. As shown in Figure 5-3, Texas Instruments took 12.2 percent of all the votes, while Philips moved up into second place from sixth last year and Siemens Semiconductor maintained third position. National Semiconductor, which has been second over the past few years, fell to fifth, no doubt owing to its divestiture of Fairchild Semiconductor.

Figure 5-3
European Semiconductor Purchasing Trends Results of Vendor of the Year Awards, 1998



n = 93
Source: Dataquest (July 1998)

Figure 5-4 examines the votes awarded to each region's suppliers in 1998. In this analysis, distributors were not included. As in previous years, North American companies received the most nominations, gaining share from all other regions to achieve 60 percent. Japan, Europe and Asia/Pacific's percentage of nominations all decreased—Japan by 4 percent, Europe by 2 percent and Asia/Pacific by 1 percent.

However, certain European suppliers have improved their performance. Europe's three major semiconductor manufacturers are all in the top five ranking in terms of customer service. In 1997, Siemens Semiconductor was number three while STMicroelectronics ranked fourth. In 1998, Philips ranked second, Siemens Semiconductor third and STMicroelectronics fourth.

Asia/Pacific suppliers continue to lag significantly behind vendors in other regions, although the reasons for this gap are related to the comparatively small number of vendors from the region with significant presence in Europe, as well as to the commodity nature of the markets in which they participate. Japan, which lost market share, is still very close to Europe in terms of percentage of nominations received.

Chapter 6

Conclusion

Yet again we see significant differences between the current snrvey results and those of previous years. Clearly, buyer requirements and the market conditions they reflect remain volatile and subject to rapid change. The radically different findings of different segments are also significant. This is consistent with the varying business conditions ranging from high-volume, short life cycle products (such as, consumer) to low-volume, specialized long lifetime products (such as, military and civil aerospace).

One of the most intriguing questions raised by this research is the difference between survey respondents' spending plans and their resulting spend. The reasons for this are discussed earlier and are probably best explained by the differing perceptions and negotiating positions of the respondents. One factor is clear from these surveys over successive years: the short-term perspective of most of the responses. Typically, the current year's spend is understated and the next year's spend is overstated. A full year ahead is a long time in many buying organizations and therefore is difficult to predict. These factors should be kept in mind when interpreting the results of the survey and should always be compared with Dataquest's current semiconductor forecast in the segment of interest. The determination of customer requirements should always be of great interest to vendors and the procurement survey remains a prime tool for this purpose.

Survey Questionnaire

A floppy disk containing the survey questionnaire is enclosed with hard copies of this document; if you are referring to the Web, the questionnaire can be obtained from Edmund Gemmell on +44 (0) 1784 487506 or Lea Davies on +44 (0) 1784 487512.

Chapter 1
Executive Summary

Total semiconductor consumption in Central and Eastern Europe (C&EE) in 1997 was $1.8 billion. The major countries in terms of semiconductor consumption were Russia, which consumed 43 percent of all semiconductors used in the region, Poland, which accounted for 21 percent of all semiconductors, and the Czech Republic and Hungary, which consumed 9 percent and 8 percent respectively.

The dominant application market within the C&EE semiconductor market was electronic data processing (EDP), which accounted for 60 percent of all semiconductors consumed in 1997; this was a slight increase over 1996's level of 57 percent. The consumer electronics market was the next largest user of semiconductors, which accounted for 17 percent of semiconductor consumption in 1996 and 1997. The communications market accounted for 11 percent of semiconductor consumption in 1997.

Direct semiconductor shipments into the region by non-C&EE semiconductor vendors accounted for 32 percent of all consumption in 1997 and 30 percent in 1996. A major contributor to these figures was PC-related semiconductors in the form of microprocessors from Intel, AMD and Cyrix, and DRAM from various vendors. In addition to direct shipments of semiconductors by vendors, the formal semiconductor distribution channel, mostly derived from Western Europe, accounts for a further 5 percent to 10 percent of the total market.

The C&EE region's semiconductor industry is several generations of technology behind the rest of the world, and a large proportion of indigenous semiconductor companies has ceased trading, while a substantial part survives at subsistence levels. However, there are several indigenous semiconductor companies that have found niche markets, primarily in southeast Asia or at home, for their product ranges. Included in this category of company are Mikron JSC, Angstrem and JSC Voronezh Semiconductor Plant (VZPP) of Russia, as well as Kvazar Micro of Ukraine, Integral of Belarus and Tesla Sezam of the Czech Republic.

©1998 Dataquest

Chapter 2
Geographic Definition

For the purposes of this report, the C&EE region is defined as Bulgaria, the Czech Republic, Hungary, Poland, Romania, Russia, Slovakia, Slovenia, Ukraine and the Rest of Central and Eastern Europe (Albania, Armenia, Azerbaijan, Belarus, Bosnia/Herzegovina, Croatia, Estonia, Georgia, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Macedonia, Moldova, Serbia/Montenegro, Tajikistan, Turkmenistan, Uzbekistan).

In addition to this top-level categorization, a subcategorization distinguishing between Central Europe and Eastern Europe is occasionally referred to. For the purposes of this report Central Europe refers to the former satellite states of the Soviet Union and includes the Czech Republic, Hungary, Poland, Slovakia and Slovenia. Eastern Europe refers to the countries which made up the Soviet Union including Russia, Ukraine, the Baltic states and those countries which are now part of the Commonwealth of Independent States (CIS).

Chapter 3
Methodology

This document is the first Dataquest publication on the C&EE semiconductor markets, and will be followed by an update later in 1998.

The information in this report is gathered from both primary and secondary sources. Primary sources include surveys and interviews of industry vendors and customers, combined with analyst knowledge and opinions. Secondary sources include government and trade sources on sales, production, trade and public spending as well as international organizations such as the World Bank and the European Bank for Reconstruction and Development. Semiconductor content assumptions are based on both surveys of producing OEMs and teardown evaluations by Dataquest analysts of representative electronic equipment.

Accurate data concerning the sales of semiconductors is particularly difficult to obtain, given the developing nature of the C&EE electronics industry, the formal distribution channels and, importantly, the informal distribution channels. It is especially difficult to establish the value of sales at the first point of invoice. Many of the semiconductors consumed in the region are imported from other regions, in which the first point of invoice sale may already have been registered. The semiconductor typically passes through two or more levels of distribution, all of which add their margin, before it reaches the equipment manufacturer. Therefore, Dataquest's estimates of semiconductor market size are based on electronic equipment production output, data for which has been collected from various economic sources as well as Dataquest's own knowledge of certain market activities.

Unfortunately, the automotive application market has been excluded from this first report as little reliable or accurate data was available for this market segment. As Dataquest's experience in this emerging market increases, future reports will incorporate the automotive application segment.

Chapter 4

Central and Eastern Europe Overview

Introduction

Much has been written about the blossoming demand for PCs, telecommunications equipment and electronic consumer goods in the emerging electronic equipment markets of the C&EE region. This *Focus Report* analyzes this blossoming demand and assesses its effects on the indigenous manufacturing infrastructure of C&EE countries and on the demand for semiconductors, both imported and locally manufactured.

Macroeconomic Trends

After seven years of continuous decline, the C&EE region as a whole witnessed the resumption of economic growth in 1997, but the projected rate for 1997 is still fragile, at less than 1 percent. Compared with 1996, average growth is likely to slow down slightly in Eastern Europe but accelerate in the Baltic states, while economic contraction seems to have finally come to an end in the CIS. This turnaround is largely the result of the improving performance of Russia and Ukraine, with Russia likely to register its first year of positive growth. Of 26 economies in the region, 11 are expected to grow at rates of 4 percent or more in 1997. Table 4-1 shows GDP growth rates of the major C&EE economies.

Inflation has been brought further under control in most of the C&EE region. Median inflation fell from 32 percent in 1995 to a projected 14 percent in 1997. Year-end inflation in 1997 is expected to be 40 percent or less in 20 of the 26 countries, and there is now single-digit inflation in nine countries. Most cases of improvement have been in the CIS, although inflation performance has not been uniform; there have been slippages both in the CIS and in some Central European countries.

Table 4-1
Major Central and Eastern European GDP Growth Rates, 1993-1998

Country	1993 (%)	1994 (%)	1995 (%)	1996 (%)	1997 (%)	1998 (%)

In Bulgaria, the loss of macroeconomic control during 1996 and early 1997 drove the economy back into extreme inflation. Year-end inflation of 311 percent was recorded in 1996 and is projected to have reached nearly 600 percent in 1997. However, since March 1997 there has been a rapid disinflation, which was reinforced by the introduction of a currency board system in July 1997.

In Romania, inflationary pressure has built up because of high levels of government debt in the second half of 1996. Despite significant monetary tightening in 1997, inflation accelerated to slightly more than 100 percent by the year-end, following the removal of administrative price controls. Table 4-2 shows inflation rates of the major C&EE economies.

Table 4-2
Major Central and Eastern European Inflation Rates, 1993-1998

Semiconductor Market

Because of the unstructured nature of a significant proportion of semiconductor distribution channels within the C&EE region, Dataquest has calculated semiconductor consumption for the region based on the value of electronic equipment output. Electronic equipment output is taken at its most liberal sense and for the purposes of this report includes all activities resulting in finished electronic goods, including simple "screwdriver" manufacturing operations.

The benefit of using this definition derives from the relatively small amount of true manufacturing in the C&EE electronics and semiconductor markets. However, as the economies of C&EE develop, demand from the region's 400 million inhabitants will begin to be satisfied by developing domestic manufacturers using domestic raw materials, as opposed to the current solution: imports from other regions and final assembly of electronic product kits. This means that although current real semiconductor demand is relatively low, in future years the C&EE electronics industry will move into value-added manufacturing, which requires the use of semiconductor components instead of board and kit-level products. Thus, the current board-level semiconductor consumption will change to semiconductor consumption as measured in the rest of the world. Analysis of the current C&EE board-level semiconductor consumption leads to an estimate of the region's future semiconductor consumption.

 ©1998 Dataquest

An example of this type of market development can already be seen in Russia. Sistema, a holding company with companies at all levels of the production chain, has recently negotiated a deal with Ericsson to build telecommunications equipment. This equipment will not simply be the usual model of final assembly; sub-assemblies for the systems will be manufactured in Russia using Russian components where possible, thus ensuring real local content and local added value in the final product.

Using this definition of electronic equipment output, the semiconductor market of C&EE based on electronic equipment production totaled $1.8 billion in 1997. In terms of significance in Europe, this makes the entire C&EE region larger in demand than Benelux and smaller than Italy. Tables 4-3 and 4-4 show total semiconductor consumption by country and by product category respectively, based on electronic equipment production, from 1994 to 1997.

Table 4-5, which gives semiconductor consumption by application, shows that, like elsewhere in the world, EDP is the dominant market application, accounting for 60 percent of the market in 1997. This is significantly higher than the 40 percent that EDP represents in the Western European semiconductor total available market. EDP's dominance in the C&EE region is undoubtedly the result of indigenous PC manufacturers' rapid entry into the C&EE market and their success in terms of the market share they hold over imported PCs. In 1997 indigenous PC manufacturers held a 73 percent share of the four largest PC markets (Russia, Poland, the Czech Republic and Hungary), an increase from 69 percent in 1996.

Table 4-5
Central and Eastern Europe—Total Semiconductor Consumption by Application, 1994-1997
(Based on Electronic Equipment Production)

Application	1994 ($M)	1995 ($M)	1996 ($M)	1997 ($M)

Source: Dataquest (April 1998 Estimates)

Table 4-6 shows the value of semiconductor sales into C&EE by nonindigenous semiconductor vendors. This shows that true sales into the region represent approximately one-third of total semiconductor consumption in C&EE. A major contributor to this amount is the microprocessor market, whose leading participants—Intel, AMD and Cyrix—sell directly into the C&EE PC market.

If PC manufacturing were removed from semiconductor consumption based on electronic equipment production output, the value of semiconductor consumption in 1996 would have been $635.4 million, and $731.2 million in 1997. True semiconductor sales would have been approximately $160 million in 1996 and $200 million in 1997.

Source: Dataquest (April 1998 Estimates)

In addition to direct sales from semiconductor vendors into the C&EE region, a significant percentage of semiconductors sold into the region originate from semiconductor distribution companies. Their business structures typically mean that their representatives in C&EE purchase semiconductors from the Western part of the organization, which in turn purchases the semiconductors direct from the semiconductor vendors. This means that within the semiconductor vendor's reporting structure the sale is recorded as being into Germany, the United Kingdom or whichever country the distributor manages its C&EE operations from. Through distribution reporting structures, vendors typically get some feedback concerning the final destination of their products. Dataquest estimates that the distribution channel generated revenue of approximately $105 million originating from the C&EE region in 1997.

Indigenous Semiconductor Industry

Until 1991 the semiconductor industry of the C&EE region was an integral part of the Warsaw Pact defense industry. In addition, no part of the industry was exposed to competitive forces. These factors have had two primary effects on the C&EE semiconductor industry.

Firstly, items produced by semiconductor companies were limited in their range. Most products were designed primarily for military purposes, which is in itself no bad thing, given that the entire US semiconductor industry grew from the same need for defense technology. However, within the Warsaw Pact community, the innovation and access to technology which would have developed these military products for nonmilitary applications and spawned new industries were stifled in an atmosphere of mistrust and secrecy. Nonmilitary applications were largely ignored or developed with second-rate technology which was regarded as safe enough to release to the general public.

 ©1998 Dataquest

Secondly, because semiconductor companies faced no competition or commercial pressures, manufacturing technologies developed only enough to ensure sufficient supply for the defense industry and paid scant regard to manufacturing costs. The lack of competition meant no single company needed to innovate manufacturing technology in order to maintain any competitive advantage, and once a level of manufacturing technology was reached that was sufficient to meet demand, innovation tended to plateau at a less-than-optimal level. This led to wafer fabrication plants with similar levels of technology and capabilities, which, although more than sufficient for military needs, were in comparison with non-C&EE technologies several generations behind. This applied to both semiconductor manufacturing and factory efficiency technologies.

Unfortunately, once exposed to free market economics and the almost overnight demise of their traditional markets and loss of governmental support in 1991 and 1992, the structural weaknesses which characterized the region's semiconductor industry left it completely unable to compete with the rest of the world's semiconductor industries. Exposed to market forces, C&EE semiconductor and electronic equipment manufacturers could only offer products with less advanced technology and lower quality assurance levels than available elsewhere, and so were denied access to new markets that could have replaced the rapidly shrinking home markets.

In 1989 there were more than 100 semiconductor wafer fabrication plants throughout the Soviet Union; approximately six years after exposure to world market dynamics, Dataquest estimates that between 30 and 40 enterprises still maintain any sort of manufacturing capabilities. These companies range from plants surviving on tens of thousands of dollars annually to several companies with tens of millions of dollars in revenue.

Among the most commercially active C&EE semiconductor vendors are Tesla Sezam in the Czech Republic; Baneasa SA in Romania; Angstrem, Mikron, VZPP of Russia; Integral from Belarus and Kvazar Micro from Ukraine, all of which have revenues measured in millions of dollars. Table 4-7 lists those semiconductor enterprises in the C&EE region that Dataquest believes to be economically active. Table 4-8 shows details of selected wafer fabrication plants.

EDP Market

The PC market of C&EE is small when compared with that in the rest of Europe. In 1997, 3.5 million PCs were shipped into the C&EE marketplace, compared with the 19.1 million units which were shipped in Western Europe. Table 4-9 compares shipments in the two regions since 1995. Within the C&EE marketplace, indigenous PC manufacturers hold the majority of market share. In 1995, C&EE PC manufacturers held 62 percent of the region's market; by 1997, this had grown to 73 percent of all shipments. Table 4-10 shows the market split between indigenous manufacturers and importers.

The largest single market was Russia, which accounted for 41 percent of the total market and 42 percent of all indigenously manufactured PCs. In addition to Russia, the PC markets of Poland, the Czech Republic and Hungary are also significant in local terms.

Table 4-9
Central and Eastern Europe and Western Europe—PC Shipments, 1995-1997
(Thousands of Units)

Region	1995	1996	1997
Central and Eastern Europe	2,220.2	2,760.5	3,500.0
Western Europe	14,708.2	16,322.9	19,073.2
Total	**16,928.4**	**19,083.4**	**22,573.2**

Import	836.1	899.6	934.5
Total	**2,220.2**	**2,760.5**	**3,500.0**

Source: Dataquest (April 1998 Estimates)

Unlike the Western European PC market, which is more or less homogenous, the PC market of C&EE is definitely heterogeneous: each country has its own set of dominant manufacturers which serve primarily their local market. Very little exporting occurs within the indigenously produced market, because within the C&EE marketplace indigenous manufacturing consists of little more than final assembly of PC units. Motherboards and all other major function boards are imported (primarily from southeast Asia); assembly is by the cheap labor pools in each C&EE local market. Little advantage can be gained by a manufacturer in one C&EE country exporting to another, because production costs are equal and additional transport costs will be incurred. Moreover, foreign manufacturers will have little knowledge of the market dynamics that apply in other countries; C&EE PC manufacturers have little capital to invest in setting up a brand name elsewhere, and experience difficulty in setting up distribution channels.

The only true consumption of semiconductors (measured from first point of invoice) within the PC production market is the purchase of microprocessors and DRAM. In the C&EE markets the same dynamics as in the rest of the world apply.

©1998 Dataquest

Communications Market

Manufacturing

The telecommunications manufacturing environment in C&EE is characterized by joint ventures. The principal non-C&EE participants are Alcatel, Lucent Technologies, Ericsson and Siemens, all of which have joint ventures in at least two C&EE countries. For the most part, these joint ventures are final assembly plants which produce products for their local markets. This means that those non-C&EE semiconductor companies with products designed in with the major telecommunications infrastructure manufacturers already have a significant presence in the region by default. However, this presence is unseen, because only board-level kits are shipped into the C&EE region by manufacturers, although there are signs that this is gradually changing.

Cellular Telephony

Table 4-11 and Figure 4-1 show shipments of cellular handsets to C&EE. While they do not give any indication of cellular handset manufacturing in the C&EE region (which is very low), they indicate the proliferation of mobile telephony in the region, which in time will be serviced with some element of local manufacturing.

Table 4-11

Modems

At the end of 1996, the C&EE modem market was worth $76.7 million in end-user revenue, and shipments totaled 230,140 units. Shipments are forecast to grow with a CAGR of 32.7 percent by 2001 to reach more than 1.2 million units.

In 1996, Russia continued to lead as the largest market for modem products, with its share increasing by 5 percent compared with 1995. The Polish market grew significantly and accounted for 21 percent of all shipments in 1996. Figure 4-2 shows a country breakdown of the C&EE modem market, while Table 4-12 shows the leading vendors in this market.

Chapter 5
Bulgaria

Introduction

Although Bulgaria's GDP fell by 7 percent in 1997, private sector output, which represented 46 percent of the nation's GDP in 1996, fell by only 1 percent in 1997. A series of major privatizations, which began during the first half of 1997 and is expected to continue until the end of 1998, is likely to boost the private sector share of GDP even further. The telecommunications monopoly will be included in 1998's privatizations, and an adviser has already been selected.

Semiconductor Market

Unsurprisingly, the difficulties of the Bulgarian economy have fed through to the electronics manufacturing industry. Output in the electronics industry compounded its position as the smallest in Central Europe by falling by 3 percent in 1997 to $59.6 million. In terms of semiconductor equipment, this equated to $16.2 million, which makes Bulgaria the smallest semiconductor market in Central Europe. Figure 5-1 shows Bulgaria's electronic equipment production broken down by application market, while Tables 5-1 and 5-2 show the resultant semiconductor consumption broken down by application market and product category respectively.

Indigenous Semiconductor Industry

Bulgaria has three semiconductor manufacturing companies of note: Microelectronica in Botevgrad, Info Semiconductor based in Sofia and DZU in Stara Zagora. Revenue data is not available for any of these companies. Microelectronica produces MOS and bipolar semiconductors in addition to discretes.

EDP Market

The Bulgarian PC market has been hit hard by the country's macroeconomic trends. Total shipments have fallen from 45,000 in 1995 to an estimated 33,500 in 1997. Within this environment however, indigenous PC manufacturers have raised their market share from 64 percent in 1995 to approximately 72 percent in 1997. Tables 5-3 and 5-4 show the split between imported and indigenously manufactured PCs in Bulgaria as well as the top 10 Bulgarian PC manufacturers and their unit shipments in 1996.

Communications Market

Manufacturing

Since 1925, when it installed its first exchanges, Siemens has held a strong presence in Bulgaria. It has a 40 percent stake in Digicom, based in Sofia, a joint venture with Incoms Telecom Holding. Digicom produces switching and transmission equipment, and in 1993 built Bulgaria's first digital telephone exchange in Varna on the Black Sea. The Bulgarian Telephone Company, the state monopoly, participates in five joint ventures that manufacture telecommunications equipment.

Cellular Telephony

Mobikom operates an NMT-450 service in Bulgaria, for which Ericsson supplies the infrastructure. Mobitel, 49 percent of which is owned by Cable & Wireless, provides a GSM service, for which Siemens supplies the infrastructure. Table 5-5 shows total cellular handset shipments to Bulgaria between 1993 and 2001.

Table 5-5
Bulgaria—Cellular Handset Shipments, Average Selling Price and Revenue, 1993-2001

	1993	1994	1995	1996	1997	1998	1999	2000	2001

Average Selling Price ($)	1,322.7	1,200.0	1,002.1	842.3	614.9	451.7	364.5	312.6	277.0
Total Revenue ($M)	0.9	7.1	14.0	18.1	17.5	21.7	25.0	29.9	37.7

Source: Dataquest (April 1998 Estimates)

Consumer Market

For political reasons, the Bulgarian cable television industry has been much slower to develop than in other C&EE countries. Although the government has been awarding operational licenses since the end of 1994, few cable television operators have started to construct networks or offer services. A total of 100,000 homes were estimated to be connected to cable at the end of 1996.

The leading Bulgarian cable television operators are Union Television and Globo Sofia Cable. Union Television has been awarded licenses for at least 16 locations and plans to link about 15 percent of the country's television-owning households by cable. Globo Sofia Cable won licenses to operate in five cities, including Sofia, with a planned total investment in network development of $39 million. Globo Sofia Cable offers up to 35 channels, including its own 24-hour service.

 ©1998 Dataquest

Chapter 6
Czech Republic

Introduction

Long considered, along with Poland, to be the leading country in the transfer to free market economics, the Czech Republic is now at a crossroads. Economic growth has slowed, export growth has stagnated and imports have risen considerably on the back of consumer demand. In addition, domestic inflation is running at a two-year high of 10 percent, unemployment is increasing and, despite a public-sector wage freeze for 1998, wages continue to rise, meaning private consumption continues to increase faster than domestic production. Growth in 1998 is expected to remain weak. Despite these economic difficulties, the electronic equipment production industry continues to grow and add value to the economy.

Semiconductor Market

The Czech Republic has the second-highest semiconductor consumption level in Central Europe (behind Poland), and the third-highest consumption level in the region (behind Russia and Poland). Within the former COMECON framework, the Czech electronics industry was technically advanced. Since the postliberalization market upheaval of 1992 and 1993, when significant numbers of electronics enterprises ceased trading, the Czech electronics industry has made a fast recovery and grew by more than 84 percent between 1994 and 1997. The semiconductor market of the Czech Republic has continued to grow in line with the electronic equipment industry during the difficulties of past years. Electronic equipment production in the Czech Republic grew by 22 percent in 1997, which led to an increase in semiconductor consumption of 19 percent in the same year. Figure 6-1 shows electronic equipment production by application in 1997, while Tables 6-1 and 6-2 show the Czech Republic's semiconductor consumption by application market and device category respectively.

Within the Czech Republic an important part of the production capacity of the electronics industry is concentrated in the greater Prague area. Other traditional areas of electronics production are in north and central Moravia and in east Bohemia. Almost two-thirds of the country's electronic equipment production is found in these four areas.

Indigenous Semiconductor Industry

Tesla Sezam in the Czech Republic is possibly the most well-known semiconductor company in the C&EE region. The Roznov-based company has been working with Motorola since 1994 on a foundry basis, producing bipolar analog ICs and transistors solely for the American corporation, which now owns 57 percent of Tesla Sezam. Revenue for 1997 was $15.1 million, which represented an increase of 60 percent over 1996's revenue.

In addition to Tesla Sezam, the Czech Republic is also home to design house ASICentrum, formerly the microelectronic division of Tesla Vust, which was established in 1978. The division's first ASICs were designed in 1986. ASICentrum became a privately owned company and restarted operations in December 1992.

Tesla Vrchlabi was a discrete power semiconductor manufacturer; now in partnership with Optrex, it makes LCDs which are sold worldwide to companies including Lucas, BMW, Philips and Blaupunkt.

EDP Market

In 1997, the EDP application market accounted for 28 percent of Czech electronic equipment production and 55 percent of semiconductor consumption. In line with the other countries in the C&EE region, PC manufacturing in the Czech Republic consists of little more than the final assembly of PC kits shipped primarily from southeast Asia. Within the Czech Republic, local PC manufacturers have the dominant share of the market, shipping 157,400 units, or 62.2 percent of the total market, in 1997.

The major Czech PC manufacturers are AutoCont, Brave and Vikomt, which hold approximately 30 percent of the indigenously produced PC market between them. In addition, Elko provides final assembly for IBM's PC 100 and PC 300 computer ranges, initially set at 1,500 units per month. H&J Computers has a similar final assembly contract with Unysis for approximately 1,000 PCs per month. Table 6-3 shows the split between indigenously manufactured and imported PC shipments, while Table 6-4 shows the top 10 indigenous manufacturers in 1997.

Communications Market

Manufacturing

During the Communist era, the Czech electronics industry suffered from state bureaucracy and a lack of investment. Measures were taken to provide greater independence for these enterprises, known as Tesla, as far back as 1989. These measures were aimed at promoting exports, and the latitude established by the measures were a precursor of later reforms, when a number of joint ventures were established, including the following:

- Tesla Trebohosticka (Research Institute) and Marconi
- Tesla Hloubetin and AT&T (later Lucent Technologies)
- Tesla Karlin and Siemens

The Tesla and Lucent Technologies joint venture distributes telecommunications equipment; Lucent Technologies also holds the majority share in Telenet, a distributor of telecommunications products.

 ©1998 Dataquest

Siemens has been present in the Czech Republic for more than 100 years. During the past five years, Siemens has invested $150 million, with another $42 million earmarked for investment until the end of the century. Siemens, operating as Tescom with its main base in Prague, employs in excess of 7,500 people at 12 sites. Tescom became a wholly owned subsidiary of Siemens in mid 1994 when the old Tesla units were restructured into regional operating centers. The company faces a major challenge in producing high-quality digital equipment on order to supply the modernization program of SPT, the privatized Czech PTO.

Cellular Telephony

EuroTel Praha provides the Czech Republic with an NMT-450 and a GSM service for which Nokia supplies the infrastructure. EuroTel Praha is 24.5 percent owned by U S WEST and 24.5 percent owned by Bell Atlantic. RadioMobil, which is part owned by DeTeMobil, provides a GSM service with Motorola infrastructure. Table 6-5 shows cellular handset shipments to the Czech Republic.

Table 6-5
Czech Republic—Cellular Handset Shipments, Average Selling Price and Revenue, 1993-2001

	1993	1994	1995	1996	1997	1998	1999	2000	2001

Source: Dataquest (April 1998 Estimates)

Consumer Market

The Czech cable television industry is well developed, with a penetration rate of 14 percent and about 580,000 households connected to cable by the end of 1996. Since 1993 a number of small, privately owned cable companies have been building their own networks. The Association of Czech Cable and Telecommunications Network Operators represents the interests of more than 30 of these operators.

The major investor in the Czech cable television industry is U S WEST, which originally purchased a 28.6 percent stake in Cable Plus in May 1995. It raised its interest to 57.5 percent in June 1996, and then increased its stake to nearly 94 percent in October 1996. Cable Plus is the largest cable television operator in C&EE, with some 424,000 customers in September 1996. By April 1997 the number of subscribers had grown to 435,000. Cable Plus has more than 1.6 million homes in its franchise areas in both the Czech Republic and Slovakia. The operator's nearest competitor, Codis, had approximately 55,000 customers at the end of 1996. The next largest competitor is Dattel, which had 15,000 subscribers in January 1997.

The Czech consumer electronics market has had several high-profile inward investments. In 1996, Panasonic created a $66 million subsidiary called Matsushita Television Central Europe s.r.o., which manufactures Panasonic televisions in Pilsen, west Bohemia. Initial production of 300,000 units per year began in 1997; full capacity will be 1 million units per year, requiring 1,500 employees. Denon Consumer Electronics has transferred a $550,000 subassembly facility from Nettetal in Germany to Liberec in north Bohemia.

©1998 Dataquest

Chapter 7
Hungary

Introduction

Following the low of 1992, when Hungary experienced many of the problems common to the rest of the region, the country has made a sustained recovery. In many respects Hungary has taken the slow and steady route to free market transformation. Private enterprise's contribution has risen from 58 percent in 1993 through successive increases to 78 percent in 1997, while GDP has grown year on year since 1994 to a projected 4 percent growth rate in 1998, the third-highest in the C&EE region.

Semiconductor Market

The electronic equipment production market of Hungary is only marginally smaller than that of the Czech Republic. In 1997 electronic equipment production grew by 7.5 percent to $902.5 million. During the four years since 1994, total electronic equipment production growth of 52 percent has been recorded against a background of approximately 9 percent GDP growth, indicating that electronic equipment production is a driving force behind Hungary's economic development.

Figure 7-1 shows the breakdown by application category of 1997's electronic equipment production statistics. Similar to the Czech Republic, industrial goods form a substantial part of manufacturing output, while EDP plays an unusually small role in the country's production output. Tables 7-1 and 7-2 show the resultant semiconductor consumption by application market and device category.

Indigenous Semiconductor Industry

Melcom and Intermos Microelectronics, both based in Budapest, represent the semiconductor industry of Hungary. Melcom started in 1970, manufacturing power transistors. Melcom's revenue of approximately $110,000 is generated primarily by sales in Hungary and Romania; the company also carried out assembly, test and packaging operations for TEMIC, with which it worked closely.

EDP Market

In 1997, the EDP segment accounts for 12 percent, or $109 million, of the Hungarian electronic equipment production market. The leading Hungarian PC companies are Albacomp and Muszertechnika, which hold almost 40 percent of the indigenous PC market between them, and almost 20 percent of the entire PC market in Hungary.

Albacomp was established in 1985 by the staff of Videoton Holding. In 1996, Albacomp employed 150 staff and had a $2.4 million revenue. Muszertechnika was established in 1981. A trading group with nearly two dozen companies, Muszertechnika's turnover in 1996 was $35 million.

 ©1998 Dataquest

The Hungarian PC market grew by 13 percent in 1997 to $140.2 million. Indigenous manufacturers held marginally more than 50 percent of the market, 3 percent lower than their market share in 1996. With the exception of the top two indigenous vendors, Hungarian manufacturers held only small market shares; only one other company—Ready Computers—exceeded 2,000 unit shipments in 1997. Table 7-3 shows the split between indigenous and import-based shipments; Table 7-4 ranks the top 10 indigenous PC manufacturers in 1997.

Table 7-3
Hungary—PC Shipments by Source, 1995-1997
(Thousands of Units)

One of the most significant foreign investors in Hungary is IBM, which launched production of hard drives in its Szekesfehervar factory in 1995. The factory's turnover in 1996 was $300 million, making IBM Storage Products Ipari Vamszabadterulet Kft. the ninth-largest domestic company in Hungary.

Nokia started assembling monitors in Pecs in 1996. Initial annual production was 100,000 units; in 1997 an increase to 500,000 units was planned. Nokia's initial investment to purchase the incumbent Hantarex Monitorgyar company was $30 million.

In 1997 Philips commenced production at its new $20 million monitor assembly factory in Szombathely. Initial plans were for 1 million units per year.

SCI Systems Inc. plans to build a 9,000 m^2 factory in Tatbanya. The $5.8 million plant will produce electronic goods for the Hungarian market, Central and Western Europe.

 ©1998 Dataquest

Communications Market

Manufacturing

Siemens has invested $41 million in a wholly owned subsidiary, Siemens Telefongyar, based in Budapest, which has been producing switching and transmission equipment since October 1992. Siemens also has a cable-manufacturing joint venture that operates under the name of Dunakabel.

Ericsson Technika is a joint venture between Ericsson and the Hungarian company Muszertechnika that manufactures telephone exchanges. Ericsson has delivered more than one million AXE lines to Hungary, gaining the vendor approximately 45 percent of the market.

AHT Communications Ltd. is a Budapest-based joint venture founded in 1990 to manufacture Alcatel business telephone exchanges. Alcatel owns 96.23 percent and Comex owns 3.77 percent of the company. Nortel also has a local operation in Hungary.

Siemens and Ericsson dominate the fixed line telecommunications market on the basis of a five-year supply contract with Matav that ended in 1996. The two vendors will continue to dominate the market as only their equipment type has the requisite approvals.

The vendors that set up local companies have positioned themselves strategically so that they would be able to meet the requirements placed on operators by their concession agreements which stipulate that in the future an increasing proportion of new telecommunications infrastructure has to be supplied by local vendors. Matav already claims to source 50 percent of its equipment requirements in Hungary.

Cellular Telephony

Westel, which is 49 percent owned by U S WEST, provides Hungary with NMT-450 and GSM services. Infrastructure for these is supplied by Nokia, Motorola and Ericsson. Pannon GSM's infrastructure is supplied by Nokia. Table 7-5 shows handset shipments to Hungary between 1993 and 2001.

Table 7-5
Hungary—Cellular Handset Shipments, Average Selling Price and Revenue, 1993-2001

	1993	1994	1995	1996	1997	1998	1999	2000	2001

Consumer Market

The Hungarian cable television industry is among the most advanced in C&EE. The market is served by about 200 cable operators, some of which are also program providers. One of the more active operators is Kabelkom, a joint venture between Time Warner and United Communications International. Kabelkom rapidly entered into joint ventures with operators in nine Hungarian cities, one of which was with Monor Group Telecom to implement a pilot cable television/telephony project in the town of Monor. In October 1996 this joint venture, called Monor Telefon Tarsasag (MTT), offered services to about 38,000 households. By the end of 1996, investment into this network totaled $90 million. MTT expects to have 40,000 cable subscribers and 80,000 telephone lines by 2000.

Chapter 8
Poland

Introduction

Poland is the largest of the transitional economies in Central Europe and is second only to Russia in the C&EE region. Since 1992, Poland has consistently shown one of the highest GDP growth rates of any of the transitional economies, growth that is set to continue at more than 5 percent per annum into 2000. However, Poland also has endured consistently above-average inflation rates. The present economic environment is characterized by expanding growth with no related reduction in unemployment, which stood at 10.6 percent in September 1997. Consumer consumption is increasing, fueled by real wage growth and a widening trade deficit, which approached 4 percent of GDP in the first half of 1997. The Polish economy is very close to overheating.

Semiconductor Market

The Polish electronic equipment production market is by far the largest in Central Europe. At almost $2 billion in 1997, it was larger than the combined electronic equipment production output of the Czech Republic and Hungary, and two-thirds of Russia's output.

The three major application markets are EDP, communications and the consumer sector. The EDP market, which is dominated by indigenous manufacturers, accounted for almost 53 percent of semiconductor consumption in 1997, while the communications market accounted for approximately 18 percent.

All aspects of the Polish electronic equipment manufacturing industry are more commercially developed than their C&EE counterparts. For example, in the Polish telecommunications market, the government has only offered type approval to those non-C&EE companies that have invested in local manufacturing companies. This may be seen as protectionist, but it has ensured the survival of the local manufacturing base. Figure 8-1 shows the Polish electronic equipment manufacturing industry broken down by industry, while Tables 8-1 and 8-2 show semiconductor consumption by application and device category respectively.

Indigenous Semiconductor Industry

Poland has two semiconductor manufacturing companies—ITE and Lamina Semiconductor International. ITE has a 3-micron plant capable of CMOS ASIC manufacture. Data on Lamina Semiconductor International is not yet available. The Institute of Electron Technology in Warsaw has set up an ASIC design center which participates in the Eurochip consortium.

EDP Market

Like many other aspects of the Polish economy, the Polish PC market is the second-largest in the C&EE region, behind only Russia. Russia is also the only market which is more dominated by indigenous manufacturers; in the Polish PC market, indigenous manufacturers accounted for more than 70 percent of 1997's shipments.

The largest local player was Optimus which held 26 percent of the indigenous PC market and more than 18 percent of the total market. The nearest local competitors were JTT and NTT, which each held 8 percent of the indigenous PC market and 6 percent of the total market. Tables 8-3 and 8-4 provide details of shipment origin and indigenous market ranking.

Communications Market

Manufacturing

In October 1992, AT&T (later Lucent Technologies) acquired Telfa, Poland's only digital exchange manufacturer, and has since brought the company's two manufacturing sites up to international manufacturing standard. Future plans envision the manufacturing of Lucent Technologies 5ESS switches. The company has been present in the Polish market since 1992 and is Poland's main switch manufacturer. Recently, it has further expanded its operation to five main subsidiaries.

In 1993, the Polish government awarded the sale of four out of five state-owned Polish telecommunications equipment manufacturers to Alcatel Alsthom and Siemens. In this way, these two companies joined Lucent Technologies as Poland's major equipment suppliers, with a virtual guarantee of all government business for the next few years.

Alcatel has been present in the Polish market for 20 years and in 1990 established its first two joint ventures. In March 1993 Alcatel SESA acquired Teletra and PZT Telekom, which were both profitable operations. Alcatel plans to retool the companies for the production of Alcatel 1000 and S-12 switches.

Siemens has been operating in the Polish market since the mid 1980s, and in 1991 entered into a joint venture. Initially $1.5 million was invested to upgrade local manufacturing capacities and a new plant began operation in 1993. CEWIS, a joint venture between Siemens and the Warsaw-based PBX manufacturer ZWUT, produces Siemens EWSD Switches. ZWUT also has supply agreements with Samsung and Italtel.

Alcatel, Lucent Technologies and Siemens are the only manufacturers to gain full type approval as switch manufacturers. According to the Polish ministry of communication's proposals, the current exclusivity accorded to these foreign suppliers to the Polish market may be extended for another three years.

Other joint ventures include: DTS-ZWUT, a joint venture between ZWUT and US-based Arnica that manufactures and sells PBXs; Nortel Elwro is a joint venture which manufactures DMS-10 central office switches; the company has a capacity of up to 50,000 lines per year. Kapsch, the Nortel Austrian licensee, also collaborated with Elwro to produce the ADS-100 product.

Cellular Telephony

Poland's GSM services are provided by Polska Telefonia (which is part-owned by U S WEST and DeTeMobil) and Polkomtel (which is part-owned by Tele Danmark and Air Touch Communications). Ericsson and Nokia supply the infrastructure for these services. In addition, Centertel offers an NMT-450 service, for which Nokia, Alcatel and Ericsson provide the infrastructure. Table 8-5 shows handset shipments to Poland.

Table 8-5
Poland—Cellular Handset Shipments, Average Selling Price and Revenue, 1993-2001

	1993	1994	1995	1996	1997	1998	1999	2000	2001

Source: Dataquest (April 1998 Estimates)

Consumer Market

Poland ended 1996 with the most developed and competitive cable television market in C&EE, with some 2.35 million subscribers. Poland's largest cable operator, with approximately 350,000 subscribers nationally at the end of 1996, is PTK, which was launched in 1990. PTK is planning to enter the cable telephony market. Its position has been strengthened by an $8 million credit from overseas agencies in 1995, a $63 million investment from the equity firm Advent International and a corporate bond issue of $130 million in early 1996. PTK's biggest rivals are Porion and Aster City, both in Warsaw, Gosat in Wroclaw, and Dami in Radom, all of which had a combined subscriber base of 340,000 in November 1996.

Thomson Consumer Electronics has invested $35 million in 51 percent of Polkolor Piaseczno to manufacture television sets, while US-based Curtis has invested in a television set production plant in Mlawa.

Chapter 9

Romania

Introduction

In Romania, 1998 is expected to be a year of recovery after a year of macroeconomic deterioration. Inflation in March 1997 stood at 31 percent per month; by October it had fallen to 6.5 percent. For 1998, an annual inflation rate of 145 percent is forecast, despite the government's attempts at economic "shock therapy." Industrial output for 1997 fell 1.5 percent, although this is expected to be regained in 1998.

A significant amount of Romanian industry is still in state hands, and 74 percent of industrial GDP was generated by the state in 1997. Although unemployment is still relatively low, this is because a large number of state-owned enterprises remain unrestructured, and increasing unemployment is expected as restructuring commences.

Semiconductor Market

The Romanian electronic equipment production market is less than half the size of the Czech market or the Hungarian market. This is primarily because of a small EDP sector and almost nonexistent communications sector. Despite the economic difficulties Romania has experienced, electronic equipment production has continued to grow. In 1997, the market was $433 million, achieving 14 percent growth over 1996. Since 1994, electronic equipment production has grown by almost 50 percent. Semiconductor consumption has grown even faster: related semiconductor consumption grew by 22 percent in 1997 and has grown by 75 percent since 1994. This is largely thanks to the indigenous EDP sector, which, although small, grew by more than 30 percent in 1997—the fastest growth rate for any semiconductor application segment in Romania. Figure 9-1 shows Romanian electronic equipment production broken down by industry application; Tables 9-1 and 9-2 show semiconductor consumption by application and device category respectively.

Indigenous Semiconductor Industry

Romania has three principal semiconductor manufacturing companies: Baneasa SA, Romes SA and Microelectronica SA.

Baneasa SA, the largest of the three companies, is primarily a supplier of discrete devices to the automotive and consumer market segments. The company achieved revenue totaling $6.7 million in 1997, which was 17 percent higher than in 1996. Of 1997's revenue, 43 percent originated from outside the C&EE region, compared with 39 percent from outside C&EE in 1996.

Romes SA, the second-largest semiconductor company in Romania, also produces discrete and optical semiconductors. Its revenue in 1997 was $190,000, which represented an increase of 31 percent over 1996's revenue. Approximately 80 percent of the company's revenue is generated within the Romanian marketplace, while the remainder comes from sales to companies in Germany, Holland and Belgium.

Revenue data is not available for Microelectronica SA, which has CMOS capabilities and also produces optoelectronics.

EDP Market

Although the Romanian PC market is one of the less significant PC markets in C&EE, indigenous PC manufacturers are performing well in their market. In 1997 Romanian PC manufacturers raised their market share by 5 percent to 60 percent of the total PC market, and shipped more units in the Romanian market than their indigenous counterparts in the Slovakian market, even though the total Slovakian PC market is 17 percent larger. Table 9-3 shows indigenous PC manufacturer market share in Romania, while Table 9-4 ranks the country's largest PC manufacturers.

Table 9-3

Communications Market

Manufacturing

Telecommunications equipment production is moving slowly from the state toward the private sector. At present, the largest enterprises are the joint ventures between Rom Telecom and foreign investors. Electromagnetica, the dominant manufacturer, produces the majority of Romanian telecommunications equipment. In conjunction with Siemens and Gold Star, the company's Emcom and Gold Star Electromagnetica joint ventures are changing production from electromechanical Pentaconta switches to digital systems.

Alcatel Network Systems Romania is another major joint-venture supplier. The company, which manufactures E10B exchanges, has Alcatel CIT as its main shareholder (51 percent), as well as IFC (10 percent), and the Romanian-based Data Tim (32 percent), Rom Telecom (6 percent), IIRUC (1 percent) and Promotion Group Romania (1 percent).

Emcom manufactures EWSD switches. Siemens is its main shareholder; the remaining shareholders are the EBRD, Electromagnetica and Rom Telecom.

Cellular Telephony

Romania's only GSM operator is Mobifon, which uses infrastructure provided by Ericsson. Telefónica Romania offers an NMT-450 service, for which Ericsson again provides the infrastructure. Table 9-5 shows statistics for handset shipments in Romania.

Table 9-5
Romania—Cellular Handset Shipments, Average Selling Price and Revenue, 1993-2001

Chapter 10
Russia

Introduction

Russia appears to be turning the economic corner. Year-on-year industrial output stopped falling for the first time since the collapse of the Soviet Union, increasing by 0.5 percent in 1997 and is set to increase by 3 percent in 1998. However, investment in the Russian economy continues to fall, which could hold serious problems for future GDP growth. In the first nine months of 1997, investment in the Russian economy fell by 7.1 percent compared with 1996's level.

Inflation was brought under control in 1997. Inflation in 1994 was 214 percent, by 1996 it had been reduced to 22 percent and in 1997 the figure was almost halved to 14 percent. Projections for 1998 show a slight rise to 17 percent because of the effects of increasing GDP on consumer demand. Foreign direct investment also has remained stubbornly low in Russia—less than 1 percent of GDP, apart from modest increases in 1996 and early 1997.

An interesting feature of the Russian transitional economy is the emergence of barter as a method of trading within industry. Although not very common in the rest of C&EE, it is now widespread in Russia. The EBRD estimates that as much as 40 percent of industrial sales are by way of barter. This is a problem for Russia in several respects: most barter transactions end up as part of the unofficial economy and therefore detract from tax revenue, which is already insufficient to cover public expenditure and is poorly administered and collected. Barter prevents the development of credit and capital markets, and, because it is a method of trade that most Western enterprises will not entertain, the prevalence of barter in the economy could be a cause of the low levels of foreign direct investment.

Semiconductor Market

Despite the continuous decline in Russia's GDP until 1997, the electronic equipment production market has been one of the factors driving economic recovery. Although the electronics industry virtually collapsed in 1992, by 1994 it had recovered to $2.3 billion. In 1997 the electronic equipment production market had grown to $3.1 billion, having achieved growth of 20 percent over 1996 and total growth of 36 percent since 1994.

Given the sheer size of Russia it is unsurprising that it has the largest electronic equipment production market in the C&EE region. Russia accounted for 38 percent of the C&EE region's electronic equipment production output in 1997. In terms of semiconductor consumption, Russia consumed 43 percent of the semiconductors used in C&EE in 1997.

The PC market is the dominant driver of the Russian electronic equipment market. In 1997, Russia accounted for 41 percent of the total C&EE PC market and 42 percent of all PCs manufactured in the C&EE region. In 1997, the Russian EDP market manufactured goods worth $1.7 billion—56 percent of total electronic equipment production in the country. This was 39 percent more than was produced in 1996 and 121 percent more than in 1994. Figure 10-1 shows electronic equipment production broken down by industry application, while Tables 10-1 and 10-2 show semiconductor consumption by application and device category respectively.

Indigenous Semiconductor Industry

Mikron JSC

Mikron JSC, based in Zelenograd, is Russia's largest semiconductor company, and was founded in March 1964. Upon privatization it inherited the state's national microelectronics research center, which became its R&D facility. Mikron JSC currently manufactures primarily bipolar digital components, SRAM and ASIC devices with up to 500,000 gates, along with MOS digital logic and discrete products.

Mikron JSC recently completed a new fabrication plant with Hong Kong's Hua Ko Electronics for the production of 0.8-micron CMOS technology on 6-inch wafers. Production is being brought online with a monthly capacity of 10,000 wafers per month. The company is planning to develop an 0.5-micron, 8-inch wafer fabrication plant which would ramp up to volume production in 2000. The investment for this project is estimated at $250 million, in addition to the $60 million spent on the first plant.

In 1997, more than 90 percent of Mikron JSC's revenue was generated outside the C&EE region. China/Hong Kong is the company's primary market; the United States accounted for a significant 28.5 percent of revenue in 1997.

Within the C&EE region, Mikron JSC's two largest markets are Ukraine and Belarus. However, this may change during 1998: Sistema, Mikron JSC's parent group, has entered a joint venture with Ericsson to produce base stations, and Mikron JSC will be designing some of its components into the system.

Angstrem

Angstrem is Russia's second-largest semiconductor company. Angstrem is based in Zelenograd too, and also faced a complete loss of its marketplace in 1992, when the Russian electronics industry faced a crisis of meltdown proportions. Since then, Angstrem has made a remarkable recovery and now conducts most of its business—8-bit and 16-bit microcontroller products—in southeast Asia.

 ©1998 Dataquest

Angstrem has two fully operational wafer fabrication plants: a 1.5-micron, 4-inch CMOS technology facility with capacity for 30,000 wafers per month, and a 1-micron, 6-inch wafer plant producing 3,000 wafers per month. The second fabrication plant is being ramped up to a capacity of 12,000 wafer starts per month with geometries reduced to 0.8 micron. In addition, Meistner & Wurst has recently completed a new plant for Angstrem, which will handle 20,000 8-inch wafer starts per month with a geometry of 0.5 microns.

Angstrem's microcontroller product lines are shipped primarily to southeast Asia, which accounted for approximately $20 million of the company's revenue in 1997.

VZPP

Unlike Mikron JSC and Angstrem, VZPP's main semiconductor market is the C&EE region. VZPP had total sales of $8.3 million in 1997, down significantly on 1996's level of $10.3 million. In 1997 only 7 percent of the company's sales originated outside the C&EE region.

Within the C&EE region, VZPP exports to seven countries, making it the most significant indigenous company in the region. Sales within Russia were $6.1 million in 1997, down from $7.5 million in 1996.

VZPP's primary product offerings are in the discrete category, mostly power related, and accounted for slightly more than half of its 1997 revenues. In addition, VZPP gained significant amounts of its revenue from bipolar digital products, as well as approximately $500,000 from MOS digital product offerings. As would be expected from a manufacturer of discrete products, VZPP's sales fall into most application categories, with EDP representing its smallest market.

Elex

Russia's fourth-largest semiconductor company is Elex, based in Alexandrov in the Vladimir region. Elex manufactures analog and discrete semiconductors, gaining $526,000 of revenue in 1997—a fall of 24 percent over 1996's level of $690,000. The major reason for the fall in revenue was a loss of market in Western Europe and the C&EE region. To compensate for the decline, Elex raised its exports to China/Hong Kong by 45 percent to $234,000 in 1997; exports to Singapore and Taiwan also grew, increasing to $143,000.

Other Companies

Of the surviving semiconductor companies in Russia, Dataquest believes the following are the most economically active:

- Komponent Plant
- Kremniy Group JSC
- R&PA Electronic Device Manufacturer

EDP Market

The PC market has been the driver of the growing level of electronic equipment production in Russia. In 1997, the EDP market accounted for 55 percent of electronic equipment production; the increase over 1996's figure of 48 percent indicates the growing importance of EDP to the electronic equipment production market.

The Russian PC market is dominated by indigenous manufacturers. In 1997 local manufacturers held 78 percent of the total market; this was a 4 percent increase over 1996's figure. The PC market has been growing at a consistent rate of about 20 percent for the past four years; in 1997 the market grew by 21 percent.

 ©1998 Dataquest

Vist is the dominant Russian PC vendor, holding 24 percent of the indigenous market and 19 percent of the total Russian PC market. R&K and Formosa are other major local manufacturers that each hold a share of more than 10 percent of the locally produced market. Table 10-3 shows indigenous and total market shipments between 1995 and 1997, while Table 10-4 ranks Russia's largest PC manufacturers.

Table 10-3

Communications Market

Manufacturing

Siemens has two joint ventures in Russia—Izhtel and Kamatel. Izhtel commissioned production of EWSD exchange systems in Izhevsk in September 1995, and Kamatel began manufacturing transmission systems in Perm in 1994.

Ericsson launched two joint-venture manufacturing projects in 1998. Ericsson Svyaz will be producing Ericsson's DRA 1900 products for radio access to fixed telephone lines in conjunction with Nitel, a former television manufacturer, in Nizhny Novgorod. In addition, Ericsson recently struck a deal with Sistema, to build Siemens AXE 10 products in Zelenograd. It is believed that this production, rather than being merely assembly-based, will include local content in the form of Russian semiconductors on Russian PCBs.

©1998 Dataquest

Alcatel established a joint venture in St. Petersburg in 1991, and has been gradually integrating the manufacturing process into the plant. In April 1998 the factory will start assembling line boards with imported semiconductors for use in the digital exchange equipment assembled there.

Lucent Technologies began manufacturing 5ESS digital switches in St. Petersburg in 1997, in a joint venture with LONIIS, the Leningrad Research and Development Institute in Telecommunications.

Cellular Telephony

In 1996, there were about 120 cellular operators in the Russian Federation. Cellular communications networks have been launched in most Russian regions, although the largest numbers of users are concentrated in Moscow and St. Petersburg. NMT-450 and GSM were chosen by the Ministry of Communications as Russia's federal standards, although there are several standards in operation including GSM, NMT-450, AMPS/D-AMPS, PCS and the old 300-MHz Altai system.

The five major cellular communications players are VimpelCom, Moscow Cellular Communications (MCC), Delta Telecom, North-West GSM and Mobile TeleSystems. Ericsson provides VimpelCom with AMPS/D-AMPS infrastructure in the Moscow region. MCC's infrastructure consists of Nokia base stations and Ericsson switches. North-West GSM uses only Nokia infrastructure.

Table 10-5 gives details of cellular handset shipments to Russia.

Table 10-5
Russia—Cellular Handset Shipments, Average Selling Price and Revenue, 1993-2001

	1993	1994	1995	1996	1997	1998	1999	2000	2001

Consumer Market

The Russian cable access industry is highly fragmented. The majority of existing networks are set up for one-way broadcast of television signals and offer only a limited number of channels.

The largest cable operator is Kosmos TV, which was established as a joint venture between Metromedia and General Center for Radio and Television. At the beginning of 1996, the operator had 1,500 subscribers in Moscow and several Moscow suburbs.

Cable services in Moscow, which have a potential audience of more than 6 million, first appeared in 1990. By 1995 there were more than 80 small cable television networks in Moscow, which in November 1995 were united into a single network called Moscow Municipal Cable Television.

Mosteletechnic, the principal contractor of the Moscow city government, has several plans for building up the network, including the building of a two-way cable television network for 105,000 subscribers. Once completed, the network's capacity will be leased out to local operators, which then will be able to use it to provide cable telephony.

Chapter 11
Slovakia

Introduction

GDP growth in Slovakia continued at a robust 4.5 percent in 1997, although this is less than the 6.9 percent growth recorded in 1996. Domestic demand, underpinned by strong growth in real wages, has been the driving factor of increasing GDP. There are major doubts about the sustainability of Slovakia's growth; the principal problems are the current-account deficit of approximately 10 percent of GDP, which is funded largely by short-term capital inflows, and the fiscal deficit, which expanded significantly during 1997. Interest rates have increased sharply as the government tries to tackle these problems, raising concerns about the ability of enterprises to finance investment and restructuring.

Privatization has proceeded quickly in Slovakia. The private sector accounts for approximately 77 percent of GDP and 70 percent of industrial output, 4 percent higher than 1996's figures. The private sector also accounts for about 45 percent of industrial employees.

Semiconductor Market

Although it grew by a healthy 17 percent in 1997 and has grown by 66 percent since 1994, the Slovakian electronic equipment production market remains one of the second-tier markets of the C&EE region, albeit substantially larger than the Bulgarian electronic equipment production market. The small size of the electronic equipment production market is not aided by the less-than-important role played by the PC production market—only 15 percent of the total—and is compounded by the fact that the two major manufacturers of PCs in Slovakia are Czech and account for all of their production in the Czech Republic. Figure 11-1 shows the Slovakian electronic equipment manufacturing industry broken down by application sector; Tables 11-1 and 11-2 show semiconductor consumption by application and device category respectively.

Indigenous Semiconductor Industry

Dataquest is aware of two semiconductor companies in Slovakia: Diotec and Tesla Piestany. Revenue data is not available for either of these companies.

EDP Market

The EDP market of Slovakia plays a relatively small part in the country's total electronic equipment production. The EDP sector's percentage share of the total has remained almost constant, at about 14 percent or 15 percent, since 1994.

In unit terms, the Slovakian PC market is one of the smallest in C&EE: only 67,000 units were sold in 1997, and growth in the same year was also very low, at slightly more than 1 percent. It is also the only market where indigenous PC manufacturers hold less than 50 percent of the local market, making Slovakian PC vendors' market share the smallest in the C&EE region. Among the indigenous vendors, Tesco and AutoCont are the significant players. Table 11-3 shows indigenous market share, while Table 11-4 shows the market ranks of Slovakian PC manufacturers.

Table 11-3

Communications Market

Cellular Telephony

Slovakia's GSM networks are operated by GlobTel (which is 35 percent owned by France Telecom Mobile International) and EuroTel Bratislava (which is part-owned by U S WEST and Bell Atlantic). EuroTel Bratislava also provides an NMT-450 network. The infrastructure for all of these services is from Ericsson, Nokia and Ascom Timeplex. Table 11-5 shows details of shipments of cellular handsets to Slovakia.

Chapter 12
Ukraine

Introduction

Ukraine is economically about one year behind Russia. Although GDP continues to fall, the rate of decrease has slowed down and in 1997 GDP fell by an estimated 3 percent as opposed to the 10 percent decline experienced in 1996. Inflation is also coming under control from its hyperinflationary levels of 1994. However, it is believed that Ukraine has a substantial informal economy, which, if added to the official economy, would show a much healthier picture for the country. This informal economy also has had repercussions on tax collection, which remains highly problematic.

Semiconductor Market

After several years of decline and stagnation, the Ukrainian electronic equipment production market increased by 17 percent to $449 million in 1997, roughly equal to 1994's production level. The EDP sector plays a significant part in this market, accounting for 38 percent of output in 1997, which was up from 27 percent in the previous year. Figure 12-1 shows the Ukrainian electronic equipment production market broken down by application, while Tables 12-1 and 12-2 show semiconductor consumption by application and by device category respectively.

Indigenous Semiconductor Industry

The Ukrainian semiconductor industry consists of the following four main companies:

- Kvazar Micro
- JSC Kwazar
- Gamma
- Rodon

Kvazar Micro, based in Kiev, produces primarily microprocessors. In 1997 the company's total revenue was $18.6 million, which was an increase of more than 80 percent over 1996's revenue. Kvazar Micro's sales are mostly to Russia, which generated three-quarters of its 1997 revenue.

JSC Kwazar, also based in Kiev, manufactures chiefly analog products, although it also derives income from MOS memory products. In 1997, the company had a total revenue of $732,000, which represented a decline of 20 percent over 1996. The Ukrainian market accounts for approximately 50 percent of its revenues; sales to Russia accounted for approximately $200,000 revenue in 1997.

 ©1998 Dataquest

Gamma, based in Zaporozhye, manufactures discrete semiconductors including a range of low- and medium-power devices.

EDP Market

The Ukrainian PC market is the fourth-largest PC market in the C&EE region. Although Ukrainian GDP has been falling for the past four years, PC production has continued to increase in value each year. PC shipments grew by 49 percent in 1997 after growing by a similar percentage in 1996.

Similar to the Russian market, local manufacturers hold a dominant share of the PC market. In 1997 indigenous manufacturers accounted for 82 percent of total PC shipments in Ukraine. No individual manufacturer has a substantial share of the market, although Elecomp TV and Spez are the two largest indigenous manufacturers. Table 12-3 shows indigenous PC market share and Table 12-4 shows indigenous PC manufacturer market rankings.

Communications Market

Manufacturing

Siemens launched its first Ukrainian joint venture with MKM Telekom in Kiev, which started manufacturing EWSD exchanges in July 1993.

Cellular Telephony

Ukraine has two cellular service providers. Ukraine Mobile Communications, whose shareholders include DeTeMobil, Tele Danmark and PTT Netherlands, operates an NMT-450 service, with infrastructure from Nokia. Bankomsvyaz operates a DCS-1800 service with Motorola infrastructure .

Table 12-5 provides details of cellular handset shipments to Ukraine.

Chapter 13

Rest of Central and Eastern Europe

Introduction

This chapter provides information relating to certain aspects of the electronic equipment production industries of other countries within the C&EE region.

Indigenous Semiconductor Industry

Outside Russia, the Baltic states and Belarus provided something of a (comparative) semiconductor powerhouse for the former Soviet Union. The following five semiconductor companies are of note:

- Integral (Belarus)
- Transistor (Belarus)
- Estel Semiconductor (Estonia)
- Alfa Semiconductor (Latvia)
- Venta (Lithuania)

Integral, which is based in Minsk, Belarus, consists of five fabrication plants, with geometries from 5 microns to 1.2 microns, and four R&D centers. The company manufactures standard logic families, DRAM and SRAM, 16-bit microprocessors, 4-bit and 8-bit microcontrollers, communications ICs, ICs for televisions and discrete semiconductors. At present no revenue data is available.

Alfa Semiconductor, based in Riga, Latvia, manufactures mostly analog semiconductors as well as discretes. The company's revenue in 1997 was $736,000, which was a 15 percent fall over 1996's revenue. Alfa Semiconductor's largest market is Russia, accounting for more than $500,000 of the company's revenue in 1997.

Venta, based in Vilnius, Lithuania, manufactures bipolar digital products as well as analog and discrete semiconductors. In 1997 the company's revenue was $290,000, the same as the previous year. Sales to Russia represented 50 percent of Venta's revenue in 1997.

EDP Market

Tables 13-1 and 13-2 provide details of the indigenous PC market in the Baltic states (Estonia, Latvia and Lithuania); Tables 13-3 and 13-4 give similar statistics for Belarus. In both cases the markets are dominated by local manufacturers.

Semiconductors Europe

Market Analysis

Microcontrollers and the European "Big Three"

Abstract: *This Market Analysis examines the success of European-based microcontroller vendors in the world market, focusing on the big three European semiconductor companies—Philips Semiconductors, STMicroelectronics and Siemens Semiconductor—and their microcontroller strategies and offerings.*

By Joe D'Elia

European Overview

European microcontroller manufacturers increased their share of the worldwide market for these devices by 17.4 percent from 1995 to 1997. Although some of this growth has been influenced by the changing ownership of certain players, most of it has come from increased penetration of developing market areas. Table 1 gives the market rankings for 1997, showing that the eight European companies that count in this segment are well spread throughout the ranking spectrum. The top European-based players are Europe's three largest semiconductor players, and are ranked either side of tenth place, with the remaining European-based companies much further down (from twenty-fourth place down to last). This *Market Analysis* focuses on the big three: Philips Semiconductors, STMicroelectronics (STM) and Siemens Semiconductor, concentrating on their geographic split, architectural split and target application areas. European companies grew faster than the segment as a whole in 1997, at 7.4 percent compared with the total segment's 5.6 percent.

NA = not applicable
Source: Dataquest (January 1999 Estimates)

Some of the data in this *Market Analysis* differs from data previously published by Dataquest for this product category. In particular, STM's revenue in 1995 and 1996 has been raised to include Dataquest's estimates of revenue from microcontroller-based smart cards, which the company had included in the EEPROM section of nonvolatile memory. This has also resulted in an increase in the total microcontroller revenue for 1995 and 1996. Table 2 gives individual company revenues for 1995 to 1997 and shows the European share of the worldwide total growing from 10.9 percent to 12.8 percent. For the purpose of this analysis, Micronas Intermetall is counted as a European company in 1997 only, because previously the company was the US-owned ITT Intermetall. Future years will see TEMIC and GEC Plessey Semiconductors disappear from the European microcontroller list as in 1998 these companies were purchased by Atmel and Mitel, respectively.

STMicroelectronics	299	366	445
TEMIC	68	78	57
Total European-Based Revenue	**1,124**	**1,303**	**1,399**
Total Worldwide Microcontroller Revenue	**10,250**	**10,322**	**10,896**
European Share of Worldwide Revenue (%)	**10.9%**	**12.6%**	**12.8%**

Note 1: These values are not included in the 1995 and 1996 European-based totals because the company was US-owned at this time
Source: Dataquest (January 1999 Estimates)

European growth in market share has come during a period in which the average selling price (ASP) of microcontrollers has been declining. However, the region's focus on devices targeted at growth areas has paid off and resulted in the increase in market share. Microcontroller-based smart cards have been a particularly rewarding area, shipment revenue having grown worldwide from $215 million in 1995 to $461 million in 1997, with the big three European companies accounting for about 80 percent of this revenue. Individual companies have targeted different application areas—a topic that is explored in the company-specific section of this *Market Analysis*.

Another interesting point is the shift in the geographic end markets of European microcontroller vendors (see Figure 1). Although the largest market for these companies' microcontroller products is Europe, their export markets are changing, with increasing focus on the Far East, where sales as a percentage of the total have grown from 16.8 percent to 22.4 percent in the Asia/Pacific region and from 1.2 percent to 2.1 percent in Japan. The geographic area that has declined as a share of the total market is the Americas, which has fallen from 22.8 percent to 14.1 percent. This shift in geographic base is again related to the applications markets that are being targeted by European microcontroller vendors—consumer and electronic data processing (EDP) products are now manufactured primarily in the Far East.

Company Overviews

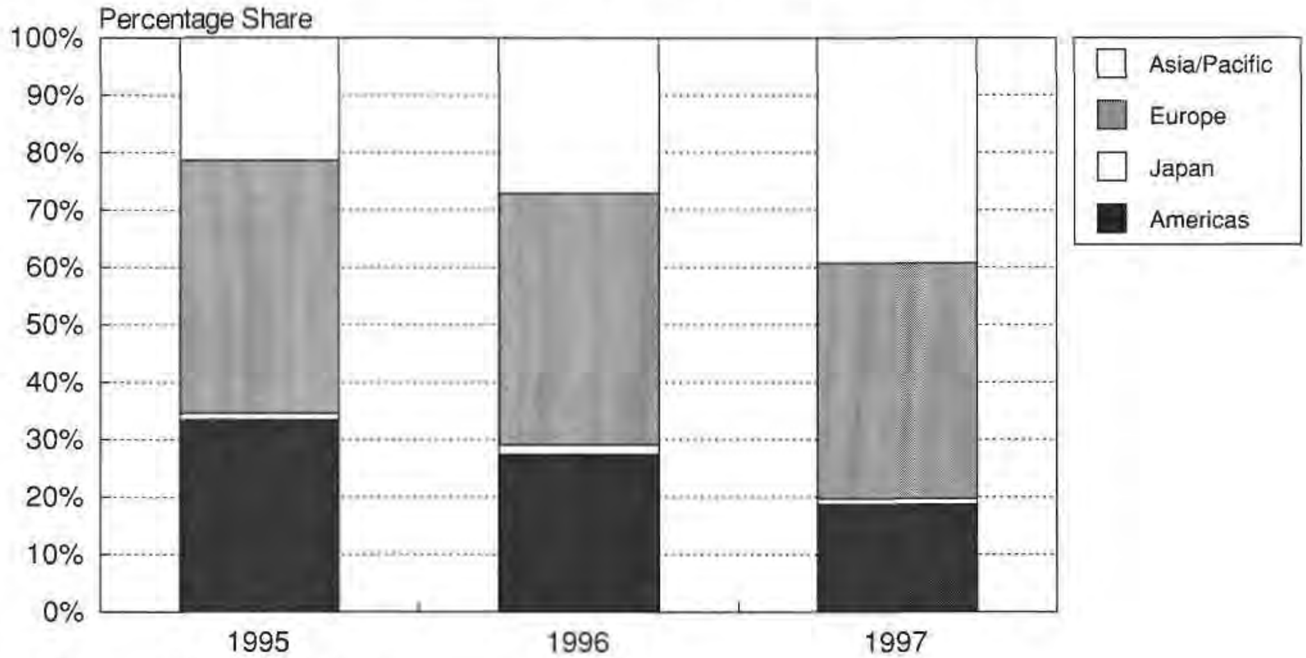
With the impending disappearance of TEMIC and GEC Plessey Semiconductors from the European list, and excluding for the moment the big three companies, we are left with three European microcontroller companies that serve the market: Micronas, Melexis and EM Microelectronics Marin. These companies are very focused on the niche markets of consumer, automotive and low-power applications respectively. With the exception of Micronas, their markets are in Europe and amounted to no more than 4.5 percent of the total. Consequently, this *Market Analysis* will not examine these companies further, but rather focus on the European big three companies and their respective market offerings.

Philips Semiconductors

Of the big three players, Philips has the most balanced geographic microcontroller revenue split. However, it is leading the charge in increasing its market share in the Asia/Pacific region. Historically, the company has been strong in the United States as a result of its Signetics roots, but as its application balance has shifted so has its geographic base. Figure 2 shows that from 1995 to 1997 the company's Asia/Pacific revenue from microcontrollers rose from 21.4 percent to 39.2 percent of the total. In 1998, the company's Asia/Pacific microcontroller revenue is likely to have been the largest portion. Shipments to the Americas over the same period fell from 33.4 percent to 18.7 percent. Shipments to Europe declined by 3.1 percent, while shipments to Japan remained at approximately 1 percent. This reapportioning of regional revenue occurred against a backdrop of falling microcontroller revenue for Philips, as the company's overall microcontroller revenue during this period fell by 4.2 percent from $524 million to $502 million. This fall resulted solely from a 31.0 percent drop in ASP that was not compensated for by a corresponding rise in unit volumes.

©1999 Dataquest

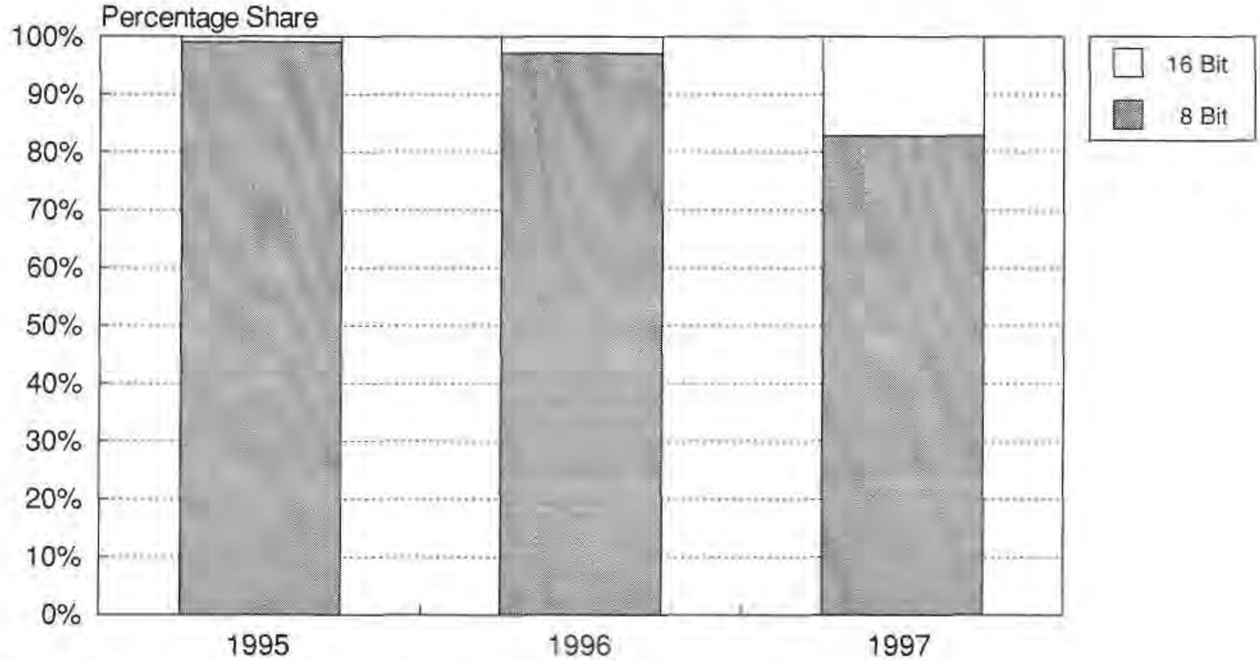
Figure 2
Philips Semiconductors' Microcontroller Revenue by Region, 1995-1997



Source: Dataquest (January 1999 Estimates)

Philips' main focus is consumer applications, and its success in developing its Asia/Pacific business is based on its dominance of the television market. Over the years the company has built up an impressive portfolio of microcontrollers based on the 8048 and 80C51 architectures aimed at television control. As the Chinese market is opening up, many of these older designs have got a "second wind" as they are well suited to the less-sophisticated requirements of this market. Philips participates in the 8-bit and 16-bit microcontroller markets with devices that are 80C51-based, and the company is the leading shipper of this architecture. Its 16-bit XA architecture is a backward-compatible extension of the 80C51 and, as can be seen from Figure 3, is gaining market acceptance, having accounted for 17 percent of Philip's microcontroller shipments in 1997.

Figure 3
Philips Semiconductors' Microcontroller Revenue by Word Length, 1995-1997



Source: Dataquest (January 1999 Estimates)

The major portion of Philip's 8-bit shipments is 80C51-based as the older 8048-based devices are declining steadily. In 1997, 8048 shipments accounted for 15 percent of Philips' total microcontroller shipment revenue. The company claims to have more than 100 variations on the 80C51, with devices targeting specific applications, such as various television functions, computer monitors, telecommunications, automotive and general-purpose applications. Products are offered primarily in ROM and OTP versions, with flash-based devices being introduced only in late 1997. Not being a company steeped in memory technology, Philips has had to look outside for this technology and has formed a partnership with Taiwanese flash manufacturer Macronix to acquire a suitable flash process module. As a by-product, Philips also gained a second source for its 16-bit XA architecture, which is no bad thing. As well as using this flash process for its XA architecture, Philips is quickly adding new flash-based 80C51 variants as it backfills some of its catalog.

The XA architecture is Philips' 16-bit offering, and the key to this product is its ability to leverage the multitude of legacy 80C51-based designs created since the introduction of this architecture in the early 1980s. There are now four variants in this family, with the latest variants using the Macronix-developed flash technology.

Looking beyond 16 bits, there are no signs that Philips is seeking to produce a standard catalog microcontroller family. The company's efforts seem to be more focused on generating ASSPs for specific applications based on MIPS cores which, historically, it has brought in from established MIPS vendors. Philips had used Toshiba cores, but in 1997 signed an agreement to use NEC's VR4300 64-bit processor core. Another factor in this arena could be Philips' "infatuation" with the multimedia processor—the company has spent considerable resources on getting its TriMedia processor to market. This effort may well have detracted from any desire to tie up resources in developing a totally new microcontroller architecture as it is improbable that the 80C51 foundations could, or should, be extended to 32 bits.

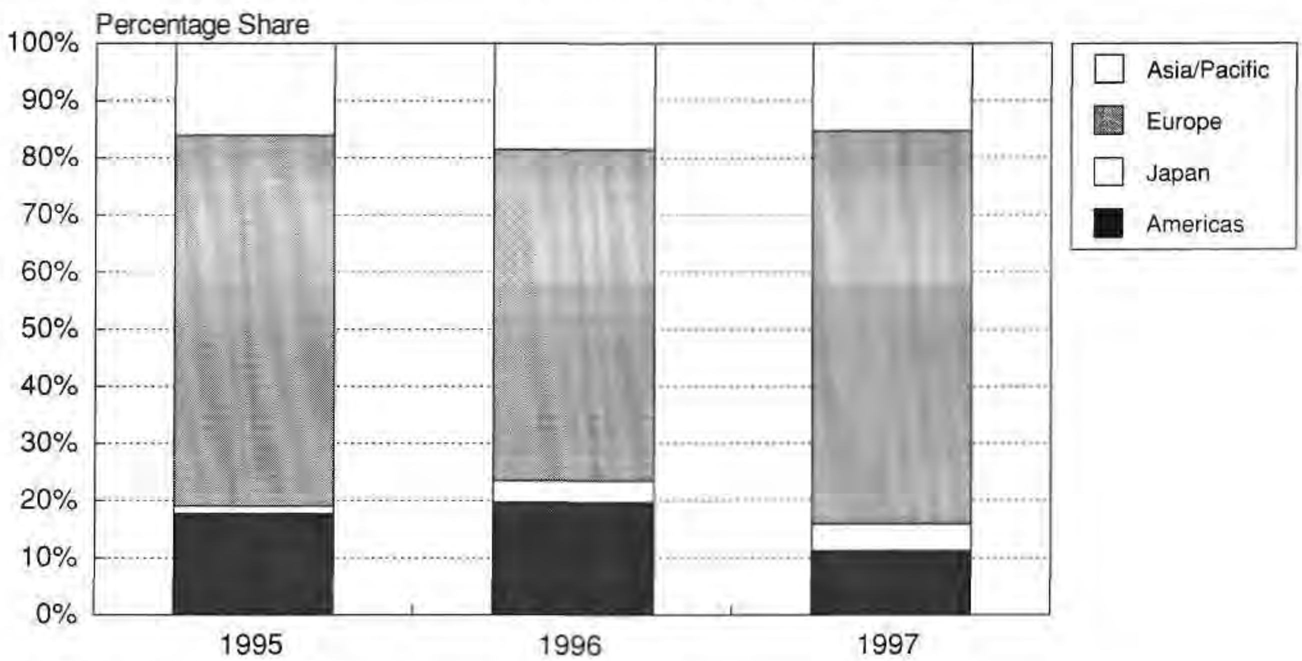
 ©1999 Dataquest

Like the other major European vendors, Philips is a player in the smart card market—albeit a minor one, with only a 5 percent market share in 1997. Philips is participating in both contact and contactless applications and has both 8-bit and 16-bit device families, both of which are based on the company's mainstream microcontroller architectures, the 80C51 and XA respectively. The new 16-bit $SMART_{XA}$ devices are aimed at the developing market for multifunction smart cards and take an innovative approach to security by incorporating an onboard hardware firewall that isolates individual applications from each other.

STMicroelectronics

The regional split of STM's markets for microcontrollers are going in the opposite direction to the other two vendors in that Europe is gaining share (see Figure 4). This is a direct result of the company's involvement in microcontroller-based smart cards, which have grown by more than a factor of two from 1995 to 1997. STM has almost doubled its share of the microcontroller-based smart card market—from 27 percent in 1995 to 45 percent in 1997, and the bulk of this market is now focused in Europe. In 1997, the company shipped $31 million worth of its 32-bit ST20 family, which is targeted at high-volume consumer applications such as digital set-top boxes and digital video broadcasting players. As a result of this targeting, the bulk of these 32-bit shipments was split between Europe and Japan. At the 8-bit level, Europe is the main focus because of the predominance of smart card shipments, while 16-bit products with their EDP and telecommunications focus were split between Europe and the Asia/Pacific region. Over the same period, STM increased its overall microcontroller revenue by 49 percent, from $299 million to $445 million.

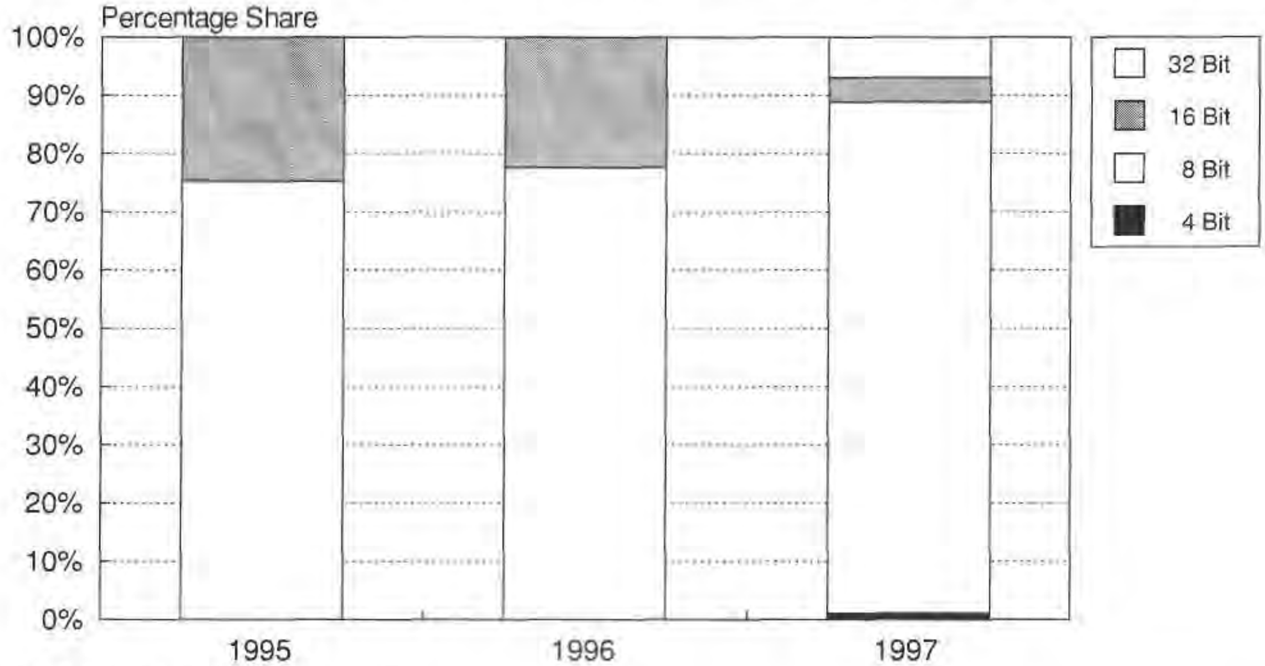
Figure 4
STMicroelectronics' Microcontroller Revenue by Region, 1995-1997



Source: Dataquest (January 1999 Estimates)

Viewed from a word-length perspective, STM has the most diverse range of products available—it has products that range in word length from 4 bits to 32 bits. Some of this diversity stems from legacy second-source products, such as the 4-bit second source of National Semiconductor's COP400 family (which is now obsolete) and the second sources of Motorola's 68HC04 and 6805. Figure 5 gives STM's microcontroller revenue by word length. It shows a leap in 8-bit share in 1997, which again resulted from the jump in smart card usage in 1997 as these devices were rolled out in many end-user programs.

Figure 5
STMicroelectronics' Microcontroller Revenue by Word Length, 1995-1997



Source: Dataquest (January 1999 Estimates)

STM has a core-based approach to building microcontrollers, which enables it to produce many variations of a basic family. Its various 8-bit architectures have about 100 different permutations of compute core, memory type and size, peripherals and so on. This is without taking into consideration what type of program memory (that is, ROM, EPROM or OTP) has been chosen. As well as devices aimed at general-purpose industrial applications, several groups of device focus on specific applications, such as televisions, satellite video receivers and computer monitors with the requisite peripheral fit to enable onscreen displays and application-specific functions. Other product groups are intended for use in automotive and portable applications.

Toward the top end of the spectrum, STM has the ST10 16-bit family—the company's first flash-based microcontroller devices. Again these are core-based and have already generated variants that are targeted specifically at the automotive and telecommunications markets. At the very top end there is the 32-bit ST20 family, which is focused on specific high-volume consumer applications. It is becoming questionable whether this class of device is a microcontroller or an ASSP. For the future, the company has joined with Hitachi to develop a 64-bit family of controllers called either the ST50 or SH5 depending on which company sells it. This agreement also gives STM the rights to Hitachi's SH4 products under the ST40 banner.

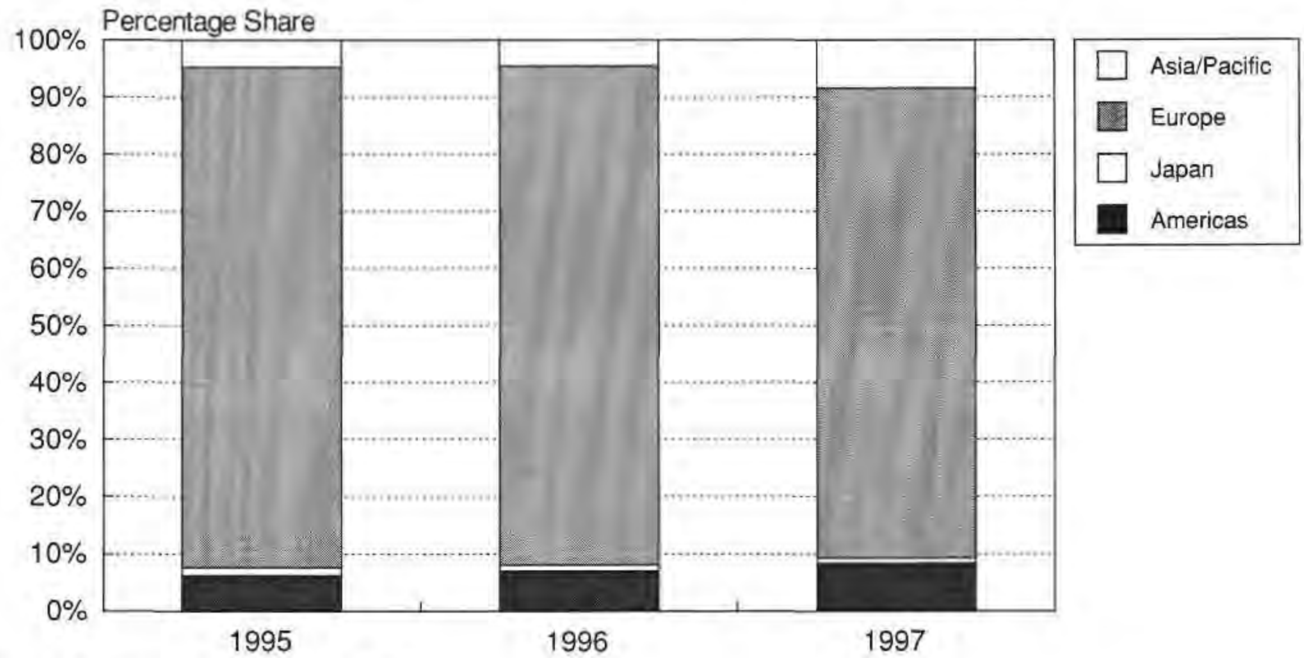
In addition to these generic microcontroller families, STM also has two families of dedicated 8-bit smart card microcontrollers that supply various permutations of core, EEPROM, RAM and ROM sizes plus specific smart card security-related peripherals such as encryption engines. These products have enabled STM to become the worldwide market leader in this product category.

 ©1999 Dataquest

Siemens Semiconductor

Of the big three companies, Siemens not only has the lowest microcontroller revenue, but also the most Eurocentric customer base, with 82 percent of its 1997 microcontroller revenue being of European origin. Figure 6 shows that Siemens is developing its foreign sales; from 1995 to 1997 Siemens increased its Asia/Pacific revenue by 75 percent (from 4.8 percent to 8.4 percent of the total) and its Americas' revenue by 35 percent (from 6.2 percent to 8.4 percent of the total). Over the same period, Siemens' overall microcontroller sales grew by 59 percent from $208 million to $333 million.

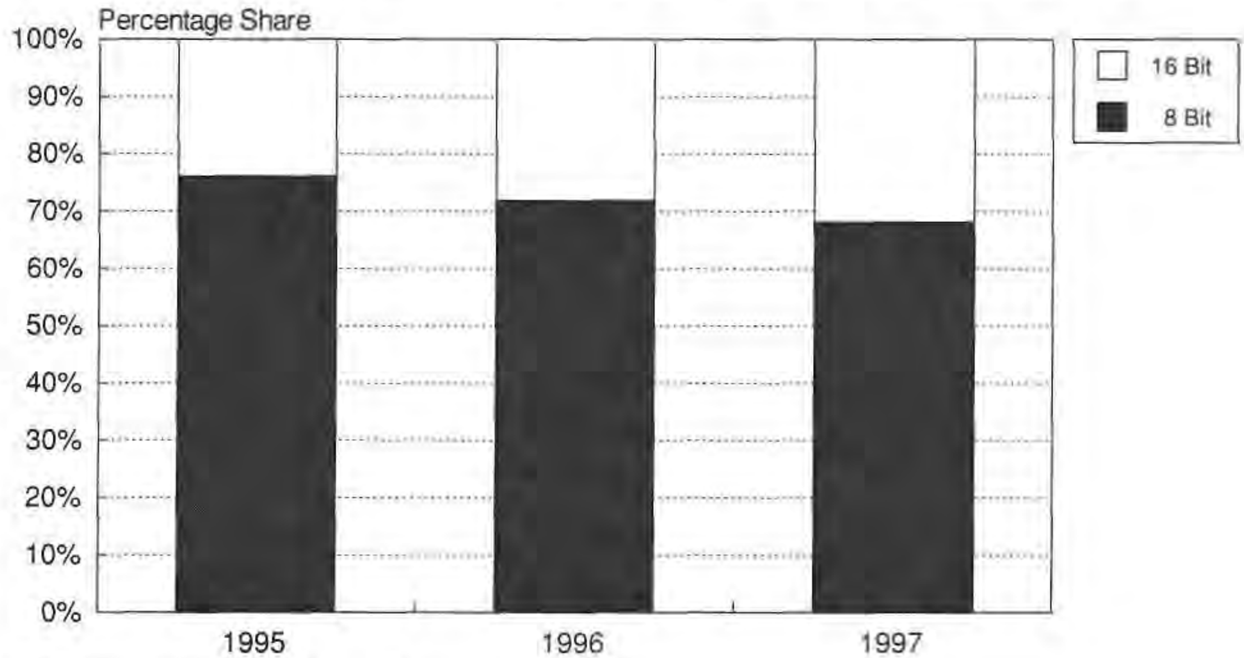
Figure 6
Siemens Semiconductor's Microcontroller Revenue by Region, 1995-1997



Source: Dataquest (January 1999 Estimates)

Like Philips, Siemens' product offerings are restricted to 8-bit and 16-bit architectures, with the 8-bit family again rooted in the 80C51 architecture. The split by word length for Siemens is less biased toward the 8 bit as the company's C166 16-bit architecture has been around for some years and had some market success. Figure 7 shows that, in 1997, the C166 took 32 percent of Siemens' microcontroller revenue, having risen from 24 percent in 1995. Siemens' C500 family of 80C51 derivatives has been around for more than ten years, over which time the company has developed a significant number of devices that focus on data storage, automotive and communications-specific applications. Much of this development has benefited from direction from Siemens' own end-equipment manufacturing divisions in these areas, which have also provided initial customers for the products. Two new family members were introduced in 1997 to attack the burgeoning market for USB peripherals. To complement these focused devices there has also been a line of more general-purpose devices targeted at less-specific industrial applications.

Figure 7
Siemens Semiconductor's Microcontroller Revenue by Word Length, 1995-1997



Source: Dataquest (January 1999 Estimates)

The C166 family also has several subsegments that are aimed at specific application areas, with the particular focus being telecommunications and automotive. The inclusion of CAN functionality on several devices makes this family popular in automotive applications. Aiding this popularity is a specialized family of CAN host controllers—the 81C90/91. Although Siemens has made its devices available in the usual memory technologies, it was short of a flash offering until late 1997 when it introduced the C163-16F, which incorporated 128KB of on-chip flash memory. Flash is being introduced in several new members of both the 8-bit and 16-bit families.

Looking to the future, Siemens has taken a novel approach to increasing the performance of its microcontrollers beyond 16 bits. In 1997, it introduced the TriCore architecture, which utilizes a microcontroller core that has a unified instruction set aimed at supporting both control and DSP tasks in a single core. Although the first derivative of this architecture, the TC10, is a highly integrated general-purpose device that is designed to tackle a wide range of multitasking embedded control applications, the future of this family must be as specifically focused ASSPs rather than as general-purpose devices. The fundamental role of the TC10 is as a proof of concept and prototyping device rather than as a high-volume microcontroller in its own right.

As with the other vendors, Siemens has two families of smart card devices. Both the SLE44 and SLE66 families are 8-bit devices. Siemens' main focus is the contact type of card, although it has some devices aimed at the contactless market. Siemens is the second-biggest player in the smart card market, with 29 percent of the worldwide revenue in this category.

 ©1999 Dataquest

Dataquest Perspective

European-based microcontroller vendors are succeeding by focusing on specific application areas and targeting those geographic areas where high-volume end-equipment production is concentrated. Despite these strategies, they will have suffered in 1998 as the whole of the microcontroller market downshifted as a result of the overcapacity that become rampant. Unit growth is up, but ASPs continue to decline faster, ensuring that revenue will decline. Furthermore, the Asian financial crisis is continuing to have an impact, driving prices down. This is especially prevalent in multisourced products. Fortunately, the variants of microcontrollers—even when based on the same root architecture—make these devices effectively sole-sourced products and therefore less susceptible to pricing pressures.

Although the list of European-owned microcontroller vendors is declining because of changes of ownership, this will be a short-term phenomenon as several new companies are starting to supply microcontrollers targeted at niche markets and will have measurable revenues in 1998. Furthermore, several of the old Russian semiconductor industry companies, who all shipped 8048/8051-based second sources, are trying to expand their horizons by marketing their products around the world. These companies should start to generate significant revenues, which will take them out of the "others" group and allow Dataquest to track them as separate companies, thereby expanding the list of European microcontroller vendors.

Market Analysis

European ASIC Design Starts Survey, 1998

Abstract: *This Market Analysis analyzes the number of ASIC design starts, device technology trends and industry sector issues in 1997 and 1998. Trends in core usage, feature size and interconnect are considered, together with the impact of system-level integration. The number of designs in each European country or region is also presented.*

By Jim Tully

Executive Summary

The number of European ASIC designs continued to grow in a difficult year for the industry. Average revenue per design has risen from $2.06 million in 1996 to a forecast $2.63 million in 1999. Gate count continues to rise, with the most common category being 100,001 to 200,000 gates at 0.35 micron in 1998. A 52 percent growth in system-level integration (SLI) designs is expected to occur in 1998 with SRAM, ROM, microcontrollers, DSP, A/D converters and cellular functions being the most common cores this year. Regionally, Germany continues to account for the largest number of designs, with the United Kingdom showing the strongest growth; the sharpest fall was in the Nordic region, owing to a reduction in cellular design activity. Analog and mixed-signal designs are continuing their growth to a point where they are challenging the supremacy of digital designs.

Dataquest's 1998 European ASIC design starts survey was based on responses from 21 vendors. These vendors account for 90 percent of the gate array and cell-based ASIC markets by revenue in 1997. The results of the survey are therefore highly representative of the overall market and provide a sound basis on which to make decisions. The main findings of the survey are summarized in a commentary with references to the corresponding tables and figures. Dataquest's conclusions are given at the end of the document.

Survey Results

- Europe accounted for 1,092 ASIC design starts in 1997, a rise of 2.2 percent over 1996. In 1998 this figure is projected to rise by 9.4 percent (see Figure 1).
- The largest band of ASIC production quantity per design will increase from the 50,001 to 100,000 devices category in 1997 to the 100,001 to 500,000 devices category in 1998 (see Figure 2).
- Our calculations show that an average ASIC design has a revenue-generating lifetime of three years, with most of the contribution in the first year after design completion. Revenue in the second year is impacted by price erosion in spite of production growth. The yearly revenue contribution is given in Table 1. On this basis, the average ASIC revenue per design in Europe will rise from $2.48 million in 1997 to $2.58 million in 1998, an increase of 4.1 percent (see Table 2).
- Cell-based designs account for approximately three-quarters of all design starts, with array designs accounting for the remainder. Embedded arrays increased their share by 2 percentage points to reach 7 percent of all design starts (see Figure 3).
- Communications applications continue to dominate ASIC design and production in Europe, growing from 58 percent to 59 percent of all designs in the 1997 to 1998 period. Industrial and consumer designs are ranked second and third respectively (see Figure 4).
- The percentage of mobile communications designs is expected to fall for the first time in many years in 1998, but it remains the single largest category and is closely followed by public switching and transmission applications (see Figure 5). The production of ASIC units in the mobile sector continued its sharp growth (although at a lower rate than in previous years); however, price erosion outpaced production growth, resulting in overall revenue decline. The data networking applications category was notable for its sharp growth from 14 percent to 18 percent of designs.
- The single largest gate count category in 1997 was less than 50,000 gates. However, this figure is expected to change to 100,001 to 200,000 gates in 1998 (see Figure 6).
- For several years up to and including 1997, 0.5-micron geometry devices led the rankings. In 1998, 0.35 micron is expected to be the dominant geometry (see Figure 7). Three-level metal interconnect will remain dominant, with a significant increase in five-level metal (see Figure 8).
- Dataquest's definition of a system-level design includes all designs above 100,000 gates, that contain a compute engine (micro or DSP core), memory and user logic. In 1998, 383 design starts are designated as SLI designs, a rise of 52 percent over 1997 (see Figure 9). These designs are undertaken by a small number of vendors and are still a small minority of all European designs, but Dataquest expects that they will dominate the ASIC market within three years.
- SRAM is by far the most commonly used core in ASIC designs, occurring in almost 60 percent of cases, followed by data conversion, ROM and microcomponents. Particularly high growth is forecast in cellular, WAN and A/D converter functions (see Figure 10). Vendors' ability to use cores in an effective SLI strategy relies upon the availability of an adequate design reuse technology. Also, the percentage of designs that are reused is an important productivity metric. Figure 11 shows that the largest category of percentage reused was the 1 percent to 15 percent band in 1997, and we anticipate this to shift to the 16 percent to 25 percent band in 1998. This corresponds to a weighted average reuse factor of 22 percent in 1997 and 33 percent in 1998.

 ©1998 Dataquest

- Germany continues to account for the largest number of designs, followed by France (see Figure 12). The German market has continued its growth for the past two years led by its telecommunications sector, following two or three years of relative decline. The percentage of designs in the Nordic region fell in line with the reduction in cellular activity mentioned earlier. The Middle East reported increased activity—notably in Israel. Two designs were reported in Africa.
- Digital designs continue to account for the bulk of ASIC design starts in Europe. However, analog and mixed-signal technology has long been of growing importance in Europe, owing mainly to the requirements of the telecommunications sector. The gap is continuing to narrow, with analog and mixed-signal design starts now at 44 percent of total designs (see Figure 13). However, analog and analog-dominated mixed-signal designs (requiring special processes) are still a relatively small percentage of total designs.
- The dividing line between customer and vendor responsibility in the design process is continuing to change. The traditional model in which customers design up to netlist level and vendors undertake physical design continues to grow in popularity (see Figure 14). However, a significant number of ASIC designs do not involve ASIC vendors, being designed entirely by customers and manufactured by independent foundries. This category of design is not represented in this *Market Analysis*, but Dataquest estimates that revenue from these channels is 10 percent to 15 percent of the overall ASIC market, and growing.

Dataquest Perspective

The past two years have been relatively poor in the recent history of the ASIC market. Growth began to slow during 1997 and the situation worsened in 1998, mainly because of unit price pressure. Market conditions such as these have a marked impact on the number of design starts in which ASIC vendors are involved. The number of design starts grew by 2.3 percent in 1997 and is expected to grow by 9.4 percent in 1998. Why, then, should the number of designs rise at a time when market growth has been moving in the opposite direction?

As the revenue resulting from ASIC designs is spread over several years, a short-term dip in the market may not have a major impact on the average revenue per design. On the contrary, revenue per design has grown over the past few years and is likely to continue growing for the next few years.

However hard ASIC vendors try to approach design projects, ultimately these projects are viewed as an overhead within the company. The goal is the revenue resulting from device shipments, not the nonrecurring engineering (NRE) charges from the design project itself. But the NRE charges that (in theory) apply to designs are often blurred as the two revenue items are frequently merged together. The design project is necessary in order to achieve the device revenue, but a larger number of design projects leads to inefficiencies as effective relationships with new customers take time to develop. In view of this, ASIC vendors naturally prefer a few high-value projects to a larger number of small-value projects. But, at a time of market downturn, the value of projects comes under pressure, forcing vendors to increase the number of projects in an attempt to drive up revenue.

Another issue affecting the profitability of design projects is the expertise of the customer's design team and the industry sector to which the design belongs. A "pecking order" exists in the ASIC industry in which specific vendors tend to pick up the high-value projects, often in mobile communications and related sectors. Other vendors are left with lower-value projects, often in the industrial sector. These lower-value projects have a double problem: their revenue contribution is lower and the customer has less knowledge of the ASIC design process. This latter problem means that unrealistic expectations are often set and the ASIC vendor's engineering effort is significantly higher. As a result, such projects tend to be far less profitable than those carried out by top-tier vendors. The challenge for these smaller ASIC vendors is to move up the value chain by focusing on a niche within a higher-value application.

The demand for more highly complex ASICs designed in a shorter time seems to be inexhaustible. This is a positive indicator for the underlying ASIC market, yet ASIC vendors and OEMs are feeling the strain. The main limiting factors are design engineers and design (EDA) tools. The rate at which new design centers have been locating in Europe has been incredible. The vendors that are strong in DRAM have been the latest entrants to establish design operations with an eye to better utilizing fab capacity for high-value ASICs, while developing embedded DRAM technology. OEM demand for ASIC designers also continues to rise sharply, yet the supply of engineers is not keeping pace. One solution is the greater use of cores and more effective overall reuse of designs and design elements; this is progressing well, as demonstrated in the survey results. However, it is a good solution for low-speed, low-technology applications but does not work well for 200-MHz designs at 0.25 micron. Here the engineering effort to integrate cores in the form of hard macros is very complex, requiring highly skilled engineers and expensive software tools. The skill shortage is a major problem that is likely to get worse before it gets better.

 ©1998 Dataquest

The shortage of engineers is one reason why many of them have formed design houses, operating on a contract basis to fill the gap for OEMs during peak loads. Engineers can often earn higher salaries in this way than by working for a permanent employer. These design houses are thriving in Europe to a greater extent than in any other region of the world and are now an essential ingredient in the success of many companies involved in ASIC design.

Some shift in the pattern of applications was evident this year, including a sharp rise in data networking designs and (significantly) a relative reduction in mobile communications designs. These shifts highlight the absolute importance of vendors developing and maintaining a strong skill base in a few chosen applications. Design support, base libraries, cores (intellectual property) and manufacturing technology must all be focused on these application categories. This is one of the primary keys to success in the modern ASIC business.

Vendors must also find ways to leverage this application focus in the development of application-specific standard products (ASSPs). Dataquest has observed a shift from ASIC to ASSP solutions as technology matures and standards stabilize. Vendors must look for further payback on their design investment by spinning off ASSPs from ASICs whenever possible.

Finally, ASIC vendors must be constantly aware of the threat posed by third-party foundry services. A significant "invisible" ASIC revenue stream is generated through these services, aided by the large number of design houses in Europe. These houses undertake designs for clients (typically OEMs) then have them manufactured by foundries. Design houses have the skills and design tools to carry out physical design using third-party libraries, such that ASIC vendors are eliminated from the process. Dataquest estimates that revenue from these channels is valued at 10 percent to 15 percent of the overall ASIC market, and rising. The primary defenses for ASIC vendors are to continue to provide a complete high-value package (design, manufacturing, test and assembly) and to be "the best" in a chosen application.

Semiconductors Europe

Competitive Analysis

Applications Focus: The Key to European Growth

Abstract: *The performance of Europe's top three semiconductor vendors in the first half of 1998 was better than the market's overall growth. This Competitive Analysis reviews these companies' performances and analyzes their strategies for future growth.*

By Edmund Gemmell

Introduction

Europe's three largest indigenous semiconductor vendors—Philips Semiconductors, STMicroelectronics (ST) and Siemens Semiconductor—accounted for 80 percent of European-based semiconductor companies' worldwide sales in 1997. They also accounted for 8 percent of the worldwide semiconductor market in 1997—up marginally on 1996. This *Competitive Analysis* reviews the performance of these companies in the first half of 1998 and their positions in the semiconductor markets. It also looks at their strategies for growth over the next few years.

STMicroelectronics

FILE COPY: MARIA VALENZUELA

Tables 1 and 2 summarize ST's performance in 1997. Tables 3 and 4 summarize the company's performance during the first half of 1997 and the first half of 1998 by application and region respectively. ST grew by 8 percent in the first half of 1998—a significant contrast to a worldwide market that contracted by 9 percent in the same period. This growth was achieved because ST increased the percentage of its differentiated, application-specific sales into vertical markets. These sales have typically been offerings to high-growth application markets.

Source: STMicroelectronics

ST organizes its products into two categories: differentiated products (ST's term for ASSPs) and standard products. Differentiated products are those of higher integration and high functionality that are typically targeted at specific application markets. ST aims for its differentiated products to contribute 67 percent of its annual revenue. To date in 1998, ST has achieved 63 percent of its sales from differentiated products, so the company is not far from its objective. Table 5 illustrates how ST's growth has been driven by its differentiated product offerings, revenue from which increased by 19 percent in the first half of 1998 compared with the first half of 1997. Table 6 shows the growth rates of the markets in which ST has significant market presence in the first half of 1988.

Table 5
STMicroelectronics' Revenue from Differentiated and Standard Products, First Half of 1997 and First Half of 1998

	First Half of 1997 ($M)	First Half of 1998 ($M)	Growth (%)
Differentiated Products	1,095.2	1,305.6	19.2%
Standard Products	819.4	770.1	-6.0%
Total	**1,914.6**	**2,075.7**	**8.4%**

Audio/Video Special IC	-1%	-13%
Power Transistor	-5%	-10%

Source: WSTS

Table 5 also illustrates ST's need for two distinct strategies for its two product categories. Revenue from the company's standard products fell by 6 percent in the first half of 1998 compared with the first half of 1997—more in line with industry levels. This is driving ST to increase the market visibility of its standard products to offset the downward price pressure that is affecting all commodity markets, and especially all memory markets.

Part of this strategy includes the joint development and marketing with Mitsubishi Electric of a new 64Mb flash product range for the mobile market. ST has been working with Mitsubishi Electric since 1993. ST has a reputation for leading the market in pricing for many of its more mature commodity products as a result of the low manufacturing costs achieved from its fully depreciated wafer fabs. The prospect of an attractive source of revenue from low-cost manufacturing and increasing sales in its commodity product ranges makes ST's participation in these markets understandable.

ST is, however, focused on its strategy for differentiated products. These products account for almost 63 percent of revenue and are driving the company's growth and ensuring profitability by maintaining gross margins that are consistently greater than 38 percent. ST's strategy is to target high-growth products in each of the major applications markets and offer differentiated products and reference designs. This overriding strategy is defining ST's strategic alliance needs and giving direction to its expanding R&D efforts. Markets that ST has identified as being of strategic interest include the following:

- Digital video
- Computer peripherals
- Information appliances
- Digital networking
- Digital mobile telephones
- Smart cards
- Automotive

In 1997, the consumer electronics application market accounted for about 19 percent of ST's revenue. In the first half of 1998, this figure rose by 20 percent. The main reason for this increase was the increasing numbers of set-top boxes (STBs) being made. ST is very strong in the STB market, having design-ins with most major service providers on every continent. Along with digital STBs, ST is targeting the digital TV and DVD markets in a category that it calls digital video.

Key differentiated products that have been designed to meet the needs of the digital video market include the STi5500, ST's complete back-end STB/DVD system on a chip, which includes an MPEG-2 audio/video decoder and a 32-bit RISC microprocessor. To address the terrestrial digital video broadcast market ST offers a four-chipset design to handle front-end receiving functions (both 2K and 8K COFDM) including demodulation, channel correcting and decoding and DSP synchronization. The developing high-definition TV market is being addressed by ST with the launch of the STi7000 device which integrates MPEG-2 decoder technology as well as advanced display and format converter technology onto a single chip.

ST gained 26 percent of its revenue from the computer applications market in 1997. To date in 1998, this figure has risen to 28 percent. Much of this increase has been driven by ST's disk drive controller products. This contrasts sharply with the company's performance in 1997, when it lost a significant amount of market share.

A major strategic alliance was announced in July 1998 that will increase the importance of this market to ST—the company announced a partnership with IBM to develop system-on-a-chip products for data storage applications and PC-compatible information appliances. Initial offerings from the partnership have been based on hard drive controller products to address a market that Dataquest expects to grow from $710 million in 1997 to $3 billion in 2002. ST expects to begin launching other products toward the end of 1999. These products could be along the lines of ST's existing x86-based ST PC Consumer. Other products from the partnership are expected to target the PC motherboard, World Wide Web browser, in-car multimedia and network PC markets.

ST is one of two European semiconductor companies that dominate the chip card market. Dataquest estimates that ST held 44 percent of the microcontroller-based chip card (smart card) market and 15 percent of the memory-based chip card (memory card) market in 1997. Dataquest estimates that the chip card market will be $3.7 billion dollars by 2002. It is, therefore, very important for ST that it continues to dominate this market. ST is well positioned to do so through its participation in the MEDEA MASSC project, which aims to develop next-generation 32-bit smart cards using VLSI manufacturing processes.

ST has supported its application-focused product development strategy and its strategic partnerships by investing heavily in R&D. ST invested $610.9 million in R&D in 1997. In the first half of 1998 ST invested $342.5 million in R&D—a 17 percent increase over the first half of 1997. In the first half of 1998, capital expenditure also increased to $453.6 million—a 21 percent rise compared with the first half of 1997.

To enhance the company's system-on-a-chip capabilities, ST has released 0.25-micron and 0.18-micron CMOS manufacturing technology at its fabrication plant in Crolles, France. ST has also announced that it will build a new 12-inch wafer research fabrication plant and pilot line at Crolles, and a new nonvolatile memory research center in Agrate, Italy. Each of these new facilities will employ about 600 researchers.

Philips Semiconductors

Philips Semiconductors began 1998 in a rather mixed position. Overall revenue in 1997 rose by 5 percent on 1996 (to $4.4 billion), but there were failures as well as successes. Revenue from the company's 8-bit microcontroller lines fell by 23 percent from 1996 to 1997, as average selling prices (ASPs) in that market fell. Philips Semiconductors' revenue from 16-bit microcontroller products increased by 438 percent to $86 million; revenue from other special consumer ICs grew by 51 percent. By far the largest revenue growth, however, came from telecommunications ICs; these generated almost $300 million, probably because of Philips Consumer Communications' increasing production of GSM mobile telephones.

Philips Semiconductors' revenue in the first half of 1998 totaled approximately Fl 4.5 million (about $2.2 billion). This was a substantial 18 percent increase over 1997's first half revenue, and consolidated the company's overall 1997 improvement. This increase in revenue is, like that of ST, indicative of the company's strengths in noncommodity products and its solid focus on application markets, as well as its continued absence from any of the memory markets. Tables 7 and 8 show Philips Semiconductors' revenue by device category and region in 1996 and 1997. Table 9 shows the growth rates of the markets in which Philips Semiconductors has significant market presence in the first half of 1998.

 ©1998 Dataquest

The first half of 1998 appears to show a consolidation of the turnaround in Philips Semiconductors' fortunes. The markets on which it has focused its newest product offerings are beginning to develop and its system-on-a-chip strategy is producing attractive products. The company's target applications include the following:

- Digital consumer
- Telecommunications handsets
- Handheld computing
- Automotive
- Emerging multimedia

Building on its traditional strengths in the consumer applications market, Philips Semiconductors is positioning itself as a major player in the digital consumer marketplace. Like ST, Philips Semiconductors is targeting the future growth markets of digital TV and digital STBs. One of its key offerings in these markets is the TriMedia processor, which it hopes to establish as the de facto standard architecture through its design-in with Philips Consumer Electronics. Currently, however, the TriMedia's versatility is proving to be a weakness as it struggles to define itself in any one particular marketplace.

Although Philips Semiconductors' position in the consumer market is strong—in 1997 it was the third-largest semiconductor vendor in the consumer applications market, with revenue of $1.7 billion—revenue from sales into next-generation, digital consumer products totaled only $65.5 million, making the company the thirteenth-largest vendor in this emerging market. Standalone MPEG-2 sales accounted for a significant amount of Philips Semiconductors' next-generation consumer sales. However, with the high rate of device integration in the digital STB market—digital STBs being one of the major applications for MPEG-2—the company will need to progress and integrate its reference designs into smaller and smaller chip numbers. Dataquest estimates that the digital STB market will grow to almost 39 million units in 2002—a CAGR of 38 percent. The related semiconductor market is estimated to grow to almost $3.8 billion—a CAGR of 26 percent. This, then, is a market in which it is well worth investing.

In 1997, Philips Semiconductors was the second-largest semiconductor supplier to the worldwide wireless communications market with revenue of $789 million, only marginally behind Motorola. This amounted to 32 percent revenue growth compared with 1996. Given the company's overall growth in the first half of 1998, this solid performance looks to have been maintained. Philips Semiconductors' growth in the wireless market is driven by its strong product offerings in RF, IF and power amplifier markets (in which it is the number-one semiconductor vendor), and the digital cellular baseband markets (where it occupies the number-three position with a 6 percent share of the market).

Philips Consumer Communications' aggressive growth plans in 1997 will have contributed to Philips Semiconductors' growth in the wireless market. However, with Philips Consumer Communications' relatively poor performance in 1998 and competition from Lucent Technologies to replace Philips Semiconductors' design wins in Philips Consumer Communications, Philips Semiconductors may not achieve similar growth rates in the wireless market this year. The expertise of Philips Semiconductors' wireless group has been highlighted by new product offerings this year. Recent offerings include a chipset for dual-band time-division multiple access cellular and PCS/DCS telephones that halves the number of components needed to build a dual-band RF system, and a dual-band GSM and satellite handset RF front end for the Asian market.

Since late 1997, Philips Semiconductors has won contracts with many major handheld PC manufacturers. The first half of 1998 will have seen Philips increase shipments of its TwoChipHCG family of RISC-based processors to companies such as Sharp, Compaq, Samsung and Quantum Micro Systems. Dataquest estimates that the handheld market in 1997 amounted to 803,000 units, and that it will grow to 3.8 million units by 2001. Given the still fragmented nature of the handheld processor market, Philips Semiconductors has an opportunity to gain significant market share.

Siemens Semiconductor

Anyone judging Siemens Semiconductor by its recent press coverage would think that the company is in the midst of a severe crisis. The DRAM market, into which Siemens Semiconductor has invested much capital in recent years, has experienced a protracted downturn that has forced DRAM manufacturers to continue accepting losses. This has led the company to close a new 8-inch wafer, 64Mb DRAM fabrication plant in England, to announce a strategy to improve its performance and to start a high-profile offensive against its DRAM competitors.

Siemens Semiconductor's DRAM division aside, this is a semiconductor company that competes successfully in many growing marketplaces. The company's worldwide revenue in 1997 was about $3.4 billion—14 percent growth compared with 1996. For the first half of 1998, Siemens Semiconductor recorded deutsche mark growth of 7 percent, although in terms of dollars, revenue was essentially flat. Revenue for the first half of 1998 (financial quarters two and three for the company) was DM 3.3 billion ($1.82 billion) compared with DM 3.1 billion ($1.83 billion) in the first half of 1997. Importantly, Siemens Semiconductor's book-to-bill ratio increased from 1.065 in the first half of 1997 to 1.091 in the first half of 1998, indicating that revenue in the second half of 1998 should be greater than that of the second half of 1997. Tables 10 and 11 give details of the company's revenue in 1996 and 1997.

In 1997, Siemens Semiconductor's largest product market was DRAM, accounting for almost 28 percent of revenue. In the first six months of 1998 the world DRAM market declined by 34 percent in dollar terms over the first half of 1997. The company's revenue has remained stable despite this decline. There are two possible explanations for this. Either the company has increased its market share in the DRAM market enough to offset price erosion, or its performance in other product markets has been sufficient to offset lost DRAM revenue. Dataquest believes the second explanation to have been the case.

Siemens Semiconductor's other major product markets include 8-bit and 16-bit microcontrollers, telecommunications ICs and small signal and power transistors. Table 12 shows the growth rates of the markets in which Siemens Semiconductor has significant market presence in the first half of 1998.

Wired and wireless telecommunications represent strategic markets for Siemens Semiconductor, both now and in future. Other key markets that the company will focus on during the next few years include the chip card market and the wider automotive and industrial markets.

In the wired telecommunications market, Siemens Semiconductor began 1998 as the seventh-largest provider of wired telecommunications ICs. The company was head and shoulders above its competitors in the ISDN market, with revenue of $108 million. Performance in 1998 is reported to be strong, despite continued price pressure in the market and increasing competition from Lucent Technologies. Siemens Semiconductor is continually updating its ISDN products to maintain its competitive advantage in 1998. Advancements in 1998 include further integration of its products to offer single-chip solutions in network termination, as well as expansions in its high-level data link controller line. The company's other major wired offerings are in the area of line cards, where it has been losing ground in recent years to competitors such as AMD, Lucent Technologies and ST.

Table 10
Siemens Semiconductor's Worldwide Revenue by Device Category, 1996 and 1997

Category	1996 ($M)	1997 ($M)	Growth (%)
Total Semiconductor	3,029	3,441	13.6%
Bipolar Digital	32	37	15.6%

©1998 Dataquest

In the wireless semiconductor market Siemens Semiconductor's performance has leapt forward in recent years. The company began 1998 as the third-largest provider of wireless communications semiconductors, only fractionally behind Motorola and Philips Semiconductors.

Siemens Semiconductor's strengths lie throughout the digital wireless market. In the GSM market, revenue from its RF/IF chips puts them in second place behind Philips Semiconductors', while Siemens Semiconductor's baseband solution ranks third. Siemens Semiconductor's challenge for 1998 is to improve the position of its HiGOLD product in the merchant market, building on its success in Siemens handsets. Part of the company's 1998 strategy is the introduction of the Carmel DSP architecture. Siemens Semiconductor dominates the DECT baseband semiconductor market, being almost three times larger than its closest competitor in 1997. This should be of importance as Dataquest predicts that DECT handset production will grow into a $1.6 billion market in 1998 (from $1.2 billion in 1997), and into a market worth more than $4 billion by 2002.

Siemens Semiconductor is the second of two European companies that dominate the chip card market. In 1997, Siemens Semiconductor was number one in the memory-based chip card (memory card) market, with a 67 percent share and revenue more than four times greater than that of its nearest competitor, ST. In the microcontroller-based chip card (smart card) market, Siemens Semiconductor began 1998 in second place behind ST, with a 29 percent market share. With chip card revenue expected to reach $3.7 billion by 2002, the chip card market should become a significant revenue generator for Siemens Semiconductor.

Other strategic targets that the company will address over the next few years include mounting a logic device marketing offensive in the communications, automotive and industrial applications markets. This strategy will produce new driver information and in-car communication products for the automotive market, and drive, control and power supply products for the industrial market.

Dataquest Perspective

Although everything (with the exception of DRAM) appears rosy for Europe's three largest semiconductor companies, there are potential problems ahead. All three companies have focused on similar application markets, namely next-generation digital consumer, digital telephone and smart cards. All three applications are very attractive and, although these companies are doing well in their target markets, many other semiconductor companies will begin to make inroads into these markets to take advantage of high growth rates. Inevitably this will detract from the profitability of these markets as they become more price sensitive. Many of these markets are already experiencing downward ASP pressure (see Tables 6, 9 and 12).

On a positive note, these companies have a head start on many of their competitors. This should enable them to maintain their advantage, at least in the short term. These companies possess the key analog and digital technologies and the intellectual property necessary to compete in future, highly integrated markets. Furthermore, many of the growth application markets that will emerge over the next few years will be driven by Europe. Examples will include DECT, smart cards and digital STBs. Continued collaboration at a European level through initiatives such as Eureka and Esprit should also assist all three companies in driving the shape of future markets.

Semiconductor Application Markets Europe

Market Analysis

LAN and LAN Internetworking Equipment Production in EMEA

Abstract: *This Market Analysis outlines the major issues affecting LAN evolution and reports on hub, switch and router equipment production in Europe, the Middle East and Africa (EMEA), comparing this with shipment statistics.*

By Andrew Phillips

Executive Summary

This document presents Dataquest's share statistics for EMEA production of LAN and LAN internetworking equipment (comprising hubs, switches, backbone routers and access routers). Manufacturing locations and subcontractors are also detailed. Although many of the major OEMs have design and manufacturing activity in EMEA, Cisco Systems' absence means that local production contributes only a small percentage toward the total equipment shipped in the region. The fastest-growing opportunities for semiconductor usage are in access routers (for the LAN internetworking market), which are forecast to grow at 31 percent compound annual growth rate (CAGR) between 1997 and 2002, and LAN switches, which are forecast to grow at 31 percent CAGR over the same period. Higher-speed protocols, such as Gigabit Ethernet, are encouraging a trend toward ASIC solutions for these products. Developments in LAN hardware configuration, protocol usage and Layer 3 switching are also presented.

LAN Equipment Definition and Evolution

Dataquest defines LAN hubs, switches and routers as follows:

- Shared media hubs: these are LAN devices that connect multiple PCs through a single node on the network.
- Switches: these provide dedicated bandwidth to one or more users on each switched port. Devices that have multiple shared media ports linked to individual switch ports (known as group switches) are treated as hubs. Layer 2 and Layer 3 switches are included.
- Routers: these are a class of network controller that determine the best routing for data transmission between a transmitter and a receiver. Routers operate at Layer 3 of the ISO-OSI model and can be segmented further into backbone routers and access routers. Access routers may be classified as branch office routers or personal routers.

Filing: Perspective
(For Cross-Technology, file in the Semiconductor Application Markets binder)

Dataquest defines EMEA networking equipment production as follows:

- Full-build: the assembly of electronic components (both active and passive) onto the main printed circuit board (PCB) in addition to the assembly of the system.
- System-build: system assembly and configuration only, using PCBs imported from outside EMEA.

Total networking production is the sum of full-build and system-build assembly, which are mutually exclusive.

In recent years, LAN communications have become critical to the success of many knowledge-based organizations. Networking products continue to evolve to meet the demands of traffic growth and new applications. As the breadth of communications dependence increases, organizations spend more time evaluating the cost/benefit and bottleneck issues relating to system hardware.

Advances in PC and workstation technology and processing power have driven this evolution. Multimedia applications, e-commerce and portable computing products have increased the demands on the LAN and the requirement for fast, reliable access to it for remote workers.

Hardware Configuration

Figure 1 illustrates the hardware configuration of a typical large business enterprise LAN and WAN. Remote workers and the branch office have access to the main office servers via the WAN. The hardware shown is representative of many installations. In this example, desktop PC subgroups, equipped with standard Ethernet network interface cards (NICs), have a twisted pair connection to a local shared media hub or switch. The hubs provide a shared bandwidth (in this case, 10 Mbit/s), while switches provide a guaranteed maximum bandwidth (10 Mbit/s) to each NIC. The backbone connection from these hubs and switches multiplexes the subgroup communications (via 100-Mbit/s Fast Ethernet in our example) to the backbone router; this router manages traffic to the servers and, via the remote access server, to the WAN. The remote workers may access the LAN using personal routers, but are more likely to use analog modems. The branch office uses dedicated equipment (that is, a branch-office router) to access the servers via a higher-bandwidth link such as ISDN or leased line.

Ethernet Evolution

Traditional LAN communications are based on a shared media approach whereby multiple users (that is, a subgroup), linked in a star configuration to a repeater hub, compete for a fixed amount of bandwidth. When the hub receives a packet of data the incoming signal must be rebroadcast to all the attached nodes. This inefficient use of bandwidth has the additional problem of reducing the average bandwidth available in the subgroup each time a new node is added.

The original solution to increased LAN traffic was to divide subgroups into smaller segments linked by bridges or routers. Routers are expensive and add delay to data throughput. A more cost-effective solution was achieved with the development of 100-Mbit/s Fast Ethernet and by using LAN switches instead of shared media hubs to allocate dedicated bandwidth to each port. These switches operate at Layer 2 of the ISO-OSI model, supporting a single subgroup address and guaranteeing bandwidth to that node. Recent price erosion in the 10/100-Mbit/s Ethernet NIC market has accelerated this trend, with 1997 EMEA sales of 10/100-Mbit/s NICs overtaking 10-Mbit/s products for the first time. Table 1 presents the major applications for various LAN protocols.

Table 1
Major Applications for LAN Protocols

Protocol	Maximum Data Rate (Mbit/s)	Major Applications
Ethernet	10	Desktop and backbone
Fast Ethernet	100	Backbone upgrades and 10/100-Mbit/s NICs
Gigabit Ethernet	1,000	Fastest-growing backbone upgrade technology
Token-Ring	4/16	Desktop and backbone, but losing share
FDDI	100	Backbone, but losing share
ATM	25/155	Backbone upgrades

Source: Dataquest (July 1998)

Backbone Bottlenecks

The emergence of the Internet, intranets and client/server applications has caused a dramatic shift in LAN traffic distribution over the past few years. Working teams are more fluid and less likely to be situated in the same physical area sharing the same subgroup. While 80 percent of traffic used to be localized within a subgroup, today a much larger percentage of traffic traverses multiple subgroup boundaries. This has increased the bandwidth requirements on the LAN backbone and, although 10-Mbit/s Ethernet is the dominant backbone, Fast Ethernet is expected to have the majority share two years from now.

Until recently, if a network became sufficiently large to require segmenting, the best way to achieve this was to put backbone routers in the network. Routers use the information contained within Layer 3 of the ISO-OSI model to segment the network, increasing efficiency and adding security and manageability in each subgroup. The routers are typically software controlled and can be programmed to provide the cheapest, fastest or least busy of all available routes to LAN or WAN interfaces.

 ©1998 Dataquest

The Layer 3 Switching Solution

By relying on lookup tables to route all the packets in a transmission, the router is inherently slow. The larger the network the larger the lookup tables and the greater the propagation delay. Today's high-performance routers achieve throughput rates of 1 million packets per second (pps). The slowest Layer 3 switches operate at millions of pps and, given their lower cost, present a price/performance benefit that cannot be ignored. Table 2 compares the features of Layer 3 switching with traditional routing.

The limitations of Layer 3 switches make them unsuitable for interface to the WAN; consequently, traditional backbone routers that were replaced by these Layer 3 switches are being redeployed in WAN interface applications. In addition, access routers, incorporating a WAN interface, are being developed for the remote-worker and branch office markets.

Table 2
Features of Traditional Routing versus Layer 3 Switching

Traditional Routing	Layer 3 Switching
Typical cost $80,000	Typical cost $30,000
Packet forwarding up to 1 million pps	Packet forwarding up to 11 million pps
CPU and software architecture	ASIC architecture
Multiprotocol support	Currently supports TCP/IP and IPX only
Supports extensive filtering	Supports some filtering
Supports multiple subgroups	Supports multiple subgroups

pps = packets per second
Source: Dataquest (July 1998)

Other Networking Considerations

Having the correct LAN configuration is clearly important, but many organizations have legacy issues to consider and networks that are expanding in terms of applications and users. LAN bottlenecks may occur in other areas. The installed base of Cat 3 (16 MHz), Cat 4 (20 MHz) and Cat 5 (100 MHz) cabling presents its own limitations. Cat 5's bandwidth restrictions have encouraged the Institute of Electrical and Electronics Engineers to work on a scheme for sending Gigabit Ethernet over copper; Cat 6 and Cat 7 cable specifications offer marginal bandwidth improvements, but at significant cost.

Moving to gigabit data rates in the backbone may move the bottleneck to the servers themselves. Amdahl's law states that an execution rate of 1 million instructions per second (Mips) is needed to utilize every Mbit/s of communications bandwidth available to the processor. Thus, 1,000 Mips are required for gigabit data rates, which equates to approximately four 200-MHz Pentium Pro processors. Raw processing power may be compromised further by server hard disk access times or Level 2 cache size and wait states.

Internet access and the increased mobility of workers have fueled voice over IP technology, increased sales of analog modem and ISDN remote access technology products and encouraged design activity in cable modem and xDSL digital modem techniques. Financing new hardware for the remote worker has the combined effect of reducing funds available to upgrade other areas of the LAN, while increasing the potential number of users and the amount of traffic.

 ©1998 Dataquest

EMEA Networking Market Overview

Shipments of networking products (hubs, switches and routers) in EMEA amounted to $6,500 million in 1997. Three manufacturers—Bay Networks, 3Com and Cisco Systems—dominate this market, and sales of their products into the region accounted for 66 percent of this revenue.

Networking products manufactured in EMEA account for only a small part of this shipment revenue—the majority of products shipped are imported into the region. Dataquest estimates that the value of EMEA production of hubs, switches and routers was $748 million in 1997. Figures 2 and 3 illustrate the share of this ex-factory revenue by product (hub, switch and router) and by manufacturer, respectively.

Table 3 lists the equipment manufactured in EMEA by the major manufacturers; Table 4 details their design and manufacturing locations. Notably absent from the list is Cisco Systems, which has a major share of the shipments of LAN switches and routers in EMEA. Newbridge Networks' UK headquarters performed some assembly, but this ceased in October 1997. Olicom has design activity only in its Denmark facility.

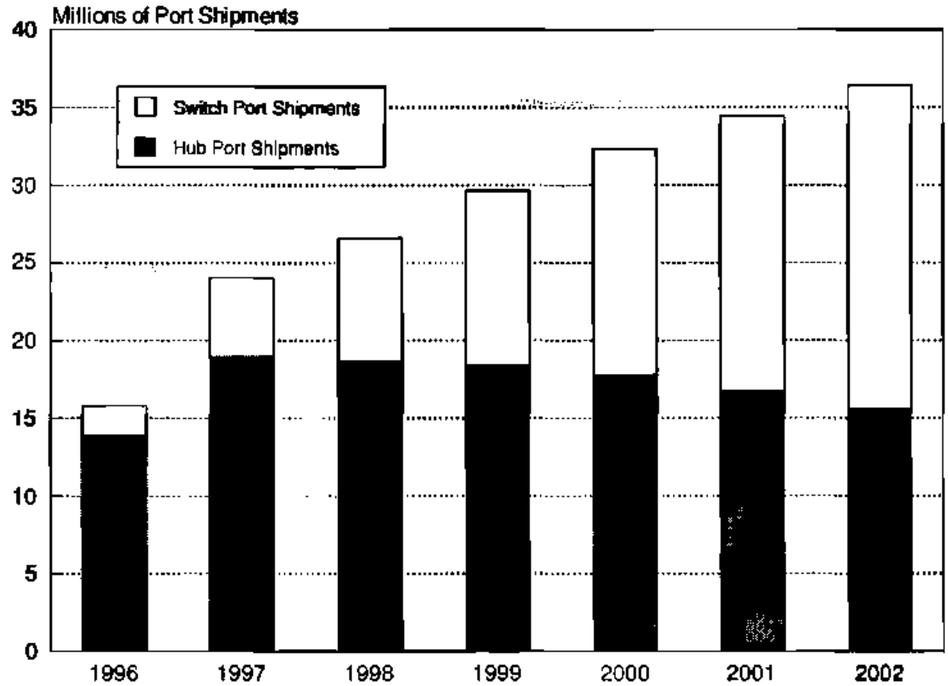
EMEA LAN and LAN Internetworking Equipment Production Forecast

Shared Media Hub and LAN Switch Forecast

EMEA shipments of 10-Mbit/s Ethernet shared media hubs continue to account for the majority (76 percent in 1997) of all shared and switched LAN ports sold. However, shared 10-Mbit/s Ethernet equipment sales are dropping, while all other types of Ethernet connection—including switched 10 Mbit/s—are growing. This trend has been encouraged during the past year by aggressive product pricing from commodity-oriented suppliers and Asia/Pacific vendors shipping autosensing 10/100-Mbit/s Ethernet switches. Combined with low-cost 10/100-Mbit/s NICs, these present a flexible and affordable solution. Fast Ethernet switches are forecast to show very strong shipment growth (48 percent CAGR from 1997 to 2002). ATM and Gigabit Ethernet switches also show strong growth, but their relatively recent introduction and backbone rather than desktop application has limited shipments. The shipment forecast for shared media hubs and LAN switches is shown in Figure 4.

Figure 4
Shared Media Hub and LAN Switch Shipment Forecast in EMEA, 1996-2002



Source: Dataquest (July 1988 Estimates)

The EMEA shared media hub and LAN switch production forecasts, shown in Figures 5 and 6, show similar trends to the shipment figures. Although Fast Ethernet shared media hub production is increasing, the overall trend in the hub market is for declining port production and ASP. To compete with the popularity of the latest switched solutions, shared media hubs have become aggressively priced. The shared media hub ex-factory ASP forecast levels off toward the end of the forecast period as Fast Ethernet hubs become a significant percentage of units produced.

LAN switch production shows increasing production volumes and decreasing ASP. The vast majority of these products are Layer 2, although Dataquest also groups Layer 3 switches in this category. Layer 3 switch production is also increasing, but volumes are very limited and account for less than 10 percent of the total port production by the end of the forecast period.

Layer 3 switches have been shipping only since 1997, and still have some technical boundaries to overcome in terms of multiprotocol interpretation. This suggests that their ASP is unlikely to fall as rapidly as that of Layer 2 switches.

Router Forecast

The router shipments forecast, shown in Figure 7, highlights the growth of this market, led by the explosion of access router products for the LAN internetworking market. Access routers are significantly less expensive than backbone products and revenue from router shipments will decline beyond 1999, even with the strong growth of access routers.

The situation for EMEA production is slightly different. Cisco Systems has the majority share of the backbone and access router market in EMEA, with more than 40 percent of total shipments, but has no production facility in the region. Figure 8 forecasts EMEA router production—which consists almost entirely of access routers. The decline in ASP reflects the fierce competition in this expanding market. With the introduction of Layer 3 switching products competing for part of the same market, it is unlikely that backbone routers will be built in significant numbers in EMEA. However, backbone routers are still necessary at the edge of the LAN to provide security and a wide-area interface, and manufacturers will focus on selling them to Internet service providers rather than the corporate network.

Figure 7
Backbone and Access Router Shipments in EMEA, 1996-2002

Application Market Forecast

Table 5 presents the market forecast and accompanying semiconductor demand for shared media hubs, LAN switches and routers.

Silicon developments for hubs and switches have focused on reducing the cost per port and integrating multiple-port functionality into ASICs. Integration of the physical layer onto these transceiver devices reduces system costs further, although power consumption issues have prevented this for 10/100-Mbit/s PHY devices.

Traditional routers are microprocessor based and software intensive, but Layer 3 switches achieve the data-forwarding function in silicon. Moving more of the routing function into hardware increases speed and has cost benefits. However, while traditional routers support a wide range of data communication protocols, commercial considerations have limited Layer 3 switches to addressing only the most popular protocols. Most Layer 3 switches support TCP/IP and in some cases Novell's IPX as well. True multiprotocol Layer 3 switches are not yet a reality.

Switches and routers have a declining semiconductor content value over the forecast period. However, as Table 5 shows, this is not significant enough to impact revenue growth in the semiconductor market.

Table 5
Shared Media Hub, LAN Switch and Router Application Market in EMEA, 1996-2002

	1996	1997	1998	1999	2000	2001	2002	CAGR 1997-2002
Shared Media Hub Ports (K)	2,200	1,919	1,674	1,575	1,475	1,375	1,300	-7.49%
Ex-Factory Port ASP ($)	77	64	56	48	46	46	45	-6.80%
Ex-Factory Revenue ($M)	169	123	94	76	68	63	59	-13.79%
Semiconductor Content ($)	7.4	6.5	6.2	6.3	6.3	6.2	6.2	-1.01%
Semiconductor Market ($M)	16	12	10	10	9	9	8	-8.43%

Dataquest Perspective

In enterprise applications, the LAN has progressed from being a novelty, to a convenience, to a necessity: in many cases, if the LAN goes down the business cannot function. This fact is affecting the development of networking products and making issues relating to quality and reliability as important as issues of functionality.

However, functionality is not standing still. Switch technology and access router products present a sales opportunity to those manufacturers that can meet the time-to-market and technology demands. This directly impacts semiconductor suppliers. They too must meet timescale and technology demands to achieve "design ins." The 1997 EMEA semiconductor market for networking products amounted to $60 million, and is forecast to exceed $170 million by 2002. Access routers and LAN switches drive this growth and application-specific standard products (ASSPs) are fundamental to these products. Silicon vendors Texas Instruments and Galileo Technology have penetrated successfully the LAN switch ASSP market, while vendors such as LSI Logic offer ASIC transceiver functions.

Production of hubs, switches and routers in EMEA accounts for only a small percentage of equipment shipped in the region. Dataquest forecasts that this percentage will increase as networking products become not only more widespread (particularly in smaller enterprises where delivery issues influence sales), but also more diverse; products such as Gigabit Ethernet hubs, Layer 3 switches and personal routers are recent examples of this diversity.

 ©1998 Dataquest

Subcontractors play an important role in LAN equipment manufacture in EMEA (see Table 4) and will benefit from semiconductor contract pricing negotiated directly by the networking vendor. Cisco Systems uses European subcontractors for occasional short production runs, but as yet has no dedicated production facility in the region.

Entry into this market may prove difficult for new players because the major manufacturers are marketing themselves using product branding and system-solution strategies rather than advertising technical features. This will encourage sales to smaller, less technically aware customers, creating more difficult market conditions for the medium-sized and specialist manufacturers. Vendor-specific protocol enhancements limit interoperability and exacerbate this problem.

As continual mergers, acquisitions and partnerships in the industry prove (for example, Intel's acquisition of Case Technology, Cabletron's acquisition of DEC's networking business, Nokia's acquisition of Ipsilon and the acquisition of Radnet by Siemens/Newbridge), this market is worth competing for. Nortel's recent agreement to acquire Bay Networks (the largest merger so far) may encourage other companies, such as Ericsson, to make similar moves.

The dynamics of the networking industry often arise from companies buying technology in order to broaden their product portfolios. Time-to-market issues and system-solution marketing strategies limit in-house development of new products. This presents an underutilized channel for semiconductor design-in. The typical acquisition trail involves the purchase of smaller start-ups by established LAN vendors that, in turn, may be acquired major industry players (such as Nortel, Cisco Systems or Lucent Technologies). Traditionally, a semiconductor vendor's application engineers focus their activity on major players. The likelihood of design-in is limited, but the potential rewards are considerable. Smaller start-ups are serviced typically by the semiconductor distribution network, which is less experienced in establishing long-term potential. However, the semiconductor design from the start-up company moves through the acquisition trail and future design-ins are effectively locked out.

Collectively, these issues should serve as a warning to any silicon vendor expecting to succeed on technology alone. A strategy for financing promising start-ups should be considered and a broader understanding of the volatility of the networking market must be attained.

Flash Talks in EMEA Digital Cellular Handset Production

Abstract: *Digital cellular phones are the single largest market for flash in Europe, the Middle East and Africa (EMEA). This article covers flash usage in digital cellular handsets and the wireless market forces driving the segment's success. Cellular phone production data, including market share leaders, is summarized.*

By Bruce Bonner and Dale Ford; adapted by Richard Gordon and David Moorhouse

Digital Cellular Handset Production Overview

A dramatic change in the technology of cellular phones has occurred in recent years. Although analog handsets represented the vast majority of worldwide cellular phone production in 1993, the manufacture of digital handsets had overtaken that of analog ones by 1996. Last year worldwide digital cellular handset production represented 80 percent of all handsets manufactured, and this figure is expected to rise to almost 100 percent by 2002. In this respect, the EMEA region is well placed as it accounted for nearly 55 percent of worldwide production of digital cellular handsets in 1997. This share is expected to hold up reasonably well in the face of production migrating to lower-cost manufacturing regions of the Far East. A forecast compound annual growth rate (CAGR) of 18 percent between 1997 and 2002 would take EMEA digital cellular handset production to 124 million units by the end of the forecast period, as shown in Table 1.

FILE COPY:
MARIA VALENZUELA

The digital GSM handset market exploded in Europe during the 1990s as European countries agreed on the unified GSM standard. This market had experienced very low cellular phone penetration rates before that time, but it took off after the introduction of the GSM standard (which allowed easier roaming between countries) and has grown quickly to become the largest digital cellular market in the world. Although many countries in other regions also have adopted the GSM standard, the Americas market has been much slower to adopt digital technology than anticipated.

As GSM has grown to become the dominant worldwide cellular standard, three variants have emerged to support different market demands: GSM900; GSM1800; and, for the US market, GSM1900. The difference between the three lies in the frequency of operation of the radio interface in each case—900, 1800

and 1900 MHz respectively.. As each of these markets has matured, there has been a technology and market trend towards handsets that can operate in more than one of these frequencies or bands—so-called multiband handsets.

The market in Europe for multiband handsets is growing rapidly, especially for the GSM900/GSM1800 combination. As the cost of these handsets is less than 10 percent more than a standard digital handset, production of multiband handsets is expected to grow rapidly and to dominate the manufacture of digital cellular phones in EMEA by the end of Dataquest's forecast period, as shown in Table 2.

In another development, digital cellular handsets that operate in more than one mode are expected to enter the European market in 1998. The first multimode products will be a combination of GSM mode and digital enhanced cordless telephony (DECT) mode. This mixing of modes will allow the introduction of handsets that offer a single phone number associated with a single handset irrespective of user location, whether at home or in the workplace, via a cordless connection to a DECT base station or via a connection to a cellular network while traveling.

Further insight of the handheld wireless market is available in Dataquest's *Market Trends* report titled "Communications Application Markets—Cellular/Broadband PCS and Cordless Telephones" (CSAM-WW-MT-9707).

How Cellular Phones Work

Cellular phones involve a relatively low-power handset corresponding with a local base station, of which there are many. The area surrounding the base station is called a "cell," and this can be visualized as a honeycomb. This simple concept yields powerful benefits. The handset can be small and light because it does not need to transmit long distances. A large number of subscribers can be connected simultaneously because their signals travel only a short distance and do not overlap with those in other cells. Traveling phones that move from one cell to another during a conversation can be accommodated by a central control's handing over responsibility for the handset from one base station to another. Multiple phones in the same area can be used at the same time by using multiple frequencies.

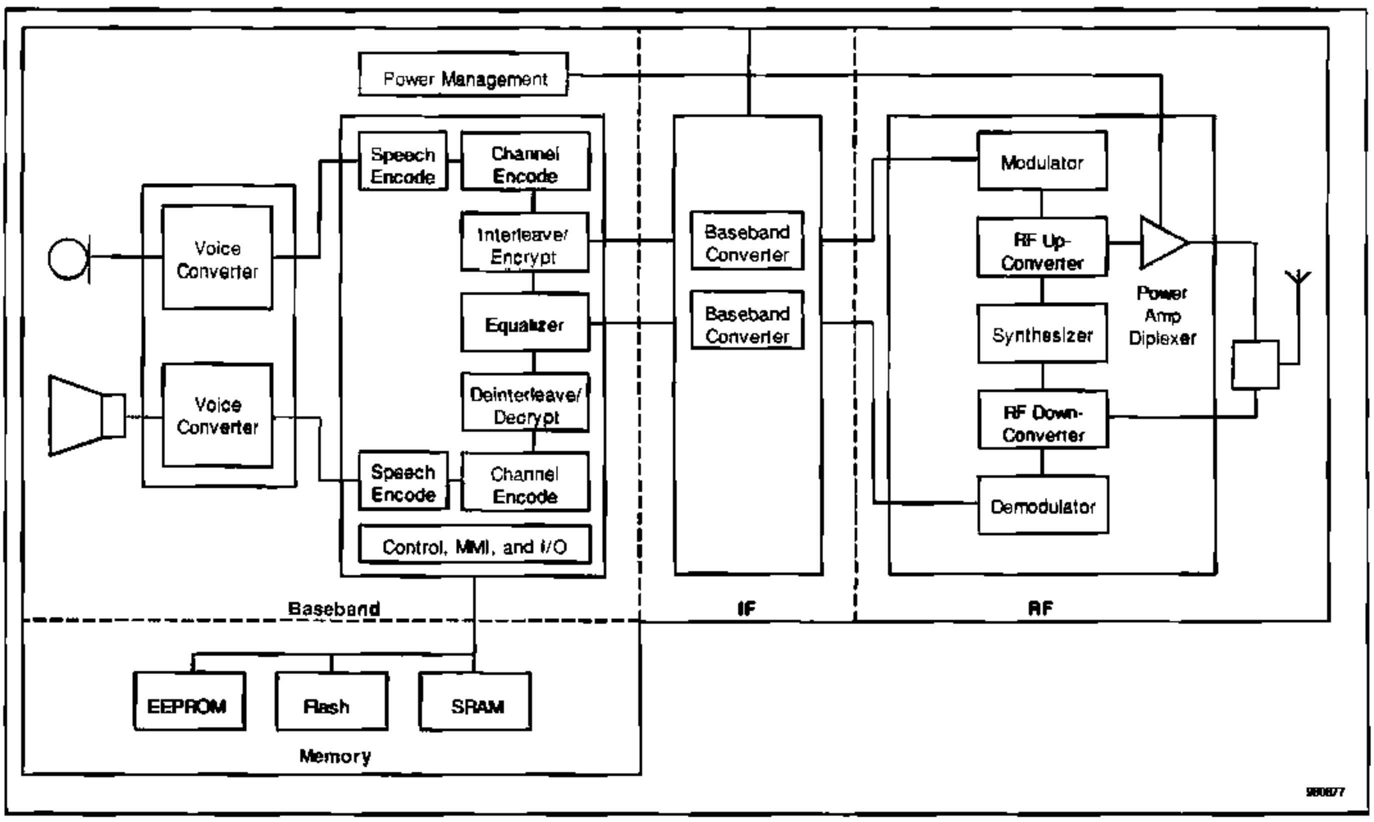
Digital Cellular Phones

Analog cellular phones were the initial standard deployed in the early days of cellular telephony. Voices are transmitted and received using a time-division multiplexing scheme, where periodic samples of the voice are frequency modulated (FM) on a carrier frequency. The advantages of an analog approach are a straightforward, minimal design for both handsets and base stations. A disadvantage, it turns out, is a lack of security for both the information (the voice) and the control signals the phone uses to stay synchronized with the cellular network. This minor technical issue became a major financial opportunity for some ethically challenged members of society, who would "clone" phone serial numbers to circumvent usage fees and having an identifying number associated with calls. Another segment of society was able to listen in on, and record, phone calls with simple scanning receivers. A better solution was needed.

 ©1998 Dataquest

Digital cellular phones were the answer to these issues. Instead of transmitting the voice as an FM signal, it was digitized and sent as ones and zeros over a network optimized for digital traffic. A major benefit of this change is the ability to service multiple handsets with a single operation frequency instead of tying up a frequency slot per handset, yielding a dramatic increase in network call capacity. Digital handsets also have better energy efficiency, yielding longer battery lives. But at the same time a digital standard was being created, encryption was added for both serial number and voice data, making cloning extremely difficult. The initial digital standard was a European product using the GSM standard; since then, code-division multiple access (CDMA, or IS-95) and time-division multiple access (TDMA, or IS-54 and IS-136) are the other digital standards that have been propagated. A block diagram of a typical digital cellular phone is shown in Figure 1, which shows a clear separation between the radio frequency (RF) and intermediate frequency (IF) sections and the baseband section. The baseband circuitry controls both the function of the phone and its connection with the phone network, using specific protocols for the system in which it is being used. But digital cellular phones are much more complex than analog models, which gave rise to the use of flash memory in them.

Figure 1
Digital Cellular Phone Block Diagram



Source: Dataquest (July 1998)

Memory Use in Cellular Phones

As shown in Figure 1, three types of discrete memory are typically used in cellular phones: SRAM, flash memory and EEPROM. SRAM is used to store information temporarily in conjunction with the baseband microcontroller. This is for interaction with both base stations and the cellular network and for remembering the status of functions used by the user. EEPROM is employed like SRAM, but as a nonvolatile memory for small amounts of operating data. Flash memory stores the firmware, the operation software, of the microcontroller. Flash memory was originally pressed into service by European cellular phone manufacturers for the rollout of GSM, when they needed regulatory approval of models they wanted to sell but for which the firmware was likely to change. The signaling protocols were complex, and they did not want delays in getting to market because a phone had to be resubmitted for approval with hardware changes. Flash memory came to the rescue by allowing the changes to be implemented in software and to be updated as necessary, mainly in production lines, but also for field units if they were returned to a service center. Analog phones normally do not use flash because the code size is small and simple, allowing a nonupdatable memory such as mask ROM or one-time-programmable EPROM to be used.

Flash Memory Use in Digital Cellular Phones

Flash memory is used as a reprogrammable storage medium for operating software in the cellular phone. It is normally written just once, when the phone is originally assembled. After that, the ability to update the code is an "insurance policy" for either a protocol function or a feature visible to the user. One idea floating in the cellular industry is for "over the air" updates to a phone—the flash memory could have a new program written to it from information moved to it over the cellular network itself. Although this *could* be used to fix bugs, the concept is more attractive to service providers because they could use it to sell new features, such as voice mail, to subscribers for additional monthly fees. This would be a win-win situation: the flash makers would sell more expensive and larger chips to the market, and more revenue would come to the providers. Alas, it is not to be for some time, because it requires extensive changes in a cellular network infrastructure focused on delivering real-time voice, not operating code.

A recent departure from this paradigm is the consolidation of the EEPROM function into the flash chip, which is discussed in more depth later.

Key Flash Device Issues

Key areas of interest for cellular phone design engineers using flash memory are operating voltage, architecture, packaging, density, speed and standardization.

Voltage

The coin of the realm for cellular flash is low operating voltage. This is a compatibility issue, because the rest of the logic in the phone reduces power dissipation as voltage is reduced. The power consumption of the flash device is not reduced as a direct result of this—in fact, it could go up if other steps were not taken, because the flash cell uses high voltages for programming and erase. The benefit of lower voltage is longer battery life, both for standby and talk time, and lighter, smaller phones from the reduced battery size.

Because cellular phones are the largest market for flash memory, many innovative products have been developed for the application. Advanced Micro Devices Inc. introduced a 1.8V 8Mb device, the Am29SL800, and Intel Corporation has 2.7V chips compatible with 1.8V logic levels in its Smart 3 product family. The Intel smart voltage concept allows both single- and dual-voltage supply operation. The dual supply usage, when an optional V_{pp} voltage is connected, speeds up programming considerably, an issue for production line loading of the contents of an entire memory. Companies are now starting work on 0.9V devices! Although these are probably at least two years away, flash companies are being driven very hard by cellular phone manufacturers, which are themselves in a fiercely competitive environment, and there is no doubt that voltage and energy will continue to drop as a result.

An interesting aspect of the AMD 1.8V product is what the company calls "zero power." This is an automatic power down to the "sleep" mode, which takes only nanoamperes of supply current, when the device is not being accessed. This addressed another concern of digital cellular phone designers: low energy usage. Instantaneous power consumption does not matter, per se. What is important is *energy*, and energy equals power times time. To say it another way, the key is the "area under the curve." This is an issue for flash because the physics of operating a flash chip do not change just because the operating voltage goes down. It still takes so many electrons on the floating gate to program a cell, and the energy required to do that stays constant no matter what the supply voltage is. This is a prime area for innovation in different technology approaches, such as DiNOR from Mitsubishi Corporation. New thinking is probably required for substantial energy usage reductions.

Architecture

Architectural issues for this application are more complex than for many other uses. The starting point is the assumption of an x16 data path, because the flash is connected to a high-performance microcontroller, often RISC-based, in a direct execute manner. A second issue is the need for asymmetrical "boot block" organizations to allow both code and control information to be stored and used efficiently. The third challenge for flash is consolidation of the EEPROM and flash memory into a single chip for space and cost savings.

As discussed previously, cellular phones use flash for "code storage," but the handsets also need to store small amounts of data during operation. Currently, this need is being filled by EEPROMs, sometimes with multiple EEPROMs in a single unit. The obstacle to moving this auxiliary storage to the flash chip is that flash is not a direct-overwrite implementation as EEPROM is, and the erase block where the data is located must sometimes be used to reset the information. Currently, an erase function in a flash chip puts it offline, not allowing it to continue executing code in parallel, which is a need for real-time operation. Writing data has the same issue. This is a problem.

One solution to this problem is called "read while write" (RWW). The flash device can be designed with duplicate peripheral circuitry for separate sections of the flash memory array. This allows concurrent reading of program information while a write or erase operation is occurring in a different part of the chip. AMD has introduced "simultaneous read/write" flash, the Am29DL800, which allows this. This 8Mb part has the flash divided into two banks, one having large "code" blocks of 64KB and the other having two 32KB, two 16KB and four 8KB "data" sectors.

Another approach is "software read while write," where a mini-OS in the phone manages the read/write transactions to the flash chip. Intel's Smart 3 Advanced Boot Block family, with 4Mb, 8Mb and 16Mb memories, does this with Intel's Flash Data Integrator software, which is supplied free of charge to designers. This device has eight 8KB data blocks and up to 31 64KB main blocks for code or data. Phone design engineers to date have preferred the straightforward hardware RWW approach, but Intel has gained early acceptance from some key cellular phone manufacturers with the software technique.

Another solution is putting a small EEPROM section on a larger flash chip, giving an integrated solution to the same problem. This is the ultimate RWW chip, but it is not very flexible as the size of the read-write memory is fixed.

Packaging

A final trend in the wireless phone industry is the constant push to make the electronics as physically small as possible. For flash, this will take two directions: either including flash in another system chip, such as the DSP, or using advanced packaging techniques to shrink the footprint of the chip on the PCB.

Embedding flash (or any memory type, for that matter) is an important trend in the consumer electronics industry, and it will be used when the amount of memory is small enough not to raise the cost of the one-chip solution significantly over the cost of a two-chip solution. Because the code size in these products is currently 8Mb to 16Mb, this merging of functions is not yet economical, so a physical approach is more appealing.

Most flash chips used in cellular handsets have a TSOP plastic package, which is thin and small. But an increasingly popular way to shrink the flash package is to use chip scale packaging (CSP) technology. Most of these packages are variations of a ball grid array method of electrically and mechanically attaching the device to the PCB. Another method is to place a memory die directly on the PCB and attach by the chip-on-board or flip-chip methods. Although this is theoretically possible now, there are many hurdles to high-volume supply and use of these, most of which are fixed by CSP. Dataquest expects CSP to win in the digital wireless flash market soon, and flip chip to become the method of choice eventually.

Density

The density sweet spot for digital cellular phones shipping now is 8Mb, but that is for the character sets of Europe and the Americas. As sales increase in Asia/Pacific and Japan, density increases to 16Mb for the more pictorial characters used there. Dataquest expects density also to increase as processor performance increases, with more code able to be executed in real time by a faster clock rate. Multifunctional units that may operate as either analog or digital phones increase the complexity of the code, and therefore its size, which is now 16Mb. Japanese Personal Digital Cellular (PDC) phones are expected to begin a transition to 32Mb later this year.

Density may also increase if new features, such as downloaded voice mail, are deployed by service providers. This would allow a user to listen to messages while not on the air (with charges) and perhaps respond to them offline for transmission later. Smart phones, which include the functionality of a handheld PC or organizer, would also need some form of mass storage-optimized flash. A possible new standard for this application is the Multimedia Card form factor proposed by SanDisk Corporation and endorsed by Siemens, Nokia, Ericsson and Motorola Incorporated.

Speed

Read access time shows the most direct adverse effects of lowering the operating voltage of a flash memory. For instance, a 5V 70-ns device may slow to 120 ns at 3V. In some cases, where an older, slower microcontroller is used, this is not an issue. But many new chipsets have RISC processors and a "need for speed." To make matters worse, cellular phone integrated circuits must operate over a negative 40° to positive 85°C temperature range. Currently, 120 ns is sufficient, but speed varies greatly, from products under 100 ns to those with latencies of 200 ns.

Dataquest foresees the use of architecture techniques, such as "page mode" designs, to give increased performance at lower voltages.

Standardization

An issue that continues to dog cellular phone design engineers is a lack of standardization for flash memory in general, especially for the devices used in advanced cellular handsets. Some of the blame for this must go to Intel and AMD, which continue to have different strategies for implementing cutting-edge designs. Pinouts and protocols continue to be different between them, not to mention erase block architectures. But the largest handset providers are pushing the flash vendors for innovative products that solve their problems, and the suppliers are responding as well as they can and as quickly as they can, which leaves standardization in the dust. Designers are advised to allow for multiple sourcing of flash chips at the earliest possible times in their design cycles to maximize purchasing flexibility, because drop-in substitutes do not exist in many cases.

EMEA Flash Market Size Estimates for the Digital Cellular Handset Application

Table 4 shows flash consumption by digital cellular handset production in EMEA in megabit and revenue terms.

Table 4
Flash Consumption by EMEA Digital Cellular Handset Production, 1993-2002

	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	CAGR 1997-2002
Units (K)	2,310	5,412	12,200	25,000	54,000	71,000	88,000	104,000	117,000	124,000	18%
Megabits (K)	9,240	27,060	73,200	174,999	431,999	674,500	1,144,000	1,664,000	2,340,000	2,976,000	47%
Revenue ($K)	62,116	98,120	153,091	346,577	410,175	410,037	500,571	619,474	741,573	852,214	16%

Source: Dataquest (July 1998 Estimates)

Dataquest Perspective

The tremendous surge in sales of digital cellular phones makes this market the largest opportunity by far for flash vendors. This is particularly true in the EMEA region, where production of digital cellular handsets is expected to account for some $850 million of flash revenue by 2002—about 60 percent of the total available market revenue of $1.4 billion in that year. As these units ramp up in emerging markets, worldwide sales will continue to expand. Because the cost of a wireless phone typically is subsidized by a service provider (although there is a trend towards direct purchasing), normal consumer demand elasticity is not an issue; the true cost of the handset is hidden from consumers and amortized into monthly charges.

The flash market recently has been very trying for the participants. They are shipping more and more products and bits but are collecting less money. Part of this has to do with a larger supplier base, but it also is because the largest cellular phone manufacturers, Motorola, Ericsson and Nokia, wield tremendous power with flash suppliers and are able to procure at commodity prices advanced products that should have hefty premiums instead.

Finally, Dataquest sees this market continuing to be key for the flash memory industry. The application values flash functionality and has the budget to pay for it. The level of innovation will prevent a true supply/demand free-for-all—but, as with most semiconductor sectors, this market is not for the faint of heart.

(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

and 1900 MHz respectively.. As each of these markets has matured, there has been a technology and market trend towards handsets that can operate in more than one of these frequencies or bands—so-called multiband handsets.

The market in Europe for multiband handsets is growing rapidly, especially for the GSM900/GSM1800 combination. As the cost of these handsets is less than 10 percent more than a standard digital handset, production of multiband handsets is expected to grow rapidly and to dominate the manufacture of digital cellular phones in EMEA by the end of Dataquest's forecast period, as shown in Table 2.

In another development, digital cellular handsets that operate in more than one mode are expected to enter the European market in 1998. The first multimode products will be a combination of GSM mode and digital enhanced cordless telephony (DECT) mode. This mixing of modes will allow the introduction of handsets that offer a single phone number associated with a single handset irrespective of user location, whether at home or in the workplace, via a cordless connection to a DECT base station or via a connection to a cellular network while traveling.

Further insight of the handheld wireless market is available in Dataquest's *Market Trends* report titled "Communications Application Markets—Cellular/ Broadband PCS and Cordless Telephones" (CSAM-WW-MT-9707).

How Cellular Phones Work

Cellular phones involve a relatively low-power handset corresponding with a local base station, of which there are many. The area surrounding the base station is called a "cell," and this can be visualized as a honeycomb. This simple concept yields powerful benefits. The handset can be small and light because it does not need to transmit long distances. A large number of subscribers can be connected simultaneously because their signals travel only a short distance and do not overlap with those in other cells. Traveling phones that move from one cell to another during a conversation can be accommodated by a central control's handing over responsibility for the handset from one base station to another. Multiple phones in the same area can be used at the same time by using multiple frequencies.

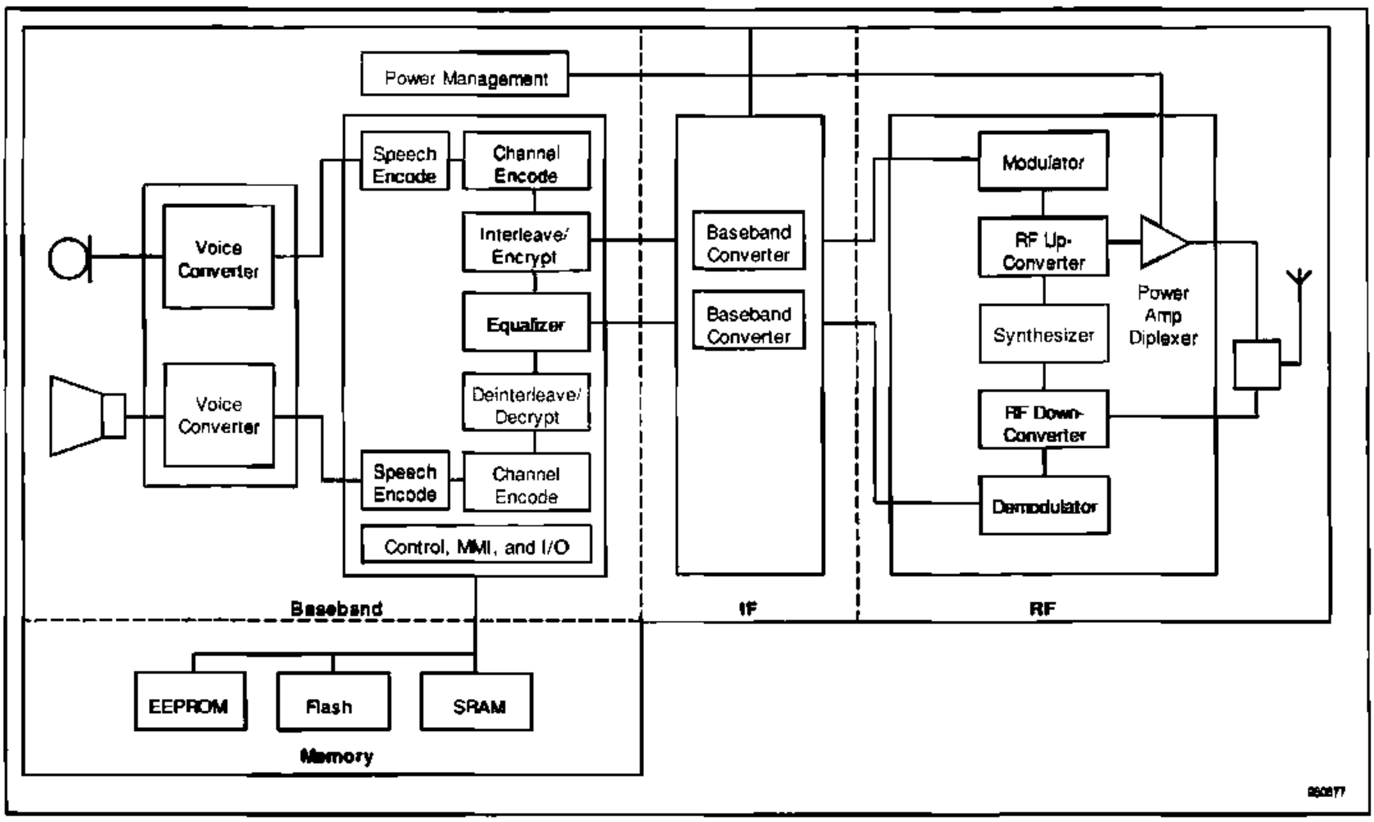
Digital Cellular Phones

Analog cellular phones were the initial standard deployed in the early days of cellular telephony. Voices are transmitted and received using a time-division multiplexing scheme, where periodic samples of the voice are frequency modulated (FM) on a carrier frequency. The advantages of an analog approach are a straightforward, minimal design for both handsets and base stations. A disadvantage, it turns out, is a lack of security for both the information (the voice) and the control signals the phone uses to stay synchronized with the cellular network. This minor technical issue became a major financial opportunity for some ethically challenged members of society, who would "clone" phone serial numbers to circumvent usage fees and having an identifying number associated with calls. Another segment of society was able to listen in on, and record, phone calls with simple scanning receivers. A better solution was needed.

 ©1998 Dataquest

Digital cellular phones were the answer to these issues. Instead of transmitting the voice as an FM signal, it was digitized and sent as ones and zeros over a network optimized for digital traffic. A major benefit of this change is the ability to service multiple handsets with a single operation frequency instead of tying up a frequency slot per handset, yielding a dramatic increase in network call capacity. Digital handsets also have better energy efficiency, yielding longer battery lives. But at the same time a digital standard was being created, encryption was added for both serial number and voice data, making cloning extremely difficult. The initial digital standard was a European product using the GSM standard; since then, code-division multiple access (CDMA, or IS-95) and time-division multiple access (TDMA, or IS-54 and IS-136) are the other digital standards that have been propagated. A block diagram of a typical digital cellular phone is shown in Figure 1, which shows a clear separation between the radio frequency (RF) and intermediate frequency (IF) sections and the baseband section. The baseband circuitry controls both the function of the phone and its connection with the phone network, using specific protocols for the system in which it is being used. But digital cellular phones are much more complex than analog models, which gave rise to the use of flash memory in them.

Figure 1
Digital Cellular Phone Block Diagram



Source: Dataquest (July 1998)

Memory Use in Cellular Phones

As shown in Figure 1, three types of discrete memory are typically used in cellular phones: SRAM, flash memory and EEPROM. SRAM is used to store information temporarily in conjunction with the baseband microcontroller. This is for interaction with both base stations and the cellular network and for remembering the status of functions used by the user. EEPROM is employed like SRAM, but as a nonvolatile memory for small amounts of operating data. Flash memory stores the firmware, the operation software, of the microcontroller. Flash memory was originally pressed into service by European cellular phone manufacturers for the rollout of GSM, when they needed regulatory approval of models they wanted to sell but for which the firmware was likely to change. The signaling protocols were complex, and they did not want delays in getting to market because a phone had to be resubmitted for approval with hardware changes. Flash memory came to the rescue by allowing the changes to be implemented in software and to be updated as necessary, mainly in production lines, but also for field units if they were returned to a service center. Analog phones normally do not use flash because the code size is small and simple, allowing a nonupdatable memory such as mask ROM or one-time-programmable EPROM to be used.

Flash Memory Use in Digital Cellular Phones

Flash memory is used as a reprogrammable storage medium for operating software in the cellular phone. It is normally written just once, when the phone is originally assembled. After that, the ability to update the code is an "insurance policy" for either a protocol function or a feature visible to the user. One idea floating in the cellular industry is for "over the air" updates to a phone—the flash memory could have a new program written to it from information moved to it over the cellular network itself. Although this *could* be used to fix bugs, the concept is more attractive to service providers because they could use it to sell new features, such as voice mail, to subscribers for additional monthly fees. This would be a win-win situation: the flash makers would sell more expensive and larger chips to the market, and more revenue would come to the providers. Alas, it is not to be for some time, because it requires extensive changes in a cellular network infrastructure focused on delivering real-time voice, not operating code.

A recent departure from this paradigm is the consolidation of the EEPROM function into the flash chip, which is discussed in more depth later.

Key Flash Device Issues

Key areas of interest for cellular phone design engineers using flash memory are operating voltage, architecture, packaging, density, speed and standardization.

Voltage

The coin of the realm for cellular flash is low operating voltage. This is a compatibility issue, because the rest of the logic in the phone reduces power dissipation as voltage is reduced. The power consumption of the flash device is not reduced as a direct result of this—in fact, it could go up if other steps were not taken, because the flash cell uses high voltages for programming and erase. The benefit of lower voltage is longer battery life, both for standby and talk time, and lighter, smaller phones from the reduced battery size.

Because cellular phones are the largest market for flash memory, many innovative products have been developed for the application. Advanced Micro Devices Inc. introduced a 1.8V 8Mb device, the Am29SL800, and Intel Corporation has 2.7V chips compatible with 1.8V logic levels in its Smart 3 product family. The Intel smart voltage concept allows both single- and dual-voltage supply operation. The dual supply usage, when an optional V_{pp} voltage is connected, speeds up programming considerably, an issue for production line loading of the contents of an entire memory. Companies are now starting work on 0.9V devices! Although these are probably at least two years away, flash companies are being driven very hard by cellular phone manufacturers, which are themselves in a fiercely competitive environment, and there is no doubt that voltage and energy will continue to drop as a result.

An interesting aspect of the AMD 1.8V product is what the company calls "zero power." This is an automatic power down to the "sleep" mode, which takes only nanoamperes of supply current, when the device is not being accessed. This addressed another concern of digital cellular phone designers: low energy

©1998 Dataquest

usage. Instantaneous power consumption does not matter, per se. What is important is *energy*, and energy equals power times time. To say it another way, the key is the "area under the curve." This is an issue for flash because the physics of operating a flash chip do not change just because the operating voltage goes down. It still takes so many electrons on the floating gate to program a cell, and the energy required to do that stays constant no matter what the supply voltage is. This is a prime area for innovation in different technology approaches, such as DiNOR from Mitsubishi Corporation. New thinking is probably required for substantial energy usage reductions.

Architecture

Architectural issues for this application are more complex than for many other uses. The starting point is the assumption of an x16 data path, because the flash is connected to a high-performance microcontroller, often RISC-based, in a direct execute manner. A second issue is the need for asymmetrical "boot block" organizations to allow both code and control information to be stored and used efficiently. The third challenge for flash is consolidation of the EEPROM and flash memory into a single chip for space and cost savings.

As discussed previously, cellular phones use flash for "code storage," but the handsets also need to store small amounts of data during operation. Currently, this need is being filled by EEPROMs, sometimes with multiple EEPROMs in a single unit. The obstacle to moving this auxiliary storage to the flash chip is that flash is not a direct-overwrite implementation as EEPROM is, and the erase block where the data is located must sometimes be used to reset the information. Currently, an erase function in a flash chip puts it offline, not allowing it to continue executing code in parallel, which is a need for real-time operation. Writing data has the same issue. This is a problem.

One solution to this problem is called "read while write" (RWW). The flash device can be designed with duplicate peripheral circuitry for separate sections of the flash memory array. This allows concurrent reading of program information while a write or erase operation is occurring in a different part of the chip. AMD has introduced "simultaneous read/write" flash, the Am29DL800, which allows this. This 8Mb part has the flash divided into two banks, one having large "code" blocks of 64KB and the other having two 32KB, two 16KB and four 8KB "data" sectors.

Another approach is "software read while write," where a mini-OS in the phone manages the read/write transactions to the flash chip. Intel's Smart 3 Advanced Boot Block family, with 4Mb, 8Mb and 16Mb memories, does this with Intel's Flash Data Integrator software, which is supplied free of charge to designers. This device has eight 8KB data blocks and up to 31 64KB main blocks for code or data. Phone design engineers to date have preferred the straightforward hardware RWW approach, but Intel has gained early acceptance from some key cellular phone manufacturers with the software technique.

Another solution is putting a small EEPROM section on a larger flash chip, giving an integrated solution to the same problem. This is the ultimate RWW chip, but it is not very flexible as the size of the read-write memory is fixed.

Packaging

A final trend in the wireless phone industry is the constant push to make the electronics as physically small as possible. For flash, this will take two directions: either including flash in another system chip, such as the DSP, or using advanced packaging techniques to shrink the footprint of the chip on the PCB.

Embedding flash (or any memory type, for that matter) is an important trend in the consumer electronics industry, and it will be used when the amount of memory is small enough not to raise the cost of the one-chip solution

 ©1998 Dataquest

significantly over the cost of a two-chip solution. Because the code size in these products is currently 8Mb to 16Mb, this merging of functions is not yet economical, so a physical approach is more appealing.

Most flash chips used in cellular handsets have a TSOP plastic package, which is thin and small. But an increasingly popular way to shrink the flash package is to use chip scale packaging (CSP) technology. Most of these packages are variations of a ball grid array method of electrically and mechanically attaching the device to the PCB. Another method is to place a memory die directly on the PCB and attach by the chip-on-board or flip-chip methods. Although this is theoretically possible now, there are many hurdles to high-volume supply and use of these, most of which are fixed by CSP. Dataquest expects CSP to win in the digital wireless flash market soon, and flip chip to become the method of choice eventually.

Density

The density sweet spot for digital cellular phones shipping now is 8Mb, but that is for the character sets of Europe and the Americas. As sales increase in Asia/Pacific and Japan, density increases to 16Mb for the more pictorial characters used there. Dataquest expects density also to increase as processor performance increases, with more code able to be executed in real time by a faster clock rate. Multifunctional units that may operate as either analog or digital phones increase the complexity of the code, and therefore its size, which is now 16Mb. Japanese Personal Digital Cellular (PDC) phones are expected to begin a transition to 32Mb later this year.

Density may also increase if new features, such as downloaded voice mail, are deployed by service providers. This would allow a user to listen to messages while not on the air (with charges) and perhaps respond to them offline for transmission later. Smart phones, which include the functionality of a handheld PC or organizer, would also need some form of mass storage-optimized flash. A possible new standard for this application is the Multimedia Card form factor proposed by SanDisk Corporation and endorsed by Siemens, Nokia, Ericsson and Motorola Incorporated.

Speed

Read access time shows the most direct adverse effects of lowering the operating voltage of a flash memory. For instance, a 5V 70-ns device may slow to 120 ns at 3V. In some cases, where an older, slower microcontroller is used, this is not an issue. But many new chipsets have RISC processors and a "need for speed." To make matters worse, cellular phone integrated circuits must operate over a negative 40° to positive 85°C temperature range. Currently, 120 ns is sufficient, but speed varies greatly, from products under 100 ns to those with latencies of 200 ns.

Dataquest foresees the use of architecture techniques, such as "page mode" designs, to give increased performance at lower voltages.

Standardization

An issue that continues to dog cellular phone design engineers is a lack of standardization for flash memory in general, especially for the devices used in advanced cellular handsets. Some of the blame for this must go to Intel and AMD, which continue to have different strategies for implementing cutting-edge designs. Pinouts and protocols continue to be different between them, not to mention erase block architectures. But the largest handset providers are pushing the flash vendors for innovative products that solve their problems, and the suppliers are responding as well as they can and as quickly as they can, which leaves standardization in the dust. Designers are advised to allow for multiple sourcing of flash chips at the earliest possible times in their design cycles to maximize purchasing flexibility, because drop-in substitutes do not exist in many cases.

Source: Dataquest (July 1998 Estimates)

Dataquest Perspective

The tremendous surge in sales of digital cellular phones makes this market the largest opportunity by far for flash vendors. This is particularly true in the EMEA region, where production of digital cellular handsets is expected to account for some $850 million of flash revenue by 2002—about 60 percent of the total available market revenue of $1.4 billion in that year. As these units ramp up in emerging markets, worldwide sales will continue to expand. Because the cost of a wireless phone typically is subsidized by a service provider (although there is a trend towards direct purchasing), normal consumer demand elasticity is not an issue; the true cost of the handset is hidden from consumers and amortized into monthly charges.

The flash market recently has been very trying for the participants. They are shipping more and more products and bits but are collecting less money. Part of this has to do with a larger supplier base, but it also is because the largest cellular phone manufacturers, Motorola, Ericsson and Nokia, wield tremendous power with flash suppliers and are able to procure at commodity prices advanced products that should have hefty premiums instead.

Finally, Dataquest sees this market continuing to be key for the flash memory industry. The application values flash functionality and has the budget to pay for it. The level of innovation will prevent a true supply/demand free-for-all—but, as with most semiconductor sectors, this market is not for the faint of heart.

Perspectives

Semiconductors Europe

Market Analysis

European Inward Investment Opportunities

Abstract: *In this Market Analysis Dataquest examines what the key factors are in attracting inward investment from the semiconductor industry, and analyzes eight major locations. Funding is no longer the critical factor it once was, while educational infrastructure is playing an increasingly significant role.*

By Edmund Gemmell

Executive Summary

FILE COPY:
MARIA VALENZUELA

Most countries in Europe are interested in, and are actively seeking, inward investment from semiconductor manufacturers. With most countries offering broadly similar incentives by way of capital grants and taxation benefits, the battleground to win high-quality inward investment is shifting to skills management. The future winners in this battle will be those that offer a combination of the correct skills in the right numbers, as well as attractive financial packages. This calls for an integrated response by each country to the demands of the semiconductor industry.

Some countries have recognized this and are rising to the challenge of developing methods to meet these demands. These will be the countries that attract the added-value inward investment projects. Some countries or regions will continue to offer large grants, but as this becomes more expensive, and as their competitors become more differentiated, the quality of inward investment that these regions or countries attract will suffer. While the focus of this *Market Analysis* is the semiconductor industry, many of the financial and fiscal incentives described are equally applicable to other industries.

Introduction

The location of a wafer fabrication plant or assembly and test plant is a key decision taken by semiconductor vendors when considering capital expenditure programs. Identifying where sufficient staffing, reliable infrastructure and suitable land can be found is becoming increasingly important. At the same time, many countries within the European Union (EU) have realized the potential benefits of having semiconductor plants located within their borders, in terms of direct employment, indirect employment, enterprise creation and regional regeneration. It is no surprise, therefore, that many countries, and

Dataquest

Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

specific regions within countries, are positioning themselves as high-technology centers and competing vigorously for new inward investment proposals. This *Market Analysis* analyzes some of the regions that a semiconductor manufacturer might consider when deciding upon a location within the EU. This *Market Analysis* also provides details of appropriate staffing availability, as well as training infrastructure and an overview of the financial incentives and support available in each location.

The locations covered in this *Market Analysis* are as follows:

- Flanders, Belgium
- Southeast France
- Western France
- Eastern Germany (Saxony)
- Ireland
- Northern England
- Central Scotland
- Central and eastern Spain

Table 1 shows the regions which have been most successful in promoting themselves to the semiconductor vendor community.

Table 1

Flanders

Recently, Flanders has been one of the more proactive regions in Europe trying to attract inward investment. The main focus of activity has been in attempting to attract a semiconductor wafer fabrication facility into the region, which, it is hoped, will act as a catalyst for the further development of the semiconductor industry within the region.

One of the most interesting ideas being investigated by the Flanders Foreign Investment Office (FFIO) is the concept of building its own wafer fabrication plant and leasing this out to semiconductor vendors on a long-term basis. The model would have the Flanders government consortium managing the plant and issues such as chemical, gas and waste handling, while the tenant vendor would be responsible for manufacturing development and core competencies. This business model is still being developed by the FFIO and Meissner and Wurst, a wafer fab design company.

Flanders is home to two semiconductor fabrication facilities. Alcatel Microelectronics, which is based in Oudenaarde, near Gent and IMEC, which has a smaller-scale facility in the region. IMEC is the largest independent microelectronics R&D center in Europe. IMEC's R&D activities are concentrated on the development of novel design methodologies, the development of processing technologies for the next generation of ULSI chips and the support of the training of VLSI design engineers on behalf of both educational institutes and industry. IMEC also provides training facilities for industrial partners upon request.

However, there are approximately ten other fabrication modules located within 150 km of Brussels. In addition to the semiconductor wafer fabrication plants and IMEC, Flanders has two other universities with specialist electronics faculties. The Flanders region also has 15 industrial engineering colleges which provide four-year electronics courses to degree standard.

The principal financial incentive offered by the Flanders government to inward investors is a series of cumulative direct subsidies. The first is a basic subsidy of 4 percent of total investment, which is available to qualifying investments that are the first operational unit by the company in Flanders. The second is a direct subsidy of up to 8 percent of the total investment, depending on the economic importance of the investment into the region. Given Flanders' eagerness to attract a semiconductor fabrication plant, it would be fair to assume that such an investment would be considered as being of great economic importance and, thus, would attract a significant part of this 8 percent. The third subsidy is based on employment growth, and can be up to 9 percent of the total investment. The combination of these three subsidies means a total direct subsidy of 21 percent of total investments is available to any qualifying inward investment project.

In addition to the direct subsidies that are available as incentives, Flanders also offer several fiscal measures to increase the value of inward investment support packages. These measures include an exemption of real estate tax for the investment site for five years and accelerated depreciation schemes. The FFIO will also participate in site acquisition and preparation.

The Flanders employment agency also participates in the sourcing of staff for any inward investment project. The Flanders employment agency, as part of an incentive package, will meet the expenses of new staff's first six to eight weeks of employment, when they usually will be in training.

France

Within France, the regions of western France and Marseilles-Provence in the southeast are two of France's primary high-technology and IT conurbations. Consequentially, both regions are being given a lot of support from the Invest in France Agency. Philips, Temic Matra (now part of Atmel) and SGS-Thomson have all located wafer fabrication plants within western France. Marseilles-Provence hosts wafer fabrication plants belonging to SGS-Thomson and Atmel. In addition, Motorola is nearby in Toulouse, and SGS-Thomson has more plants close by in Grenoble.

The importance of this high level of wafer fabrication plants is that both regions have been acclimatized to the high levels of service that wafer fabrication investments need in terms of ground preparation requirements, planning permission, waste material management, traffic and customs infrastructure, and supply infrastructure. In addition, the regions also have an existing skill base and orientation towards high-technology industries.

 ©1998 Dataquest

Western France

As well as the wafer fabrication plants located in western France, the region also has a high concentration of R&D facilities, including CNET (applied telecommunications research organization), CCETT (applied audiovisual research) and the microelectronics center for the west of France (CCMO), which is a collaboration between three electronics educational establishments in Rennes together with SGS-Thomson, Matra and SOREP. CCMO provides R&D facilities as well as further training facilities and courses for workers in the electronics industry.

Western France is also home to more than 50 university- or engineering-school-based laboratories or departments with a high-technology orientation. These laboratories and departments are in 13 universities or engineering schools specializing in electronics, data processing and telecommunications.

The primary financial incentive available to companies investing in western France is the regional development grant (PAT). Most areas within western France qualify for a subsidy of up to FF 50,000 (approximately $8,250) per job created, although some areas within the region qualify for up to FF 70,000 (approximately $11,500) per job created. PAT is available to all companies investing at least FF 20 million (approximately $3.3 million) and creating 20 permanent jobs over three years. Neither of these restrictions would pose much of a problem for a semiconductor vendor considering investing in a new operation. The PAT incentive is limited to 17 percent of total investment. Some exceptional levels of financial assistance are available from PAT in western France, however, because of the restructuring of the French defense industry.

In addition to PAT, other assistance schemes are available for training programs and ensuring that manufacturing facilities are environmentally friendly. Full or partial exemption from business tax (a local tax) is also negotiable for up to five years for inward investment projects. In PAT-qualifying areas, local authorities are also prepared to become involved in land acquisition and preparation, and may provide a discount of up to 25 percent on purchase or lease costs.

Marseilles-Provence

The Marseilles-Provence region in the southeast of France has, as stated earlier, many wafer fabrication plants either in the region or close by. Additionally, the region has several technology parks serving the electronics industry, including Rousset, Aixles-Milles industrial development park, the Chateau-Gombert science park and the Arbois Europole project.

Within these parks and the region's universities there are 30 laboratories carrying out research in various fields of microelectronics. These laboratories are based around the four universities in the Bouches du Rhone region. In addition, Marseilles-Provence is home to the Microelectronics Regional Study Center on Silicon (CREMSI), which has some 40 members, including SGS-Thomson, Atmel, Gemplus and DuPont Photomasks, and 10 R&D laboratories. CREMSI is focused on furthering microelectronics in the Marseilles-Provence region and undertakes joint research for those companies involved. The Marseilles-Provence region also provides training programs and facilities for the technicians and senior technicians required to populate semiconductor fabrication plants.

Financial incentives in the Marseilles-Provence region are structured as those for western France. Marseilles-Provence is one of the few regions in the southeast of France which qualifies for PAT. The PAT rate for Marseilles-Provence is FF 70,000 per job created, subject to a maximum of 25 percent of total investment.

Ireland

Analog Devices' investment in Limerick in 1976 was the catalyst for Ireland's interest in attracting electronics-related investment. Since then, in addition to attracting a prestigious investment from Intel, Ireland has attracted several other semiconductor-related inward investments in the form of design houses.

Ireland has focused its efforts to attract future inward investment by building an infrastructure to supply the key staff for future technology. In addition to the National Microelectronics Research Centre base at University College Cork, which has a 3-inch foundry, IC design group, and interconnect and packaging laboratory, Ireland has eight universities with electronic engineering faculties, which produce between 600 and 700 electronics engineering graduates per year. Also, the Irish government has put in place an Ir£50 million ($68 million) program aimed at developing additional engineering courses.

As well as its higher education establishments, Ireland also has 12 regional technical colleges offering electronics-related courses. Included in these courses is one codesigned by Hewlett-Packard and Intel to develop a suitably educated pool of technician-level staff.

One of the major financial attractions for investing in Ireland is the level of corporation tax levied against companies. The standard corporate tax rate is set at 10 percent until 2010. From 2010 until 2025 the rate will be 12.5 percent, which is significantly lower than that of most other countries. Surprisingly, other financial incentives aimed at attracting investment are significantly lower than those that some other regions are offering. The Irish Development Agency (IDA) offered Intel approximately IR£30,000 ($40,000) per job, which was significantly below some other offers, for a total commitment of 2,800 jobs, yet it still won the bid. This speaks volumes for the quality of staff on offer.

The IDA tends to work on an investment incentive per job created basis. However, once an amount per job has been fixed, it is broken down into three constituent parts: a capital grant based on the value of fixed assets; an employment grant, which, typically, would not exceed Ir£10,000 ($14,000) per job; and a training grant, which would cover up to 100 percent of agreed training costs.

Saxony, Germany

The former East German state, now one of the new German *Länder*, is positioning itself as the microelectronics center of eastern Germany. Since the reunification of Germany, Siemens has built a new DRAM wafer facility, in which it is planning its new 300-mm pilot line, and AMD is close to completing a new wafer fabrication plant for the manufacture of microprocessors. These developments are on top of the semiconductor infrastructure which existed when Saxony was part of East Germany. Zentrum Mikroelektronik Dresden (ZMD), which produces primarily memory products, has been located in Dresden since 1987. Prereunification, ZMD employed more than 3,000 staff in the microelectronics industry. Today it employs approximately 500, but the supply base for skilled employees, many of which worked in high-technology industries prior to reunification, remains.

Saxony, and Dresden in particular, offers a significant R&D and university infrastructure; Dresden has more than 30 educational and research institutes. Included in this number are the Institute for Semiconductor and Microsystems Technology, the Institute for Communications Systems, the Institute for Information Systems and the Institute for Technical Informatics, all at the Technical University (TU) Dresden, which has 21,000 students. In addition to TU Dresden, TU Chemnitz, FHS Mittweida, FHS Zwickau and FHS Zittau-Goerlitz all have IC design courses. Dresden is also home to the Fraunhofer Institutes for Microelectronic Circuits and Systems, the Fraunhofer Institute for Material Physics and Layer Technology and the Fraunhofer Institute for Integrated Circuits.

The financial incentives offered to inward investors in Saxony, and the new *Länder* of eastern Germany in general, are quite significant. Both Siemens and AMD received funding of approximately DM 800 million (approximately $450 million) to assist in their fabrication plant location decision.

Start up grants can reach 28 percent for large inward investment firms in the surrounding areas of Dresden and Leipzig. In other regions of the new federal states, grants can reach 35 percent of total inward investment. These grants are from the Improvement of Regional Economic Structures Program, which is funded by the Saxony Government, the federal government of Germany and the EU.

In addition to grants, several tax incentives are available to inward investors. Included in these are an investment allowance and a special accelerated depreciation allowance. The investment allowance returns 5 percent of any investment in movable depreciable equipment. Given that the cost of facilitizing a state-of-the-art wafer fabrication plant is now in the region of $1 billion, this allowance on its own is worth approximately $50 million. The special accelerated depreciation allowance allows companies to depreciate their capital equipment by between 20 percent and 40 percent above the normal depreciation rates.

United Kingdom

The United Kingdom has three regions that are focusing their attention on attracting semiconductor inward investment. These regions are the central belt of Scotland, stretching from the east coast around Edinburgh to the west coast around Glasgow, northern England and South Wales.

In 1996, semiconductor companies with manufacturing locations in the United Kingdom, along with the UK government, founded the National Microelectronics Institute (NMI). The NMI's role is to coordinate and enhance the activities of all parts of the UK semiconductor industry's support infrastructure. Included in this is the development of supporting industries and the coordination of further- and higher-education activities related to the microelectronics industry, as well as facilitating cooperation between companies in noncompetitive areas.

The NMI treats the three geographic areas as a single cluster, given their relative geographical proximity, coordinating all its activities to assist each area equally. The NMI has, with semiconductor vendors, developed two further-education courses designed to supply the semiconductor industry with appropriately qualified operators and technicians. To date, four further-education colleges in Scotland, and ten in the United Kingdom, offer these courses. In addition, the NMI has also created and had accredited a microelectronics MSc qualification for the development of engineer-level staff.

The main financial incentives provided to those considering investing in any of the three regions are, in principle, the same, although in the last round of inward investment, which involved Hyundai, the peculiar situation of two regions within the cluster trying to outbid each other occurred. Regional Selective Assistance (RSA) is the main financial incentive and applies to all three regions. Locate in Scotland, the inward investment agency, and the Northern Development Agency say only that RSA is negotiable on an individual basis, but is based on levels of capital expenditure and jobs created. In addition to RSA, all three regions have enterprise zones, which attract additional benefits of exemption from property taxes for 10 years and 100 percent depreciation allowance for buildings in the first year of operation.

 ©1998 Dataquest

Investors into the three regions will also be eligible for training and employment grants. Typically, these grants cover up to 50 percent of training costs, with a maximum of £4,000 ($6,500) per eligible employee.

An example which shows other potential benefits for investors is available in Scotland, where other substantial benefits including site acquisition and preparation, as well as considerable assistance with site management costs have been made available. An example of these is Hyundai's ongoing (and delayed) investment in Dunfermline, where it was reported that in an assistance package which totaled £151 million ($250 million) for a total maximum investment of £2.3 billion ($3.8 billion), amounts of £9.6 million ($16 million) for site acquisition, £23.4 million ($39 million) for site preparation (including new road infrastructure) and £9 million ($15 million) for waste treatment facilities were included.

Central Scotland

Since the mid 1970s, when National Semiconductor opened its first fabrication plant in Greenock, Scotland has recognized the increasing importance of high-technology manufacturing as a driver of national growth and large-scale provider of jobs. Since the 1970s, central Scotland has tried to reposition itself as the high-technology center of Europe, going so far as to coin the term "Silicon Glen."

The central belt of Scotland is home to six semiconductor companies, which have a total of ten wafer fabrication plants between them, and a further two plants are in planning or under construction. Central Scotland is therefore very adept at dealing with the requirements of semiconductor wafer fabrication plants.

In addition to the NMI infrastructure, central Scotland also houses 11 institutes and research centers related to the microelectronic industry. These are based at eight universities throughout the central belt region. Four of these universities are participating in a project with Cadence Design Systems to establish the world's first system-level integration institute. There are also 46 further education colleges, in and around the central belt, offering two-year electronic or electronic engineering courses.

Northern England

In addition to the regions' participation in the NMI, northern England also has a significant electronics-oriented training infrastructure, which produces more than 800 electronics-related graduates per year. In early 1998 the North of England Microelectronics Institute, a joint venture between the region's universities, Siemens and Fujitsu, opened in North Tyneside. The £16.5 million ($26 million) site includes laboratories for testing post-wafer processing reliability and design fault analysis, together with a new interconnection research project.

The region also has two universities: the University of Newcastle upon Tyne and Durham University, which both have a number of research groups related to the microelectronics industry. The University of Newcastle upon Tyne includes the Semiconductor Technology Group, the Microelectronic Systems Design Group and the DSP Group. Durham University includes the Centre for Molecular Electronics and the Centre for Electronic Systems. Durham University also manages a course developed by Fujitsu and continued by Siemens to fulfil the educational needs of both companies.

Spain

FILE COPY:
MARIA VALENZUELA

Spain appears to be something of an enigma in the field of attracting inward investment from the semiconductor industry. Since attracting Lucent Technologies to Madrid in the late 1980s it has not attracted any other major semiconductor fabrication investment.

Spain has set up two scientific parks focusing on the semiconductor industry. The first is Valles Technology Park located just outside Barcelona, and the second is Tres Cantos Technology park in Madrid, where Lucent Technologies has its wafer fabrication plant. In and around Valles Technology Park are the Spanish National Microelectronics Center, the Regional General Testing and Research Laboratory, and the New Materials Center, which is part of the Higher Center for Scientific Research. The National Microelectronics Center also has a site in the Tres Cantos Technology Park.

The principal financial incentive offered in Spain is for investment in certain regions. This is offered by the state, and varies from 20 percent to 60 percent of a project's capital expenditure. However, neither of the scientific parks mentioned above fall into one of the qualifying regions and, thus, they receive no regional incentive from the Spanish central government. In addition to the central government regional aid, each autonomous region also offers its own smaller-scale investment packages.

Spain has also created a $420 million high-technology fund called the ATYCA initiative, which will run until the end of 1999. The program is financed by the Ministry of Industry and Energy, and can provide funding for the improvement of the technology infrastructure and training.

Dataquest Perspective

Potentially useful manufacturing locations are essentially products for which there is a very small, but valuable, customer base. When Europe started attracting semiconductor inward investment, each country's offerings were essentially commodities, where, typically for commodities, price played the pivotal role in deciding which country won the inward investment. Price in this marketplace was represented by the amount of cash a region or country would pay to convince the prospecting company to move to their location.

However, the market has moved on; in the marketplace of inward investment the emerging key differentiator is the supply chain for appropriate human resources. Those regions or countries that develop a coherent and integrated road map to supply sufficient numbers of appropriate graduates and other technical staff will be the winners in attracting the quality inward investment projects in most cases.

For some, though, location will remain a commodity product and price (in the form of capital grants) will still have a key role to play. It could be argued that AMD's investment in Dresden, Germany was an example where "price" was the determinant factor whereas Intel's investment in Ireland was an occurrence where the differentiator won out over the highest bidder—the differentiating factor being the availability of staff at all levels of engineering expertise.

Some regions are further along the differentiation curve than others. For those lagging behind, price, in the form of subsidies, will continue to be their major attraction. For some companies this may be enough, although the dynamic is changing. Companies are beginning to want more than just a massive cash handout at the beginning of a project. They now want to ensure the long-term future of their plants and maximize the value they add to the company.

©1998 Dataquest

Equally, countries want more than a cash for jobs equation, especially as the amount of cash required to win becomes unaffordable. They want investment in their communities and participation in their educational infrastructure. We may not have seen the last of the bidding wars that occurred in the fight to attract inward investment in the 1980s and early 1990s, but they will be fewer, as will be the participants involved in the fight. The next step for the inward investment market may well be its segmentation, on both the part of the semiconductor vendor and the regions.

Competitive Analysis

A Comprehensive Analysis of Compaq's Acquisition of Digital Equipment

Abstract: *On January 26, Compaq Computer Corporation announced an agreement to acquire Digital Equipment Corporation for $9.6 billion, the largest acquisition in the history of the computer industry. The ramifications of this merger impact every corner of the IT industry. This Perspectives provides a Dataquest-wide analysis of the effects of this acquisition on the IT market, the competition, and on the future of Compaq and Digital Equipment.*

By Dataquest Analysts

Introduction

This Perspective represents a Dataquest-wide effort to explore the significance and meaning behind Compaq Computer Corporation's acquisition of Digital Equipment Corporation. This acquisition is touted as the largest deal ever to take place in the history of the computer industry, thus catapulting Compaq to new heights as one of the world's top computer companies. The following pages explore the impact this merger will have on the industry, the competitive landscape, and the future of Compaq and Digital Equipment.

The Largest Acquisition in the History of the Computer Industry

On January 26, Compaq Computer Corporation and Digital Equipment Corporation announced, to a somewhat surprised public, that Compaq will acquire Digital Equipment. The deal, worth $9.6 billion, is the largest acquisition in the history of the computer industry. This announcement came amidst ongoing speculation that Compaq was talking with Digital Equipment, but many industry pundits would have bet that the resulting deal was for Digital Equipment's profitable services business, as opposed to the entire company. Under the terms of the agreement, Compaq will complete the purchase with a combination of stock and cash. Digital Equipment shareholders will receive $30 in cash and about 0.945 shares of Compaq common stock for each share of Digital Equipment stock. Compaq will issue about 150 million shares of Compaq common stock and $4.8 billion in cash. Estimates indicate that the acquisition cost works out to between $60 and $65 per share. Pending approval by Digital Equipment's shareholders and clearance under antitrust laws, Digital Equipment will become a wholly owned subsidiary of Compaq.

(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

The true cost of Digital Equipment to Compaq, however, is much less. Digital Equipment, at the end of December 1997, had just over $2 billion in cash—making the net cash outlay only $2.8 billion and the 150 million shares representing 19 percent of Compaq's shares outstanding. This means that if Digital Equipment produces no earnings, Compaq's earnings per share would be diluted by 19 percent. However, if Compaq is successful in making whatever parts of Digital Equipment it keeps, as profitable as the rest of Compaq, there will be no dilution. As a result, Dataquest expects Compaq to act swiftly in realigning the parts of Digital Equipment it will keep and spinning off whatever remains.

Who Is the Biggest of Them All?

As part of its announcement, Compaq made the claim that once combined with Digital Equipment, the resulting company will be the second largest computer company in the world after IBM; Table 1, in some ways, supports Compaq's boast. In total revenue, Compaq combined with Digital Equipment comes in fifth place. Backing out noncomputer revenue is difficult at best. However, Dataquest's best estimate shows the combined revenue of computer-related products from Compaq and Digital Equipment to be second only to IBM. Table 1 and Table 2 present a breakout of this data.

Table 1
Total Worldwide Company Revenue, 1996 and 1997
(Millions of Dollars)

Company	1996	1997
IBM	75,947	78,508
Hitachi	65,207	68,735
Hewlett-Packard	38,420	42,895
NEC	34,904	39,907
Compaq and Digital Equipment	34,572	37,646
Fujitsu	29,160	36,318

Note: All numbers are Dataquest estimates.
Source: Dataquest (January 1998)

Table 2
Total Worldwide Computer Revenue, 1996 and 1997
(Millions of Dollars)

Company	1996	1997
IBM	72,222	74,777
Compaq and Digital Equipment	32,593	35,800
Hewlett-Packard	31,559	35,449
Hitachi	34,174	35,325
Fujitsu	23,286	30,887
NEC	27,340	30,540

Note: All numbers are Dataquest estimates.
Source: Dataquest (January 1998)

For Compaq to maintain its role as the second largest computer company, it must effectively integrate Digital Equipment's operations into its own with minimal cannibalization, while continuing to grow at its stated growth rate of 25 percent per year or better. Clearly, Compaq will not be able to keep all of Digital Equipment's market share in PCs and low-end servers, making the combined companies' revenue not completely additive. However, even with an assumed loss of 75 percent of Digital Equipment's PC revenue, Compaq is still ahead of Hewlett-Packard Company after backing out HP's test and medical equipment revenue (but not by much). In essence, the race for the No. 2 position in the computer industry is a dead heat between the combined Compaq and Digital Equipment, HP, and Hitachi. Fujitsu and NEC are not far behind.

A key benefit for Compaq is Digital Equipment's core enterprise business, which occupies a market position that Compaq has been unsuccessful at penetrating because of its Intel-based architecture. However, Digital Equipment's Alpha business is the clear technical leader in large computing system hardware, but it has been unsuccessful in a marketing sense. Compaq can take the Alpha systems business and dramatically accelerate it through Compaq's powerful sales and marketing skills. If it succeeds, the prize will be large—Table 2 indicates that there is plenty of money in this particular pot.

How Does the Acquisition Impact the Competition?

Prior to the acquisition, Compaq competed against IBM's and HP's products. Today and in the future, the battle will be waged over solutions that Dataquest defines as the strategic bundling of products and services. IBM is still by far the world's largest computer company. However, its hardware revenue is dominated by aging legacy systems such as S/390 mainframes, AS/400 midrange systems, and its UNIX-based RS/6000 products. The inevitable maturation of Windows NT should have a profound effect on IBM's ability to keep its business from shrinking. Compaq's acquisition of Digital Equipment puts increasing pressure on IBM to decide whether to aggressively pursue a Windows NT-based product and services strategy as have HP and Compaq. If IBM continues to shy away from a similar strategy, its customers may become fodder for HP and Compaq's growth. The ultimate key challenge for Compaq is to create its own solutions methodology, thus moving away from a products-only strategy.

As for PC companies, Compaq has moved significantly ahead of its traditional competition. Dell Computer Corporation must decide whether to become a computer company or stay a very efficient channel for PC products. A major risk for PC and other systems vendors is that Compaq, IBM, and HP will become the primary product and service suppliers for end users. Customers may not see the need to include more than three vendors on their short lists. This may have force other competitors to become niche solution providers.

 ©1998 Dataquest

How Will the Acquisition Impact Products and Technologies?

A Dataquest analyst made the analogy that "the merger of these two enterprises and cultures will be like two galaxies colliding: slow to happen, and some worlds may collide and be destroyed." This comment reflects the multitude of perceived product overlaps within Compaq, Tandem, and Digital Equipment. Understandably, these redundancies will be remedied—the perceived outcome is the eradication of certain products and technologies. Perhaps the more interesting question is which products and technologies have enough brand and market value to succeed under the new Compaq regime. Dataquest briefly explores these questions by product and technology type.

Workstations

With the workstation market in a period of major transition, Compaq's acquisition of Digital Equipment has the potential to significantly change the balance of power. Although it is relatively new to the workstation business, Compaq has shown itself to be one of the movers and shakers in the rapidly growing Windows NT workstation market. By comparison, Digital Equipment has not been doing as well—not only losing market share in the stagnant UNIX market, but more importantly losing ground in the Windows NT segment where it was one of the early leaders. Digital Equipment workstation customers stand to gain from Compaq's leadership and momentum. Almost immediately, Compaq can challenge HP more effectively for the No. 1 position in the Windows NT market segment by pooling the market share of both companies (Compaq and Digital Equipment).

Compaq also gains significantly on the technology front with a technically credible UNIX offering. The most significant impact of this could be in the graphics area. Until now, Compaq has had no graphics strategy of its own, relying upon third-party cards while HP and Intergraph have been able to differentiate their Windows NT product lines with proprietary high-end graphics capabilities. Along with Digital Equipment's workstation business, Compaq has gained the high-end graphics technology from Megatek, which Digital Equipment acquired in 1996. Compaq has the opportunity to add the fruits of this venture to its workstation business potentially filling one area of weakness.

Servers

The issues dealing with the operating system of choice take place most predominantly in the server space. Compaq supports Windows NT, SCO UnixWare, and Novell's NetWare; Digital Equipment provides Windows NT and its proprietary UNIX, as well as systems based on VMS. The third element of the new company, Tandem (acquired by Compaq in June 1997), has its proprietary NonStop Kernel (NSK), a small investment in UNIX, and Windows NT. Also there is a mix of processors (that is Intel, Alpha, and MIPS) within the new company and the operating system decision goes jointly with the chip selection.

Dataquest foresees that Compaq will opt to keep Tandem's high-end systems and operating system while at the same time maintaining Digital Equipment's UNIX variety. There may be an opportunity to migrate the NSK operating system to an Intel design in the future, but it is well after the turn of the century. The Alpha solutions gain credibility with Compaq's endorsement and can provide a path from IA 32-bit to the Merced technology. The real test of strengths will be the price/performance ratings of the processors and operating systems after Merced is stabilized and Microsoft's next generation matures.

 •1998 Dataquest

Personal Computers

Through the first three quarters of 1997, Compaq sold roughly as many PCs every month as Digital Equipment did the entire period. This underscores the fragility of the Digital Equipment PC business as part of a much larger Compaq. Although Dataquest believes that Digital Equipment brings valuable technology and engineering to the table, these attributes will be more effectively leveraged in Compaq branded PCs. Therefore, Dataquest ultimately foresees the death of Digital Equipment branded PCs.

As customers' short list of vendors becomes dominated by IBM, HP, and Compaq, this may force other computer vendors (PC and otherwise) to target niche markets. Ultimately, this standardizes and simplifies the desktop, leading to a real commodity market where vendors must search long and hard to add significant value and differentiation. Whether customers will accept single vendor solutions is an open question.

As for the mobile portion of the PC business, there are no immediate magic bullets—it is truly a draw between the mobile technology of Compaq or Digital Equipment. Dataquest believes, however, that the acquisition may allow Compaq to finally get a shot at obtaining the kind of flagship product that instantly defines the entire line and its potential. Additionally, Digital Equipment design engineers and marketers have a chance to join a mobile team that has been one of the top three in the world for the past few years. Compaq has been vying for the top spot on the mobile PC vendor heap for almost as long as there have been mobile PCs. The addition of Digital Equipment's products and skills will help Compaq compete more effectively.

Microprocessors

Digital Equipment's Alpha chip will afford Compaq the chance to penetrate and grow its business in the data center environment. It raises Compaq to the elite ranks of HP and IBM as a provider of a full suite of systems and services and allows Compaq to let the PC business evolve into a box-delivery component of its overall system strategy. Compaq's server growth will no longer be limited by any perception that Compaq is just a PC company, and the opportunity to mate the advanced Alpha servers with Compaq's marketing and sales skills could lead Compaq to significantly higher overall margins by the end of the decade. Therefore, after the dust settles, there is a third major contender for the enterprise systems market as Compaq joins HP and IBM.

What's the Impact on IT Services?

The addition of Digital Equipment's services business to Compaq fills an immense void that has kept Compaq from becoming a significant player in the enterprise computing market. Compaq's distinct lack of a service business (especially in terms of field personnel), even with its acquisition of Tandem last June, had a "pigeonhole" effect on it as a product company. It could offer great technology that was admissible for workgroup computing, but would never fly in the enterprise because of the company's lack of mission-critical services infrastructure and IT integration and management skills. Compaq attempted to minimize its lack of robust enterprise services by crafting partnerships with Digital Equipment and Unisys. However, IBM and HP continually attacked this leveraged support model in competitive bid situations, even though they, too, used partners.

The addition of a direct service business is a major boost for Compaq. It now has a chance at the enterprise and may be able to give IBM and HP a run for their money, provided the integration runs smoothly and there is an increased focus on providing solutions. This move also places more distance between Compaq and its PC competitors, particularly Dell and Apple. Compaq can now go to market competing on product and service while most others will not be able to compete at this level in the services arena.

In terms of skills and resources, Digital Services Division consists of 22,000 service professionals split between its three service business units. These business units and the specific skills sets contained therein are as follows:

- Multivendor Customer Services (MCS): This group accounts for 66 percent of fiscal 1997 service revenue ($3.8 billion). MCS delivers hardware service, support, and maintenance services, as well as multivendor availability and management services that focus on providing technical expertise in UNIX and Windows NT for mission-critical environments. Compaq leverages the MCS organization as a global service partner. Overall, the MCS group will be challenged to maintain its vendor neutrality as a vendor-to-vendor service partner.
- Network and System Integration Services (NSIS): This group accounted for 24 percent of fiscal 1997 service revenue ($1.4 billion). It has competencies in application solutions for mail and messaging, Internet/intranet services, electronic commerce, and manufacturing and telecomm industry solutions. Strong technology solutions have also been built around NT. Compaq made an initial foray into the network business with its acquisition of Thomas Conrad and Networth several years ago. To date, Compaq has not figured the nuances in delivering service for networks versus delivering services for desktops. This NSIS group will help better define Compaq's role as a network integrator.
- Operations Management Services (OMS): This group accounted for 10 percent of fiscal 1997 service revenue ($0.6 billion). Service offerings include operations support for distributed client/server environments, including desktop systems infrastructure management, application operations management, and Internet/intranet management. The services and skills in OMS will enable Compaq to offer life cycle management services to its customer base.

The integration of Digital Services into Compaq is, in theory, like finishing a puzzle—almost. Dataquest perceives certain weaknesses in Digital Equipment's services business that may directly translate into lost opportunity for Compaq. Specifically, Dataquest cites its lack of a mature applications integration practice as a major hole in Digital Equipment's capabilities. These skills are essential for a major play in the enterprise. As both companies are aware of this distinct lack, there is a chance that there may be additional acquisitions down the road.

Once the integration process gets under way between the two companies, Dataquest foresees a potential culture clash between product-oriented Compaq and the Digital Equipment's services business. Although Compaq's executives understand the need for services, there is a distinct lack of understanding about how to shift from a product to a solutions model. Compaq needs to make a concerted effort to leverage the knowledge and expertise housed within Digital Equipment in order to effectively make this transition. Compaq may very well end up integrating into Digital Equipment's service culture rather than the other way around. Dataquest believes Compaq's best bet is to let current Digital Services management remain in full control of services.

The existence of a Compaq/Digital Equipment service partnership prior to the acquisition may help move the integration process along. In fact, Compaq stated that talks between the companies first began because of the services partnership. However, there's a concern that Compaq will continue to be quite focused on the capabilities offered by Digital Equipment's Multivendor Customer Services (MCS) business unit, which are quite product support oriented. Compaq needs to expand its services vision and leverage the outsourcing and network services skills housed in Digital Equipment's other services units.

Lastly, there are several looming questions—the answers will directly impact the success of Compaq's merger with Digital Equipment and their future success as a unified company. Some of these key questions are as follows:

- How will Compaq manage its channel relationships given that it now has a direct service capability?
- Will Digital Equipment be able to sustain its reputation and viability as a multivendor service provider given that it is now a Compaq-owned company?
- Does Digital Equipment bring the right mix of service expertise that Compaq needs to deliver enterprise solutions to the Fortune 1000?
- How will Compaq integrate the Tandem and Digital Equipment professional services capabilities?

Dataquest believes that most of the elements are in place for Compaq to compete squarely in the demanding enterprise services arena. However, it needs to take a hint from IBM and HP: lead with solutions, not just products.

What's the Impact on the Channel?

The potential for product channel conflict is technology dependent. Clearly in an open technology market such as PCs, channel conflict is a key issue because a reseller can make the decision to switch brands if it is concerned that it is competing for business with the vendor. With Digital Equipment's PC business expected to be merged into Compaq's business, this should not be an issue—particularly since Digital Equipment's existing business is almost exclusively indirect.

Further up the technology curve, segmenting between direct and indirect channels is more difficult; it is a question that companies such as HP and Digital Equipment have struggled with, especially as WinTel technology has encroached into the workstation and midrange computer spaces. If technology is proprietary and demanded by users, then a vendor can operate through both direct and indirect channels. More difficult for vendors is how to stop and separate sales organizations from competing against each other. HP's solution is to put both sales organizations under the same umbrella. Compaq will need to move in this direction.

Channel relations regarding service could be a touchy subject, as Compaq now has direct service capabilities. However, considering Compaq's recent redesign of its Authorized Service Provider (ASP) program around customer requirements and satisfaction, and Digital Equipment's multivendor services accomplishment of integrating services at point of product purchase, there will be plenty of service opportunity for the channel. Current business partners focused on the services side of the equation have compelling reasons to stay the course or even upgrade their relationships with both companies.

Compaq needs the channel's support. Even with the Digital Services Division under its belt, the company still needs the channel's core competencies such as broad customer reach and custom software expertise. HP and IBM have recognized this and it is reflected in their channel strategies. The Digital Equipment acquisition puts Compaq in a more powerful position when dealing with the channel, but there are alternatives that resellers can choose. Resellers will be watching Compaq very closely in the coming months.

©1998 Dataquest

What's the Impact on Sales and Marketing?

Neither Compaq nor Digital Equipment has as yet determined the overlap between accounts. Digital Equipment's MCS organization is already supporting many Compaq environments—all signs indicate that Compaq intends to preserve this vendor neutral asset. Digital Equipment's product and service top accounts map closely in Fortune 1000 market segments. Its services business has helped Digital Equipment penetrate Fortune 2000 and middle market segments with little overlap on the product side. Digital Equipment's strengths are in middle market and global enterprise organizations. Compaq views its markets slightly differently. Compaq clearly plays in the small office/home office segment and in what it labels the small/medium business, middle market, and global/mission-critical enterprises.

In terms of sales resources, Digital Equipment has about 1,000 dedicated service sales specialists worldwide who prospect for and close the company's service business. A number of these dedicated service sellers line up to strategic accounts and sell to end users as members of Digital Equipment's Enterprise Sales Force (ESF) account teams. They also include channel sales representatives who sell to, through, and with partners. ESF staffs about 2,000 people worldwide and sells the company's technology products; it segments into three types of selling orientations. One group is assigned to about 500 strategic corporate accounts, another group has a territory responsibility covering from two to 25 accounts, and the rest are devoted to prospecting for new business and generating leads for Digital Equipment's partners.

A potential concern however, before the acquisition and now, is the lack of sufficient consultative selling talent in both companies. Compaq's model is indirect through partners, with limited experience in the business solution sell at the top of the enterprise. Digital Equipment's only real engagement managers are in the OMS business and are already stretched. Pockets of excellence exist within Digital Equipment's service sales organization, with considerable talent in networks, business-critical support, migration, mail, and messaging. However, the new entity will require a prudent sales retention, conversion, and recruitment effort designed to bring the enterprise selling talent to a level commensurate with the new and considerable enterprise capabilities.

The new value proposition is one of client choice of highly engineered products and technology platforms, superb service capability, true global distribution and service infrastructure, and a wealth of experience in managing complex distributed computing environments. This proposition gives the combined salesforce some powerful new selling opportunities that cannot afford to wait six months or even one year.

 •1998 Dataquest

Dataquest Perspective: What's the Bottom Line?

Overall, Dataquest regards Compaq's acquisition of Digital Equipment as a positive move. Critical synergies exist that will greatly improve both companies' future positions and bring added value to existing and future customers. In the short term, Compaq will continue as it has been: driving NT over UNIX and proprietary systems, and leading the world selling PCs. Further down the road, Dataquest foresees significant product, technology, and service implications as a result of the acquisition.

One of the primary overlaps between companies is in the personal computer market. It is likely that Digital Equipment's PC business will be subsumed totally under the Compaq brand because of overlap and limited brand equity. Digital Equipment's mobile PC business will also be absorbed, but the company's pioneering work in low-profile large-screen products could combine with Compaq's solid mainstream devices to allow the combined company to challenge Toshiba from the No. 1 slot. Dataquest believes that Compaq will retain Alpha and Digital UNIX because they have the strategic implication of expanding Compaq's reach into the enterprise—that is until Intel's IA-64 architecture delivers a compelling alternative to the market (not until 2001 at the earliest) and NT matures. The combination of Tandem's NonStop Kernel, Alpha and Digital UNIX, and Compaq's PC contribution creates a powerful technology engine that will allow the combined company to compete against a wide variety of competitors.

On the services side, Compaq has historically been penalized for its lack of a substantial services business. With the acquisition, it gains a service giant, 22,000-people strong with global capabilities. Dataquest anticipates some form of a culture clash between the two companies as Compaq struggles to make room for services in its product world. Despite the addition of a formidable services business, Dataquest questions whether Digital Services has the precise array of services required to provide full solutions to enterprise customers. One of Digital Equipment's key weaknesses is its lack of application integration skills that are quickly becoming a requirement given the burgeoning enterprise resource planning market. Because both companies seem to be aware of this deficiency, Dataquest can't help but wonder if there are other acquisitions waiting in the wings.

Taken as a whole, the ultimate challenge will be the integration of products and technology with services. Compaq's goals of becoming one of the top three computer companies in the world and reaching $50 billion in revenue by the millennium are largely dependent on its success at solutions selling. Dataquest perceives that most of the working materials are in place to make the new Compaq a full solutions provider, with the exception of data center and application integration skills. Aside from these holes, Dataquest anticipates a success-filled future for Compaq as an enterprise player.

Market Analysis

The Great White Hope Turned into a Great White Shark

Abstract: *Far from recovering, the DRAM market has taken another nosedive in 1998 and the next 18 months will be critical for all concerned. This Market Analysis updates the EMEA market statistics, specifically detailing DRAM unit shipments, ASPs and revenues for 1998 by month, and for 1999 by quarter.*

By Richard Gordon

Just When You Thought It Was Safe ...

FILE COPY:
MARIA VALENZUELA

If only Steven Spielberg's 30-foot rubber shark was all the DRAM vendors had to worry about in their struggle for survival! Unfortunately, in the churning waters of the DRAM industry things are not so straightforward—death by a thousand cuts is more likely than by a single killer bite from "Jaws." There have already been bloody casualties and so it is, with a heightened sense of panic, that the remaining DRAM players swim for their lives, the relative safety of the shoreline tantalizingly close.

The companies that survive and drag themselves out of the water will have to deal with the following market conditions:

- EMEA DRAM revenues are expected to decline by 32 percent to almost $2.8 billion in 1998
- Average selling prices (ASPs) are expected to fall to about $1.15 per megabyte during the second half of 1998
- Bit growth of 82 percent will result in more than 900 million 16Mb equivalents shipped in 1998
- In 1999, more than 75 percent of all DRAM bits are expected to ship as 64Mb devices
- The ASP decline is expected to slow to settle at an average of slightly less than $1.00 per megabyte in 1999
- More than 1.5 billion 16Mb equivalents are expected to ship in 1999, following modest bit growth of 67 percent over 1998
- Modest growth of 8 percent will help DRAM revenues recover to reach almost $3.0 billion in 1999

When Will the Madness End?

An unprecedented third successive year of declining DRAM revenues is now inevitable. The prevailing view within the DRAM industry is that all the leading vendors were selling DRAM products at prices below variable production cost during much of the first half of 1998. Once the decision to sell at this level has been taken, forecasting price trends becomes almost impossible because rational business behavior has, by that time, been abandoned. The effect of this kind of pricing policy is to reduce any revenue forecast to the status of idle speculation, but, as the fourth quarter approaches, there are signs that some semblance of sanity will return. It is doubtful whether this forthcoming period of calm will mark a dramatic turnaround in the DRAM market—that may be several quarters away—but it ought at least to mark the low point. The remainder of 1998 and all of 1999 is therefore a critical period that will shape the strength of the expected DRAM boom that will follow it. It is with this thought in mind that this DRAM forecast update has been complied, presenting, as it does, a detailed short-term view with increased granularity.

Table 1 shows the annual history and forecast detail for the EMEA DRAM market, for the period 1992-1999.

1998

Despite healthy bit growth of 82 percent over 1997, EMEA DRAM revenues are expected to decline by 32 percent to almost $2.8 billion in 1998. Prices have continued to fall throughout the first half of 1998—by about 50 percent in the case of high-volume 16Mb and 64Mb devices—which means that, even if prices were to stabilize for the remainder of the year and even when a continued increase in unit shipments is taken into account, revenues in the second half of 1998 will still be lower than those in the first half.

Covering the 4Mb, 16Mb and 64Mb densities, a detailed monthly breakdown history and forecast for EMEA DRAM units, ASPs and revenues in 1998 is shown in Table 2.

In 1998 first half revenues of about $1.5 billion are expected to exceed those in the second half, which are estimated at about $1.2 billion. Clearly the trend is towards higher shipments of the 64Mb density so that, by the end of 1998, it will account for about 75 percent of all bits shipped into the EMEA DRAM market. ASPs are expected to stabilize during the second half of 1998 as the PC industry increases its demand for 64Mb PC100 devices, because there are signs that there could be localized shortages of this high-end DRAM device as vendors struggle with yields during the shift of allocation of production capacity from the 16Mb EDO generation to the 64Mb PC100 device generation.

1999

Dataquest is forecasting the beginning of recovery in EMEA DRAM market revenues in 1999 based on more modest bit growth of 67 percent and a gentle decline in ASPs. A detailed quarterly breakdown history and forecast for EMEA DRAM units, ASPs and revenues covering the 4Mb, 16Mb and 64Mb densities in 1999 is shown in Table 3.

The expected slowdown in ASP erosion will result in EMEA DRAM revenue of almost $3.0 billion in 1999, an increase of 8 percent over 1998. A critical factor in this revenue forecast for 1999 is the global production capacity outlook. If, as expected, overcapacity remains in place for much of the year, then there will be continued downward pressure on ASPs, and this assumption forms the basis of the forecast for 1999. However, this outlook probably represents a downside scenario in revenue terms for two reasons. First, if market conditions do not improve significantly it is conceivable that further capacity could be forced out of the industry (in addition to Siemens' closure of a leading-edge DRAM fab in the United Kingdom), thus restricting supply. Secondly, with a rapid move to 64Mb PC100 devices, it is likely that there will be a tightening of supply, because fewer vendors will have the capability to produce these devices in high volume. Both these factors could result in price stability which, in turn, could lead to higher revenue growth than forecast next year.

Table 3
EMEA DRAM Consumption Forecast by Quarter, 1999

	First Quarter	Second Quarter	Third Quarter	Fourth Quarter	Total 1999
Units (Millions)

Total Revenue					**2,975.0**

Source: Dataquest (August 1998 Estimates)

Dataquest Perspective

The EMEA DRAM market for 1998 can already be written off as a financial disaster for the vendors. Although it may have been possible to remain profitable in 1996 and 1997, this is certainly not the case in 1998, and when the companies' accounts are finalized, it will have to be acknowledged that the global DRAM industry has operated at a loss.

More positively, there are signs that 1998 will mark the low point in this most recent DRAM recession. Sooner or later, market forces will prevail and the DRAM industry will return to profit. The slowdown in capital spending that has resulted because of the reduction in DRAM profits in the past two years will ripple through to cause undercapacity in 2000 and beyond. This will mean undersupply and, therefore, stable price and increasing revenues, assuming that the insatiable demand for increased DRAM bits remains in place—and there are no signs that the demand for DRAM is likely to slacken off.

Semiconductor Application Markets Europe

Market Analysis

Semiconductors Second Quarter 1998: A Buyer's Boon and a Supplier's Gloom

Abstract: *Since the release of Dataquest's spring worldwide semiconductor forecast, severe DRAM price erosion and economic downturns have begun to affect the revenue not only of MOS memory but also of all other major semiconductor product categories. The consumer and data processing electronic equipment markets are showing further signs of weakening. Capital spending forecasts have declined 15 percent. Weakened by economic turmoil in Asia/Pacific and financial weakness in Japan, prices on electronic imported goods arriving at Europe's and America's doorsteps have declined for seven consecutive months. The DRAM downturn that began in December 1995 is taking the rest of the market down. This very long downturn is reminiscent of the DRAM nosedive that began in January 1985. Many companies barely survived, and those that did were lucky to walk away bruised and battered. How do these events affect Dataquest's clients and current forecast?*

By Mary Ann Olsson

A Worldwide Forecast Update

For two and one-half years, there has been both decline and growth in semiconductor products. MOS memory devices have led the decline. In terms of historical volume and driving overall profit, DRAMs, the powerhouse products, have been pivotal to this decline (down 38 percent in 1996, down 20 percent in 1997). Judging from the decline in prices during the first half of 1998, there will be a third year of decline in DRAMs. This decline could go beyond 23 percent, taking DRAM revenue below $16 billion in 1998.

Although multiple forecasts and scenarios different from Dataquest's original forecast have been publicized, Dataquest has tried to avoid following the herd. This Perspective offers the most likely scenario for the market and, possibly, moments of sanity that rise above soothsaying.

The spring publication of Dataquest's worldwide semiconductor forecast for semiconductors and ICs showed the optimistic forecast; the most likely downside scenario for 1998 is shown in Table 1. Barring major economic downturns that even Dataquest cannot predict, we believe that the market will fall within this range.

Analysis and Assumptions

Since the first quarter of 1998, significant events have occurred that have affected not only industry dynamics but also Dataquest's initial forecast. The Asian financial crisis has worsened, weakening the financially struggling Korean semiconductor companies. Overcapacity is still prevalent. A price collapse continues to erode the DRAM market. Continued oversupply and unbalanced currencies in Asia/Pacific and Japan and competitive posturing by the 64Mb DRAM suppliers are the main cause of this erosion. Are those cries of dumping in the distance?

It is Dataquest's view that vendors will continue to lower prices, even to the point of selling at or below cost, to gain share or just to fill the fabs. The aggressive capital spending and overexpansion that continued through 1997 exacerbated the problems of a market already in the throes of overcapacity and accelerated DRAM technology die shrinks. In 1996, overcapacity in DRAM was about 20 percent, and it was rumored to be at 40 percent in 1997. With the shrink factor and the addition of net capacity over the last year and a half, the signs do not bode well for an 8 percent growth in 1998. Add to that a recent downward trend in microprocessor (MPU) and logic prices, and Dataquest's most likely scenario becomes more reasonable.

Buyers of semiconductor products are happy about these prices. But the risks are great. Building too much inventory in a shaky market with weak trading partners coupled with low import pricing could send the entire semiconductor industry spiraling into a recession. Many suppliers (merchant and foundry) are scurrying to fill fabs with non-DRAM products, offering lucrative contract pricing for products in the non-DRAM sectors. Many buyers are building low-priced inventories to keep up with pricing pressures while meeting demand for lower-end systems in the data processing, consumer, and communications sectors. Is the market spiraling out of control, and is this a market transition of electronic equipment demand growth from less sophisticated business sectors? Or is this simply a downshift in revenue growth as the equipment market becomes a commodity market?

Unless something miraculous happens during the next two quarters, stronger near-term semiconductor market growth is not expected.

©1998 Dataquest

Product Analysis

MOS Memory

DRAM has always been the key driver of growth and the key culprit in decline in the semiconductor industry. In the major DRAM and overall semiconductor market downturns, excess (capacity or strategic inventory) is the real culprit. There are many similarities between this market downturn and the market downturn that began in 1985. Some of these are listed in Table 2.

A stroll down memory lane might jangle some nerves but would help many to understand what is happening in the semiconductor industry. The DRAM market declined 52 percent, from $3.5 billion in 1984 to $1.7 billion in 1985. In 1984, suppliers hoarded products and buyers double-ordered on contracts to guarantee shipments. In 1985, as suppliers began dumping products and lowering prices, buyers canceled long-range contracts to reap the benefits of lower prices. Pricing wars raged until trading wars and dumping issues resulted in government intervention, and foreign market value (FMV) duties were imposed. The suppliers in this market suffered the worst losses and faced the worst price erosion. Several companies made well-publicized withdrawals from the DRAM market during that year. The manufacturers that fared best were those well positioned in the 256K DRAM market, which enabled them to shift their revenue base as the 64K market declined.

The historical path of DRAM revenue versus non-DRAM revenue through the historical eyes of World Semiconductor Trade Statistics (WSTS) data reveals that a slowdown in market growth actually occurred in the last three months of 1984 (see Figure 1), before the DRAM market took a nosedive in January 1985. It took the market and its suppliers 27 months, from January 1985 through March 1987, to return to growth.

Table 2
Market Comparisons: 1985 through 1987 versus 1995 through 1998

1985-through-1987 Market	1995-through-1998 Market
Product hoarding/double-ordering led to supply excess, which precipitated price erosion.	Excessive capital spending added to overcapacity that precipitated price erosion.
Capital spending was depressed in the United States because of uncertainty about proposed tax reforms.	Capital spending was depressed in the United States, Japan, Europe, and Korea because of a capital spending binge.
International trade issues over product prices below fair market values led to antidumping duties on DRAMs and EPROMs.	Uncertainty about antidumping duties on DRAMs rises as rumors abound about dumping products at below cost to gain market share.
Damaged by price erosion, a depressed market, and aggressive competitors, Mostek, Intel, and Inmos disappeared from key market sectors.	Damaged by excessive spending, price erosion, and aggressive competitors, some DRAM suppliers are evaluating departure from the market.
A crossover point in price was reached between the 64K DRAM and 256K DRAM. The 1Mb DRAMs reached price-per-bit parity with 256K at the end of 1987.	In a dance of death, 64Mb DRAM chases the 16Mb DRAM. Price-per-bit parity could be reached by the end of 1998. A 4Mb-to-16Mb crossover could occur during this time.
There was a dramatic change in the yen exchange rate, from ¥254/dollar in 1985 to ¥128.4 at the end of 1987.	The yen/dollar exchange rate changed dramatically from ¥129.73 for the spring forecast period to ¥143 for 1999. The Korean won lost 50 percent of its value against the dollar, like the yen in 1985 through 1987.
Price erosion affected all memory products.	Price erosion affects the majority of ICs.

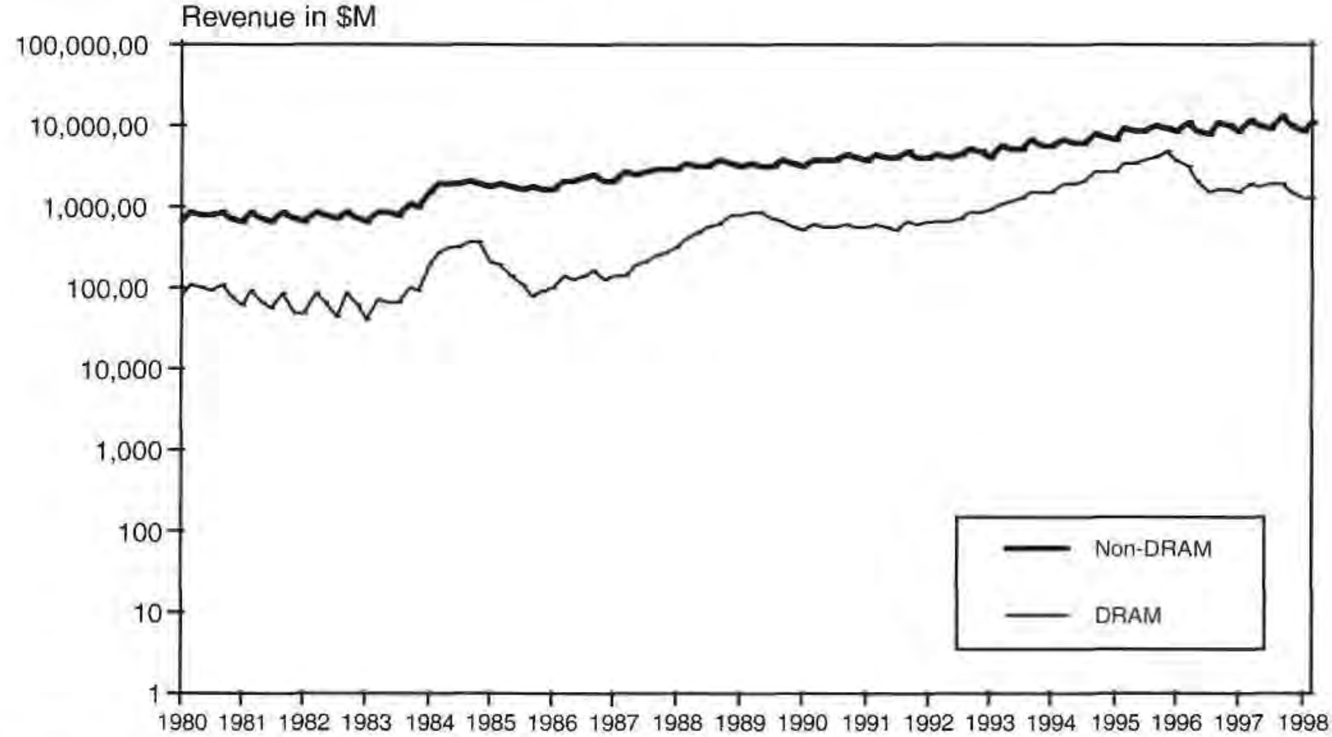
Figure 1
DRAM versus Non-DRAM Revenue over Time



Source: WSTS

Today's market is very reminiscent of that downturn. DRAM growth slowed during the fourth quarter of 1995, and the decline began December 1995. From that time, it has been 29 months of more or less declining revenue. There was a brief respite in September 1996. There were gasps of minor growth in February and March 1997, growth mostly propelled by the Korean suppliers. There was a lull in April before revenue strengthened from May through September, and then the second downturn hit during the fourth quarter of 1997.

Figure 2 shows that DRAM shipments over time were very smooth in the shortage years (1992 through 1995) but quite bumpy in times of oversupply (all other years). Do smooth shipments represent extremely tight allocation, with factories operating at maximum efficiency? If this is true, then the bumpy times reflect opportunistic buying binges followed by times of feasting off the excess purchases. This figure has been extended to include the first four months of shipments in 1998. Given the fact that overcapacity remains, this period of decline could extend beyond 29 months into a 31-to-34-month decline in revenue.

There are two major differences between history (1986) and the present day. First, the 1997 market had about a six-month resurgence in spending in DRAM, which did not happen in 1986. On the bright side, the market for front-end equipment grew over 50 percent in 1988, which would correspond to 2000 in Dataquest's current forecast. Second, changes occurring now in the PC sector, the major area of consumption for all semiconductor products, not just DRAM, are exacerbating the situation even further.

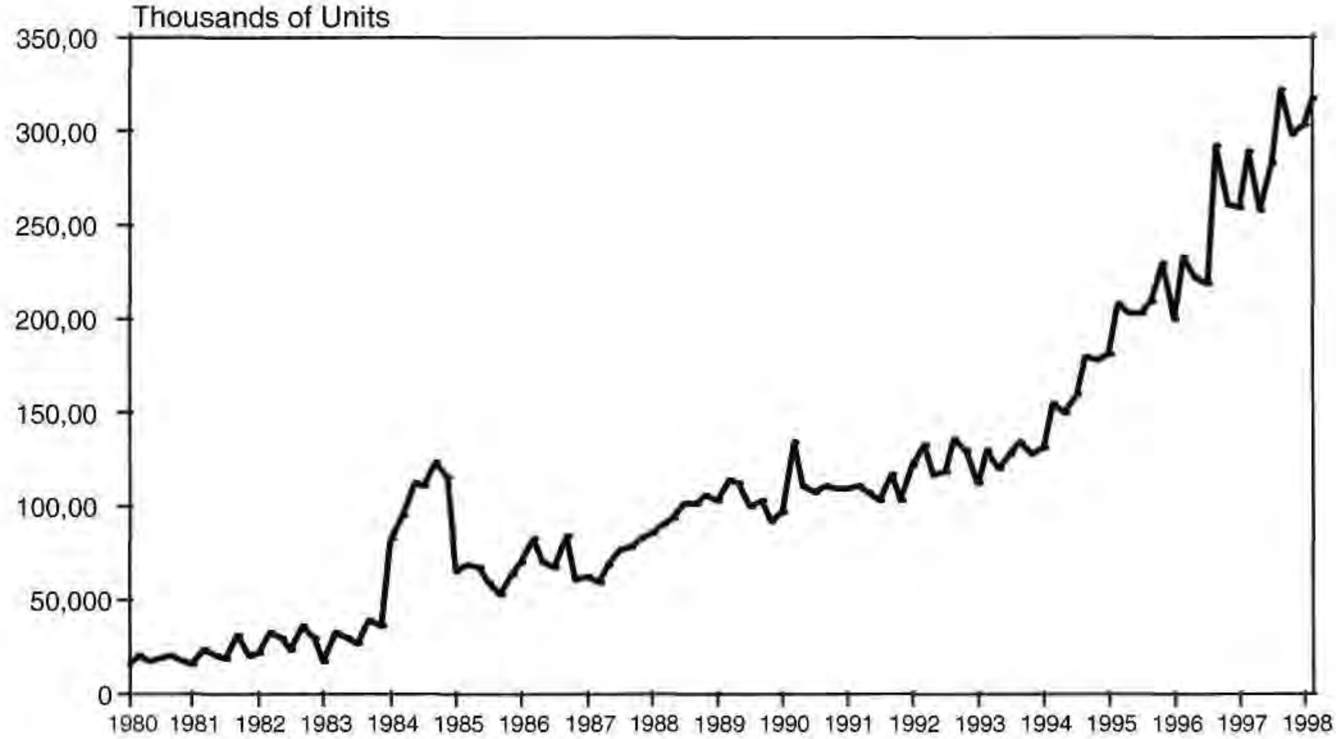
Figure 2
Historical DRAM Shipments



Source: WSTS

Microcomponents

What are the lingering effects of this lengthy price pressure on the market? As with memory, microprocessor pricing is also in the throes of downturn. Some attribute this to increased competition from Advanced Micro Devices Inc. and Cyrix Corporation, while others blame the increasing visibility of sub-$1,000 personal computers. Dataquest argues that the real culprit behind microprocessor price erosion is the declining number of $2,000 and $3,000 personal computers in the sales mix. With the performance of today's low-end and midrange machines, few users feel the need to pay top dollar for the fastest machines they can buy. Some of this desktop MPU price pressure may be offset later in the year as Intel introduces processors priced at $1,000, $2,000, and $4,000, specifically targeted at servers and workstations. Although sold in far smaller volumes than desktop MPUs, the new high-end devices could still contribute mightily to microprocessor average selling prices (ASPs). The combination of one $4,000 microprocessor and 38 $100 processors still results in a $200 average for the lot overall. If Intel's plan works as expected, the second half of the year will produce far stronger MPU revenue than the first.

Logic

Logic is also under pricing pressure and feeling the effects of the turmoil in Asia, but to a much lesser degree than DRAM and microprocessors. Programmable logic devices (PLDs) are a good leading indicator among logic products, and this market has slowed noticeably in the first half of 1998. Pricing pressure can be blamed to some degree, but this market has seen rapid price reductions for some time as suppliers bid for market share. The gate array market is most vulnerable because a large portion of these devices are consumed in Japan, so at least a 10 percent decline can be expected in this market in 1998. Cell-based ICs are still the shining star, but they too have slowed in the first six months of the year.

Price/Cost Analysis

Although megabytes of DRAM grew 77 percent in 1996 and 95 percent in 1997, price-per-bit and price-per-byte declines have eroded DRAM revenue growth potential. Non-DRAM products are expected to continue on a growth path through the end of the year, but pricing pressures in microprocessors, logic, analog, and discrete products have reduced the market's non-DRAM revenue potential from Dataquest's original estimate of $138.3 billion to a more likely scenario of $133.2 billion.

The price forecasts for the most popular 1Mbx16 DRAM part had a contract price value of $3.50 in first quarter 1998. The second quarter 1998 price dropped to $2.55 and could drop to $1.80 by the year's end. The 4Mbx16 DRAM part was $24.00 in first quarter 1998. By second quarter 1998, it had dropped to $11.40 (below Dataquest's $15.00 estimate) and is expected to decline to $8.00 by the end of the year.

Dataquest's original forecast was based on a price per megabyte averaging $2.37 in 1998. A quick review of WSTS worldwide DRAM data (note that revenue for February and April 1998 was restated) is an eye-opening documentation of the disastrous downturn the market has taken since our forecast (see Table 3).

Specific densities show even more cause for concern. Units of 16Mb DRAMs have declined significantly, while 64Mb units increased less, causing an overall decline in bit shipments of 11 percent from March 1998 to April 1998.

Table 3
Price per Megabyte Stays below the Cost Line

Month	Price/Megabyte ($)	Growth (%)	Cost Trend ($)	Price/Cost Change (%)
October 1997	3.10	-9	2.99	104
November 1997	2.59	-16	2.89	90
December 1997	2.19	-15	2.80	78
January 1998	1.96	-11	2.71	72
February 1998	1.97	0	2.63	75
March 1998	1.67	-15	2.54	66
April 1998	1.63	-2	2.46	66

Source: WSTS, Dataquest (June 1998)

Application Market Analysis

Economic growth in Asia/Pacific and now Japan is grinding to a standstill, and that will almost certainly lower electronics demand even further. Japan's deteriorating economic circumstances are particularly distressing. Most forecasters now expect Japan to experience a sharp contraction in economic activity this year. If recent estimates of this contraction (a drop of 0.2 to 0.9 percent) are realized, then Japanese electronics demand will decline precipitously. This downward tumble in Japan would not only affect Japan's already hobbled electronics industry, but it would also seriously affect Asia/Pacific's export production.

The falling yen compounds this problem. The yen recently fell below ¥140 to the dollar and appears well on its way to falling even further, U. S. Treasury Department intervention notwithstanding. To be sure, the continuing depreciation of the yen could provide some stimulus to Japan's sagging economy. However, it is likely to reduce dollar-valued Japanese electronics activity. Moreover, by making Japanese exports less expensive, it almost certainly increases the economic stress of Japan's afflicted Asia/Pacific competitors. In the worst case, a deflating yen could raise the specter of competitive currency devaluation between Japan and its Asia/Pacific neighbors (notably China) that could depress both electronics and semiconductor activity well beyond 1998.

Given all these potential developments, it is not too unreasonable to believe that Dataquest's electronic equipment forecast, shown in Table 4, could also have a most likely scenario that may go well below 4.4 percent. When analyzing semiconductor activity from an end-use perspective, it is important to remember that semiconductor growth is ultimately driven by growth in electronics production and the semiconductor content of electronics. In short, the formula is as follows:

Semiconductor Growth = Electronic Equipment Growth + Semiconductor Content Growth

For 1998, a no-growth scenario is possible if (dollar-valued) electronics production slows significantly and average semiconductor content is reduced. Slower electronics growth now seems very likely, given economic circumstances in Japan and Asia/Pacific. A decline in the average semiconductor content of electronic equipment also appears highly likely, given the apparent inelasticity of DRAM demand in the face of falling DRAM prices. Added to that, Dataquest believes that the growing price competition in several key electronics markets (PCs!) is likely to curtail average semiconductor content as manufacturers struggle to preserve margins by holding the line on semiconductor consumption.

Inventory was a real issue for some PC suppliers during the fourth quarter of 1997 and the first quarter of 1998, and they have slowed their chip orders significantly in the second quarter of 1998. Added to this, server systems are sluggish as spending on these is being cut in favor of funding year 2000 software consultants. The cost concerns of year 2000 issues could be enormous if the additional cost hits from insurance protection and litigation potential are included.

More worrisome is the state of the rigid disk drive business. This sector remains in a prolonged overcapacity as prices and production plans continue to be cut. This pain has also been passed along to the semiconductor suppliers.

In the communications sectors, LAN and Internet access systems saw even worse price pressure than expected. This also affected the semiconductor suppliers because they were also pressured into lowering prices.

The segment that should come under close scrutiny in all regions is consumer electronics. Reports now indicate that the consumer sector is faring worse than expected as the financial turmoil in Japan and Asia/Pacific cuts spending in that area.

Table 4
1998 Electronic Equipment Production Forecast Downside Scenario (Billions of Dollars)

	Actual 1997	Actual 1998	Most Likely 1998 Scenario
Electronic Equipment Production	906.6	968.9	946.5
Growth (%)	6.8	6.9	Greater than or equal to 4.4

Regional Analysis

Asia/Pacific

The overall business climate in the Asia/Pacific region is weak and unstable. It is Dataquest's opinion that the Korean semiconductor market is dead. Korean semiconductor capital spending as a percentage of Asia/Pacific capital spending has traditionally been very aggressive. Korean DRAM suppliers originally gained access to the DRAM market during the government negotiations between Japan and U.S. DRAM suppliers during the trade wars of 1986 and 1987. Korean companies accounted for just over 14 percent of all capital spending worldwide in 1997, but it now appears that all new Korean semiconductor investment projects have stopped. Dataquest's capital spending forecast assumes that Korean companies will cut spending 40 percent in U.S. dollars. This is a total of about $3.3 billion for the big three companies (Hyundai Electronics Company Ltd., LG Semicon Co. Ltd., and Samsung Electronics Company Ltd.). DRAM price drops caused by the Asian turmoil are changing the outlook for 1998 DRAM growth in the region. DRAM, which originally was expected to contract 0.7 percent, is now expected to drop 31.0 percent. This could translate to a 0.6 percent contraction in Asia/Pacific semiconductor revenue for 1998. Asia/Pacific is a trade-intensive region that is basically in a trade recession. Its largest trading partner, Japan, has now become its largest trading competitor. China and Taiwan appear to be the more stable areas of the region. However, capital spending in Taiwan has begun to slow this quarter compared with the previous quarter.

Japan

The analysis from Japan does not bode well for a quick return to market growth. The biggest change has been felt in price declines in various MOS digital products—not just DRAM but also flash memory, microprocessors, microcontrollers, and application-specific ICs (ASICs). In the logic product markets, there have been mild price changes in cell-based ICs, while prices for application-specific standard products (ASSPs, the "other MOS logic" category) are falling rapidly. DRAM prices have come down below cost. In the microprocessor and logic product markets, vendors are offering aggressive prices that could bring revenue growth down substantially from the levels forecast at the beginning of 1998. It now appears that the yen/dollar exchange rate, assumed for Dataquest's spring forecast to be ¥129.73, will be closer to ¥138 for 1998 and ¥143 for 1999. This translates to a 6.3 percent yen depreciation against the spring forecast assumption. During recent interviews with Japanese semiconductor vendors, they gave estimates for growth in Japan ranging from a 5 percent contraction to flat for 1998. Contacts in the consumer applications believe that there may be a yen-based total semiconductor contraction this year.

Europe

The continued decline in DRAM pricing is affecting all device categories for European vendors, although analog, discrete, and optoelectronic product growth appears to be more robust than that of the more complex products. Microcomponent growth is down, even though unit demand continues to grow. Regional PC demand in the first quarter was unexpectedly strong, with first quarter 1998 shipments up 26 percent over the first quarter of 1997. Demand has been weaker in the second quarter. The third quarter is historically weakest; however, strong fourth quarter demand should hold the year to the 14.3 percent PC unit growth forecast.

 ©1998 Dataquest

Production of other high-volume products, such as digital cellular handsets, remains robust, with the equipment manufacturers reveling in low prices, short lead times, and minimal inventories. A de facto just-in-time ordering system seems to be the norm on commodity products, with equipment manufacturers happy to have the semiconductor vendors acting as their warehouses and transferring products to their own ownership at the last possible moment. This has enabled them to decrease their inventories, but this is a dangerous game because, when the upturn comes, lead times will rise overnight, leaving less astute purchasers without adequate backlog coverage.

The current forecast for Europe is for 8.6 percent growth, but that the change in circumstances makes this an unlikely occurrence. On the basis of the reasonably strong end-equipment growth still forecast for Europe, Dataquest expects the region to outperform the worldwide market with growth, at best, at about 3 percent for the year.

Americas

The Americas region, originally forecast to grow around 10.9 percent, could instead decline to growth of about 4 to 5 percent. Americas investment in DRAM is minor compared with that of Asia/Pacific and Japan. The major price declines in other memory products (SRAM, flash, and EEPROM), microprocessors, and logic/ASIC devices are an indirect result of other market downturns and DRAM system price pressures. All the major North American semiconductor and front-end equipment suppliers are posting declines in quarterly earnings. Some have chosen more drastic measures, layoffs, to stem the revenue decline. National Semiconductor Corporation, Motorola Incorporated, and Applied Materials Inc. have all announced major layoffs. Lam Research Corporation has chosen a two-week plant shutdown. Even with the U.S. Federal Trade Commission breathing down its back, Intel Corporation has buckled under the system pricing pressures and announced price reductions of up to 20 percent on various MPU products. The automotive and consumer application markets are stable, but the communications sector, especially the cellular telephone market, has weakened.

What about Capital Spending Now?

A "technology" spending cycle during 1997, normal in the middle stages of an oversupply-driven downturn, was much stronger than expected, driven by the sheer momentum of an increased number of new and inexperienced players in the market. The correction in spending is now under way, following very closely, and perhaps exceeding, the downside scenario presented by Dataquest in January ("Wafer Fab Equipment Market Forecast Update: Question Marks for 1998," SEMM-WW-DP-9801, and "Conference Call on Capital Spending and Wafer Fab Equipment Year-End Forecast Update," SEMM-WW-DP-9803). A revised capital spending forecast will be released in mid-July; however, the current view is that 1998 spending is likely to be 14 to 16 percent lower in 1998 than 1997. The weakness is the underlying chip market in 1998 should delay a recovery in spending until 2000, meaning that 1999 should be a single-digit growth year, at best.

 ©1998 Dataquest

Dataquest Perspective

The tried and true survivors of the semiconductor industry understand the angst of these memory boom-to-bust death cycles. The length of this DRAM downturn will weaken the growth potential of 1999. At this time, Dataquest does not expect memory IC revenue to return to 1995 growth levels until after 2000, when balance returns to the market. Despite the ups and downs of the semiconductor industry, semiconductors are fundamental to information technology. The market has seen revenue set back for the last two and one-half years. This may turn into a full three-year downturn or it may be temporary, unless the markets in Asia/Pacific and Japan weaken further.

Is there a bright side somewhere? A return to growth could come from many of the top 10 emerging consumer, communications, and data processing equipment markets. These are expected to account for about 70 percent of semiconductor consumption through 2002. The PC market is undergoing an intense transition from the high-end desktop products to the low-end, low-priced systems. There is concern about demand for the system above 300 to 400 MHz, which will drive DRAM megabyte growth. Is real demand developing for high-end thin servers and workstations? Intel could make that demand real, based on its recent price decrease efforts. Prices for various 300-to-400-MHz devices have recently been cut from 12 to 20 percent. The wireless and new digital consumer application markets continue to drive digital signal processor, embedded, and digital ASIC growth.

Dataquest will continue to closely monitor regional, product, and application events as they occur. Comments on updates are always welcome.

Market Analysis

Semiconductors Second Quarter 1998: A Buyer's Boon and a Supplier's Gloom

Abstract: *Since the release of Dataquest's spring worldwide semiconductor forecast, severe DRAM price erosion and economic downturns have begun to affect the revenue not only of MOS memory but also of all other major semiconductor product categories. The consumer and data processing electronic equipment markets are showing further signs of weakening. Capital spending forecasts have declined 15 percent. Weakened by economic turmoil in Asia/Pacific and financial weakness in Japan, prices on electronic imported goods arriving at Europe's and America's doorsteps have declined for seven consecutive months. The DRAM downturn that began in December 1995 is taking the rest of the market down. This very long downturn is reminiscent of the DRAM nosedive that began in January 1985. Many companies barely survived, and those that did were lucky to walk away bruised and battered. How do these events affect Dataquest's clients and current forecast?*

By Mary Ann Olsson

A Worldwide Forecast Update

FILE COPY:
MARIA VALENZUELA

For two and one-half years, there has been both decline and growth in semiconductor products. MOS memory devices have led the decline. In terms of historical volume and driving overall profit, DRAMs, the powerhouse products, have been pivotal to this decline (down 38 percent in 1996, down 20 percent in 1997). Judging from the decline in prices during the first half of 1998, there will be a third year of decline in DRAMs. This decline could go beyond 23 percent, taking DRAM revenue below $16 billion in 1998.

Although multiple forecasts and scenarios different from Dataquest's original forecast have been publicized, Dataquest has tried to avoid following the herd. This Perspective offers the most likely scenario for the market and, possibly, moments of sanity that rise above soothsaying.

The spring publication of Dataquest's worldwide semiconductor forecast for semiconductors and ICs showed the optimistic forecast; the most likely downside scenario for 1998 is shown in Table 1. Barring major economic downturns that even Dataquest cannot predict, we believe that the market will fall within this range.

Analysis and Assumptions

Since the first quarter of 1998, significant events have occurred that have affected not only industry dynamics but also Dataquest's initial forecast. The Asian financial crisis has worsened, weakening the financially struggling Korean semiconductor companies. Overcapacity is still prevalent. A price collapse continues to erode the DRAM market. Continued oversupply and unbalanced currencies in Asia/Pacific and Japan and competitive posturing by the 64Mb DRAM suppliers are the main cause of this erosion. Are those cries of dumping in the distance?

It is Dataquest's view that vendors will continue to lower prices, even to the point of selling at or below cost, to gain share or just to fill the fabs. The aggressive capital spending and overexpansion that continued through 1997 exacerbated the problems of a market already in the throes of overcapacity and accelerated DRAM technology die shrinks. In 1996, overcapacity in DRAM was about 20 percent, and it was rumored to be at 40 percent in 1997. With the shrink factor and the addition of net capacity over the last year and a half, the signs do not bode well for an 8 percent growth in 1998. Add to that a recent downward trend in microprocessor (MPU) and logic prices, and Dataquest's most likely scenario becomes more reasonable.

Buyers of semiconductor products are happy about these prices. But the risks are great. Building too much inventory in a shaky market with weak trading partners coupled with low import pricing could send the entire semiconductor industry spiraling into a recession. Many suppliers (merchant and foundry) are scurrying to fill fabs with non-DRAM products, offering lucrative contract pricing for products in the non-DRAM sectors. Many buyers are building low-priced inventories to keep up with pricing pressures while meeting demand for lower-end systems in the data processing, consumer, and communications sectors. Is the market spiraling out of control, and is this a market transition of electronic equipment demand growth from less sophisticated business sectors? Or is this simply a downshift in revenue growth as the equipment market becomes a commodity market?

Unless something miraculous happens during the next two quarters, stronger near-term semiconductor market growth is not expected.

©1998 Dataquest

Product Analysis

MOS Memory

DRAM has always been the key driver of growth and the key culprit in decline in the semiconductor industry. In the major DRAM and overall semiconductor market downturns, excess (capacity or strategic inventory) is the real culprit. There are many similarities between this market downturn and the market downturn that began in 1985. Some of these are listed in Table 2.

A stroll down memory lane might jangle some nerves but would help many to understand what is happening in the semiconductor industry. The DRAM market declined 52 percent, from $3.5 billion in 1984 to $1.7 billion in 1985. In 1984, suppliers hoarded products and buyers double-ordered on contracts to guarantee shipments. In 1985, as suppliers began dumping products and lowering prices, buyers canceled long-range contracts to reap the benefits of lower prices. Pricing wars raged until trading wars and dumping issues resulted in government intervention, and foreign market value (FMV) duties were imposed. The suppliers in this market suffered the worst losses and faced the worst price erosion. Several companies made well-publicized withdrawals from the DRAM market during that year. The manufacturers that fared best were those well positioned in the 256K DRAM market, which enabled them to shift their revenue base as the 64K market declined.

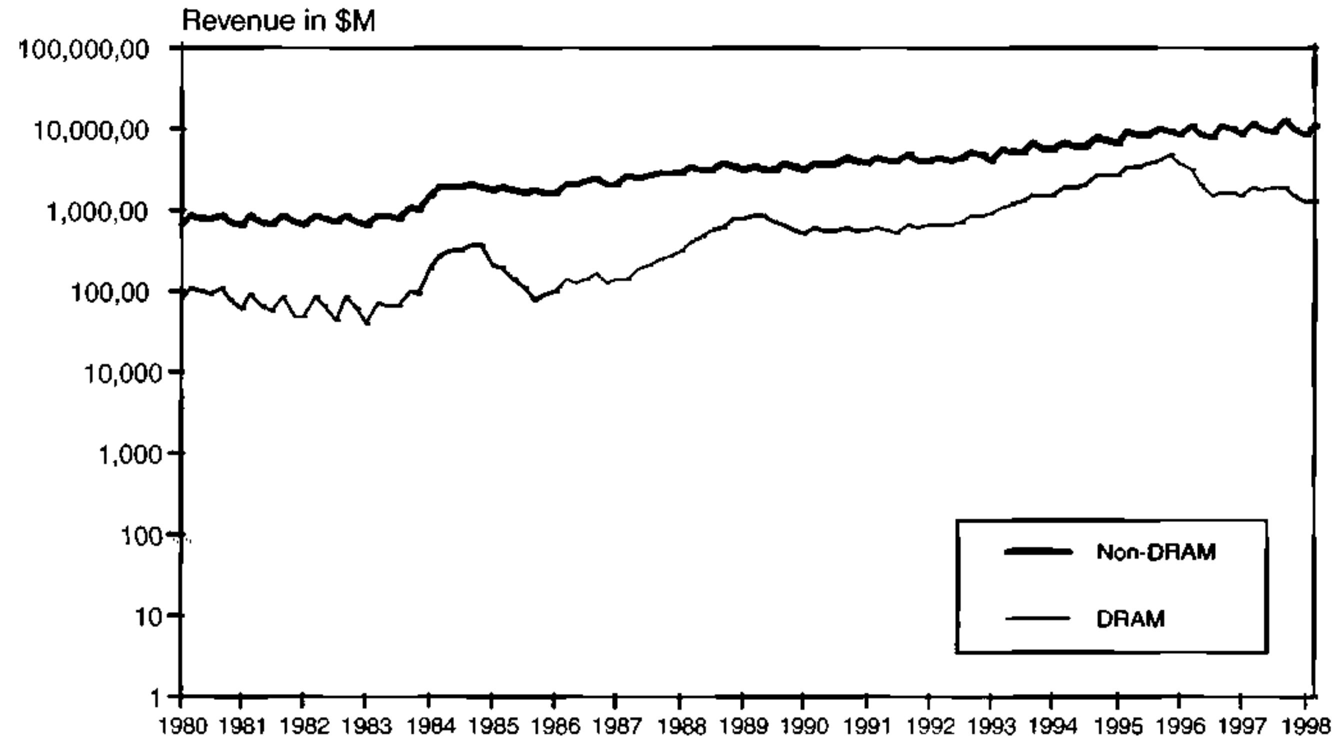
The historical path of DRAM revenue versus non-DRAM revenue through the historical eyes of World Semiconductor Trade Statistics (WSTS) data reveals that a slowdown in market growth actually occurred in the last three months of 1984 (see Figure 1), before the DRAM market took a nosedive in January 1985. It took the market and its suppliers 27 months, from January 1985 through March 1987, to return to growth.

Table 2
Market Comparisons: 1985 through 1987 versus 1995 through 1998

1985-through-1987 Market	1995-through-1998 Market
Product hoarding/double-ordering led to supply excess, which precipitated price erosion.	Excessive capital spending added to overcapacity that precipitated price erosion.
Capital spending was depressed in the United States because of uncertainty about proposed tax reforms.	Capital spending was depressed in the United States, Japan, Europe, and Korea because of a capital spending binge.
International trade issues over product prices below fair market values led to antidumping duties on DRAMs and EPROMs.	Uncertainty about antidumping duties on DRAMs rises as rumors abound about dumping products at below cost to gain market share.
Damaged by price erosion, a depressed market, and aggressive competitors, Mostek, Intel, and Inmos disappeared from key market sectors.	Damaged by excessive spending, price erosion, and aggressive competitors, some DRAM suppliers are evaluating departure from the market.
A crossover point in price was reached between the 64K DRAM and 256K DRAM. The 1Mb DRAMs reached price-per-bit parity with 256K at the end of 1987.	In a dance of death, 64Mb DRAM chases the 16Mb DRAM. Price-per-bit parity could be reached by the end of 1998. A 4Mb-to-16Mb crossover could occur during this time.
There was a dramatic change in the yen exchange rate, from ¥254/dollar in 1985 to ¥128.4 at the end of 1987.	The yen/dollar exchange rate changed dramatically from ¥129.73 for the spring forecast period to ¥143 for 1999. The Korean won lost 50 percent of its value against the dollar, like the yen in 1985 through 1987.
Price erosion affected all memory products.	Price erosion affects the majority of ICs.

Source: Dataquest (June 1998)

Figure 1
DRAM versus Non-DRAM Revenue over Time



Source: WSTS

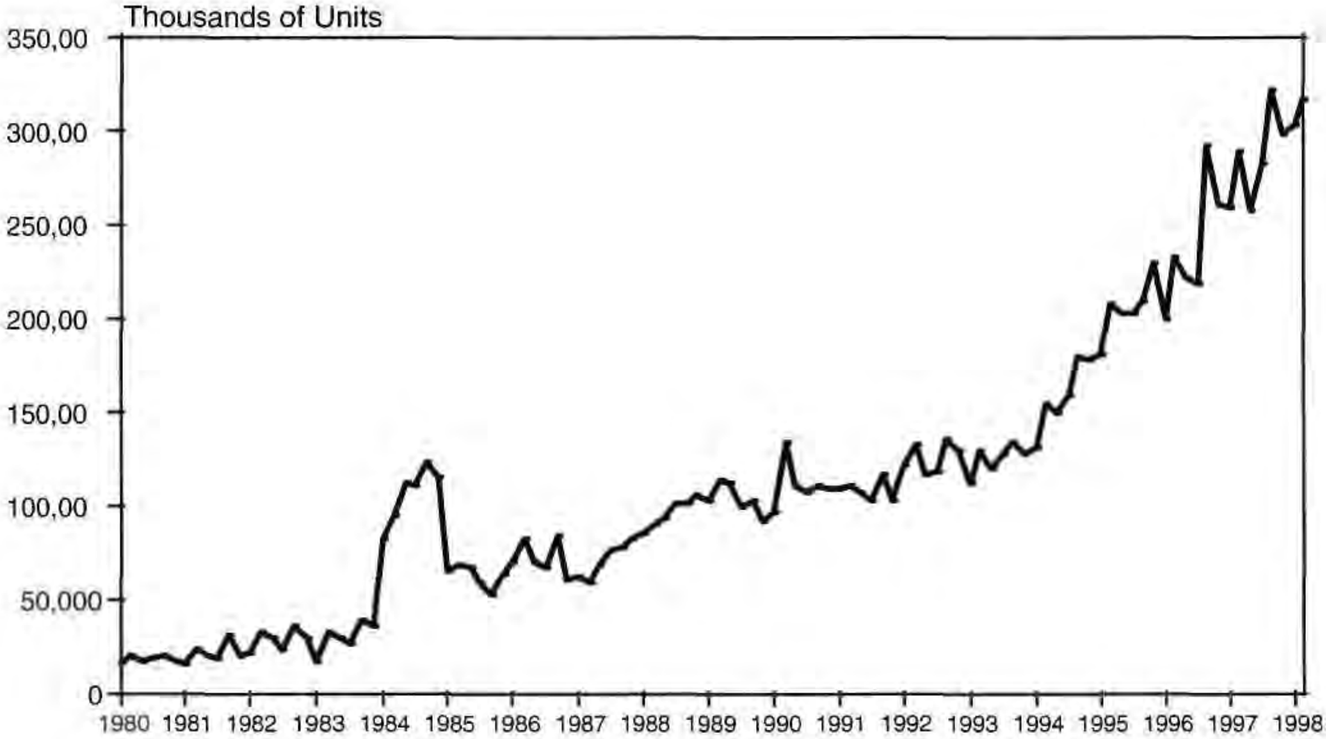
Today's market is very reminiscent of that downturn. DRAM growth slowed during the fourth quarter of 1995, and the decline began December 1995. From that time, it has been 29 months of more or less declining revenue. There was a brief respite in September 1996. There were gasps of minor growth in February and March 1997, growth mostly propelled by the Korean suppliers. There was a lull in April before revenue strengthened from May through September, and then the second downturn hit during the fourth quarter of 1997.

Figure 2 shows that DRAM shipments over time were very smooth in the shortage years (1992 through 1995) but quite bumpy in times of oversupply (all other years). Do smooth shipments represent extremely tight allocation, with factories operating at maximum efficiency? If this is true, then the bumpy times reflect opportunistic buying binges followed by times of feasting off the excess purchases. This figure has been extended to include the first four months of shipments in 1998. Given the fact that overcapacity remains, this period of decline could extend beyond 29 months into a 31-to-34-month decline in revenue.

There are two major differences between history (1986) and the present day. First, the 1997 market had about a six-month resurgence in spending in DRAM, which did not happen in 1986. On the bright side, the market for front-end equipment grew over 50 percent in 1988, which would correspond to 2000 in Dataquest's current forecast. Second, changes occurring now in the PC sector, the major area of consumption for all semiconductor products, not just DRAM, are exacerbating the situation even further.

©1998 Dataquest

Figure 2
Historical DRAM Shipments



Source: WSTS

Microcomponents

What are the lingering effects of this lengthy price pressure on the market? As with memory, microprocessor pricing is also in the throes of downturn. Some attribute this to increased competition from Advanced Micro Devices Inc. and Cyrix Corporation, while others blame the increasing visibility of sub-$1,000 personal computers. Dataquest argues that the real culprit behind microprocessor price erosion is the declining number of $2,000 and $3,000 personal computers in the sales mix. With the performance of today's low-end and midrange machines, few users feel the need to pay top dollar for the fastest machines they can buy. Some of this desktop MPU price pressure may be offset later in the year as Intel introduces processors priced at $1,000, $2,000, and $4,000, specifically targeted at servers and workstations. Although sold in far smaller volumes than desktop MPUs, the new high-end devices could still contribute mightily to microprocessor average selling prices (ASPs). The combination of one $4,000 microprocessor and 38 $100 processors still results in a $200 average for the lot overall. If Intel's plan works as expected, the second half of the year will produce far stronger MPU revenue than the first.

Logic

Logic is also under pricing pressure and feeling the effects of the turmoil in Asia, but to a much lesser degree than DRAM and microprocessors. Programmable logic devices (PLDs) are a good leading indicator among logic products, and this market has slowed noticeably in the first half of 1998. Pricing pressure can be blamed to some degree, but this market has seen rapid price reductions for some time as suppliers bid for market share. The gate array market is most vulnerable because a large portion of these devices are consumed in Japan, so at least a 10 percent decline can be expected in this market in 1998. Cell-based ICs are still the shining star, but they too have slowed in the first six months of the year.

©1998 Dataquest

Price/Cost Analysis

Although megabytes of DRAM grew 77 percent in 1996 and 95 percent in 1997, price-per-bit and price-per-byte declines have eroded DRAM revenue growth potential. Non-DRAM products are expected to continue on a growth path through the end of the year, but pricing pressures in microprocessors, logic, analog, and discrete products have reduced the market's non-DRAM revenue potential from Dataquest's original estimate of $138.3 billion to a more likely scenario of $133.2 billion.

The price forecasts for the most popular 1Mbx16 DRAM part had a contract price value of $3.50 in first quarter 1998. The second quarter 1998 price dropped to $2.55 and could drop to $1.80 by the year's end. The 4Mbx16 DRAM part was $24.00 in first quarter 1998. By second quarter 1998, it had dropped to $11.40 (below Dataquest's $15.00 estimate) and is expected to decline to $8.00 by the end of the year.

Dataquest's original forecast was based on a price per megabyte averaging $2.37 in 1998. A quick review of WSTS worldwide DRAM data (note that revenue for February and April 1998 was restated) is an eye-opening documentation of the disastrous downturn the market has taken since our forecast (see Table 3).

Specific densities show even more cause for concern. Units of 16Mb DRAMs have declined significantly, while 64Mb units increased less, causing an overall decline in bit shipments of 11 percent from March 1998 to April 1998.

Table 3
Price per Megabyte Stays below the Cost Line

Month	Price/Megabyte ($)	Growth (%)	Cost Trend ($)	Price/Cost Change (%)
October 1997	3.10	-9	2.99	104
November 1997	2.59	-16	2.89	90
December 1997	2.19	-15	2.80	78
January 1998	1.96	-11	2.71	72
February 1998	1.97	0	2.63	75
March 1998	1.67	-15	2.54	66
April 1998	1.63	-2	2.46	66

Application Market Analysis

Economic growth in Asia/Pacific and now Japan is grinding to a standstill, and that will almost certainly lower electronics demand even further. Japan's deteriorating economic circumstances are particularly distressing. Most forecasters now expect Japan to experience a sharp contraction in economic activity this year. If recent estimates of this contraction (a drop of 0.2 to 0.9 percent) are realized, then Japanese electronics demand will decline precipitously. This downward tumble in Japan would not only affect Japan's already hobbled electronics industry, but it would also seriously affect Asia/Pacific's export production.

The falling yen compounds this problem. The yen recently fell below ¥140 to the dollar and appears well on its way to falling even further, U. S. Treasury Department intervention notwithstanding. To be sure, the continuing depreciation of the yen could provide some stimulus to Japan's sagging economy. However, it is likely to reduce dollar-valued Japanese electronics activity. Moreover, by making Japanese exports less expensive, it almost certainly increases the

©1998 Dataquest

economic stress of Japan's afflicted Asia/Pacific competitors. In the worst case, a deflating yen could raise the specter of competitive currency devaluation between Japan and its Asia/Pacific neighbors (notably China) that could depress both electronics and semiconductor activity well beyond 1998.

Given all these potential developments, it is not too unreasonable to believe that Dataquest's electronic equipment forecast, shown in Table 4, could also have a most likely scenario that may go well below 4.4 percent. When analyzing semiconductor activity from an end-use perspective, it is important to remember that semiconductor growth is ultimately driven by growth in electronics production and the semiconductor content of electronics. In short, the formula is as follows:

Semiconductor Growth = Electronic Equipment Growth + Semiconductor Content Growth

For 1998, a no-growth scenario is possible if (dollar-valued) electronics production slows significantly and average semiconductor content is reduced. Slower electronics growth now seems very likely, given economic circumstances in Japan and Asia/Pacific. A decline in the average semiconductor content of electronic equipment also appears highly likely, given the apparent inelasticity of DRAM demand in the face of falling DRAM prices. Added to that, Dataquest believes that the growing price competition in several key electronics markets (PCs!) is likely to curtail average semiconductor content as manufacturers struggle to preserve margins by holding the line on semiconductor consumption.

Inventory was a real issue for some PC suppliers during the fourth quarter of 1997 and the first quarter of 1998, and they have slowed their chip orders significantly in the second quarter of 1998. Added to this, server systems are sluggish as spending on these is being cut in favor of funding year 2000 software consultants. The cost concerns of year 2000 issues could be enormous if the additional cost hits from insurance protection and litigation potential are included.

More worrisome is the state of the rigid disk drive business. This sector remains in a prolonged overcapacity as prices and production plans continue to be cut. This pain has also been passed along to the semiconductor suppliers.

In the communications sectors, LAN and Internet access systems saw even worse price pressure than expected. This also affected the semiconductor suppliers because they were also pressured into lowering prices.

The segment that should come under close scrutiny in all regions is consumer electronics. Reports now indicate that the consumer sector is faring worse than expected as the financial turmoil in Japan and Asia/Pacific cuts spending in that area.

Table 4
1998 Electronic Equipment Production Forecast Downside Scenario (Billions of Dollars)

	Actual 1997	Actual 1998	Most Likely 1998 Scenario
Electronic Equipment Production	906.6	968.9	946.5
Growth (%)	6.8	6.9	Greater than or equal to 4.4

Regional Analysis

Asia/Pacific

The overall business climate in the Asia/Pacific region is weak and unstable. It is Dataquest's opinion that the Korean semiconductor market is dead. Korean semiconductor capital spending as a percentage of Asia/Pacific capital spending has traditionally been very aggressive. Korean DRAM suppliers originally gained access to the DRAM market during the government negotiations between Japan and U.S. DRAM suppliers during the trade wars of 1986 and 1987. Korean companies accounted for just over 14 percent of all capital spending worldwide in 1997, but it now appears that all new Korean semiconductor investment projects have stopped. Dataquest's capital spending forecast assumes that Korean companies will cut spending 40 percent in U.S. dollars. This is a total of about $3.3 billion for the big three companies (Hyundai Electronics Company Ltd., LG Semicon Co. Ltd., and Samsung Electronics Company Ltd.). DRAM price drops caused by the Asian turmoil are changing the outlook for 1998 DRAM growth in the region. DRAM, which originally was expected to contract 0.7 percent, is now expected to drop 31.0 percent. This could translate to a 0.6 percent contraction in Asia/Pacific semiconductor revenue for 1998. Asia/Pacific is a trade-intensive region that is basically in a trade recession. Its largest trading partner, Japan, has now become its largest trading competitor. China and Taiwan appear to be the more stable areas of the region. However, capital spending in Taiwan has begun to slow this quarter compared with the previous quarter.

Japan

The analysis from Japan does not bode well for a quick return to market growth. The biggest change has been felt in price declines in various MOS digital products—not just DRAM but also flash memory, microprocessors, microcontrollers, and application-specific ICs (ASICs). In the logic product markets, there have been mild price changes in cell-based ICs, while prices for application-specific standard products (ASSPs, the "other MOS logic" category) are falling rapidly. DRAM prices have come down below cost. In the microprocessor and logic product markets, vendors are offering aggressive prices that could bring revenue growth down substantially from the levels forecast at the beginning of 1998. It now appears that the yen/dollar exchange rate, assumed for Dataquest's spring forecast to be ¥129.73, will be closer to ¥138 for 1998 and ¥143 for 1999. This translates to a 6.3 percent yen depreciation against the spring forecast assumption. During recent interviews with Japanese semiconductor vendors, they gave estimates for growth in Japan ranging from a 5 percent contraction to flat for 1998. Contacts in the consumer applications believe that there may be a yen-based total semiconductor contraction this year.

Europe

The continued decline in DRAM pricing is affecting all device categories for European vendors, although analog, discrete, and optoelectronic product growth appears to be more robust than that of the more complex products. Microcomponent growth is down, even though unit demand continues to grow. Regional PC demand in the first quarter was unexpectedly strong, with first quarter 1998 shipments up 26 percent over the first quarter of 1997. Demand has been weaker in the second quarter. The third quarter is historically weakest; however, strong fourth quarter demand should hold the year to the 14.3 percent PC unit growth forecast.

Production of other high-volume products, such as digital cellular handsets, remains robust, with the equipment manufacturers reveling in low prices, short lead times, and minimal inventories. A de facto just-in-time ordering system seems to be the norm on commodity products, with equipment manufacturers happy to have the semiconductor vendors acting as their warehouses and transferring products to their own ownership at the last possible moment. This has enabled them to decrease their inventories, but this is a dangerous game because, when the upturn comes, lead times will rise overnight, leaving less astute purchasers without adequate backlog coverage.

The current forecast for Europe is for 8.6 percent growth, but that the change in circumstances makes this an unlikely occurrence. On the basis of the reasonably strong end-equipment growth still forecast for Europe, Dataquest expects the region to outperform the worldwide market with growth, at best, at about 3 percent for the year.

Americas

The Americas region, originally forecast to grow around 10.9 percent, could instead decline to growth of about 4 to 5 percent. Americas investment in DRAM is minor compared with that of Asia/Pacific and Japan. The major price declines in other memory products (SRAM, flash, and EEPROM), microprocessors, and logic/ASIC devices are an indirect result of other market downturns and DRAM system price pressures. All the major North American semiconductor and front-end equipment suppliers are posting declines in quarterly earnings. Some have chosen more drastic measures, layoffs, to stem the revenue decline. National Semiconductor Corporation, Motorola Incorporated, and Applied Materials Inc. have all announced major layoffs. Lam Research Corporation has chosen a two-week plant shutdown. Even with the U.S. Federal Trade Commission breathing down its back, Intel Corporation has buckled under the system pricing pressures and announced price reductions of up to 20 percent on various MPU products. The automotive and consumer application markets are stable, but the communications sector, especially the cellular telephone market, has weakened.

What about Capital Spending Now?

A "technology" spending cycle during 1997, normal in the middle stages of an oversupply-driven downturn, was much stronger than expected, driven by the sheer momentum of an increased number of new and inexperienced players in the market. The correction in spending is now under way, following very closely, and perhaps exceeding, the downside scenario presented by Dataquest in January ("Wafer Fab Equipment Market Forecast Update: Question Marks for 1998," SEMM-WW-DP-9801, and "Conference Call on Capital Spending and Wafer Fab Equipment Year-End Forecast Update," SEMM-WW-DP-9803). A revised capital spending forecast will be released in mid-July; however, the current view is that 1998 spending is likely to be 14 to 16 percent lower in 1998 than 1997. The weakness is the underlying chip market in 1998 should delay a recovery in spending until 2000, meaning that 1999 should be a single-digit growth year, at best.

 ©1998 Dataquest

Dataquest Perspective

The tried and true survivors of the semiconductor industry understand the angst of these memory boom-to-bust death cycles. The length of this DRAM downturn will weaken the growth potential of 1999. At this time, Dataquest does not expect memory IC revenue to return to 1995 growth levels until after 2000, when balance returns to the market. Despite the ups and downs of the semiconductor industry, semiconductors are fundamental to information technology. The market has seen revenue set back for the last two and one-half years. This may turn into a full three-year downturn or it may be temporary, unless the markets in Asia/Pacific and Japan weaken further.

Is there a bright side somewhere? A return to growth could come from many of the top 10 emerging consumer, communications, and data processing equipment markets. These are expected to account for about 70 percent of semiconductor consumption through 2002. The PC market is undergoing an intense transition from the high-end desktop products to the low-end, low-priced systems. There is concern about demand for the system above 300 to 400 MHz, which will drive DRAM megabyte growth. Is real demand developing for high-end thin servers and workstations? Intel could make that demand real, based on its recent price decrease efforts. Prices for various 300-to-400-MHz devices have recently been cut from 12 to 20 percent. The wireless and new digital consumer application markets continue to drive digital signal processor, embedded, and digital ASIC growth.

Dataquest will continue to closely monitor regional, product, and application events as they occur. Comments on updates are always welcome.

Market Analysis

EMEA DRAM Market: 1997 in Review and the Outlook for 1998

Abstract: *This Market Analysis reviews the Europe, Middle East and Africa (EMEA) DRAM market in 1997 and provides an early outlook for 1998. Taking into account current market conditions and upcoming product and technology trends, it also provides scenario-based bit, ASP and revenue forecasts for 1998.*

By Richard Gordon

Casey Jones, A-Steamin' and A-Rollin' ...

The light at the end of the tunnel might just be an oncoming locomotive. No doubt some DRAM manufacturers will feel that they have already been run over by Casey Jones during the latest DRAM market downturn; however, it looks as though the Cannonball Express might just be coming down the line again ...

1997 Review

Bit Demand

A surge in DRAM bit demand late in the third quarter and into the fourth quarter last year helped to lift the moving average annual growth rate for worldwide DRAM revenue in 1997 from a low of almost minus 60 percent in April to about minus 15 percent by year end. In fact, Dataquest estimates that bit growth last year reached an unprecedented 107 percent, driven by demand for increased PC main memory. It appears that PC manufacturers were finally able and willing to pass on savings in DRAM prices to end users, and this trend manifested itself in a rapid move from 16MB-configured machines to a 32MB base fit as standard during the fourth quarter of 1997. As 1998 gets under way, the trend towards higher main-memory fit is continuing as high-end Windows NT 4.0-targeted machines hit the streets fitted with 64MB as standard. However, there seems to be no justifiable rationale for a trend towards higher PC DRAM content in the short term other than an opportunistic move by PC vendors to differentiate product offerings at a time when adding more memory is a low-cost option.

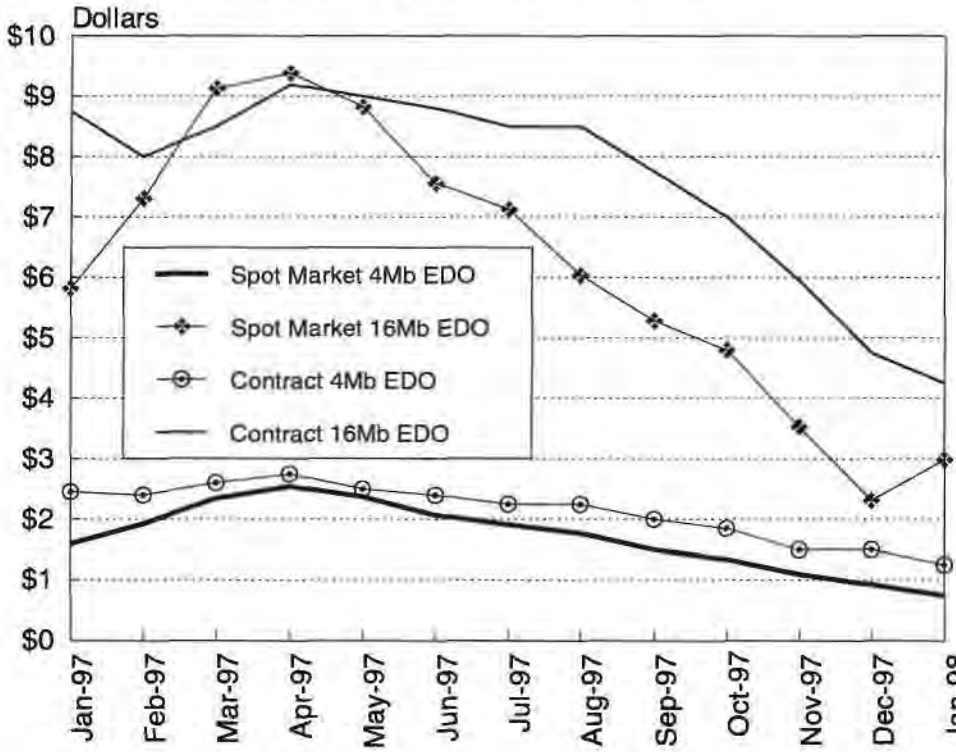
ASPs

Despite the surge in bit demand, global overcapacity remained a feature of the DRAM industry throughout 1997 and ASPs continued to decline steadily, as shown in Figure 1. There were "false dawns" during the year when spot market ASPs briefly twitched upwards, but these upticks were short-lived and confined to specific device configurations. Although there was talk of production cutbacks to ease the oversupply situation and stabilize prices, concrete action failed to materialize; as a result, there are still no signs that the fundamental problem of overcapacity in the short term has been addressed.

Figure 1
Worldwide DRAM ASPs—Spot Market versus Contract, 1997-1998



Source: Dataquest (March 1998 Estimates)

Vendors

In this competitive marketplace, initial soundings suggest that tier-one DRAM vendors have consolidated their market leadership positions. This makes sense for a number of reasons: for example, thanks to abundant supply, customers could deal exclusively with preferred suppliers at little price premium; and, as demand increased for DRAM incorporating technology developments such as the 64Mb density and the synchronous interface, supply was largely the preserve of the leading vendors. However, we will have to wait until the spring, when Dataquest publishes its final vendor market share numbers, for this view to be confirmed.

Regulatory Issues

Regulatory issues, although in the headlines for much of 1997, thankfully were not allowed to interfere with the DRAM marketplace in the EMEA region. Within the European Union (EU), the free market was allowed to determine DRAM market conditions as the European Commission (EC) finally dispensed with DRAM antidumping legislation. Although this legislation was nominally in place for a time, it was not enforced in practice, suggesting that the EC had lost patience with trying to police the price of DRAM imports.

 ©1998 Dataquest

As DRAM prices fell day by day, the imposition of reference pricing for DRAM imported from the Far East would have been difficult to implement and would have had serious implications for European electronic equipment production. In a global economy, purchasing and production decisions would have been reviewed, and the European electronics and semiconductor markets would have suffered as a result. The interests of Europe-based DRAM suppliers are being served now via "gentlemen's agreements" between the European Electronic Component Manufacturers Association, the Korean Semiconductor Industry Association and the Electronics Industry Association of Japan. Common sense appears to have prevailed on this issue, although it remains to be seen how effective this self-regulation will be.

There was also good news last year on the subject of tariffs. As momentum continues to build towards a global zero semiconductor import tariff (under the direction of the International Technology Agreement and the World Semiconductor Council), the EC announced last year an accelerated reduction to zero of DRAM tariffs. This has resulted in zero tariffs being in force from January 1, 1998 for DRAM imports into the EU.

Investment and Capacity

Despite many high-profile announcements of cutbacks in DRAM fab investment, the wafer fab equipment market grew by about 3 percent in 1997 over 1996. An increase in DRAM capital spending was driven by a surge in technology purchases in the second half of last year, particularly on the part of Taiwanese DRAM vendors. However, because overcapacity in the DRAM market has been ever present since late 1995 and is an enduring feature, any increase in capital spending will serve only to make matters worse—especially in the light of recent and continuing efficiency improvements in DRAM manufacturing.

When Dataquest published its latest DRAM market forecasts in October 1997, DRAM supply and demand were expected to come into balance towards the end of 1998. That assumption had a bearing on our outlook for future DRAM pricing trends, hence affecting our revenue forecasts. Dataquest is no longer convinced that DRAM supply and demand will be balanced by the end of this year—unless some capacity is actively removed from the market it looks increasingly likely that such equilibrium will be deferred until 1999, thus keeping prices lower for longer and reducing the likelihood of price stability this year. Whether that happens depends largely on the actions of the South Korean DRAM vendors in response to the Asian financial crisis, but the suspicion is that significant reductions in supply will not be forthcoming, so supply will have to wait for demand to catch up.

Asian Financial Crisis

Much has been written about the implications of the Asian financial crisis on the electronics and semiconductor industries in general. In the case of DRAM the impact of the crisis on the South Korean semiconductor industry is the most critical factor, because South Korean companies account for more than 30 percent of global DRAM revenue.

The fall of the Korean won against other world currencies and the restructuring of investment financing required by the IMF will result in two key effects, one short term, the other long term.

Short-Term Effects

Throughout 1997 DRAM was priced at a level near the cost of manufacture, as oversupply forced prices down to levels effectively defined by the need to avoid antidumping allegations. Dataquest expects continuing overcapacity in 1998, forcing manufacturers to continue their efforts to keep prices low to maintain market share.

This situation has been exacerbated by a recent devaluation of the won in South Korea, which has effectively lowered the costs of manufacturing DRAM in that country (as measured in any other currency). Dataquest estimates that at least 55 percent of the cost to manufacture a South Korean DRAM is borne in won-based transactions rather than foreign-currency-based transactions. Therefore, as a result of local currency devaluation, South Korean manufacturers have a significantly cheaper DRAM manufacturing cost in dollar terms than either their Japanese or their US competitors do.

There are two possible consequences of this state of play, both of which are winning situations for the South Korean DRAM manufacturers. Firstly, South Korean suppliers could reduce the selling price of a DRAM to a point where their Japanese and US counterparts could not compete without being accused of dumping. If the South Koreans are interested simply in increasing market share, then they can drop DRAM prices, outprice their competitors and sell a larger DRAM volume. Using this approach, the South Korean companies could run their facilities at full capacity while forcing their competitors to close their fabs. This is an extreme scenario; nevertheless, Dataquest believes that South Korean manufacturers' share of the worldwide DRAM market will increase in 1998. Alternatively, South Korean vendors could maintain current DRAM market prices and reap the windfall of much greater profits per device sold.

Buyers outside the Asia/Pacific region, always eager to get the best deal, will be pushing hard for price reductions, playing the trump card of continued market oversupply to force the South Koreans' hand.

Long-Term Effects

One condition of the IMF bailout of Southeast Asian economies is that loans must be granted based upon standard good business practices, rather than on less tangible reasons. Consequently, South Korean DRAM manufacturers are less able to obtain loans for new equipment—previously, a company's mission to become a market leader was sufficient reason for the granting of a loan, but now the prospect of repayment is more important. Under this restriction, South Korean DRAM manufacturers have cut their spending plans to the bare minimum.

Reduced DRAM capital spending in 1998 will take about two years to ripple through to the marketplace. By the end of the decade, Dataquest expects to see a deficiency of competitive manufacturing capacity in South Korea; as a result, the South Korean market share gains anticipated by Dataquest in 1998 will begin to be lost to other countries as 2000 approaches. The winners will be those companies that have invested continuously while South Korean companies have cut back.

The turn-of-the-century time frame coincides with the period in which Dataquest expects to see a worldwide DRAM capacity shortage. Owing to more drastic cutbacks in DRAM capital investment by the South Koreans, this shortage is likely to be more marked than first envisaged.

 ©1998 Dataquest

Outlook for 1998

Following the global DRAM market turmoil of 1996, last year closed in recovery mode, prompting optimistic forecasts for 1998. As the DRAM market made a significant upswing during the second half of last year, growth in 1997 over 1996 recovered to approximately minus 15 percent, and healthy positive growth was widely predicted for 1998. However, several factors have combined to temper optimism for a continued strong DRAM recovery during 1998; if it comes, it will be weighted heavily towards the back end of the year and may not be strong enough to pull annual growth above zero.

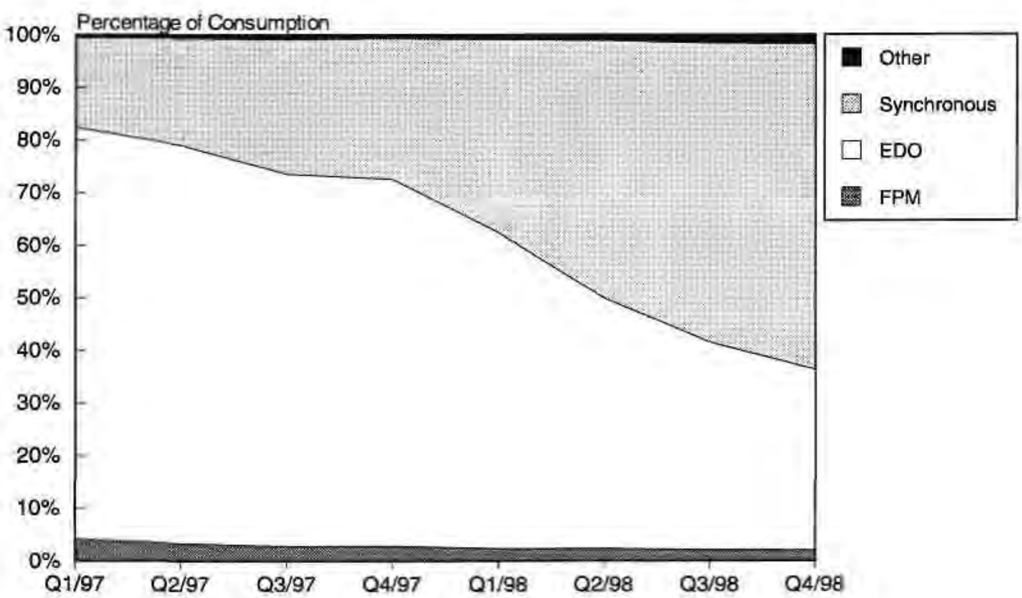
DRAM Technology Issues

EDO to Synchronous Transition

Although the transition from EDO to synchronous DRAM is well under way (as shown in Figure 2), the introduction of the eagerly awaited PC100-specification PC memory bus is required for the synchronous market to really take off. The expected rapid uptake of this initiative by PC manufacturers will lead to a recovery in the worldwide DRAM market as a predicted shortage of 100-MHz synchronous DRAM leads to a strengthening of DRAM prices.

However, there are a couple of good reasons why DRAM vendors should not be looking to 1998 as the year of this recovery. Firstly, for PC100 to establish itself, chipsets have to be available in volume. A limited number of chipsets are available already, particularly for use with non-Intel "socket 7" microprocessor solutions, but the Intel 440BX chipset, which will support a 100-MHz memory bus, is not due to be launched until later in the first quarter of 1998—and typically it takes two quarters from the launch of a new chipset to volume utilization. Secondly, new microprocessors that make use of the 100-MHz bus specification are not due for release until the second quarter of this year, and it is usual for at least four quarters to elapse between the launch of a new microprocessor and its incorporation into mainstream PC manufacture. Consequently, although synchronous DRAM will become increasingly common through 1998, it is the 66-MHz variant that will predominate; moreover, the price premium over EDO can be expected to be modest and hardly likely to give the DRAM market a major boost.

Figure 2
DRAM Interface Technology Transitions, 1997-1998

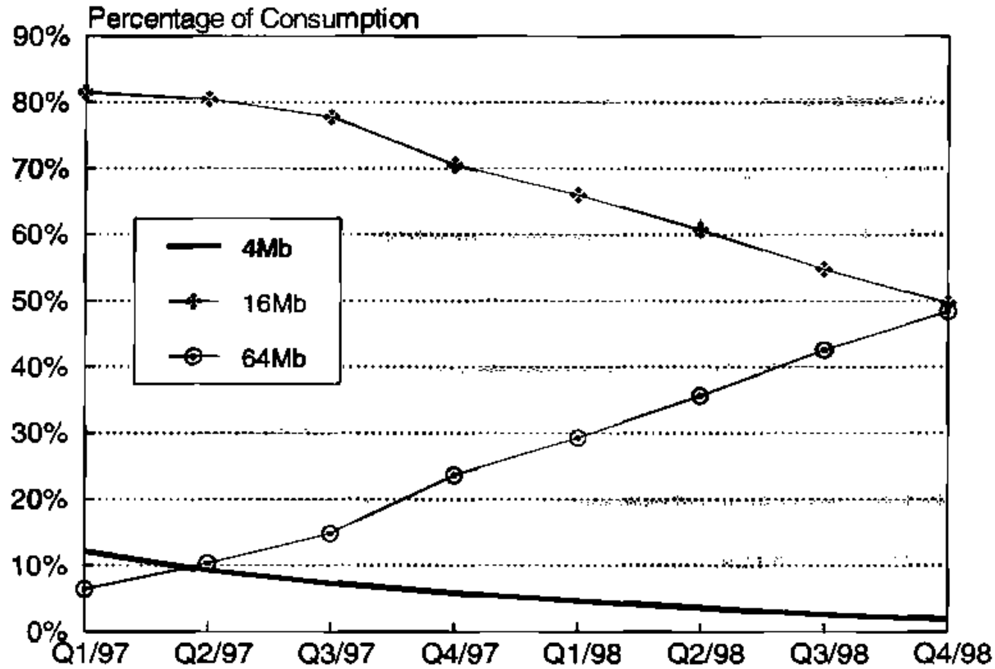


Source: Dataquest (March 1998 Estimates)

16Mb to 64Mb Transition

Although won devaluation as a result of the Asian financial crisis may fan the dying embers of the 16Mb device density by allowing further ASP reductions, price crossover between the 16Mb and 64Mb device densities is approaching fast. Time is running out for the 16Mb; certainly by the fourth quarter of 1998 demand will have switched to the 64Mb, as shown in Figure 3.

Figure 3
Worldwide DRAM Bit Consumption by Chip Density, 1997-1998



Source: Dataquest (March 1998 Estimates)

Bit-Growth Outlook

PC Production Outlook

Dataquest estimates that PC production in the EMEA region grew by a healthy 18 percent in 1997 over 1996, to reach approximately 21 million units. A compound annual growth rate of about 15 percent is expected to raise this figure to 40 million units by 2002. In parallel with this growth in PC production, PC main-memory requirements will increase as new applications are introduced.

Software Application Drivers

The introduction of the Windows 98 operating system in mid 1998 is not expected to lead to a step-function increase in PC main memory largely because the vast majority of new PCs are shipping with 32MB as standard, which is sufficient to run the new Windows offering. However, as Windows NT continues to penetrate the corporate PC environment, and version 4.0 becomes established, more and more PCs will leave the factory with 64MB of DRAM fitted as standard; therefore, a general shift upwards in average PC main-memory content will continue. Although fueled by more feature-rich and graphics-intensive application software, the absence of a veritable "killer" software application will lead to steady rather than spectacular annual bit growth in excess of 60 percent over the next five years. In other words, an average PC main-memory fit of about 30MB in 1997 is anticipated to rise to about 170MB by 2002.

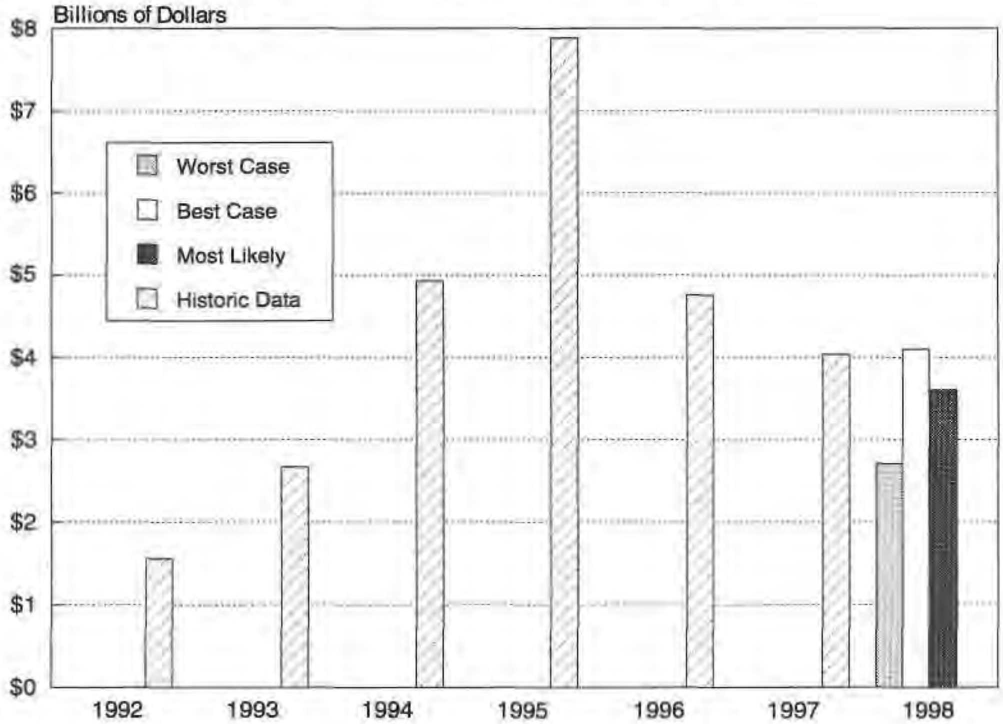
 ©1998 Dataquest

EMEA DRAM Forecast for 1998

Forecast Assumptions

Rather than simply presenting a table of data for this EMEA DRAM forecast outlook, Dataquest has decided to provide additional analysis and present forecast assumptions for a number of scenarios. In practical terms, this approach offers a forecast range based on best case, worst case and most likely scenarios for 1998, as shown in Figure 4.

Figure 4
EMEA DRAM Revenue History and Forecast, 1992-1998



Source: Dataquest (March 1998 Estimates)

Best Case Scenario for 1998: Bit-price crossover between the 16Mb and 64Mb occurs in the second quarter of this year, and a rapid move to PC100 occurs during the third quarter. This leads to product-mix-related undersupply and DRAM prices firm up. PC main-memory fit continues to increase so that more than 50 percent of PCs ship with 64MB in the fourth quarter of 1998. DRAM content averages 46MB per system. These conditions would result in the following:

- The price per megabyte stabilizing for 1998 at January levels.
- Bit growth remaining healthy, albeit lower than during the "bit boom" of 1997.

Worst Case Scenario for 1998: The Asian financial crisis allows South Korean manufacturers to continue to cut costs. The 16Mb device ASP declines steadily throughout 1998, pulling the price of the 64Mb device lower and delaying bit parity until 1999. The need for increased PC main memory fails to materialize, and the vast majority of PCs ship with 32MB throughout 1998. DRAM content averages 36MB per system. These conditions would result in the following:

- ASPs declining by 30 percent in line with the historic cost-reduction curve.
- Bit growth stalling as the need for higher PC main memory is not recognized.

Most Likely Scenario for 1998: Although DRAM ASPs are likely to fall further during the coming months, there is an overwhelming desire by the leading DRAM vendors to move the market to the 64Mb device density. An ongoing shift in production mix will allow DRAM vendors to benefit from economies of scale in the manufacture of 64Mb devices while reducing the oversupply of 16Mb. A move from EDO DRAM to synchronous DRAM also will occur, but this might be restricted to the 66-MHz variety until the final quarter of this year when PC100 chipsets begin to penetrate the market. These transitions are likely to cause a strengthening of ASPs in the second half of 1998.

Although the levels of bit growth seen in 1997 are unlikely to be repeated this year, there is an expectation among PC end users that PC vendors will continue to increase main-memory fit, especially in high-end machines fitted with the latest 300-MHz-plus microprocessors. This momentum to take advantage of what are perceived to be low DRAM prices may take some time to slow down, so DRAM content should easily reach an average of 42MB per system during 1998.

These conditions would result in the following:

- ASPs declining during the first half of 1998 until restricted supply of 64Mb and synchronous devices leads to firmer ASPs in the second half.
- Bit growth remaining healthy as last year's bit boom spills over into this year.

Dataquest Perspective

The DRAM outlook for 1998 remains very difficult to call. By this point in the industry cycle, a recovery in DRAM ASPs normally would have been expected along with a resultant recovery in revenue. In a new departure, whether this happens depends on events outside the semiconductor industry. The semiconductor industry cycle is usually out of step with global economic cycles, but the semiconductor industry perhaps cannot remain isolated from external economic factors this time, such has been the scale of the Asian financial crisis. The unique situation in South Korea—where the semiconductor arms of large conglomerates are almost entirely dependent on DRAM revenue, and account for more than 30 percent of global DRAM revenue—could send the DRAM industry into a siding for the next few quarters, effectively stalling the long-awaited recovery until 1999.

The Impact of the Asian Financial Crisis on Worldwide Electronics Production and the Semiconductor Market

Abstract: *The Asian financial crisis will dampen the growth in 1998 of worldwide electronic equipment production and the semiconductor market to lower than previously forecast by Dataquest. This document examines the negative impact the Asian crisis will have on these forecasts.*

By Semiconductor Industry Analysts

Section I: Introduction

The financial crisis in Asia is a daily topic of discussion and in publications as the world tries to assess the impact of the crisis on worldwide financial markets, stock markets, banking systems, and national economies. At Dataquest, clients are continually asking us to assess the impact of the Asian crisis on the electronics, PC, and semiconductor industries, and much has been written by Dataquest about this.

In particular, our semiconductor clients are asking us how Asia's financial woes will affect Dataquest's 1998 semiconductor industry and electronic equipment production forecasts. These forecasts were released in October 1997, and much has happened since then. To date, we have refrained from issuing new formal forecasts mainly because the situation is still very, very fluid, and we felt we were unable to publish accurate 1998 forecasts until more information was at hand. Nevertheless, our clients want to know what our thinking is.

FILE COPY:
MARIA VALENZUELA

This document is a summary of Dataquest's current thinking about the impact of the Asian financial crisis on electronics production, the semiconductor market, including DRAMs, and semiconductor capital spending. The analysis presented in this document represents a qualitative point of view of the potential impact. Dataquest will issue new formal 1998 forecasts at the end of April. In the interim, we will keep our clients up to date as the Asian crisis evolves and more information becomes available.

Dataquest

Program: Semiconductors Europe
Product Code: SEMI-EU-DP-9803
Publication Date: February 4, 1998
Filing: Perspectives
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

This analysis represents the collective thinking of Dataquest's semiconductor analysts in all regions of the world. Further information on any of the topics is available from the analysts listed at the end of each section or by referring to the other documents, noted in the text, that Dataquest has already published on Asia's financial crisis.

The Bottom Line

The following are the major conclusions of this analysis:

- In 1998, worldwide electronic equipment production will likely decline from Dataquest's previously forecast $1,009 billion to $953 billion. This means that 1998 electronic equipment production will grow only about 3 percent instead of the 9 percent previously forecast.
- Solely because of the decrease in electronic equipment production, the worldwide semiconductor market is likely to decline from our previously forecast $175 billion to $165 billion.
- Also, because of the potentially lower cost of DRAM manufacturing, the 1998 DRAM market could decline by $3 billion to $5 billion from our previous forecast.
- Combining the effects of decreased electronic equipment production and the lower DRAM market, the overall 1998 worldwide semiconductor market could be as low as $160 billion. Our previous 1998 forecast (released in October 1997) was $175 billion, for a growth of 17 percent over 1997. The new forecast of $160 billion represents a growth of about 7 percent over 1997.
- Capital spending is forecast to be down 4 percent in 1998 to $43 billion and does reflect the conditions in Asia through December. Dataquest has also published a detailed downside capital spending scenario with a set of changed assumptions that places the downside risk at $39 billion, about a 12 percent decline from 1997 levels.

It is important to note that the numbers presented in this document are not "official forecasts" but are meant to provide guidance to clients until we do publish firmer forecasts. This forecast represents our current thinking about the impact of the Asian financial crisis and is subject to change as the situation continues to unfold.

Section II: Background on the Asian Financial Crisis

The beginning of summer 1997 saw the devaluation of the Thai baht amid escalating difficulties in the Thai banking and finance community, which forced the Thai government to finally surrender to the currency speculators. At that time, few people, if any, would have predicted this to be the start of a financial storm sweeping throughout Asia, with far-reaching global implications.

Shortly after the Thai baht devaluation, the governments of Malaysia, Indonesia, and the Philippines succumbed one by one to the speculative currency attacks. The rapid currency devaluation sent shock waves through the regional stock markets of Thailand, Malaysia, Indonesia, and the Philippines. Singapore and Hong Kong, which remained largely unaffected initially, saw their stock markets tumble in October amid growing investor anxiety.

The financial crisis deepened in November as it spread to Korea and Japan, the world's 11th-largest and second-largest economies, respectively. The value of the Korean won dropped sharply, along with Korea's stock market, after the Korean government gave up its battle to prop up its currency in November. A $57 billion rescue package led by the International Monetary Fund (IMF) was negotiated for Korea, after $40 billion and $17 billion were negotiated for Indonesia and Thailand, respectively. In the meantime, Japan saw the closure of its

 ©1998 Dataquest

fourth-largest securities company, Yamaichi Securities Company, on November 24, following the closure of Hokkaido Takushoku Bank, its 10th-largest commercial bank, a week earlier.

Behind these events lies a tale of massive regional expansion based largely on politically manipulated debt directed over the past 40 years to conglomerates that are now unable to pay the money back.

Simply stated, the current Asian financial crisis stems from the inability of South Korean and other regional companies to repay their short-term debts. The expansion that has given South Korea an average annual gross domestic product (GDP) growth rate of 8.6 percent during the past 30 years has been achieved largely on the back of massive, politically backed short-term borrowing, which was rolled over regularly and renewed by the country's top companies—family-run conglomerates, commonly known as chaebols. Problems have occurred with this short-term borrowing strategy because many of the investments made were long term and not suited to short-term returns. More important, the primarily South Korean banks, which in turn borrowed mainly US dollars from Japanese banks, are now unable to continue rolling over the debts and granting extensions. Inevitably, huge debts are now due for repayment. There are several factors that have caused this.

Until mid-1997, the Southeast Asian currencies and the Korean won were pegged to the US dollar. With the growth in the strength of the dollar since mid-1995, caused by the improving performance of the US economy, the won and the Southeast Asian currencies also strengthened, in conjunction with the US dollar. The strong local currencies resulted in the slowdown of Southeast Asian and Korean exports because they became more expensive and less competitive in a worldwide market that was already showing signs of slowing and overcapacity. The slowdown in exports contributed to the large current account deficit in Southeast Asian countries and Korea, which ultimately left the currencies in those countries susceptible to devaluation.

The dramatic currency devaluation that occurred in Southeast Asian countries and Korea will now make exports more cost-competitive. However, these devaluations increased the local value of debts borrowed in foreign currencies, massively increasing the amount of home currencies required by banks and conglomerates to repay their debts.

The second catalyst for the crisis concerns the primarily Japanese banks that, by lending to the region's banks, including South Korean banks, financed the growth of South Korea and other countries. Japanese banks were unable to renegotiate their South Korean debts because of their own liquidity problems. Much of the security on which Japanese banks based their value was property and stock market-based investments; however, in the early 1990s, the Japanese property and stock markets collapsed, taking with them much of the equity on which Japanese banks relied. The loss of equity and the effectively defaulted loans of Japanese companies caught in the collapse impaired their ability to borrow money on the international money markets; thus, less new money was available to renegotiate South Korean debts. South Korean loans therefore came due for repayment.

The problem is so severe that the South Korean ministry of finance and economy estimates that about $21.5 billion of external debt will be due for repayment in the first three months of 1998. In the first six months of 1998, about $70 billion of external liabilities will be payable—this represents about 70 percent of the nation's total external debt.

 ©1998 Dataquest

These debt levels, devaluing currencies, and slowing revenue mean that mass restructuring will be needed in the South Korean and other Southeast Asian economies to restore the market confidence necessary to allow the region to recover. This restructuring will involve mass layoffs as loss-making companies and insolvent banks are closed down and the giant chaebols are restructured to focus on core competencies.

Section III: The Macroeconomic Effects of Asia's Financial Crisis and the Impact on Electronics Production and Semiconductor Consumption

Asia's Macroeconomic Outlook for 1998 Has Changed Dramatically

Asia's currency and financial crisis has dramatically changed the macroeconomic outlook for most Asian economies. Changes in outlook have been the greatest for the economies most affected by the crisis: Indonesia, South Korea, and Thailand. Economic forecasters have uniformly downgraded their estimates of GDP for Asia's troubled Pacific Basin region in 1998. Based on a survey of prominent forecasters, Dataquest estimates that 1998 GDP for the region will be reduced about $690 billion from the levels expected at the time of Dataquest's fall forecasts. GDP estimates for Indonesia, South Korea, and Thailand have been reduced especially sharply. These significant changes in the outlook for GDP have been accompanied by equally significant changes in the outlook for inflation. Inflation is expected to increase markedly throughout the region, especially for Indonesia, South Korea, and Thailand, as lower currency values push up the prices of imports.

Macroeconomic Outlook Elsewhere Remains Mixed but Could Sour If Asia's Troubles Worsen

The macroeconomic outlook for the rest of the world remains mixed in the face of Asia's troubles. Forecasters have generally downgraded their outlook for Japan in 1998. They have done this not so much because of Asia's crisis but because of continuing economic difficulties in Japan. Japan remains deeply mired in an ongoing economic recession. Continued troubles in Asia pose a significant threat to Japan's recovery. Because most Asian currencies have depreciated far more against the dollar than the yen has since summer, Japan has lost much of the competitive advantage it had regained from its Asian rivals during the past few years. More important, Japan holds significant amounts of the dollar-denominated debt floated by Asian economies before the onset of the crisis. Outright default on this debt would likely paralyze Japan's already crippled financial system. As things currently stand, Dataquest estimates that Japanese 1998 GDP will prove $650 billion lower than expected.

Forecasters' outlooks for the United States remain surprisingly bright. The prospects for economic growth in the United States remain strong in spite of Asia's troubles. Asia's difficulties are expected to exert some drag on the US economy, but America's domestic economy is currently so strong it appears capable of overcoming adverse effects from Asia. The outlook for Western Europe is somewhat more enigmatic. For the moment, most forecasters appear to believe that economic growth will not be adversely impacted by Asia's troubles. But this outlook is qualified with the recognition that Western Europe could suffer serious impacts if Asia's difficulties were to worsen significantly. Western Europe has extensive economic and financial ties with many of Asia's crisis-afflicted economies. What is more, ongoing economic growth in Western Europe is still heavily dependent on exports. A tidal wave of Asian debt default combined with a collapse of Asian imports would hobble Western European economic performance. All in all, Dataquest estimates that 1998 GDP for the United States and Western Europe combined will be about $80 billion lower than previously expected because of the US dollar's continuing strength against Western European currencies.

Macroeconomic Impacts on 1998 Electronics Production and Semiconductor Consumption

We can use this information about changing macroeconomics in combination with Dataquest's fall forecasts of electronics production and semiconductor consumption to infer the potential impact of changing macroeconomics on worldwide electronics production and semiconductor consumption. We want to warn readers up front that the following discussion is an inexact first-order analysis based on some very simplifying assumptions about the links between macroeconomics and the markets for electronics and semiconductors. It is important to note that a comprehensive and conclusive analysis would require extensive study of interrelated demand and supply impacts in both the electronics and semiconductor markets.

Worldwide Electronics Production to Decline about $56 Billion

The analysis begins by linking macroeconomic changes to electronics demand. For this simplified analysis, we believe it is reasonable to assume that electronics demand is related to GDP and will vary with changes in GDP. Research by the Technology Foresight Programme, a British government-sponsored organization, estimates that Asia's Pacific Basin economies expend about 5 percent of their GDP on electronics consumption. For Japan, it estimates that about 3 percent of GDP is expended on electronics consumption. For the United States and Western Europe, the estimate is 3.5 percent. These numbers compare favorably with Dataquest's own estimates of worldwide expenditure on electronics relative to GDP. Based on figures from our fall forecasts and IMF estimates of world GDP, we estimate worldwide electronics spending amounted to about 3 percent of world GDP in 1997.

Unfortunately, these various figures reflect average rates of expenditure on electronics from GDP. They do not tell us how electronics spending will change as a result of changes in GDP. For that, we would need to know the marginal rates of expenditure on electronics from GDP. There is good reason to believe the marginal rates of expenditure on electronics from GDP in all these regions are actually higher than the average rates cited earlier. Because of this, impacts based on these average rates could be understated.

Nonetheless, the result of applying these average rates to the changes in 1998 GDP noted earlier is that electronics demand is likely to be reduced $34.5 billion in Asia's Pacific Basin, $19.5 billion in Japan, and $2.8 billion in the United States and Western Europe combined. For the sake of simplified analysis, the decline in worldwide demand reflected in the sum of these figures is assumed to generate an equal decline in worldwide electronics production. Please note that Dataquest is not assuming that the declines in demand for each region generate equal declines in production for each region. As discussed later, this certainly will not be the case. Given this assumption, Dataquest expects 1998 electronics production to decline $56 billion relative to the fall forecast, which was $1,009 billion. This represents a decrease of 5.6 percent from the fall forecast.

Semiconductor Consumption to Decline about $10 Billion

Naturally, the forecast decline in electronics production has implications for semiconductor consumption. Here again, Dataquest makes a simplifying assumption. In the fall semiconductor consumption forecast, we estimated that worldwide semiconductor consumption would average 17.3 percent of worldwide electronics production value in 1998. Assuming that semiconductor content remains unaffected by the changing macroeconomics stemming from Asia's financial crisis, Dataquest estimates that worldwide semiconductor consumption will fall about $9.8 billion from the previous forecast for 1998. This would (again) represent a 5.6 percent decline from the fall semiconductor forecast, which was $175 billion, resulting in an estimated $165 billion semiconductor forecast for 1998.

 ©1998 Dataquest

More Detailed Demand and Supply Analysis Needed

Once again, it is important to emphasize that these results are based on several simplifying assumptions in lieu of more detailed demand and supply analysis. These assumptions are open to serious question. The potential bias to these results that stems from using average rates of expenditure on electronics from GDP in the analysis instead of marginal rates of expenditure has already been discussed. Also, these results may be biased by the assumption that a forecast decline in worldwide electronics demand will generate an equal decline in worldwide electronics production.

In the final analysis, the dollar-valued volume of electronics produced worldwide is determined by the interaction of demand and supply in the market for electronics. Dataquest's assumption that declining electronics demand will generate an equal decline in electronics production is tantamount to assuming that electronics supply is perfectly price elastic and will remain unaffected by the changing macroeconomics of Asia's crisis. The former seems highly unlikely, and the latter is almost certainly not true. Although we cannot be absolutely certain, we suspect that electronics production may ultimately decline less than electronics demand. As demand subsides, it is likely that electronics prices will fall, especially for Asian goods whose producers are both willing and able to press the production cost advantage that currency devaluations have given them. Backed by aggressive marketing, declining electronics prices could stimulate sufficient new demand to counter much of the decline being forecast.

Dataquest's results are also likely to be biased by the assumption that the semiconductor content of electronics will remain unaffected by changing macroeconomics. Like the dollar-valued volume of electronics produced and semiconductors consumed from which it is derived, semiconductor content emerges from the outcome of market interactions among electronics and semiconductor producers. Precisely because semiconductor content is ultimately determined by the mechanics of the electronics and semiconductor markets, it is unreasonable to assume values for it. Changes in semiconductor content must be deduced from detailed analysis of forecast changes in market demand and supply for both the electronics and semiconductor markets. On the whole, we are inclined to believe that semiconductor content will decline in 1998. Dataquest believes that the interaction of declining semiconductor demand induced by lower electronics production and of increased semiconductor supply induced by lower production costs in Asia will cause dollar-valued semiconductor consumption to decline more than electronics production. This would de facto lower semiconductor content.

Currency and Financial Impacts on Electronics and Semiconductor Supply—Asian Producers Face Potential Double Bind

The dramatic declines in Asian currency values, the most visible aspect of the crisis, have at least temporarily altered the relative economics of both electronics and semiconductor production across regions. Despite the very real pain these devaluations have caused, they have imparted a potentially large production cost advantage to Asia, especially to countries such as South Korea that have experienced the sharpest devaluations. Of course, this cost advantage is somewhat tempered by devaluation-induced increases in the cost of components and subsystems that must be imported from Japan and outside Asia. Still, there is an advantage to exploit if Asian electronics producers can maintain the working capital needed to finance their day-to-day operations.

In this regard, South Korean producers could paradoxically emerge as the crisis' biggest winner, at least over the short term. Assuming that Korean electronics producers can retain sufficient working capital, they appear well-positioned to increase significantly their share of electronics and semiconductors sold outside Asia. Unfortunately, they could have trouble defending their increased

©1998 Dataquest

share over the long term if they are unable to generate the investment capital necessary to expand capacity. By the same token, producers outside Asia now have increased incentive to locate production in the region. Although this is unlikely to happen so long as economic and political uncertainty remained heightened, it is likely to occur once stability is re-established and the crisis appears to be moving toward resolution, especially if Asian currency values remain at or near their current levels.

Non-Asian Producers Also Face Risks

The currency upheavals and financial upset of Asia's crisis threaten consequences not only to the fortunes of Asian companies but also to the operations of non-Asian companies. In 1996, Asia/Pacific-based electronics equipment manufacturers accounted for $29.7 billion, or about 21 percent, of worldwide semiconductor sales. About 18 percent of American semiconductor sales, 18 percent of Japanese sales, and nearly 25 percent of European sales were derived from sales to Asia/Pacific. This, in turn, fed electronics manufacturing worth $153.7 billion, about 18 percent of the worldwide total. Clearly, a significant decline in semiconductor demand among Asian electronics producers could harm non-Asian semiconductor companies dependent on the region.

The perils to continuing business in Asia for both Asian and non-Asian companies is probably best illustrated with circumstances in South Korea. Most manufacturing locations within South Korean are locally owned. This means liquidity problems arising from Korea's financial difficulties are a real issue for these manufacturers. With IMF restrictions in place, South Korean companies will now find it very difficult to obtain letters of guarantee, which are essential if they are to make purchases on credit. Without these letters, their only option is to pay cash for purchases of semiconductors. Currency devaluation has made this cash now twice as expensive to obtain, and obtaining it may prove very difficult.

The availability of credit is potentially one of the major issues of the crisis. Should credit in the form of letters of guarantee and the like become available again through IMF intervention, the liquidity issues that indigenous manufacturers face will be significantly reduced, and they will be able to continue purchasing the raw materials needed for manufacturing. Only then will they be able to press home the cost advantage that currency devaluations have given them. If, however, these letters do not become available, manufacturing in South Korea, as well as in other crisis-impacted countries, could be seriously curtailed as manufacturers run out of raw materials, with only a diminished ability to purchase operational stocks. Indeed, the issue of credit availability has already been raised in a recent announcement from Atmel Corporation.

Just recently, this American supplier of nonvolatile memory and application-specific ICs (ASICs) announced a fourth quarter charge of $160 million, citing "credit problems with specific Asian customers." Although this statement may be open to further scrutiny, it does raise the important point that non-Asian companies may be exposed to the risk of potential bad debts and future loss of market because of the inability of Asian OEMs and contract equipment manufacturers (CEMs) to obtain letters of guarantee. Should similar problems be encountered by other semiconductor manufacturers with their "Asian customers," then potentially significant semiconductor market share could be put at risk.

Summing Up

Dataquest believes that both worldwide electronics production and semiconductor consumption will be affected in 1998 as a result of Asia's financial crisis. Our simplified analysis suggests that electronics production will be reduced about $56 billion and semiconductor consumption about $10 billion. These

 ©1998 Dataquest

changes represent about a 5.6 percent decline from Dataquest's fall forecast for 1998. We remain uncertain about the prospects for individual regions and consumers. Although it is clear that Asian-based electronics and semiconductor producers have gained some production cost advantages owing to currency devaluations, it is not clear that they will be able to press home those advantages because of potential problems with liquidity and credit arising from the financial upsets of the crisis. Moreover, many non-Asian companies are clearly at risk owing to their strong dependence on Asia and their close financial relationships with Asian producers. Although we do not believe that Asia's financial crisis will break worldwide electronics and semiconductor markets, we do believe it will test them as never before.

Section IV: Impact of the Crisis on DRAM Costs and the Forecast

The effect of the Asian financial crisis on Dataquest's DRAM forecast will be caused mainly by the fall of the Korean won against other world currencies and by some of the restructuring of financing the IMF has required of the Korean chaebols. These two causes will result in two key effects, one short term and the other long term. Taiwanese DRAM manufacturers are disregarded in this analysis because, in 1996, Korean companies provided 33.6 percent of the world DRAM market, while Taiwanese companies shipped only 2.4 percent (*Worldwide Memory Market Share 1994 to 1996*, MMRY-WW-MS-9701, May 1997).

Short-Term Effects

Throughout 1997, DRAMs have been priced at a level near their manufacturing cost, a minimum that must be followed if antidumping measures are to be avoided. Going into 1998, Dataquest sees a continuing overcapacity, forcing manufacturers to continue their efforts to keep prices low to win the fight for their share of their customers' business, a fight they encounter at buyers' desks.

In a competitive market, semiconductor manufacturers use manufacturing cost reductions to reduce the selling price of their products. A knowledge of semiconductor manufacturing cost trends is useful for projecting long-term costs/selling price relationships, which vary from product to product and company to company, as well as by market and business conditions.

What happens with a devaluation of the Korean won against other currencies? It only stands to reason that a devaluation of the won would lower manufacturing costs (as measured in any other currency). How much impact will the devaluation have? Dataquest has analyzed the situation, and it appears that at least 55 percent of the cost to manufacture a DRAM is in won-based transactions rather than foreign currency-based transactions ("Dataquest's Tactical Memories Newsletter, Volume II, No. 26," MMRY-WW-DP-9733, December 1997).

The Dataquest semiconductor cost model uses 16 variables of semiconductor manufacturing. These variables cover the main areas where costs accrue and processes can improve. The variables that have the most influence over cost are wafer processing, wafer size, die size, sort yield, package type, and final test yield. The financial crisis in Asia has caused major changes in Asian cost structures based on devalued local currencies, compared with the US dollar. The costs affected are those whose basis is predominantly local Asian currencies. This category includes all the major costs associated with wafer processing and test ("Dataquest's Tactical Memories Newsletter, Volume II, No. 26," MMRY-WW-DP-9733, December 1997). For the purposes of this conservative model, we have assumed that 50 percent of all wafer processing and test costs are won-based.

 ©1998 Dataquest

Table 1 shows the DRAM cost model and compares the DRAM costs before won devaluation and after devaluation. Differences in this cost model are based mainly on exchange rate variations, but Dataquest has also included a comparison of costs for different die sizes (Micron Technology Inc. alone has a 42-mm^2 16Mb DRAM, whereas die sizes for Korean and Japanese manufacturers range from 58 mm^2 to more than 90 mm^2.)

For the past year, DRAM price levels have hovered at or near cost levels to the extent that few suppliers were or are profitable in this business. The cost model highlights how changes in local currency costs dramatically alter the cost structure as reported in dollars. Using Micron as an efficient 16Mb DRAM cost benchmark, this model shows that, even with die shrinks and lower wafer processing costs, Micron still cannot produce at a lower cost than the Korean companies, because the revalued won has substantially reduced wafer processing and test costs, even with a larger Korean die.

The upshot of this analysis is that Asian companies now have a significantly less expensive DRAM cost of manufacture in dollar terms than either their Japanese or American competitors. This also means that the Korean companies could sell DRAM at a lower price than the other regional manufacturers without running the risk of dumping charges. In other words, the Korean suppliers could reduce the selling price of a DRAM to a point at which the Japanese or American companies will not be able to compete without being accused of dumping. How will the Korean companies behave?

If they are interested in simply increasing market share, then they can drop DRAM prices, outprice their competitors, and sell a larger DRAM volume. Using this approach, these companies could run their facilities at full capacity while forcing their competitors to close their fabs. Although it is unlikely that such a severe change will occur, Dataquest believes that in 1998 Korean manufacturers' share of the DRAM market will increase.

Alternatively, they could maintain current DRAM market prices and reap the windfall of much greater profits per device sold. Both scenarios are win/win situations for the Korean DRAM manufacturers. In both, their foreign currency cash flow increases significantly, as do their profit margins.

Buyers outside Asia/Pacific, always eager to get the best deal, will be pushing hard for price reductions, playing the trump card of continued market oversupply to force the Korean companies' hand. In the current oversupplied market, it remains to be seen which way Asia/Pacific suppliers will go in pricing their newly profitable product lines.

This discussion has examined Asia/Pacific only as a DRAM supplier. What about the demand side? Most of the DRAM consumed in Asia/Pacific is used to produce computing equipment sold in the Americas, Europe, and Japan. The cost of DRAM to the end users in these three regions is unaffected by the exchange rate in the Asia/Pacific country where the system is assembled. Dataquest believes that the devaluation will not affect the price or quantity of DRAM purchased in Asia/Pacific as much as it affects Asia/Pacific wages compared with the wages in other regions. More competitive wages should shift more manufacturing away from other regions and into Asia/Pacific.

Dataquest expects to lower the DRAM forecast by $3 billion to $5 billion to compensate for the combined effects of the Asian financial crisis and the additional DRAM capacity that was put into place in 1997. The net effect will be a decrease of the 1998 DRAM market to between $22 billion and $25 billion, representing a growth range of 0 percent to 7 percent over 1997's estimated $22 billion.

Long-Term Effects

One condition of the IMF bailout is that loans must be granted based on standard good business practice, rather than on less tangible reasons. For this reason, Korean DRAM manufacturers find it harder to get loans for new equipment. Previously, a company's mission to become a market leader was a sufficient reason for a loan to be granted, but now the prospects for repayment are more important. Under this restriction, Korean DRAM manufacturers have cut their spending plans to the bare essentials.

The full ramifications of reduced capital spending in 1998 will take about two years to appear. In 2000, Dataquest expects to see a relatively severe deficiency of competitive manufacturing capacity in Korea as Korean fabs start to lag the technology available in other countries. As a result of this, the Korean market share gains that Dataquest expects to see in 1998 will be lost to other countries in 2000. The winners will be those that have invested continuously during the time that Korean companies have cut back.

This coincides with the period in which Dataquest expects to see a mild worldwide DRAM capacity shortage, and prices will firm for about half a year to a full year.

There will be a Dataquest Telebriefing on February 13, 1998, at 8:30 PST, discussing the impact of the Asian financial crisis on the spring memory forecast. To confirm attendance, please call Carole Phillips at (408) 468-8376 or Jenny Williams at (408) 468-8263 or fax them at (408) 468-8044.

Section V: How Will the Asian Financial Crisis Impact Capital Spending?

Even without the Asian financial crisis, the fundamentals have not changed much and indeed may have gotten worse as a result of the aggressive spending patterns in 1997. Overcapacity never went away, and acceleration of shrinks has actually exacerbated the situation.

In DRAM, with the shrink factor and the addition of net capacity of the last 18 months, the situation has not improved. Given these facts, Dataquest is no longer convinced that the market will be balanced by the end of 1998 unless capacity is actively removed from the market.

Dataquest's analysis of supply and demand in the foundry industry at 0.35-micron technology continues to show that, although demand is strong, supply base plans are about three months ahead of demand for the leading-edge 0.35-micron technology through 1999. Evidence supporting this can be found in the continued pricing pressure, with greater than normal declines. Given the evidence that more suppliers are entering the foundry business, this situation is likely to deteriorate somewhat during the next year.

Dataquest is therefore continuing to call 1998 an essentially flat spending year overall. The stronger-than-expected 1997 actually pushes the sustained recovery in spending, driven by a balance in capacity, into mid-1999. Companies will continue to concentrate on technology, with emphasis on 0.25-micron and 300-mm technology, along with investments in new interconnect materials and processes.

 ©1998 Dataquest

What Are the Assumptions and Downside Risks for 1998 Capital Spending?

Dataquest's forecast and assumptions are more explicitly detailed in a Perspective ("Wafer Fab Equipment Market Forecast Update: Question Marks for 1998 as the Second Half of the 'W' Unfolds," SEMM-WW-DP-9801, January 1998) and a Market Trends Report to be published shortly (*Year-End 1997 Forecast: Capital Spending, Wafer Fab Equipment, and Silicon Markets*, SEMM-WW-MT-9801). The base forecast calls for an essentially flat year, with capital spending down 3 percent and wafer fab equipment experiencing 2 percent growth.

Dataquest has developed a detailed second scenario for the 1998 wafer fab equipment market to give clients a "window" of outcomes possible if several of the key assumptions are changed based on the Asian financial crisis. For the most part, these changes simply reflect the timing differences of spending plans. For the "downside risk" scenario, the following assumptions are made:

- Korean companies will cut back spending almost 60 percent in US dollar terms, with at least one project in Europe falling out of 1998 (quite likely Hyundai's, because LG Semicon. has significantly lower debt-to-equity ratios). Dataquest's forecast assumes a 40 percent cut.
- Taiwanese companies' DRAM spending will be cut by 45 percent overall in US dollar terms as funding from Japan is lost and profitability concerns govern loan approvals. The forecast assumes a 15 percent cut.
- Taiwanese foundry spending growth is assumed to remain at 40 percent, because the primary source of funds is the profitable players.
- Taiwanese company spending overall would therefore be down only 2 percent, to $6 billion. The forecast assumes growth of 13 percent to $6.9 billion.
- Japanese companies will cut spending overall by 8 to 10 percent in yen terms, or 14 percent in US dollar terms, compared to 1997. Dataquest's forecast assumes an overall spending cut of only 5 percent in US dollar terms.
- Spending on 300-mm equipment will be reduced to $700 million, based on the timing of shipments into Japan and the United States. Siemens' project appears safe in 1998 because the German government is funding a portion. Dataquest's forecast assumes that $1.1 billion will be spent on 300-mm equipment.
- The US and European major companies that are increasing spending in 1998 will cut these levels back 5 to 10 percent. This places the group at a 4 percent growth instead of the forecast scenario of 10 percent and makes Intel Corporation's spending flat (excluding the Digital Equipment Corporation plant acquisition), compared to 1997. Philips Electronics NV, SGS-Thomson Microelectronics B.V., and Advanced Micro Devices Inc. will continue to increase spending in this scenario for 1998.

Putting this all together, capital spending levels would be cut by about $3.7 billion compared to the 1998 forecast scenario, with these cuts reflected primarily in discretionary equipment spending and with all regions being affected. The wafer fab equipment market would be reduced by about $2.4 billion, with about 70 percent of the difference being related to lower DRAM spending. These reductions have about a 9 to 10 percentage point negative impact on growth of spending in 1998.

The US market would be the least affected, because the reduction in Korean company spending is already accounted for in the forecast scenario; the European and Asia/Pacific markets are likely to see the largest negative impacts. The equipment technologies focused on enabling logic and 0.25-micron processing, such as chemical mechanical polishing (CMP) and deep-UV steppers, would not be affected much by these changed assumptions.

However, the equipment segments dependent on capacity or DRAM-sensitive investment, such as diffusion tubes and implant, would be more heavily affected.

Should the downside scenario come to pass, there should be a silver lining—the DRAM market will likely come into balance sooner, leading to stronger profitability in the chip sector and renewed higher growth in spending on equipment.

Section VI: Worldwide PC Market Overview

Despite the volatility experienced in some Asia/Pacific countries during the second half of 1997, preliminary Dataquest estimates indicate that the worldwide PC industry's unit growth rate was just under 16 percent, off slightly from Dataquest's original forecast of 17 percent. Dataquest estimates that more than 82 million PCs were shipped by manufacturers in 1997.

Although both Japanese and Asia/Pacific demand for PCs did not meet our expectations in 1997, flourishing markets in the United States and Western Europe aided greatly in keeping the global PC industry healthy. At the beginning of last year, Dataquest had predicted that the Japanese market would grow by 9.6 million PCs and that Asia/Pacific would experience growth resulting in 11.4 million additional units.

Dataquest now estimates that actual PC shipments into Japan were 7.9 million units and that Asia/Pacific absorbed 9.7 million units. We expect that Japan's unit growth rate will be less than 10 percent in 1998 and that the Asia/Pacific region will grow at a respectable 15 percent.

Dataquest believes now that the strong growth in the United States and Western Europe will continue to offset in part the setbacks in Japan and Asia/Pacific. We still expect worldwide PC unit growth to be in the mid-teens. Total PC production will exceed 94 million units.

For many years, total worldwide demand for personal computers has sustained sensational growth, and Dataquest expects this trend to continue through the foreseeable future. Regardless of fluctuating economies, the demand fundamentals are compelling for both the commercial PC market and the consumer market. The most significant of these demand fundamentals is the concept of "critical mass." In effect, this Dataquest theory asserts that when the majority of participants in a specific PC market segment require a personal computer, then all participants in that segment must acquire and use a PC.

"Critical mass" has already been reached in the United States and other regional commercial PC market segments, and the requirement for personal computers in US homes is growing each year. Dataquest estimates that more than 42 percent of all US households have at least one PC. We are near "critical mass" in the US home market, and this phenomenon will spread throughout the world well into the next century.

Solid unit growth will continue for years to come. However, solid revenue growth may elude many PC manufacturers and component suppliers in the coming years. Dataquest believes that the pricing trends followed in the US consumer market last year will spill over into the commercial PC market as early as the second quarter of 1998. The sub-$1,000 PC is a harsh reality, and this price point is as appealing to the business segment as to the home segment; its allure will reach all regions by year's end.

©1998 Dataquest

The sub-$1,000 PC is possible for two major reasons. First, component suppliers have been drained of their customary "rightful share of profits." There simply is not enough money in a $700 PC for everyone. Second, successful PC manufacturers have adjusted to a business model of return on investment rather than gross margin. "Velocity manufacturing" is a requisite in this industry, and it manifests itself as build to order, channel assembly, and contract manufacturing.

Finally, Dataquest expects that the "elite few" PC manufacturers that captured nearly 70 percent of growth in the worldwide PC market in 1997 will continue to dominate the industry, forcing continued consolidation and straining the deep pockets of some megaparents.

Section VII: What about China?

Dataquest has recently published a detailed analysis of China/Hong Kong's electronics production in a Focus Report (*China/Hong Kong's Computers, Communications, and Consumer Electronics Industry in 2001*, SEMI-CH-FR-9701, November 1997). The highlights are presented in this section.

Dataquest believes that the Asian financial crisis has a lot to do with speculative investment "bubbles" in property, construction, semiconductors, and other industries. It is clear what happens when rapid economic growth occurs in the absence of a transparent financial system and clean government regulations: overcapacity and irrational loans. The effects of these bubbles can become so serious as to bring down entire financial systems and impair international confidence and, hence, economic growth.

China and Hong Kong are not immune to these problems, although they seemed to be dealing with these bubbles more effectively by popping them before they get too big. China's economic czar, Zhu Rongji, burst the stock market bubble, property bubble, and construction bubble in 1996 and 1997. After 1997's October party congress, he is now more empowered than ever to pop the next speculative runs, whatever they may be. In 1998, he will be promoted to prime minister. Zhu's charter is to fix the state-owned enterprises to avoid overwhelming the financial system with bad loans. If China slacks off, its financial system will face serious problems, potentially worse than those of Korea. China is learning to avoid Korea's expensive lesson—although having $200 billion in combined reserves with Hong Kong will help, too. Strong economic growth in North America and Europe will be critical to China and the region because Japanese consumption is weakening with its own economic malaise.

That China's currency is not convertible may help in the short run, although this does not necessarily insulate China from the possibility of a major depreciation. In 1994, the Chinese government significantly devalued its renminbi. It may have to do so again in the near future because of mounting pressure in the region and because of competition from Asian neighbors on the export front. However, because the government's stated long-term goal is to merge the renminbi with the Hong Kong dollar, it is not likely that the Hong Kong dollar will lose its US dollar peg.

Currency depreciation has lowered production costs in various Southeast Asian countries and Korea. So, will China become less competitive for its vital export markets? Currency depreciation will lower export costs in numerous Asia/Pacific countries, but only to the extent that they do not need imported components (most do, though).

This means that short-term competition with China for exports and possible long-term competition for foreign investment will come from Southeast Asian countries and Korea. However, there are even broader issues facing China, including the currencies and economies in neighboring countries, which are highlighted as follows:

- Raising the competitiveness of its faltering domestic companies, especially state-owned enterprises, before entering the World Trade Organization
- Countering the serious slowdown in foreign investments resulting from rising costs of doing business in China
- Maintaining 7 percent to 10 percent GDP growth and raising the rate of domestic consumption to absorb excess capacity and overdependence on exports
- Dealing with a slowdown in Japanese imports of consumer electronics and PCs from Asia/Pacific. China may be hurt most because its currency has not depreciated, and therefore its costs are increasing relative to other countries.
- Responding to the heavy reliance on exports by Korea and other affected countries as they try to pull themselves out of their economic turmoil

The following factors will help China counter these major challenges and maintain relatively strong electronic growth:

A large proportion of Chinese electronics companies are successfully competing against major multinational corporations, particularly in the computer and consumer equipment markets. The priority for the government is to improve efficiencies and quality; therefore, information technology will continue to be rapidly deployed as an infrastructure necessity.

- Although total investment was down in 1997, production capacity of the large multinational corporations and local electronics manufacturers has increased by more than 50 percent. Furthermore, the two main reasons for investing in China remain intact: to develop the long-term potential of the domestic market and to take advantage of an abundant, inexpensive labor force.
- Inflation was the major concern in 1996; now deflation is the top priority of the government. Interest rates are likely to fall to stimulate growth.
- Japanese manufacturers are shipping goods worldwide from China. Exports of electronics to Japan from China represent 10 to 15 percent of China's total electronics exports. Therefore, Japan's slowdown in consumption has a minor effect on Chinese production.
- Korean and other affected Asia/Pacific electronics and semiconductor companies may have an increasing currency advantage for exports relative to China in the short term. However, these companies are being seriously hurt by increasing debt-service costs.

In summary, China/Hong Kong has not been affected significantly by this financial crisis in the short term because of the stable renminbi and Hong Kong dollar, which are backed by about US$200 billion in combined foreign reserves. However, Dataquest has outlined the deflation and investment challenges within China. Most notably, Southeast Asia and Korea are likely to receive increased investment in the future that would otherwise have gone to China (after four years of very high foreign investment levels in China). However, the power of the Chinese market and its production prowess for international markets will continue to attract investment, enabling it to extend its lead as the largest and fastest-growing semiconductor market in Asia/Pacific.

The Implications of the Asian Financial Crisis on the European Semiconductor Industry

Abstract: *The current financial crisis in Asia/Pacific will have consequences throughout the world. This Market Analysis examines and quantifies the European semiconductor industry's exposure to the events on the other side of the world.*

By Edmund Gemmell

Introduction

Much has been heard about the current financial crisis in South Korea and Southeast Asia in general; however, the implications of the crisis for all sectors of industry are much less clear. Dataquest has been following the events of the past few months and analyzing their implications for the European semiconductor industry, and this *Market Analysis* discusses the possible ramifications for European semiconductor manufacturers.

Where Does the Crisis Stem From?

Simply stated, the crisis stems from the inability of South Korean companies to repay their short-term debts. The expansion that has given South Korea an average annual gross domestic product (GDP) growth rate of 8.6 percent over the past 30 years has been achieved largely on the back of massive, politically-backed short-term borrowings, which were rolled over regularly and renewed by the country's top companies—family-run conglomerates, commonly known as chaebols. Problems have occurred with this short-term borrowing strategy because many of the investments made were long term and not suited to short-term returns. More importantly, the primarily South Korean banks, which in turn borrowed mainly US dollars from Japanese banks, are now unable to continue rolling over the debts and granting extensions. Inevitably, the huge amounts of debt are now due for repayment. There are several factors that have caused this.

(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Until mid-1997, several Southeast Asian currencies, including the South Korean won, were pegged to the US dollar. With the growth in the strength of the dollar since mid-1995, caused by the improving performance of the American economy, the won and the other currencies also grew in strength. This growth made Southeast Asian exports more expensive and uncompetitive in a worldwide market that was already showing signs of slowing down and overcapacity because of overinvestment. In an attempt to revive South Korea's failing export-led economy, the dollar pegging was abandoned and the won devalued in order to make South Korean goods cheaper in the world marketplace. This devaluation, however, increased the won value of debts borrowed in foreign currencies, massively increasing the amount of won required by banks and chaebols to repay their debts. In May 1997 the won/dollar rate was approximately \$1:W900. As of January 8, 1998 the rate was \$1:W1,800, meaning that South Korean companies now have to pay twice as much won for their dollar-based debt as they did in May 1997.

The second factor concerns the primarily Japanese banks that, by lending to South Korean banks, financed South Korea's growth. Japanese banks were unable to renegotiate their South Korean debts because of their own liquidity problems. Much of the security upon which Japanese banks based their value was property-based investments; however, in the early 1990s the Japanese property market collapsed, taking with it much of the equity that Japanese banks relied upon. The loss of equity impaired their ability to borrow money on the international money markets, thus, less new money was available to renegotiate South Korean debts. South Korean loans therefore became due for repayment.

The problem is so severe that the South Korean ministry of finance and economy estimates that approximately \$21.5 billion of external debt will be due for repayment in the first three months of 1998. In the first six months of 1998 approximately \$70 billion of external liabilities will be payable—this represents about 70 percent of the nation's total external debt.

Behind these statistics lies a myriad of companies with liabilities unheard of in Western economies. Halla Group, South Korea's twelfth-largest conglomerate declared bankruptcy on December 6, 1997 with a debt-to-equity ratio of almost 20:1 (its debts were 20 times greater than its net worth). Halla Group is not alone, 1996 financial statements by South Korean chaebols reported that of the top 25 chaebols, 22 have debt-to-equity ratios greater than 3:1 and 10 have ratios greater than 5:1. In 1996 the top 25 companies had combined total assets of \$192.0 billion and debts totaling \$149.5 billion.

What Is the Significance of the Crisis for the European Semiconductor Industry?

To consider the answer to this question, South Korea should be reviewed both as a competitor and as a consumer.

South Korea as a Competitor

As explained in *Dataquest Tactical Memories Newsletter* (vol. II, no. 26), much of South Korea's DRAM manufacturing costs are based in won. As the value of the won slides against international currencies, so too do the costs of the South Korean DRAM manufacturers. Given that the won has devalued by 50 percent against the dollar in the past eight months, this "cost holiday" gives South Korean DRAM manufacturers significant opportunity to cut dollar-based prices while maintaining won-based margins. In the short term, this means that in an already deflated DRAM market further price pressure can be brought to bear by South Korean and other Southeast Asian DRAM manufacturers. This will enable them to achieve greater market share and generate much-needed revenue and profit-making dollars while putting pressure on non-Southeast Asian competitors to such an extent that antidumping inquiries, so recently resolved, may be put back on the political agenda.

 ©1998 Dataquest

Similarly, however, many non-Southeast Asian semiconductor companies have packaging and test plants throughout the Southeast Asia region. Where these companies have fixed and variable costs based in local currencies, marginal savings will be realized because of the depreciation of those local currencies. These savings will provide those non-Southeast Asian semiconductor companies with some extra leeway to respond to competitive pricing from Southeast Asian semiconductor companies.

South Korea as a Consumer

Perhaps of greater significance may be Europe's exposure to the loss of purchasing power in Southeast Asia. In America, Atmel, the nonvolatile memory and ASIC supplier, has announced a fourth-fiscal-quarter charge of $160 million, citing "credit problems with specific Asian customers." While this statement may be open to further scrutiny, it does raise the point that companies may be exposed to risks regarding the occurrence of potential bad debts and future loss of custom as a result of the inability of Southeast Asian OEMs and contract equipment manufacturers (CEMs) to obtain letters of guarantee from their banks, which are essential when they wish to trade on credit.

In 1996 European semiconductor companies achieved sales of $3.4 billion (25 percent of their total revenue) through sales into the Southeast Asian region; the percentage is likely to be similar for 1997. South Korea represents 17 percent of Asia/Pacific's semiconductor consumption. Using this percentage on Europe's revenue total means that South Korea represents approximately $500 million of European semiconductor companies' revenue. Most manufacturing locations within South Korea are owned locally, and this represents a problem for European semiconductor manufacturers. With IMF restrictions in place, South Korean companies will find it very difficult to obtain letters of guarantee. Without these letters their only option is to pay cash for purchases of semiconductors—cash which is twice as expensive to buy as it was eight months ago, and which may prove very difficult to obtain. This potentially puts at risk a substantial proportion of the $500 million revenue realized by European semiconductor companies, both in the current and future financial years, because of a loss of South Korean purchasing power.

Other Southeast Asian Countries

Within the rest of the Southeast Asian region the situation is varied. The Philippines, Thailand, Indonesia and Malaysia all have problems similar to South Korea, and all have experienced IMF intervention in their economies to some degree. In total, the four countries have received more than $30 billion in IMF-led relief. The constrictions associated with IMF intervention and the currency crises being experienced in these countries will affect indigenous producers in these countries as they have affected South Korean manufacturers. A significant proportion of OEMs and CEMs in these countries are, however, non-Southeast Asia-based. These companies will therefore experience a cost holiday, which may encourage them to ramp up production while costs are low. Therefore, the position of semiconductor demand in these countries is unclear. Any potential loss of demand from indigenous manufacturers because of loss in purchasing power may well be countered by increasing demand from nonindigenous manufacturers benefiting from cost holidays.

Taiwan, Singapore and China/Hong Kong are in a significantly different position to the four countries discussed above, as their economies are financially more advanced. External debts within these countries are minimal in comparison to those of the above countries and government reserves are more than adequate to cover these debts and protect the currency when necessary, although Hong Kong is coming under increasing pressure. With the exception of a general loss of confidence because of their geographical proximity, these countries have been much less severely affected, although all have experienced weakening of their currencies and stock markets.

The Potential Effects of Lost GDP

In December 1997 the OECD projected that the Asian financial crisis would reduce the GDPs of Asia/Pacific countries, including Japan, by 1.4 percent in 1998, and that the knock-on effect would reduce the GDPs of Europe and the United States by 0.4 percent. Dataquest estimates that approximately 4.5 percent of GDP is spent each year on consumption of electronic equipment in Southeast Asia. We estimate that in Japan the percentage is approximately 3.0 percent. Given a 1.4 percent reduction in GDP across the Asia/Pacific region this would lead to a fall in electronics equipment consumption of $2.5 billion. This would equate to semiconductor revenue of approximately $500 million. In terms of European revenue, given Europe's current market share of the worldwide total available market, this would mean lost revenue of approximately $50 million. However, since the OECD made its December forecast, much has come to light which would indicate a worsening situation. For each additional 1 percent fall in Asia/Pacific GDP, worldwide semiconductor revenue would fall by approximately $360 million, equating to European revenue of roughly $36 million.

A major assumption in this calculation is that with decreasing GDP, the marginal propensity to consume would also decrease at a uniform rate. In reality, however, the loss of confidence in the market and consumers' worry over job security and desire to save would almost certainly make the marginal propensity to consume decrease at a faster rate than the reducing GDP. Thus, electronics equipment consumption would fall more sharply leading to a larger fall in semiconductor revenues. In addition, for each 0.5 percent fall in the rest of the world's GDP, $600 million would be lost from worldwide semiconductor revenue, equating to approximately $60 million of European semiconductor revenue.

A secondary issue that arises from the current crisis is the effect on European inward investment. Already, all three major South Korean DRAM manufacturers have announced reduced capital investment levels for 1998. Most notably, Hyundai has announced a delay in the facilitation of its new fabrication plant in Dunfermline, Scotland. However, reduced inward investment may be apparent from other sources.

Asia represents 44 percent of Japan's export market. Already faced with a troubled economy at home, reduced consumer demand from Southeast Asia will represent a further major headache for Japanese conglomerates. It will also make a Japanese recession that much more likely in 1998. Consequently, any new major investment from Japan into Europe carries increased risk of delay or cancellation.

©1998 Dataquest

Dataquest Perspective

While it can be seen from some of the figures shown in this *Market Analysis* that the current financial turmoil in Southeast Asia has the capacity to impact the revenues of European semiconductor companies, it cannot be overstated that the current situation is far from clear and has some time to go before the full facts are known.

For several years, semiconductor manufacturing capacity, and indeed manufacturing capacity in general, throughout the world has been growing faster than demand. The crisis in the Asia/Pacific region can be interpreted as a shaking-out of the market to bring supply and demand back into equilibrium. Those firms with sound financial footing and successful product lines will flourish as competition becomes less intensive in the medium term. Those with a less sound financial footing may be the losers of this shakeout; it is very unlikely that any European firms would fall into this category. A danger does exist though that Asia/Pacific-owned manufacturing locations in Europe may suffer.

Of more immediate interest to the European semiconductor industry is quantifying the potential for losses of revenue. As we have shown, although exposure does exist in actual dollar terms, it is relatively small when compared to overall revenue. The OECD's forecast for falling GDPs would lead to a loss of revenue for European semiconductor firms of slightly more than 0.5 percent of 1996's total revenue, which is significantly less than disastrous.

x86 Processor Review 1997—All Change, But No Change

Abstract: *The year 1997 saw great technological development in the x86 processor market. Competitive x86 devices were introduced and Intel's position came under serious challenge. This Market Analysis examines the companies, products and market involved and previews the possibilities for 1998.*

By Joe D'Elia

The Year

The past twelve months have seen many developments in the x86 processor arena, exciting new products launched, some players retired from the ring, a new player made its entrance, another was taken over, but at the end of the day, the net effect was minimal. The industry still consists of one giant with a handful of dwarfs nibbling at its ankles, hoping that by so doing they will topple the giant. In this they have not succeeded, although they have forced the giant to recognize that they exist and can be a nuisance. In this report we will examine the companies, their products and the status of the x86 compute microprocessor market as it enters 1998.

The Companies

There were two exits from the x86 compute processor arena in 1997: Texas Instruments and SGS-Thomson Microelectronics (STM) both called it a day. The reality was that both were or had been dependent on Cyrix for their technology and, owing to contract reasons or an inability to successfully transfer technology respectively, both had been excluded from the first-generation Pentium clone market and therefore their exit from the standard x86 market was inevitable. However, we should not count STM totally out of the fray, as in May 1997 it purchased a majority stake in Metaflow Technologies Inc., based in San Diego, California, a design group working on next-generation x86 devices. A further indication of STM's future direction can be gained from the company's launch in June 1997 of a high-integration multimedia PC on a single chip, known as the ST PC Consumer. While the company has not announced any major design wins for this product, its existence, plus the general STM strategy of focusing on high-volume differentiated products and other developments by the company in the key area of multimedia, would indicate that we should expect further announcements in early 1998 in the consumer PC/compute appliance arena.

MARIA VALENZUELA

Dataquest
Program: Semiconductors Europe
Product Code: SEMI-EU-DP-9801
Publication Date: January 14, 1998
Filing: Perspectives

In November National Semiconductor Corporation (NSC) completed its purchase of Cyrix and together they also appear to be heading down the high-integration consumer PC/compute appliance path. All announcements subsequent to the takeover focused on the sub-$1,000 and sub-$500 highly integrated PC segments and the company's desire not to compete directly with Intel. The fusion of NSC's proven Super I/O, networking, communications and analog skills with Cyrix's CPU cores, plus the multimedia expertise that NSC has been quietly accumulating over the past 15 months though acquisition of small focused start-ups, makes for a very powerful combination.

NSC's purchase of Cyrix does not bode well for IBM, Cyrix's sole remaining production fab and partner prior to the takeover. Current contracts run until late 1998 and early 1999, but there is no obligation to continue beyond these dates, and with NSC ramping up its 0.25-micron fab in Portland, Maine and therefore able to provide Cyrix with sufficient capacity, there is no expectation that the IBM contract will be renewed. This leaves IBM with the problem of deciding what to do in 1999 if it wants to remain in the x86 market. Dataquest expects that IBM will exit the market as the x86 has always seemed an opportunistic play by the vendor, with the minimum of engineering resource invested in turning Cyrix devices into products worthy of the IBM brand. The salesforce of IBM has been somewhat more enthusiastic about the product and has consistently been more aggressive in its pursuit of orders than Cyrix's own salesforce, another reason for Cyrix/NSC not to renew the contract. With its captive design center having been ensnared by NSC, it would require considerable investment by IBM to continue in the x86 market past the current generation of devices. This we do not believe will be forthcoming, unless IBM can find another partner to take the Cyrix role, as IBM is focusing away from commodity products, even high-technology commodities like DRAMs and x86 processors, into ASICs, ASSPs and embedded PowerPC, which are more profitable.

The surprise of 1997 was the entry of Integrated Device Technology (IDT), though its Centaur Technology subsidiary, into the x86 market. While this has had no perceptible impact on the market yet, owing to the product needing to be quickly upgraded and therefore not shipping, the company should show results in 1998. Its low-key strategy of leveraging the channel infrastructure put in place by existing players to service tier-2 and tier-3 accounts will no doubt result in meaningful sales in 1998.

AMD has cause simultaneously to celebrate and to regret the events of 1997. On the celebration front, the new infrastructure that the company had put together in 1996, spinning off the x86 organization into a separate, focused division with different channels to the normal semiconductor products, began to pay off. The company finally launched a product—the K6—that was on a performance par with Intel's latest mass market offerings and was in demand by many companies, including several significant international players. Life seemed good. However, the regret is that AMD failed to execute and could not deliver the volume of products that the market demanded in the mix that it wanted, and so the company exited 1997 leaving a bad taste in the mouths of a lot of smaller PC vendors. AMD did not get the speed distribution that it expected from its 0.35-micron process and the switch to 0.25 micron proved more difficult than expected. The company focused on servicing key accounts in major regions and "cut loose" the small nonstrategic local assemblers that play the x86 market on an opportunistic basis. Therefore, AMD should not suffer in the long term from its inability to execute in 1997.

Having discussed the dwarfs, we come to the giant: Intel, the largest semiconductor vendor in the world, with the bulk of its sales geared to x86 processors. Intel exited 1997 having lost some market share in the x86 market, which was expected, as 1996 was an exceptional year in which it had total domination of the market.

It is useful at this point to restate the 1996 figures and compare them with Dataquest's latest forecast for 1997. In 1996 the worldwide compute x86 revenue was $15.4 billion, of which Intel accounted for $14.7 billion or a 95 percent market share; in 1997 Dataquest expects the worldwide figure to be $20.6 billion, with Intel accounting for $18.4 billion or 89 percent. Therefore Intel lost six percentage points to AMD, Cyrix and IBM combined, dropping the company's share below the 1995 figure of 91 percent.

From a unit perspective, the competition has always had a larger share of the market; 16 percent in 1996 and a forecast 18 percent in 1997. This small increase in unit market share is good news for Intel's competitors as it shows that they have managed to raise their average selling prices (ASPs) and therefore gained more revenue for each unit shipped.

One of the consequences of the improved market share of the "alternative" x86 manufacturers ("clone" no longer being an appropriate term to describe their products) is the boom in the sub-$1,000 PC market, especially in the United States. With its strategy of constantly pushing the performance envelope upwards, this unexpected development has left Intel without a product specifically targeted at this segment, an omission that the other vendors have been quick to exploit. This development, together with others that result in further fragmentation of the PC market, has caused Intel to rethink its product strategy for 1998.

The Products

The first half of 1997 saw all players introduce new sixth-generation products which will be at the core of most PCs built in 1998 and 1999. We will review each manufacturer's introductions and the update to product strategy that each provided at the 1997 Microprocessor Forum in October.

AMD Benefits from Nexgen Purchase

In March AMD launched the first fruits of its Nexgen purchase, the K6, officially known as the AMD-K6. Introductory speeds on a 0.35-micron process were 166 MHz, 200 MHz and 233 MHz; benchmarks quickly showed that the product was speedier than Intel's Pentium and Pentium MMX products at the same clock speeds. AMD also entered into an agreement with Via Technology to codevelop chipsets that would provide optimum support for the K6 and, as the year developed, these efforts resulted in support of the K6 by all leading BIOS companies and saw most third-party motherboard vendors offering K6-compatible products. Late 1997 saw AMD quietly announcing a 266-MHz product with the promise of 300 MHz in the new year, this being the first result of the K6's migration to 0.25 micron.

At the Microprocessor Forum, AMD launched its plans for 1998, revealing that in early 1998 the company would ship the K6 3D, an improved device fabricated on its 0.25-micron process. As well as a 300-MHz introductory clock speed, the device would benefit from two major refinements. Firstly, the system bus would be increased to 100 MHz, thereby giving improved L2 cache and main memory performance. Secondly, and more radically, the device would have its MMX performance improved by the addition of a second MMX execution unit and the introduction of MMX-like floating point instructions called AMD-3D which will be incompatible with any other manufacturer's MMX instructions. The new instructions will facilitate improved 3D graphics performance as a result of faster execution of 3D geometry and lighting algorithms.

Late in 1998 AMD will improve K6 performance yet again with the introduction of the K6+ 3D, which will add onboard L2 cache running at processor core speed to the package announced in the first quarter. All these improvements are geared to prolonging the life of Socket 7 and are given the generic title of

Super 7 by AMD. With these improvements onboard, the K6 should have a useful life into 1999, when AMD will launch the K7, which should finally give it a product to go head-to-head with the slot-based Pentium II products.

Hot from Cyrix—Cayenne

Early in the first quarter of 1997, Cyrix revealed MediaGX, a highly integrated device that combined its 5x86 core with a graphics accelerator, a memory controller and a PCI interface onboard. This product, together with the Cx5510 companion device—which provides an ISA interface and a sound codec—and some external DRAM is all that is needed to implement a low-cost PC. At the MediaGX launch Cyrix was also able to announce that Compaq was utilizing the device in the Presario 2100, the first of the big-name vendor sub-$1,000 machines that were to prove so popular in 1997.

It was not until late second quarter that Cyrix finally launched the M2 as the 6x86 MX. Like the previous 6x86, Cyrix did not stick to the same clock speed and bus speed as Intel products; therefore there is again the confusion of having to compare actual clock speeds with PR (Pentium-equivalent clock speed) ratings. As in the previous generation, this also meant that Cyrix products were not directly supported by Intel chipsets, which are only guaranteed to 66-MHz bus speed, while Cyrix parts run with an external bus of 75 MHz. However, this time there were third-party chipsets available designed to run at the higher speeds, and therefore the initial adoption rate of the M2 has been higher than that of the M1.

The M2 was introduced at PR166-, PR200- and PR233-equivalent performance ratings, and Cyrix's path is to migrate the device from the current 0.35-micron process to a 0.30-micron process, which will result in an increase in bus speed to 83 MHz, enabling a PR266-equivalent performance device in the first quarter of 1998. This will be followed by a further migration to a 0.25-micron process in the middle of 1998 that will give a PR300-equivalent performance rating.

Late July 1997 saw the announcement of Cyrix's intended merger with National Semiconductor, and releases since have focused on high integration. At the Microprocessor Forum, Cyrix announced the Cayenne core that was to be at the heart of its future products. Products utilizing Cayenne are expected in the third quarter of 1998, however very little has been released regarding specific implementations, so the core itself must be examined to see what kind of devices are possible. The core will be based on a 0.25-micron process and will be very similar to the M2, but will feature a 100-MHz bus and a new floating point unit to address the M2's weakness in this area. MMX performance will also be addressed with a higher-performance MMX unit which will also feature MMXFP, Cyrix's proprietary enhancements to the MMX instruction set.

The first product that Cyrix has previewed using the Cayenne core is the MXi, the next device in the product path started by the MediaGX. The MXi incorporates the Cayenne core, an AGP-compliant memory controller, enhanced 2D/3D/DVD-capable graphics engine and PCI interface. Used in conjunction with external DRAM and a "south bridge" chip that handles ISA interface, graphics RAMDAC and audio codec, this device should give performance equivalent to 300-MHz and 400-MHz Pentium II devices.

Beyond Cayenne, there are whispers of Jalapeno, which is the code name for what was previously the M3. Little is known of this and what National Semiconductor intends to do at this level of performance or how it would fit into a high-integration product strategy.

 ©1998 Dataquest

IDT/Centaur Technology, a Surprise Contender

May 1997 saw the introduction of the C6 from Centaur Technology, a subsidiary of IDT specifically set up to address the Intel-compatible x86 compute processor market. The C6 device was developed in great secrecy by a team led by Glenn Henry, an industry veteran, who had set out to prove that by going back to basic RISC concepts it was possible to design an x86-compatible device that was much simpler, and therefore smaller and cheaper than those currently on offer. This was achieved with the C6, which offered Pentium MMX-like performance at the initially offered speeds of 180 MHz and 200 MHz.

While IDT has considerable microprocessor experience in the MIPS-embedded market, it has never been a player in the mainstream PC arena and therefore the company has had to evolve a strategy that enables it to leverage the existing channel infrastructure in place to serve tier-2 and tier-3 customers. This results in IDT having to make a minimal investment in developing its own channels specifically aimed at the PC market and gives its channel partners another product line they can offer to the assembler community.

At the Microprocessor Forum, IDT announced a renaming of the product to the Winchip C6, as well as the introduction of 225-MHz and 240-MHz offerings. More importantly, the company outlined its plans to develop the Winchip C6+. Like all manufacturers to date, this involves ultimately migrating to a 0.25-micron process, a faster system bus, an improving of MMX performance by proprietary extensions to the instruction set, and an improved floating point unit. Like AMD's K6+ the new fully developed device will also have the option of 256KB of onboard L2 cache running at core speed, which will be 300 MHz at introduction. Versions of the C6+ without onboard cache and fabricated on a 0.28-micron process will be offered at incremental clock speeds throughout the year, with the first 266-MHz devices due late first half 1998.

IDT has modest plans for its products, hoping to gain 1 percent to 2 percent market share, a goal that would add $250 million to $500 million revenue in 1998. For a company that is currently in the $600 million range, this is a considerable gain.

Intel, Active on all Fronts

Finally we come to Intel, whose 1997 was extremely busy with several major product family introductions and a market that again had choice, forcing an accelerated ride down the price curve. February saw the launch of the 166-MHz and 200-MHz Pentium MMX (originally P55C), incorporating the first major additions to the x86 instruction set since it became 32 bit in 1986. MMX instructions are geared to dealing with data types used in media-rich applications and will result in increased performance and therefore higher-quality graphics and audio.

Unlike previous introductions, the mobile version of Pentium MMX was launched at the same performance level as the desktop devices, and a few weeks later a new mobile module was unveiled that enabled portable PC manufacturers to upgrade their product lines easily. This module incorporates an MMX processor, a "north bridge" chip, L2 cache and power management circuitry on a small daughtercard that plugs into a motherboard. Keeping all speed-related products on the one daughterboard will enable mobile PC vendors to have common units that can be upgraded merely by plugging in the latest version of the module, allowing the latest processors to be brought to market very quickly.

The highlight of Intel's product launches was in May, when the company introduced the Pentium II (originally Klamath). The second generation of the Pentium Pro family, this added MMX to that family, as well as reduced production costs by using a daughterboard concept, enabling Intel to utilize off-the-shelf L2 cache rather than custom devices, as had previously been used in the Pentium Pro. The Pentium Pro had introduced the concept of a separate bus for the L2 cache that was available only to the processor. In the Pentium Pro, this was achieved by using a multichip package with the special L2 die placed in the same cavity as the processor, running at processor speed. This was an expensive solution, owing to the cost of the package and the custom L2 SRAM die.

With Pentium II, Intel kept the separate L2 bus, but ran it at half processor speed, enabling the use of merchant-market SRAM devices and conventional packaging for the processor itself. As introduced, the Pentium II consists of a printed circuit board on which the processor, four SRAM devices and a cache tag device are mounted. The board is then packaged in a plastic shell which has thermal management features and is connected to the motherboard via an edge connector. It is with this connector, called Slot 1, and the associated Pentium Pro bus, that Intel has split from all other x86 vendors and placed the industry in a major quandary. Intel claims that to achieve scalable speed improvements the old packaging concepts were running out of bandwidth and it would be difficult to achieve the tight interconnect necessary on a commercial motherboard. Intel has therefore decided that putting all the relevant elements on a daughterboard in a controlled environment was the only guaranteed way that it could give all customers the performance increases expected over the next few years.

Intel's competition respond that this solution is just a method of locking customers into Intel, as the Pentium Pro bus and the Single Edge Cartridge (SEC), as the daughterboard is known, are protected by patents and copyright. The competition also argues that scalable performance can be achieved through higher integration, such as that seen on the K6+ and C6+, and faster buses. Whatever the rights and wrongs of either argument, the split between slot-based devices and the established Socket 7- and Socket 8-based products has divided the industry.

A shortcoming of the Pentium II that was not addressed by its 233-MHz, 266-MHz and 300-MHz introductory speeds and its 512KB onboard L2 cache was an inability to have more than two devices in a multiprocessor system. This meant that in August Intel had to launch a version of the 200-MHz Pentium Pro with a 1MB onboard L2 cache to keep its SMP server customers happy until the launch of Deschutes in 1998.

In September Intel launched the latest of the Pentium MMX chips when it announced the 200-MHz and 233-MHz mobile Pentium MMXs based on the Tillamook die. The significance of this is that these are the first production 0.25-micron products from Intel and (as well as their mobile role) will allow desktop Pentiums to go to 266 MHz and above if deemed necessary.

Microprocessor Forum saw the true highlight of Intel's year when it and Hewlett-Packard, its long-standing partner in the project, finally started the Merced "striptease." Merced is the first product in what Intel and Hewlett-Packard are now calling EPIC (Explicitly Parallel Instruction Computing) technology, the basis for the new 64-bit instruction set architecture (IA-64) which will provide the platform for mainstream computing in the next decade.

As Merced is not due until 1999 and IA-64 will not impact mainstream PCs until the new decade, we will not go into any detail, but look at what we can expect from Intel in 1998. Starting in the first quarter, Intel is expected to launch Deschutes, a 0.25-micron Pentium II family that will address both the high-end workstation and server markets and will allow Pentium II performance to be utilized in portables for the first time. During the year we will see four main iterations of Deschutes, a Slot 1-based product to address the mainstream desktop, a Slot 2-based device to address multiway SMP servers and workstations and two differently packaged versions for the portable market to address the competencies of different vendors. By the end of 1998, products at the top end will be running at 450 MHz with a 100-MHz bus, at least bringing Intel in line with the competition on this one point.

Beyond Deschutes are Katmai and Willamette, which will expand the Pentium II envelope further and keep the flame of IA-32-based computing going well into the next decade. These are targeted for 1999 release, so we will not speculate on what little is known about them at this time.

Intel wants to exit 1998 with slot- or mobile module-based Pentium II products dominating every market sector. To do this, the vendor will have to launch products to address the burgeoning sub-$1,000 PC sector. Although Intel has not discussed these products openly, Dataquest believes that such devices exist in the line-up for 1998, and that, even further from public sight, Intel is working on high-integration, not slot-compatible, devices that will address the sub-$500 compute appliance markets. If they are not developing these devices, some of the initiatives that the company launched in 1997 into automotive, WebTV, lean clients and other areas do not make any sense.

As well as the above major processor launches, Intel launched several new chipsets and many platform initiatives geared to maintaining its dominance of the PC market. Despite all this activity the single event that most people will remember about Intel in 1997 was that it was sued by Digital Equipment Corporation. Interestingly, unlike many past litigation sagas in which Intel was involved, this one was resolved (assuming that US government approval is forthcoming) in a matter of months and outside the courts. Unlike previous litigation, both companies came out of this surprisingly well, with both having gained something they wanted. Readers are referred to other Dataquest documents that cover the settlement in depth.

The Marketplace

Figure 1 shows that Dataquest expects the worldwide x86 market to grow from $15.4 billion in 1996 to $44.2 billion in 2002, a CAGR of 16 percent over the forecast period from 1997 to 2002. Intel's percentage share of that revenue will fall from 95 percent in 1996 to 82 percent in 2002; this reflects an actual revenue of $14.7 billion in 1996 growing to $36.4 billion in 2002 and a CAGR of 15 percent over the period 1997 to 2002.

Non-Intel revenue will rise from $0.7 billion in 1996 to $7.8 billion in 2002, with a CAGR of 28 percent from 1997 to 2002. The highest growth for competing products occurred in the jump from 1996 to 1997, when they grew 210 percent, increasing their share from 5 percent to 11 percent. In subsequent years the growth will be less spectacular but will result in a steady attrition of Intel's market share.

Figure 2 shows the forecast relating to worldwide unit shipments and, as previously mentioned, the competition has a higher market share when viewed from a shipment perspective. Over the period 1996 to 2002, shipments are expected to grow from 77.6 million units to 188.1 million units, a CAGR of 16 percent from 1997 to 2002.

Intel shipments are expected to grow at a CAGR of 11 percent, resulting in 126.0 million units shipments in 2002, while the competition will grow substantially faster with a CAGR of 30 percent over the same period, resulting in unit shipments of 62.1 million in 2002.

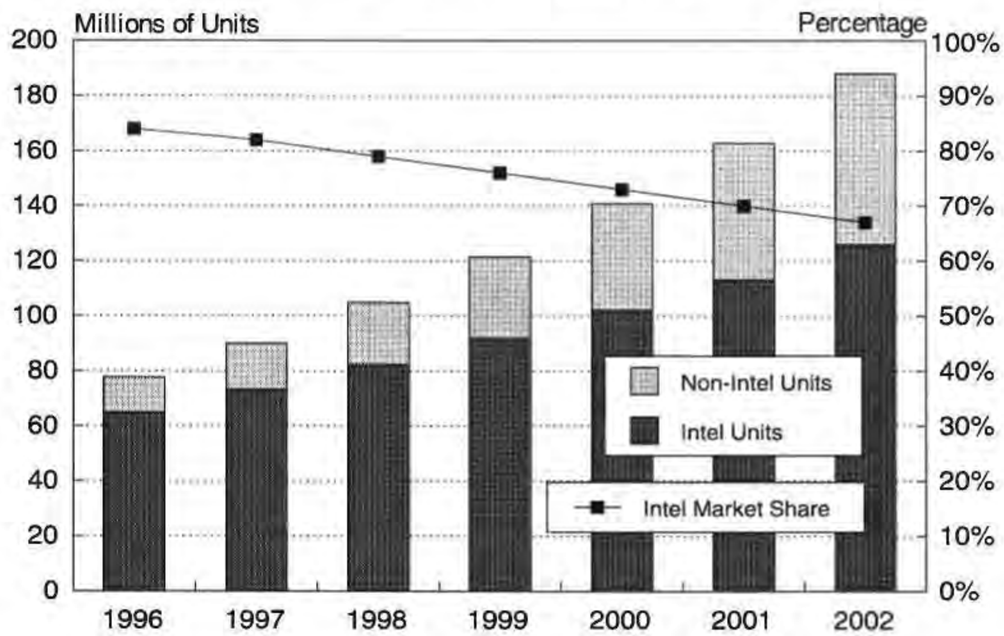
Source: Dataquest (January 1998 Estimates)

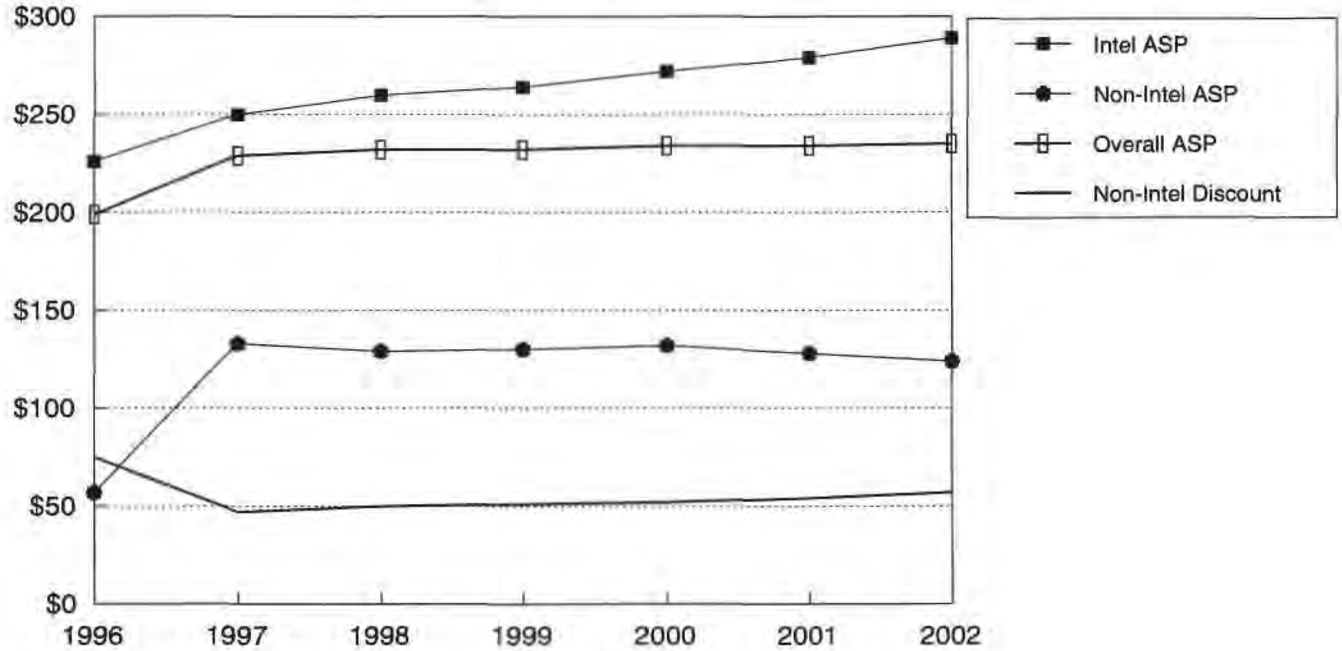
Figure 2
Worldwide x86 Processor Shipments, 1996-2002



Source: Dataquest (January 1998 Estimates)

Faster unit shipment growth for Intel's competition will result in the competition's ASP eroding over the forecast period and the non-Intel discount—or Intel premium—increasing after a temporary drop in 1997. This is shown in Figure 3, which also shows the ASP for Intel rising over the period, resulting in an essentially flat overall ASP from 1997 to 2002.

Figure 3
Worldwide x86 Processor Average Selling Prices, 1996-2002



Source: Dataquest (January 1998 Estimates)

Over the next five years we will see some generational changes as Intel and the other players introduce new products to keep the performance envelope expanding. The year 1997 saw the last vestiges of fourth-generation products, as residual traces of 486 devices were flushed from the market. More importantly, it saw the start of the transition from fifth-generation (that is, Pentium, Pentium MMX, Cyrix M1 and AMD K5) to sixth-generation products such as Pentium II, Cyrix M2 and AMD K6. The year 1998 will be dominated by these sixth-generation products and by the end of 1998 there should be no fifth-generation products in volume production.

In 1998, Dataquest expects to see a much wider spectrum of sixth-generation products, as both Intel and the competition introduce improved members of their current families. How well the competition does will be determined by how well it succeeds in prolonging the life of Socket 7 and the growth of the sub-$1,000 PC segment.

Dataquest Perspective

From an analyst's perspective, this was an exciting market to cover in 1997, with the prospect of 1998 being even more so. Apart from the new products, the real issue is whether the PC industry is so enamored of processor choice that it will support the infrastructure needed to keep two package architectures viable. Will slot-based technology drive all vestiges of Socket 7 from the market or will the Super 7 initiative from AMD and the programs from other vendors keep Socket 7 viable?

The key to this question will be whether Intel's competitors can subdue their egos and work collectively toward a single alternative solution. Fragmentation is already evident in the various announcements made for 1998, as all three camps announce proprietary MMX extensions and claiming extensive support for their particular "flavor." Unfortunately history is not on the side of the competitors; when Intel announces its MMX extensions (MMX2) the industry will swing to those, and all other contenders will vanish unless they have been able to establish a strong single alternative with a reasonable share of the market.

 ©1998 Dataquest

The three are supposed to be secretly talking about this kind of rationalization, however it is going to take some strong ego-suppression to get them all to agree on a common position. For their own good and for the good of the industry, we hope that some humility and common sense can come into play at these discussions.

Looking further ahead, and accepting the inevitability of Intel establishing slot-based products as the dominant products on the market, the next area that Intel's competitors need to address is a common slot-based alternative that launches with the Jalapeno and K7 generation. AMD has stated that it will have an SEC product based on a bus similar to that employed by Digital's 21264 device. Cyrix and IDT are keeping quiet but must be reviewing their options. A common solution is a must: the various chipset manufacturers, BIOS writers and motherboard manufacturers can support two different infrastructures—Intel and one other, if the other is of a viable size. With three alternatives to Intel, two will not survive. Assuming that common sense prevails, in 1998 the dwarfs should grow in stature such that they can start attacking the giant at knee height, and so having a better chance of toppling him over in the future!

Intel will have to address the sub-$1,000 PC issue and has two alternatives: extend the life of Socket 7 Pentium MMX devices as a low-cost entry vehicle or introduce cost-reduced slot-based Pentium II devices. Dataquest believes the latter is more likely, as extending the life of Socket 7 devices will legitimize its competitors' efforts to sustain that market, and Intel is not renowned for knowingly helping the competition.

An Introduction to Dataquest's European Semiconductor Group, 1998

Introduction

The aim of this *Guide* is to help you, our client, to get the most from your Dataquest research program by explaining the best way to work with our analysts. This document covers the following:

- The role of our analysts, and what you should expect from them
- Who the analysts are, their specialist subject areas and how to contact them
- The scope of research undertaken by Dataquest's European Semiconductor group

Analyst Charter

Analysts in the European Semiconductor group have two roles. Firstly, they are responsible for conducting research into every aspect of the European semiconductor market, the European semiconductor industry and European-headquartered semiconductor manufacturers. Secondly, they are responsible for providing a local (same time zone) contact point for subscribers to any of Dataquest's 25 or more worldwide semiconductor-related research programs. These roles are equally important.

When providing support to clients based in Europe who subscribe to non-European research programs, our analysts will do their best to answer your inquiry, but it is likely that they will have to refer the question to our experts at other research locations—either Dataquest's worldwide research headquarters in San Jose, California, United States or our regional headquarters in Tokyo, Japan or Seoul, South Korea (our Asia/Pacific headquarters). In no way does this process preclude you from making direct contact with analysts in any of Dataquest's research sites around the world; our European staff are simply there to provide support if you prefer to deal with a local contact.

The Analysts

We recruit our analysts because they possess certain skills. Generally we recruit staff from either an engineering or a marketing background in the semiconductor industry. A review of our biographies on pages 8 to 13 of this *Guide* reflects this preference.

The role of the analyst in the account relationship is to ensure that your company receives the information it requires in a timely manner. After you have subscribed to a research program, our team of analysts becomes the primary link between your company and Dataquest. The analyst team is responsible for the following:

- Communicating the scope and subject areas covered by Dataquest's semiconductor service
- Responding to your inquiries in a timely manner
- Proactively seeking the participation of your firm in research studies that might be of particular interest to your organization
- Alerting you, either personally or through *Dataquest Alerts,* to industry developments that might impact your strategy or your markets
- Soliciting your company's suggestions on new areas for research
- Responding to questions your company might have about using Dataquest's semiconductor service

©1998 Dataquest

You will elicit the quickest response to your inquiry by directing it to the analyst who specializes in the area that concerns you. However, occasionally it may not be clear who the right analyst is, or indeed the specialist may not be available. In this case please feel free to contact any member of the group.

Client Contact

On the other side of the equation, we need to know how you want to work with us, and who in your organization will be the users of our service. It is important for us to know who you have authorized to use the inquiry hours you have purchased from Dataquest.

From an administrative point of view, the working arrangement is fairly straightforward. One individual in your company—usually the person responsible for, and decided at the time of, signing the agreement for your Dataquest subscription—is designated the "binderholder," and is our point of contact for issues regarding billing, shipping, renewal and so on.

However, from an operational viewpoint, clients prefer a variety of working arrangements, particularly with regard to the use of the inquiry service. Some companies prefer to funnel all inquiries through an individual they hold responsible for managing the overall usage level; other companies nominate several individuals to use the service at will. It is very helpful for us to understand how you want the relationship to work—once we do, we will be in a much better position to both deliver the service effectively and support your objectives.

Inquiry Service

The value of the information and analysis we publish in our documents becomes evident to you only when it finds a practical application in your company's market intelligence and business planning activities. In many instances you will have specific questions about markets, competitors' offerings or the business environment that can be addressed directly through the use of the material we have published. However, you may require further insight into our data, analysis and conclusions, and this is when our inquiry service can maximize the value of your investment. You will receive a specified number of hours of consultative inquiry support as part of your contract with Dataquest, giving you ongoing access to Dataquest's European Semiconductor group over the 12 months of your program subscription.

What Is an Inquiry?

For many clients, our inquiry service is the most valuable element of their Dataquest subscription. Most use this service frequently, and with a high level of satisfaction. By understanding the inquiry process, we believe that you will be better able to use this service effectively.

We define an inquiry as a question or questions that fall(s) within the scope of the published research you receive as part of your research program subscription, and that can be answered by our analysts in less than two hours of dedicated research time.

We want the process to appear simple and transparent to you whenever you call us. We have carefully constructed our inquiry support process to ensure a swift and thorough response, and have structured our senior staff to be readily available to address those inquiries that require a higher-level response. The bottom line is that we work very hard at providing the best possible inquiry support to you, and we continually look for ways to be more efficient and helpful.

 ©1998 Dataquest

Before Calling with an Inquiry

Our ability to meet your information needs is only as good as your ability to formulate your requests to our industry analysts. Therefore, please keep the following guidelines in mind:

Formulate your inquiry questions carefully—It is especially important to think through carefully each inquiry request and to give us as much background information as possible so that we fully understand your needs. What should you do if you are not quite sure what questions to ask or what information you need? Call an analyst. Our extensive experience of working with clients will help you to formulate your market research requirements properly.

Please limit "rush" inquiries—Try to anticipate your information needs so that you can give us enough time to respond to your inquiries. No-one can prevent the last-minute question that comes up just as you are entering a meeting, but the likelihood of us being able to give you the information you need in a crunch is far less than when we are given more time to access all of our sources.

Try to avoid multiple inquiries—Clients generally are allowed one active inquiry per program subscription at any time. If you must make more than one inquiry at a time, our analysts will work with you to prioritize your active inquiries.

Sensitive information gathering—When structuring an inquiry, please keep in mind that we are able to provide responses based only on information that is in the public domain. If you are asking for a type of more sensitive information which your company would not be willing to disclose, it is unlikely that we would be able to obtain similar information from your competitors.

Industry analysts are more than "data diggers"—Our analysts should be seen as consultants on call. They can give you valuable feedback as you refine your service marketing strategies, programs and policies.

How to Place an Inquiry

There are three means of communicating your inquiries to your assigned analyst/account manager, namely telephone, fax and e-mail. In most cases the appointed analyst will acknowledge receipt of your inquiry, in one form or another, to inform you that your request has been received. However, it is advisable that you follow up with a telephone call to the analyst after logging your inquiry to check that it has been received.

When Will You Receive an Answer to Your Inquiry?

Most inquiries are answered within five working days, but please remember that this is an average. An analyst will discuss with you a reasonable expectation for answers and will call to let you know if an inquiry will require more time to complete.

How Will Answers Be Communicated to You?

Dataquest will respond to your inquiries in the most effective means possible, which may include the telephone, fax, e-mail, or a regular or express mail service.

Inquiry Management Systems and Databases

All Dataquest inquiries are logged in a database so that we can track all active and historical inquiries, and conduct searches on past inquiries. This system allows us to respond to your questions quickly by reducing the number of times we have to "reinvent the wheel," and to give you an up-to-the-minute status report on your inquiries.

 ©1998 Dataquest

Furthermore, if you are curious about your inquiry usage for the year, we can produce a report that tells you the number of hours you have consumed and the number of hours you have remaining. If you use up your assigned inquiry hours before your contractual term ends, additional inquiry hours may be purchased to fulfill your requirements for the remainder of your contract's duration. Any unused inquiry hours are forfeited once your subscription has expired.

Custom/Fee-Based Projects

Questions that require more than two hours of effort are better handled on a special-fee basis. There are two alternatives: speaking and short engagements and custom consulting. Speaking and short engagements are fee-based projects that can be completed within two to three days of dedicated research and/or analysis. If the project you are requesting goes beyond that timescale, custom consulting is the next option. Our inquiry analysts will work with you to determine the best method to get your questions answered.

We encourage you to use the interactive inquiry process to gain maximum value from your investment, and look forward to a long-term productive relationship based on an ongoing dialog.

Group Structure

Figure 1 shows how Dataquest's European Semiconductor group is organized, and Tables 1 and 2 provide directories of research expertise by analyst and by subject respectively. This information is ensued by a biography of each group member.

 ©1998 Dataquest

Jim Eastlake
Vice President and Director, European Semiconductor Group

Mr. Eastlake is the director of Dataquest's European Semiconductor group, based in Egham, England, and he has more than 18 years' experience in the electronics industry. Prior to joining Dataquest, Mr. Eastlake worked in Texas Instruments' Northern European semiconductor division, and in his most recent post at Texas Instruments he ran the European distribution program for the linear functions business group. Earlier he managed Texas Instruments' advanced bipolar logic families and was responsible for launching the company's programmable logic families and bit-slice functions in Northern Europe. He also held a product marketing position for 8- and 16-bit microprocessors and peripherals.

Mr. Eastlake graduated from the University of Newcastle-on-Tyne, England, with an honors degree in Physics.

+44-1784-487511

jim.eastlake@gartner.com

Ellie Babaie
Associate Analyst, Research Operations (Semiconductors)

Ms. Babaie works very closely with the European Semiconductor group. Her main responsibilities include conducting market research, analysing data and gathering market share information. Ms. Babaie joined Dataquest after completing an MBA degree, prior to which she worked for an international company, where she was involved in strategic planning, analysis of entry barriers for new product markets and conducting negotiations with suppliers and buyers. She has also carried out various research projects within the public sector.

Ms. Babaie graduated from the University of Manchester Institute of Science and Technology in England with a B.Sc. (Hons) in Computation, and gained her MBA at Aston Business School, England.

+44-1784-488799

ellie.babaie@gartner.com

 ©1998 Dataquest

Lea Davies

Group Coordinator, European Semiconductor Group and Research Operations

Mrs. Davies joined Dataquest in the spring of 1996 as group coordinator for the European Semiconductor and Research Operations groups. Her main responsibilities include coordinating the itinerary of research analysts for European conferences and sales trips. She is also in charge of all procurement for the groups as well as general administrative duties. Prior to joining Dataquest, Mrs. Davies worked as an account manager for a large blue-chip company, where she dealt with the management of client accounts and was responsible for their aftersales care. As a result, Mrs. Davies has gained vast knowledge and experience regarding client relations.

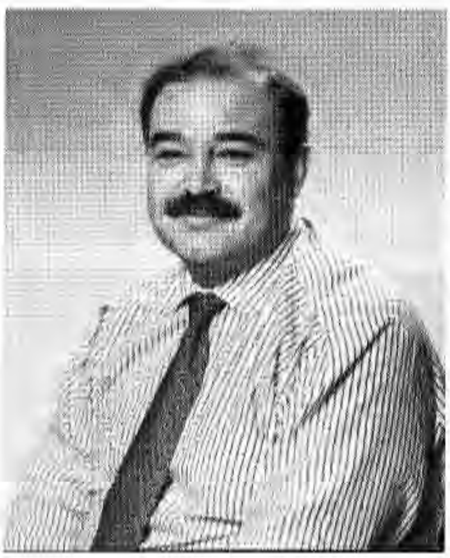
Mrs. Davies holds a Diploma in Business and Finance.

+44-1784-487512

lea.davies@gartner.com

Joe D'Elia

Associate Director, European Semiconductor Group



Mr. D'Elia is an associate director and manages the Semiconductors Europe program. He is based at Dataquest's European headquarters in Egham, and has worked in the semiconductor industry for 28 years. Before joining Dataquest, Mr. D'Elia held the position of European customer marketing director for LSI Logic in Munich, managing a team responsible for providing tactical marketing support for all of the company's products, and prior to this he was based at LSI Logic's Californian headquarters as an international marketing manager. Earlier Mr. D'Elia spent 4 years at Intel Corporation in major accounts management and in EPLD marketing, 8 years at National Semiconductor in field applications, sales and market development, and 10 years at Texas Instruments in manufacturing and consumer applications. Mr. D'Elia's research responsibilities as an analyst encompass microcomponents, vendor market shares in Europe, the Middle East and Africa (EMEA), and the EMEA PC manufacturing industry and associated technology.

Mr. D'Elia is a member of the IEEIE.

+44-1784-487505

joe.delia@gartner.com

 ©1998 Dataquest

Edmund Gemmell
Associate Analyst, European Semiconductor Group

Mr. Gemmell is an associate analyst in Dataquest's Semiconductor group in Egham, and has 3 years' research experience within the semiconductor industry. Mr. Gemmell is responsible for researching European geopolitical and competitive issues, including the emerging semiconductor markets of Eastern Europe. He also compiles the monthly semiconductor industry newsletter, *I.C. Europe*. Before joining Dataquest, Mr. Gemmell worked at National Semiconductor's European headquarters outside Munich, where his main role was to develop and implement a European marketing research function in support of the European product marketing groups. Furthermore, he carried out substantial research into the developing markets of Eastern Europe.

Mr. Gemmell holds a degree in Business and Marketing from Stirling University, Scotland.

+44-1784-487506

edmund.gemmell@gartner.com

Richard Gordon
Industry Analyst, European Semiconductor Group

Mr. Gordon is an industry analyst responsible for Dataquest's European memories research, based at Egham, and he has 11 years' experience in the electronics and semiconductor industries. Before joining Dataquest, Mr. Gordon worked at Advanced Micro Devices as senior product engineer, supporting nonvolatile memory product customers across Europe. Prior to this he was a transputer device engineer at the INMOS wafer fab in South Wales, and earlier he spent 2 years with A.B. Electronics in the subcontract electronics assembly industry.

Mr. Gordon holds a B.Sc. (Hons) degree in Electronics from the University of Glasgow, Scotland, and has a Postgraduate Diploma in Marketing from the Chartered Institute of Marketing.

+44-1784-487508

richard.gordon@gartner.com

David Moorhouse
Associate Director, European Semiconductor Group

Mr. Moorhouse is an associate director based at Egham, and he manages Dataquest's Semiconductor Application Markets Europe and Electronic Equipment Production Monitor Europe programs. His research domain is communications applications, and he has worked in the European electronics industry for the past 16 years. Prior to joining Dataquest, he was a senior consultant with design house ID Devices, responsible for product developments in fiber-optic communications and speech synthesis systems. His previous marketing experience was gained at Standard Telephones and Cables (STC) hybrids division as product marketing manager and applications manager. Before STC Mr. Moorhouse worked for GEC Avionics as a designer in high-speed serial data bus systems used in military and civil aircraft.

Mr. Moorhouse is a graduate of Salford University, England, with a degree in Electronics.

+44-1784-487509

david.moorhouse@gartner.com

Paul O'Donovan
Industry Analyst, European Semiconductor Group

Mr. O'Donovan is an industry analyst covering consumer applications within the European Semiconductor group, his main area of responsibility being video and audio application segments. Mr. O'Donovan is based at Dataquest's European headquarters in Egham and has more than 12 years' experience in the semiconductor industry. Before joining Dataquest he worked at National Semiconductor's European headquarters outside Munich, where he had pan-European responsibility for managing the company's logic families through its distribution network. His primary tasks were the gathering and analysis of trends for his product responsibilities and the setting of tactics and strategies. Prior to this role he was a marketing assistant at National Semiconductor's headquarters in the United Kingdom within the digital logic group, and earlier he worked in production planning.

Mr. O'Donovan studied Sales and Marketing with the Chartered Institute of Marketing.

+44-1784-487504

paul.o'donovan@gartner.com

 ©1998 Dataquest

Andrew Phillips
Industry Analyst, European Semiconductor Group

Mr. Phillips is an analyst who works on Dataquest's Semiconductor Application Markets Europe program and is based at the European headquarters in Egham. His research covers electronic data processing and data networking applications, and he has 9 years' experience in the semiconductor industry. Before joining Dataquest, Mr. Phillips worked for semiconductor distributor SEI Macro, which involved commercial and technical promotion of many semiconductor manufacturers' products (including Hitachi, Motorola, National Semiconductor, Philips, Siemens, Sony, TEMIC and Texas Instruments) and specific focus on developing imaging- and multimedia-based markets.

Mr. Phillips holds a B.Sc. (Hons) degree in Electronics and Communications Engineering from the Polytechnic of North London, England.

+44-1784-487507

andrew.phillips@gartner.com

Jim Tully
Principal Analyst, European Semiconductor Group

Dr. Tully is the principal analyst in Dataquest's European Semiconductor group, based at Egham. He is responsible for Dataquest's electronic design automation (EDA), ASIC and semiconductor user and buyer research in Europe. Before joining Dataquest in 1990, Dr. Tully spent 7 years with EDA company Racal Redac Limited in the United Kingdom, where he had design engineering, engineering management and, later, worldwide marketing management responsibilities. Before this, he held design, design management and production management roles within the Armstrong Organization (now Mitsubishi), Ferranti Limited, the UK Atomic Energy Authority and Rediffusion Cable TV. In these roles, he designed, specified and purchased a wide range of electronic components and systems.

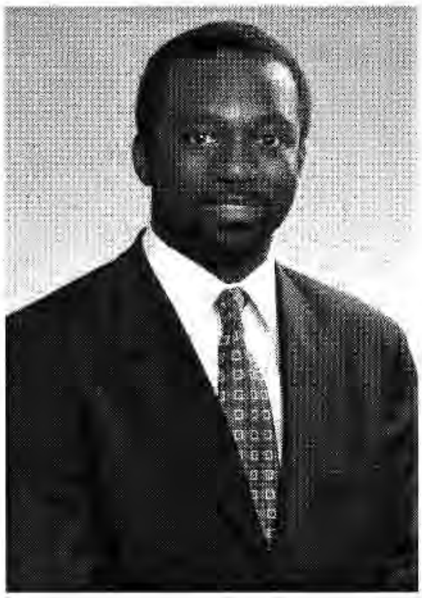
Dr. Tully is a chartered electronic engineer. He holds M.Sc. and Ph.D. degrees in electrical and electronic engineering from the University of Bradford, England, and an MBA from the University of Warwick, England.

+44-1784-487503

jim.tully@gartner.com

 ©1998 Dataquest

Mike Williams
Senior Industry Analyst, European Semiconductor Group



Mr. Williams is a senior industry analyst for Dataquest's Semiconductor Application Markets Europe program and is based at Egham. He has 11 years' experience in research and analysis into the semiconductor industry. Although his main area of expertise is automotive application markets, Mr. Williams also conducts specific research into the computer and consumer application segments. Prior to joining Dataquest, he worked for Aidcom International, a consumer marketing research company based in London.

Mr. Williams studied Computer Management at the Institute of Data Processing Management in London.

Overview of Research Programs

The European Semiconductor group divides its research focus into two main areas, namely industry and applications.

The industry side of the group focuses on the following:

- Semiconductor product market research (memories, microcomponents, ASICs and so on)
- Vendor analysis
- European geopolitical issues (trade, tariffs, investment and so on)
- Semiconductor technology trends
- Purchasing issues and trends (what the customer thinks and does)
- The EDA market
- Eastern European devices and applications markets

The applications side of the group deals with electronic applications that use semiconductors and other electronic components and subassemblies.

The group provides four research programs in total. There are two "industry" programs and two "applications" programs, as follows:

- Industry
  - Semiconductors Europe (SEMI-EU)
  - Electronic Design Automation Worldwide (CEDA-WW)
- Applications
  - Semiconductor Application Markets Europe (SAMM-EU)
  - Electronic Equipment Production Monitor Europe (SAPM-EU)

Following you will find a description of the research contents and scope of each of these programs.

Semiconductors Europe

Dataquest's Semiconductors Europe program provides clients with quantitative and qualitative analysis of product, regional and technology trends in EMEA. Dataquest maintains databases containing information about company market shares, capital and R&D investment and manufacturing capability, to which clients have access through this service. Vendor strategies are monitored closely. The program also follows and analyzes the many geopolitical issues affecting both vendors and users of semiconductors in EMEA, and the impact of these factors is reflected in Dataquest's product and regional market forecasts.

Topical Coverage

Topics covered by this program include the following:

- Competitive dynamics
- Investment
- Industry trends
- Purchasing trends

 ©1998 Dataquest

Regional Coverage

Market estimates and forecasts are provided for the following countries or regions:

- Africa
- Benelux
- Eastern Europe
- France
- Germany
- Italy
- Middle East
- Nordic
- Rest of Western Europe
- United Kingdom and Ireland

Product Coverage

Market share estimates and forecasts are provided for the following product categories:

- ASICs—Gate arrays, programmable logic devices, cell-based ICs, custom ICs
- Memories—DRAM, SRAM, EPROM, EEPROM, flash, ROM
- Microcomponents—Microprocessors, microcontrollers, microperipherals, digital signal processors
- Analog and mixed-signal ICs
- Discretes
- Optocomponents

Key Databases

This program maintains the following databases to monitor and analyze Europe:

- EMEA semiconductor fabrication database
- Capital and R&D investment by European vendor
- Major OEMs' annual semiconductor spend
- EMEA semiconductor market shares by vendor
- EMEA semiconductor forecasts by product and region

The Analysts

The program manager for Semiconductors Europe is Joe D'Elia. Analysts researching this program along with Joe are Richard Gordon, Edmund Gemmell and Jim Tully.

Semiconductor Application Markets Europe

Dataquest's Semiconductor Application Markets Europe program is the leading information source for market statistics and strategic analysis of the European semiconductor market. The program provides demand-side information and decision support on electronic equipment production and design trends. It has been developed to aid the marketing and strategic planning of semiconductor and other electronic component manufacturers, and it provides market estimates and forecasts of European electronic equipment production and semiconductor consumption.

©1998 Dataquest

Primary Application Coverage

Detailed forecast and trend analysis is provided for the following:

- Electronic data processing—Including PCs, computer peripherals, storage devices and IC cards
- Communications—Central office switches, telephone handsets, data communications equipment and mobile/cellular communications
- Consumer—Including analog and digital audio and video systems, set-top boxes, personal electronics and domestic appliances
- Automotive—Including in-car entertainment systems, body control and vehicle control electronics, driver information (including navigation), power train, and safety and convenience systems

Market Overview

Market estimates and forecasts are provided for the following six basic application markets:

- Electronic data processing
- Communications
- Consumer
- Industrial
- Military and civil aerospace
- Automotive

Key Market Statistics

The following statistics are included:

- Electronic equipment production forecasts in units and revenue
- Semiconductor market forecasts by application
- European country market forecasts by application
- Vendor market shares by application
- High-volume electronic equipment unit production forecasts

Regional Coverage

Market estimates and forecasts are provided for the following countries or regions:

- Benelux
- France
- Germany
- Italy
- Nordic
- United Kingdom and Ireland

The Analysts

The program manager for Semiconductor Application Markets Europe is David Moorhouse. Analysts researching this program along with David are Mike Williams, Andrew Phillips and Paul O'Donovan.

©1998 Dataquest

Electronic Equipment Production Monitor Europe

Dataquest's Electronic Equipment Production Monitor Europe program is the leading source of information on component content trends of new and/or high-volume electronics systems manufactured in Europe. It is intended to be of interest to all vendors of electronic components, from semiconductors to subassemblies. The core research activity involves the disassembly, or "tear-down," of key electronics products. Once dismantled, a bill-of-materials listing is made and component prices estimated for each product. A report analyzing the content of the product is then produced, and it includes: a complete listing of all the electronic components found, their sources, quantities per system and estimated prices; commentary on future trends in component usage within the product being analyzed; and, on behalf of the OEM/designer, the identification of scope for cost savings through redesign, using knowledge of emerging component solutions and methods.

Primary Application Coverage

The program will provide analysis of the following 34 key items of electronic equipment:

Electronic Data Processing	Communications
Optical disk drives	Analog cellular telephones
Page (laser) printers	Analog cordless telephones
PC motherboards	Answering machines
PCs	Central office line cards
Rigid disk drives	Corded telephones
Serial printers	Digital cellular telephones
Smart cards	Digital cordless telephones
Workstations	Fax machines
	LAN cards
Consumer	Modems
Analog camcorders	Pagers
Analog set-top boxes	PBX line cards
Color TVs	
Digital camcorders	**Automotive**
Digital set-top boxes	Airbag systems
Digital still cameras	Antilock braking systems
DVD players	Engine control units
Personal stereos	Navigation systems
VCRs/VTRs	Stereo systems

Market Statistics

The program maintains the following market statistics databases:

- High-volume European electronic equipment production—Provides history and a five-year forecast of European electronic systems unit production for the 34 products listed, with their factory production ASP and total production value.
- Major European electronic equipment manufacturing locations—Identifies by product, region and company the locations of major European manufacturers of the 34 items of electronic equipment listed. This database, updated annually, is an indispensable marketing tool providing the client with vital information about key potential customers.

 ©1998 Dataquest

The Analysts

The program manager for Electronic Equipment Production Monitor Europe is David Moorhouse. Analysts researching this program along with David are Andrew Phillips, Mike Williams and Paul O'Donovan.

Electronic Design Automation Worldwide

Dataquest's Electronic Design Automation Worldwide program provides detailed analysis of the industry trends, players, products and end-user issues that drive the market for EDA applications and tools. The program covers the three major EDA application areas—IC layout, electronic CAE and PCB/MCM/hybrid layout tools—and provides the most reliable worldwide market size, market share and market forecast estimates available. The program also provides data, advice and analysis to help clients make informed planning decisions. Publications include a mix of analytical articles, weekly news bulletins and event-driven faxes. Periodic briefings and conferences bring clients together with analysts to share insights and opinions.

Key Topics

Topics covered by this program include the following:

- ES level (ESDA)—Virtual prototypes, hardware and software codesign
- RTL design—VHDL and verilog, synthesis, design for test
- Gate-level design—Schematic capture, analog design, analysis tools
- IC CAD—Physical verification, floor planning, FPGA fitters, IC layout
- PCB design—PCB, MCM and hybrid place and route
- Miscellaneous—Accelerators and emulators, libraries, interoperability tools

Regional Coverage

The program covers the following countries or regions:

- Asia/Pacific (by country)
- Europe (by country)
- Japan
- North America
- Rest of World
- Worldwide

Standard Data Metrics

The following data metrics are covered:

- Total factory, hardware and software revenue
- Service revenue
- Revenue by operating system
- Software shipments
- Revenue by industry sector
- 37 different subapplications by end use and by platform

The Analysts

The program manager in Europe for Electronic Design Automation Worldwide is Jim Tully.

An Introduction to Dataquest's European Semiconductor Group, 1998

Introduction

The aim of this *Guide* is to help you, our client, to get the most from your Dataquest research program by explaining the best way to work with our analysts. This document covers the following:

- The role of our analysts, and what you should expect from them
- Who the analysts are, their specialist subject areas and how to contact them
- The scope of research undertaken by Dataquest's European Semiconductor group

Analyst Charter

Analysts in the European Semiconductor group have two roles. Firstly, they are responsible for conducting research into every aspect of the European semiconductor market, the European semiconductor industry and European-headquartered semiconductor manufacturers. Secondly, they are responsible for providing a local (same time zone) contact point for subscribers to any of Dataquest's 25 or more worldwide semiconductor-related research programs. These roles are equally important.

When providing support to clients based in Europe who subscribe to non-European research programs, our analysts will do their best to answer your inquiry, but it is likely that they will have to refer the question to our experts at other research locations—either Dataquest's worldwide research headquarters in San Jose, California, United States or our regional headquarters in Tokyo, Japan or Seoul, South Korea (our Asia/Pacific headquarters). In no way does this process preclude you from making direct contact with analysts in any of Dataquest's research sites around the world; our European staff are simply there to provide support if you prefer to deal with a local contact.

The Analysts

We recruit our analysts because they possess certain skills. Generally we recruit staff from either an engineering or a marketing background in the semiconductor industry. A review of our biographies on pages 8 to 13 of this *Guide* reflects this preference.

The role of the analyst in the account relationship is to ensure that your company receives the information it requires in a timely manner. After you have subscribed to a research program, our team of analysts becomes the primary link between your company and Dataquest. The analyst team is responsible for the following:

- Communicating the scope and subject areas covered by Dataquest's semiconductor service
- Responding to your inquiries in a timely manner
- Proactively seeking the participation of your firm in research studies that might be of particular interest to your organization
- Alerting you, either personally or through *Dataquest Alerts*, to industry developments that might impact your strategy or your markets
- Soliciting your company's suggestions on new areas for research
- Responding to questions your company might have about using Dataquest's semiconductor service

©1998 Dataquest

You will elicit the quickest response to your inquiry by directing it to the analyst who specializes in the area that concerns you. However, occasionally it may not be clear who the right analyst is, or indeed the specialist may not be available. In this case please feel free to contact any member of the group.

Client Contact

On the other side of the equation, we need to know how you want to work with us, and who in your organization will be the users of our service. It is important for us to know who you have authorized to use the inquiry hours you have purchased from Dataquest.

From an administrative point of view, the working arrangement is fairly straightforward. One individual in your company—usually the person responsible for, and decided at the time of, signing the agreement for your Dataquest subscription—is designated the "binderholder," and is our point of contact for issues regarding billing, shipping, renewal and so on.

However, from an operational viewpoint, clients prefer a variety of working arrangements, particularly with regard to the use of the inquiry service. Some companies prefer to funnel all inquiries through an individual they hold responsible for managing the overall usage level; other companies nominate several individuals to use the service at will. It is very helpful for us to understand how you want the relationship to work—once we do, we will be in a much better position to both deliver the service effectively and support your objectives.

Inquiry Service

The value of the information and analysis we publish in our documents becomes evident to you only when it finds a practical application in your company's market intelligence and business planning activities. In many instances you will have specific questions about markets, competitors' offerings or the business environment that can be addressed directly through the use of the material we have published. However, you may require further insight into our data, analysis and conclusions, and this is when our inquiry service can maximize the value of your investment. You will receive a specified number of hours of consultative inquiry support as part of your contract with Dataquest, giving you ongoing access to Dataquest's European Semiconductor group over the 12 months of your program subscription.

What Is an Inquiry?

For many clients, our inquiry service is the most valuable element of their Dataquest subscription. Most use this service frequently, and with a high level of satisfaction. By understanding the inquiry process, we believe that you will be better able to use this service effectively.

We define an inquiry as a question or questions that fall(s) within the scope of the published research you receive as part of your research program subscription, and that can be answered by our analysts in less than two hours of dedicated research time.

We want the process to appear simple and transparent to you whenever you call us. We have carefully constructed our inquiry support process to ensure a swift and thorough response, and have structured our senior staff to be readily available to address those inquiries that require a higher-level response. The bottom line is that we work very hard at providing the best possible inquiry support to you, and we continually look for ways to be more efficient and helpful.

©1998 Dataquest

Before Calling with an Inquiry

Our ability to meet your information needs is only as good as your ability to formulate your requests to our industry analysts. Therefore, please keep the following guidelines in mind:

Formulate your inquiry questions carefully—It is especially important to think through carefully each inquiry request and to give us as much background information as possible so that we fully understand your needs. What should you do if you are not quite sure what questions to ask or what information you need? Call an analyst. Our extensive experience of working with clients will help you to formulate your market research requirements properly.

Please limit "rush" inquiries—Try to anticipate your information needs so that you can give us enough time to respond to your inquiries. No-one can prevent the last-minute question that comes up just as you are entering a meeting, but the likelihood of us being able to give you the information you need in a crunch is far less than when we are given more time to access all of our sources.

Try to avoid multiple inquiries—Clients generally are allowed one active inquiry per program subscription at any time. If you must make more than one inquiry at a time, our analysts will work with you to prioritize your active inquiries.

Sensitive information gathering—When structuring an inquiry, please keep in mind that we are able to provide responses based only on information that is in the public domain. If you are asking for a type of more sensitive information which your company would not be willing to disclose, it is unlikely that we would be able to obtain similar information from your competitors.

Industry analysts are more than "data diggers"—Our analysts should be seen as consultants on call. They can give you valuable feedback as you refine your service marketing strategies, programs and policies.

How to Place an Inquiry

There are three means of communicating your inquiries to your assigned analyst/account manager, namely telephone, fax and e-mail. In most cases the appointed analyst will acknowledge receipt of your inquiry, in one form or another, to inform you that your request has been received. However, it is advisable that you follow up with a telephone call to the analyst after logging your inquiry to check that it has been received.

When Will You Receive an Answer to Your Inquiry?

Most inquiries are answered within five working days, but please remember that this is an average. An analyst will discuss with you a reasonable expectation for answers and will call to let you know if an inquiry will require more time to complete.

How Will Answers Be Communicated to You?

Dataquest will respond to your inquiries in the most effective means possible, which may include the telephone, fax, e-mail, or a regular or express mail service.

Inquiry Management Systems and Databases

All Dataquest inquiries are logged in a database so that we can track all active and historical inquiries, and conduct searches on past inquiries. This system allows us to respond to your questions quickly by reducing the number of times we have to "reinvent the wheel," and to give you an up-to-the-minute status report on your inquiries.

 ©1998 Dataquest

Furthermore, if you are curious about your inquiry usage for the year, we can produce a report that tells you the number of hours you have consumed and the number of hours you have remaining. If you use up your assigned inquiry hours before your contractual term ends, additional inquiry hours may be purchased to fulfill your requirements for the remainder of your contract's duration. Any unused inquiry hours are forfeited once your subscription has expired.

Custom/Fee-Based Projects

Questions that require more than two hours of effort are better handled on a special-fee basis. There are two alternatives: speaking and short engagements and custom consulting. Speaking and short engagements are fee-based projects that can be completed within two to three days of dedicated research and/or analysis. If the project you are requesting goes beyond that timescale, custom consulting is the next option. Our inquiry analysts will work with you to determine the best method to get your questions answered.

We encourage you to use the interactive inquiry process to gain maximum value from your investment, and look forward to a long-term productive relationship based on an ongoing dialog.

Group Structure

Figure 1 shows how Dataquest's European Semiconductor group is organized, and Tables 1 and 2 provide directories of research expertise by analyst and by subject respectively. This information is ensued by a biography of each group member.

 ©1998 Dataquest

Jim Eastlake
Vice President and Director, European Semiconductor Group

Mr. Eastlake is the director of Dataquest's European Semiconductor group, based in Egham, England, and he has more than 18 years' experience in the electronics industry. Prior to joining Dataquest, Mr. Eastlake worked in Texas Instruments' Northern European semiconductor division, and in his most recent post at Texas Instruments he ran the European distribution program for the linear functions business group. Earlier he managed Texas Instruments' advanced bipolar logic families and was responsible for launching the company's programmable logic families and bit-slice functions in Northern Europe. He also held a product marketing position for 8- and 16-bit microprocessors and peripherals.

Mr. Eastlake graduated from the University of Newcastle-on-Tyne, England, with an honors degree in Physics.

+44-1784-487511

jim.eastlake@gartner.com

Ellie Babaie
Associate Analyst, Research Operations (Semiconductors)

Ms. Babaie works very closely with the European Semiconductor group. Her main responsibilities include conducting market research, analysing data and gathering market share information. Ms. Babaie joined Dataquest after completing an MBA degree, prior to which she worked for an international company, where she was involved in strategic planning, analysis of entry barriers for new product markets and conducting negotiations with suppliers and buyers. She has also carried out various research projects within the public sector.

Ms. Babaie graduated from the University of Manchester Institute of Science and Technology in England with a B.Sc. (Hons) in Computation, and gained her MBA at Aston Business School, England.

+44-1784-488799

ellie.babaie@gartner.com

 ©1998 Dataquest

Lea Davies

Group Coordinator, European Semiconductor Group and Research Operations

Mrs. Davies joined Dataquest in the spring of 1996 as group coordinator for the European Semiconductor and Research Operations groups. Her main responsibilities include coordinating the itinerary of research analysts for European conferences and sales trips. She is also in charge of all procurement for the groups as well as general administrative duties. Prior to joining Dataquest, Mrs. Davies worked as an account manager for a large blue-chip company, where she dealt with the management of client accounts and was responsible for their aftersales care. As a result, Mrs. Davies has gained vast knowledge and experience regarding client relations.

Mrs. Davies holds a Diploma in Business and Finance.

+44-1784-487512

lea.davies@gartner.com

Joe D'Elia

Associate Director, European Semiconductor Group

Mr. D'Elia is an associate director and manages the Semiconductors Europe program. He is based at Dataquest's European headquarters in Egham, and has worked in the semiconductor industry for 28 years. Before joining Dataquest, Mr. D'Elia held the position of European customer marketing director for LSI Logic in Munich, managing a team responsible for providing tactical marketing support for all of the company's products, and prior to this he was based at LSI Logic's Californian headquarters as an international marketing manager. Earlier Mr. D'Elia spent 4 years at Intel Corporation in major accounts management and in EPLD marketing, 8 years at National Semiconductor in field applications, sales and market development, and 10 years at Texas Instruments in manufacturing and consumer applications. Mr. D'Elia's research responsibilities as an analyst encompass microcomponents, vendor market shares in Europe, the Middle East and Africa (EMEA), and the EMEA PC manufacturing industry and associated technology.

Mr. D'Elia is a member of the IEEIE.

+44-1784-487505

joe.delia@gartner.com

Edmund Gemmell
Associate Analyst, European Semiconductor Group

Mr. Gemmell is an associate analyst in Dataquest's Semiconductor group in Egham, and has 3 years' research experience within the semiconductor industry. Mr. Gemmell is responsible for researching European geopolitical and competitive issues, including the emerging semiconductor markets of Eastern Europe. He also compiles the monthly semiconductor industry newsletter, *I.C. Europe*. Before joining Dataquest, Mr. Gemmell worked at National Semiconductor's European headquarters outside Munich, where his main role was to develop and implement a European marketing research function in support of the European product marketing groups. Furthermore, he carried out substantial research into the developing markets of Eastern Europe.

Mr. Gemmell holds a degree in Business and Marketing from Stirling University, Scotland.

+44-1784-487506

edmund.gemmell@gartner.com

Richard Gordon
Industry Analyst, European Semiconductor Group

Mr. Gordon is an industry analyst responsible for Dataquest's European memories research, based at Egham, and he has 11 years' experience in the electronics and semiconductor industries. Before joining Dataquest, Mr. Gordon worked at Advanced Micro Devices as senior product engineer, supporting nonvolatile memory product customers across Europe. Prior to this he was a transputer device engineer at the INMOS wafer fab in South Wales, and earlier he spent 2 years with A.B. Electronics in the subcontract electronics assembly industry.

Mr. Gordon holds a B.Sc. (Hons) degree in Electronics from the University of Glasgow, Scotland, and has a Postgraduate Diploma in Marketing from the Chartered Institute of Marketing.

+44-1784-487508

richard.gordon@gartner.com

David Moorhouse
Associate Director, European Semiconductor Group

Mr. Moorhouse is an associate director based at Egham, and he manages Dataquest's Semiconductor Application Markets Europe and Electronic Equipment Production Monitor Europe programs. His research domain is communications applications, and he has worked in the European electronics industry for the past 16 years. Prior to joining Dataquest, he was a senior consultant with design house ID Devices, responsible for product developments in fiber-optic communications and speech synthesis systems. His previous marketing experience was gained at Standard Telephones and Cables (STC) hybrids division as product marketing manager and applications manager. Before STC Mr. Moorhouse worked for GEC Avionics as a designer in high-speed serial data bus systems used in military and civil aircraft.

Mr. Moorhouse is a graduate of Salford University, England, with a degree in Electronics.

+44-1784-487509

david.moorhouse@gartner.com

Paul O'Donovan
Industry Analyst, European Semiconductor Group

Mr. O'Donovan is an industry analyst covering consumer applications within the European Semiconductor group, his main area of responsibility being video and audio application segments. Mr. O'Donovan is based at Dataquest's European headquarters in Egham and has more than 12 years' experience in the semiconductor industry. Before joining Dataquest he worked at National Semiconductor's European headquarters outside Munich, where he had pan-European responsibility for managing the company's logic families through its distribution network. His primary tasks were the gathering and analysis of trends for his product responsibilities and the setting of tactics and strategies. Prior to this role he was a marketing assistant at National Semiconductor's headquarters in the United Kingdom within the digital logic group, and earlier he worked in production planning.

Mr. O'Donovan studied Sales and Marketing with the Chartered Institute of Marketing.

+44-1784-487504

 ©1998 Dataquest

Andrew Phillips
Industry Analyst, European Semiconductor Group

Mr. Phillips is an analyst who works on Dataquest's Semiconductor Application Markets Europe program and is based at the European headquarters in Egham. His research covers electronic data processing and data networking applications, and he has 9 years' experience in the semiconductor industry. Before joining Dataquest, Mr. Phillips worked for semiconductor distributor SEI Macro, which involved commercial and technical promotion of many semiconductor manufacturers' products (including Hitachi, Motorola, National Semiconductor, Philips, Siemens, Sony, TEMIC and Texas Instruments) and specific focus on developing imaging- and multimedia-based markets.

Mr. Phillips holds a B.Sc. (Hons) degree in Electronics and Communications Engineering from the Polytechnic of North London, England.

+44-1784-487507

andrew.phillips@gartner.com

Jim Tully
Principal Analyst, European Semiconductor Group

Dr. Tully is the principal analyst in Dataquest's European Semiconductor group, based at Egham. He is responsible for Dataquest's electronic design automation (EDA), ASIC and semiconductor user and buyer research in Europe. Before joining Dataquest in 1990, Dr. Tully spent 7 years with EDA company Racal Redac Limited in the United Kingdom, where he had design engineering, engineering management and, later, worldwide marketing management responsibilities. Before this, he held design, design management and production management roles within the Armstrong Organization (now Mitsubishi), Ferranti Limited, the UK Atomic Energy Authority and Rediffusion Cable TV. In these roles, he designed, specified and purchased a wide range of electronic components and systems.

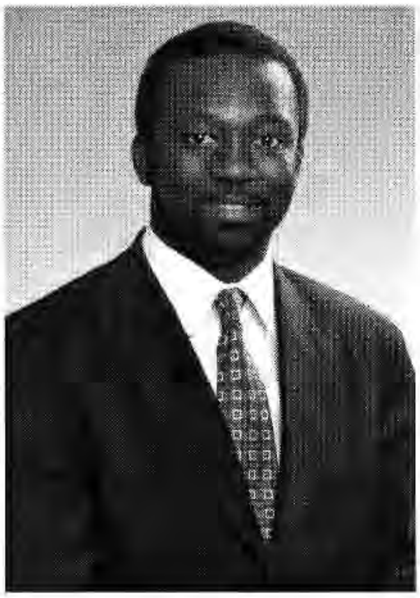
Dr. Tully is a chartered electronic engineer. He holds M.Sc. and Ph.D. degrees in electrical and electronic engineering from the University of Bradford, England, and an MBA from the University of Warwick, England.

+44-1784-487503

jim.tully@gartner.com

 ©1998 Dataquest

Mike Williams
Senior Industry Analyst, European Semiconductor Group



Mr. Williams is a senior industry analyst for Dataquest's Semiconductor Application Markets Europe program and is based at Egham. He has 11 years' experience in research and analysis into the semiconductor industry. Although his main area of expertise is automotive application markets, Mr. Williams also conducts specific research into the computer and consumer application segments. Prior to joining Dataquest, he worked for Aidcom International, a consumer marketing research company based in London.

Mr. Williams studied Computer Management at the Institute of Data Processing Management in London.

mike.williams@gartner.com

 ©1998 Dataquest

Overview of Research Programs

The European Semiconductor group divides its research focus into two main areas, namely industry and applications.

The industry side of the group focuses on the following:

- Semiconductor product market research (memories, microcomponents, ASICs and so on)
- Vendor analysis
- European geopolitical issues (trade, tariffs, investment and so on)
- Semiconductor technology trends
- Purchasing issues and trends (what the customer thinks and does)
- The EDA market
- Eastern European devices and applications markets

The applications side of the group deals with electronic applications that use semiconductors and other electronic components and subassemblies.

The group provides four research programs in total. There are two "industry" programs and two "applications" programs, as follows:

- Industry
  - Semiconductors Europe (SEMI-EU)
  - Electronic Design Automation Worldwide (CEDA-WW)
- Applications
  - Semiconductor Application Markets Europe (SAMM-EU)
  - Electronic Equipment Production Monitor Europe (SAPM-EU)

Following you will find a description of the research contents and scope of each of these programs.

Semiconductors Europe

Dataquest's Semiconductors Europe program provides clients with quantitative and qualitative analysis of product, regional and technology trends in EMEA. Dataquest maintains databases containing information about company market shares, capital and R&D investment and manufacturing capability, to which clients have access through this service. Vendor strategies are monitored closely. The program also follows and analyzes the many geopolitical issues affecting both vendors and users of semiconductors in EMEA, and the impact of these factors is reflected in Dataquest's product and regional market forecasts.

Topical Coverage

Topics covered by this program include the following:

- Competitive dynamics
- Investment
- Industry trends
- Purchasing trends

 ©1998 Dataquest

Regional Coverage

Market estimates and forecasts are provided for the following countries or regions:

- Africa
- Benelux
- Eastern Europe
- France
- Germany
- Italy
- Middle East
- Nordic
- Rest of Western Europe
- United Kingdom and Ireland

Product Coverage

Market share estimates and forecasts are provided for the following product categories:

- ASICs—Gate arrays, programmable logic devices, cell-based ICs, custom ICs
- Memories—DRAM, SRAM, EPROM, EEPROM, flash, ROM
- Microcomponents—Microprocessors, microcontrollers, microperipherals, digital signal processors
- Analog and mixed-signal ICs
- Discretes
- Optocomponents

Key Databases

This program maintains the following databases to monitor and analyze Europe:

- EMEA semiconductor fabrication database
- Capital and R&D investment by European vendor
- Major OEMs' annual semiconductor spend
- EMEA semiconductor market shares by vendor
- EMEA semiconductor forecasts by product and region

The Analysts

The program manager for Semiconductors Europe is Joe D'Elia. Analysts researching this program along with Joe are Richard Gordon, Edmund Gemmell and Jim Tully.

Semiconductor Application Markets Europe

Dataquest's Semiconductor Application Markets Europe program is the leading information source for market statistics and strategic analysis of the European semiconductor market. The program provides demand-side information and decision support on electronic equipment production and design trends. It has been developed to aid the marketing and strategic planning of semiconductor and other electronic component manufacturers, and it provides market estimates and forecasts of European electronic equipment production and semiconductor consumption.

 ©1998 Dataquest

Primary Application Coverage

Detailed forecast and trend analysis is provided for the following:

- Electronic data processing—Including PCs, computer peripherals, storage devices and IC cards
- Communications—Central office switches, telephone handsets, data communications equipment and mobile/cellular communications
- Consumer—Including analog and digital audio and video systems, set-top boxes, personal electronics and domestic appliances
- Automotive—Including in-car entertainment systems, body control and vehicle control electronics, driver information (including navigation), power train, and safety and convenience systems

Market Overview

Market estimates and forecasts are provided for the following six basic application markets:

- Electronic data processing
- Communications
- Consumer
- Industrial
- Military and civil aerospace
- Automotive

Key Market Statistics

The following statistics are included:

- Electronic equipment production forecasts in units and revenue
- Semiconductor market forecasts by application
- European country market forecasts by application
- Vendor market shares by application
- High-volume electronic equipment unit production forecasts

Regional Coverage

Market estimates and forecasts are provided for the following countries or regions:

- Benelux
- France
- Germany
- Italy
- Nordic
- United Kingdom and Ireland

The Analysts

The program manager for Semiconductor Application Markets Europe is David Moorhouse. Analysts researching this program along with David are Mike Williams, Andrew Phillips and Paul O'Donovan.

 ©1998 Dataquest

Electronic Equipment Production Monitor Europe

Dataquest's Electronic Equipment Production Monitor Europe program is the leading source of information on component content trends of new and/or high-volume electronics systems manufactured in Europe. It is intended to be of interest to all vendors of electronic components, from semiconductors to subassemblies. The core research activity involves the disassembly, or "teardown," of key electronics products. Once dismantled, a bill-of-materials listing is made and component prices estimated for each product. A report analyzing the content of the product is then produced, and it includes: a complete listing of all the electronic components found, their sources, quantities per system and estimated prices; commentary on future trends in component usage within the product being analyzed; and, on behalf of the OEM/designer, the identification of scope for cost savings through redesign, using knowledge of emerging component solutions and methods.

Primary Application Coverage

The program will provide analysis of the following 34 key items of electronic equipment:

Electronic Data Processing	**Communications**
Optical disk drives	Analog cellular telephones
Page (laser) printers	Analog cordless telephones
PC motherboards	Answering machines
PCs	Central office line cards
Rigid disk drives	Corded telephones
Serial printers	Digital cellular telephones
Smart cards	Digital cordless telephones
Workstations	Fax machines
	LAN cards
Consumer	Modems
Analog camcorders	Pagers
Analog set-top boxes	PBX line cards
Color TVs	
Digital camcorders	**Automotive**
Digital set-top boxes	Airbag systems
Digital still cameras	Antilock braking systems
DVD players	Engine control units
Personal stereos	Navigation systems
VCRs/VTRs	Stereo systems

Market Statistics

The program maintains the following market statistics databases:

- High-volume European electronic equipment production—Provides history and a five-year forecast of European electronic systems unit production for the 34 products listed, with their factory production ASP and total production value.
- Major European electronic equipment manufacturing locations—Identifies by product, region and company the locations of major European manufacturers of the 34 items of electronic equipment listed. This database, updated annually, is an indispensable marketing tool providing the client with vital information about key potential customers.

©1998 Dataquest

The Analysts

The program manager for Electronic Equipment Production Monitor Europe is David Moorhouse. Analysts researching this program along with David are Andrew Phillips, Mike Williams and Paul O'Donovan.

Electronic Design Automation Worldwide

Dataquest's Electronic Design Automation Worldwide program provides detailed analysis of the industry trends, players, products and end-user issues that drive the market for EDA applications and tools. The program covers the three major EDA application areas—IC layout, electronic CAE and PCB/MCM/hybrid layout tools—and provides the most reliable worldwide market size, market share and market forecast estimates available. The program also provides data, advice and analysis to help clients make informed planning decisions. Publications include a mix of analytical articles, weekly news bulletins and event-driven faxes. Periodic briefings and conferences bring clients together with analysts to share insights and opinions.

Key Topics

Topics covered by this program include the following:

- ES level (ESDA)—Virtual prototypes, hardware and software codesign
- RTL design—VHDL and verilog, synthesis, design for test
- Gate-level design—Schematic capture, analog design, analysis tools
- IC CAD—Physical verification, floor planning, FPGA fitters, IC layout
- PCB design—PCB, MCM and hybrid place and route
- Miscellaneous—Accelerators and emulators, libraries, interoperability tools

Regional Coverage

The program covers the following countries or regions:

- Asia/Pacific (by country)
- Europe (by country)
- Japan
- North America
- Rest of World
- Worldwide

Standard Data Metrics

The following data metrics are covered:

- Total factory, hardware and software revenue
- Service revenue
- Revenue by operating system
- Software shipments
- Revenue by industry sector
- 37 different subapplications by end use and by platform

The Analysts

The program manager in Europe for Electronic Design Automation Worldwide is Jim Tully.

Dataquest Document Checklist
October - December 1998

Dear Dataquest Client,

This checklist is mailed to you on a quarterly basis to help you verify that you have received every printed document that has been produced by this research program during the quarter. Please review this checklist against the contents of your program binder. If you never received any of the documents listed, let us know and we'll be glad to send you a replacement copy.

Semiconductors Japan—SEMI-JA

Insight

SEMICONDUCTORS JAPAN

Dataquest's Semiconductors Japan program provides quantitative and qualitative information on the products, markets, technologies, and companies driving the Japanese semiconductor industry. This program provides a comprehensive view of all aspects of the industry, including manufacturing and consumption by application market.

Key Business Issues

Want to learn more about Dataquest?

Please visit our Internet web site at ***www.dataquest.com***

The Semiconductors Japan program provides advice and analysis to help clients make successful business decisions. Publications include a mix of analytical articles, weekly news bulletins and event-driven faxes, focused reports, and timely market statistics published on a regular schedule throughout the year. Briefings and conferences bring clients together with analysts to share insights and opinions.

Key semiconductor issues covered throughout the year in our publications and briefings will include:

- Will Japan continue to lag behind other regions in semiconductor market growth?
- How will digitization of consumer equipment contribute to Japanese semiconductor consumption?
- Who among the users are increasing semiconductor purchase in Japan?
- Will the wafer industry benefit from SLI?
- Will the soft DRAM market continue to persist in the Japanese market?
- Will the arrival of SLI pose an opportunity or a threat to Japanese semiconductor companies?
- Will Japanese semiconductor companies lead in the race for 300 mm wafer fab construction?
- Is foundry going to be an alternative in Japanese companies' strategies?
- Will Japanese companies increase capital spending within Japan, or overseas?

Market Coverage

The program provides timely strategic viewpoints related to semiconductor production and consumption in Japan.

Product Segmentation

This program covers the following product markets:

- ASIC and standard logic
- MOS memories
- MOS microcomponents
- Analog ICs
- Discretes
- Optoelectronics

Geographic Coverage

- Japan
- Worldwide

Application Coverage

Market estimates and forecasts are provided for key applications:

- Data processing
- Communications
- Industrial
- Consumer
- Military/aerospace
- Transportation

Market Statistics

Dataquest provides the following market statistics and growth projections:

- Japanese semiconductor market share estimates
- Detailed Japanese semiconductor market forecast by product
- Electronic equipment production in Japan
- Semiconductor consumption by application in Japan
- Japanese semiconductor industry monitors:
  - Wafer fabrication facilities
  - R&D and capital spending trends
  - Strategic alliances
- Worldwide consumption forecasts by region

WHAT YOU WILL RECEIVE AS A CLIENT

SEMICONDUCTORS JAPAN

Perspectives

Dataquest Perspectives: These research newsletters provide analysis and commentary on key technologies, companies, products, market opportunities, events, user and distribution trends, and strategic issues in the industry. Topical in nature, these documents provide timely information and advice to help you stay ahead of your competition.
Published Monthly Throughout 1998

Market Trends

Market Trends Report—Japanese Semiconductor Market: This comprehensive report analyzes key factors driving the growth of the major segments of the semiconductor industry, including market share estimates for key players and five-year forecasts for major product segments. ***Q3 1998***

Worldwide Semiconductor Forecast: Five-year revenue forecasts for the global semiconductor market by region. ***Q2 and Q4 1998***

Electronic News

News and analysis delivered directly to your desktop

DQ Monday Report: Weekly news and commentary on semiconductor industry events and issues with a monthly snapshot of semiconductor pricing for 25 key semiconductors in six regions. ***Available Weekly via Internet E-mail***

Dataquest Alerts: These fax bulletins provide analysis of fast-breaking news, events, or announcements in the Japanese semiconductor industry, as they unfold. ***Event-Driven Faxes***

Inquiry Support

Personalized inquiry support is a primary component of your research subscription. You have direct access to experienced analysts who can provide fast answers to fact and data questions, as well as advice tailored to the needs of your business.

Information Resource Centers

Clients may visit Dataquest information resource libraries worldwide to perform their own research using our extensive print and online resource collections.

Market Statistics

Japanese Semiconductor Market Share: Market share by company for total semiconductors; total ICs; bipolar digital, memories, logic; MOS digital, memories, microcomponents, logic; analog ICs; discretes; and optoelectronic semiconductors. ***Q2 1998***

Japanese Semiconductor Consumption by Application Market: Five-year revenue forecasts of the semiconductor-value composition of various categories of electronic equipment, derived by applying I/O ratios to the equipment production forecast estimates. ***Q2 and Q4 1998***

Japanese Electronic Equipment Production Forecast: Five-year forecasts for six categories and 21 subcategories of electronic equipment, providing a demand-side view of the Japanese semiconductor market. ***Q2 and Q4 1998***

Japanese Wafer Fabrication Facilities: Pilot and production fab lines by company, location, fab name, products produced, process technology, minimum linewidth, wafer diameter, and estimated wafer capacity. ***Q4 1998***

Reports

Japanese Semiconductor Strategic Alliances: This report summarizes the new alliances created during the prior year and compares these statistics with those of previous years. ***Q1 1998***

Focus Report: A special report focusing on a hot topic in the Japanese semiconductor market will provide you with essential information to support your tactical and strategic planning needs. ***Q3 1998***

Competitive Trends: Details of the organizational structure, financial status, product portfolio strengths/weaknesses, and strategic directions of major Japanese semiconductor vendors will be provided in a comprehensive report on competitive semiconductor trends in Japan. ***Q4 1998***

Conferences and Briefings

Semiconductors '98, this year's annual Semiconductor Group conference, will be held in San Diego, California on October 19-21, 1998. For more information, contact GartnerGroup Events in Tokyo at +81-3-3481-3670, or in the United States at 1-800-778-1997. Conference seat is priced separately.

Binder Request — FaxBack

To: GartnerGroup Production Department
City: Stamford, Connecticut
Country: U.S.A
FAX #: + 203-975-9029

If you require a replacement Dataquest binder, please fill out this form and return it to the fax number listed above. Your binder will be shipped to you promptly.

Thank you for helping us to serve you better.

Name of Dataquest research program for which you need a binder:
(Must be filled in so that we will know what size binder to mail you.)

____

Your Name: ______________________________________

Company: ______________________________________

Street Address: __________________________________

Stamford, CT, 10212, USA

Binder Update Instructions

Attached you will find the 1998 binder spine, tabs, and marketing materials/datasheet for the Dataquest research program to wbich you currently subscribe. To prepare your current binder to receive the new research publications we will send you during 1998, please follow these instructions:

Move 1997 materials to storage:

1. Remove the 1997 binder spine.
2. Open your 1997 binder and remove all contents, including tabs.
3. Move these publications into storage, as desired.

Prepare binder to receive 1998 publications:

1. Insert the new 1998 spine.
2. Insert the new tabs into binder.
3. Place the program datasheet and marketing materials into the front binder pocket, for future reference.
4. As you receive your 1998 Dataquest Perspectives, Market Statistics books, and special reports from this program throughout the year, use this binder to file and organize these publications, as usual.

PLEASE NOTE: If for any reason you require a new binder (your old one is damaged or lost), please use the attached ***FaxBack*** form to order a new one. Just fill it out, fax it to the number listed on the form, and we will be happy to send you a replacement binder.

Dataquest

January 1998

Dear Dataquest Client,

Best wishes for the festive season and welcome to 1998! This is destined to be a year of exciting changes in the IT industry, and we are looking forward to working closely with you to make it your best year ever.

Like the industries we track, Dataquest is always evolving to keep pace with the times. I am writing to inform you of some of the important changes we have made to better serve you — our valued client — in 1998.

First, you will notice a change to our binder distribution procedures this year —

It has been our policy in past years to provide clients with new research program binders every January. However, because more and more of our clients are moving to electronic delivery via our web site and CD-ROM, binders are becoming less important for filing and retrieving our research publications than in the past. In recognition of this trend, beginning this year we are moving to an "evergreen" binder which is reused year upon year. This means that you will use your current binder to house your 1998 DQ document collection. A binder spine, tab dividers, and instructions for updating your binder are provided in this mailing.

Second, please look for your "DQ Archive CD-ROM" in January * —

Toward the end of January, you will receive your *DQ Archive CD-ROM.* This customized tool — created just for you — will house electronic copies of documents published through December 1997 for all of the research programs to which you subscribed during that year. We believe that this CD-ROM will serve as a handy electronic archive whenever you need to look back at a document from 1997, and will enhance your productivity in using past issues of Dataquest's market research publications. (* Current clients of our CD-ROM will receive this archive CD as part of the normal, monthly CD-ROM mailing.)

Third, we are improving our publishing system in 1998 —

I am pleased to announce that we will be moving to continuous publishing during 1998 — a tremendous step forward for Dataquest. As our research documents are released from editing, this automated publishing system converts them to web, CD-ROM, and paper formats with only minor intervention required by our Interactive Services staff. The benefit to you is that documents are published more quickly and efficiently in hard copy format, and reach the web site more rapidly.

Lastly, we will be introducing our new brand identity —"Gartner Market Dynamics"—
All companies in the GartnerGroup family will reflect a new corporate brand identity, which will roll out over the course of 1998. We will continue to be called ***Dataquest,*** but you will also see us referred to as a part of Gartner Market Dynamics, the market research arm of Gartner's Advisory Services. **You will see this branding reflected as** we update our letterhead and marketing collaterals during the year.

So, you can see that 1998 is going to be a year of changes for Dataquest. By streamlining operations and introducing you to electronic delivery via the *DQ Archive CD-ROM*, we are positioning Dataquest to better serve you — now and in the future.

As always, I welcome your comments and feedback on Dataquest directions.

Sincerely,

R. And Holtvedt

R. Andrew Holtvedt
President of Dataquest and Senior Vice President, GartnerGroup

X

Perspective

Semiconductors Japan
Market Analysis

Restructuring Goes On at Japanese Semiconductor Fabs

Abstract: *In 1998, industry reorganization has emerged as a trend against the backdrop of an unprecedented downturn in the worldwide semiconductor industry. A variety of factors, including the protracted semiconductor slowdown, weakening profits, changing dynamics for product-specific markets, and system-level integration (SLI) efforts, are forcing chip makers to reconsider their businesses. In this Perspective, Dataquest reviews fab construction trends among the Japanese manufacturers based on the results of Dataquest's fall 1998 semiconductor fab survey. Please note that we are still in the process of finalizing the results of this survey on a global basis, and therefore, our final release of data may vary slightly from what is presented in this Perspective.*
By Yoshihiro Shimada

Overview of 1998 Fab Survey

Three main observations were made from the results of the 1998 fab survey of Japanese semiconductor manufacturers. They are as follows:

- There are no announced plans for building new fabs.
- DRAM fabs are being substantially reorganized.
- Overseas fabs are being substantially reorganized.

Some of these moves have already been announced by chip makers. Moreover, these results are reasonably predictable considering the current state of supply and demand and the earnings environment. However, a comparison with past low points in the market cycle indicates that more significant steps are being taken this time around.

The survey results for Japanese manufacturers are shown in Figures 1 and 2. Note that the numbers provide a comparison with the situation at the end of 1997.

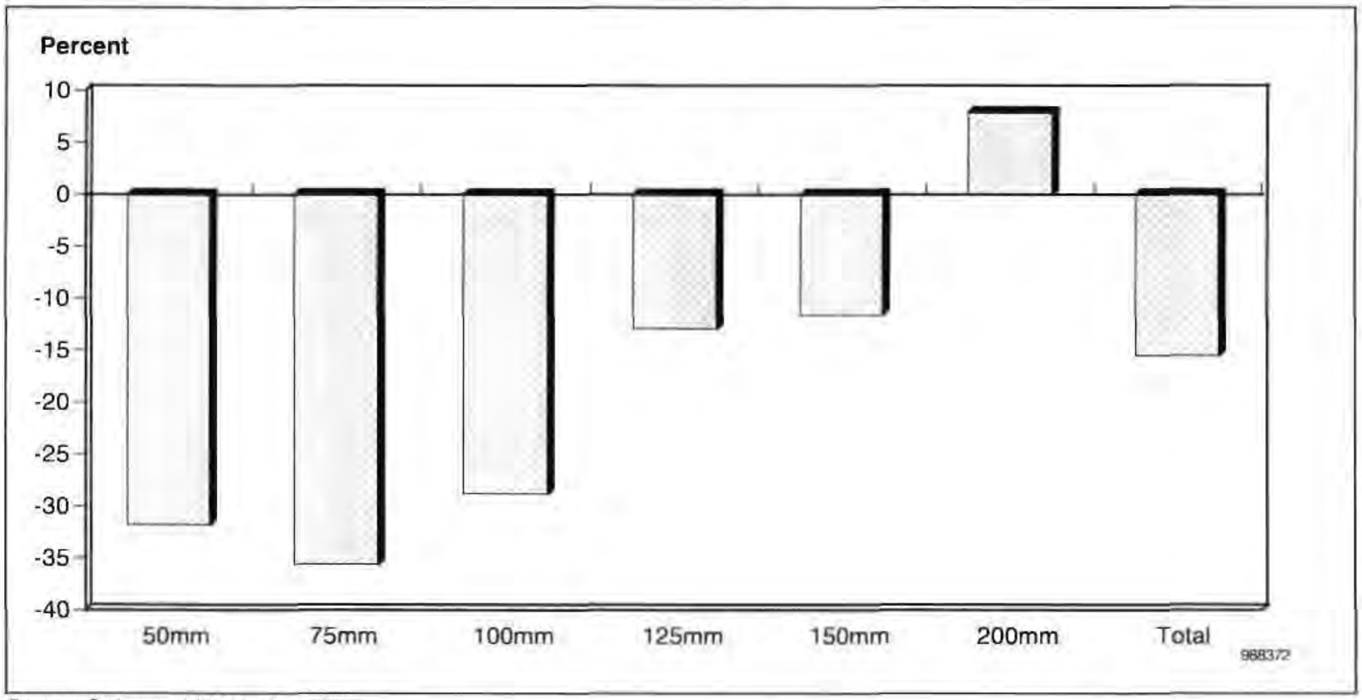
FILE COPY:
MARIA VALENZUELA

Dataquest
Program: Semiconductors Japan
Product Code: SEMI-JA-DP-9812
Publication Date: January 4, 1999
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

The key points are listed below:

- Among the wafer processing capacity categories, the 50mm to 100mm segments contracted substantially, the 125mm and 150mm segments contracted slightly, and the 200mm segment rose.
- The 0.35-micron process is becoming the mainstay design rule for MOS digital.
- There are 0.25-micron fabs being launched.
- Some chip makers have 300mm fab pilot line plans, but volume production line plans are undetermined.

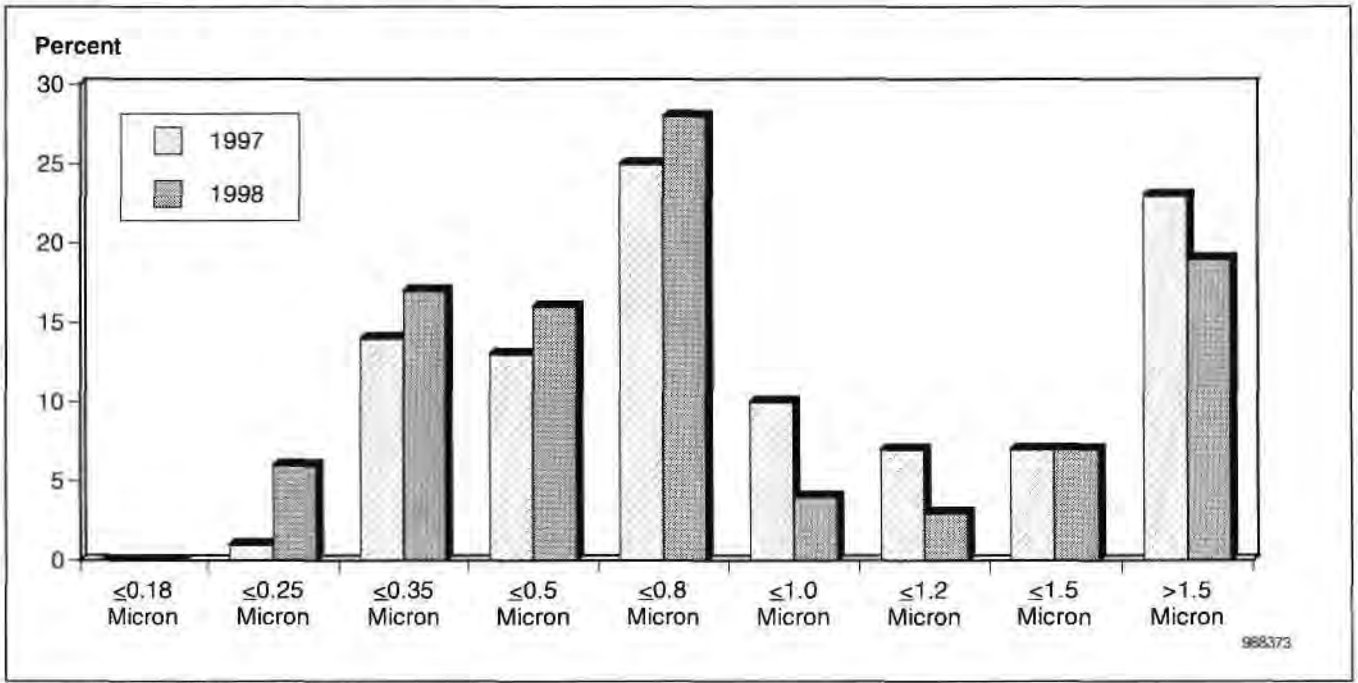
Figure 1
1998 Japanese Manufacturers' Wafer Processing Capacity by Wafer Size (Change over the Previous Year)



Source: Dataquest (December 1998)

 ©1999 Dataquest

Figure 2
Japanese Manufacturers' Production Capacity by Operating Minimum Geometry (Change over the Previous Year)



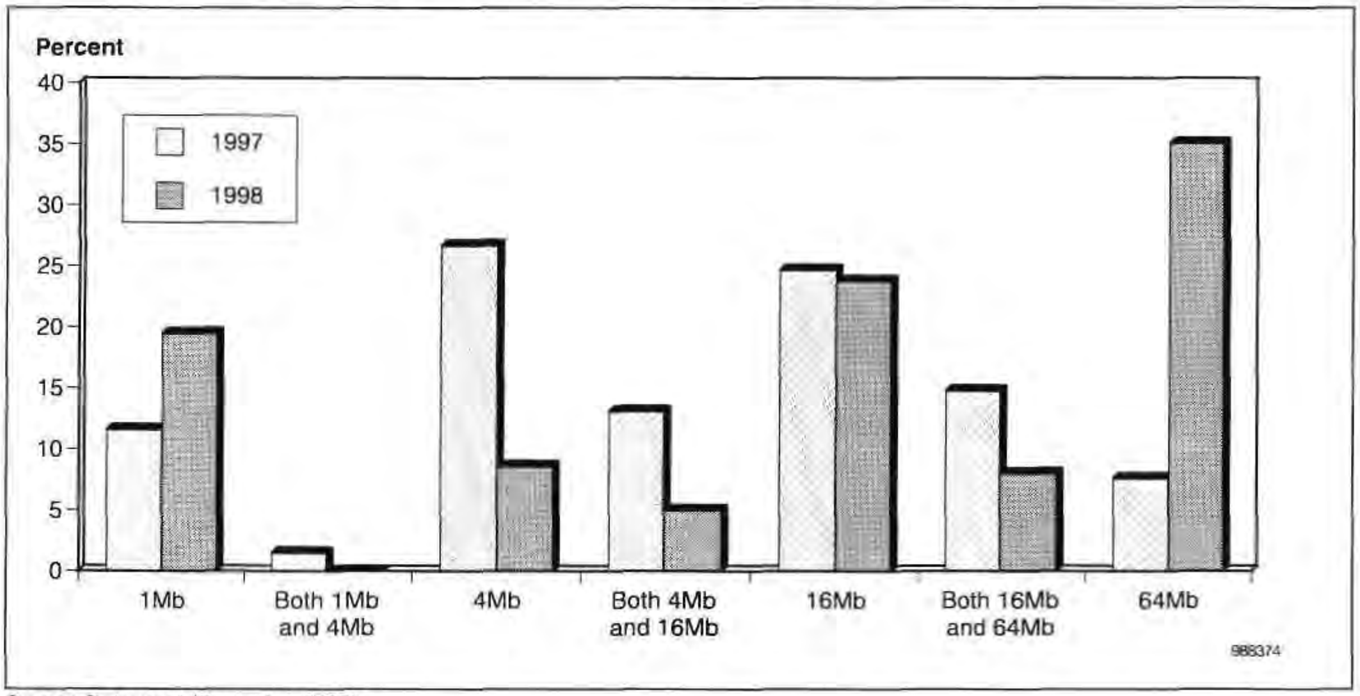
Source: Dataquest (December 1998)

Figure 3 shows the state of DRAM production capacity by memory size for Japanese chip makers. The 200mm fabs designed primarily for DRAMs began operation in 1994 and continued to be built to keep up with the sharp increases in semiconductor demand from the PC boom. Facility launches were equally harried, with only six months between the start of volume production and escalation to maximum equipment output levels. Unable to apply the brakes to this rapid expansion of wafer processing capacity, new facility launches continued even after the DRAM market conditions reversed their course from the end of 1995. However, by 1997, new fab construction had ended, and no new line launches were reported for 1998.

Chip shrink techniques, which have gained rapid acceptance by chip makers as a way of improving profitability, dramatically increase the number of devices obtained from a fixed amount of wafer processing capacity and have worked against the dissolution of excess production capacity. Even though this makes it possible to achieve production capacity expansion while delaying the construction of new 200mm fabs, Dataquest expects continued investment in 200mm fabs by the semiconductor industry as a whole; this is because investment in 64Mb-and-later-generation, high-speed DRAM facilities is being given priority, and the useful life of 200mm fabs is being extended by a move to push back the timing of a switch to 300mm fabs. The question is whether Japanese chip makers will make these investments on their own or whether they will utilize resources outside of their own operations.

 ©1999 Dataquest

Figure 3
Japanese Manufacturers' DRAM Production Capacity by Memory Size



Source: Dataquest (December 1998)

Despite the shift for MOS digital devices to 200mm fabs, 150mm fab facilities are relatively stable with support from the shift by analog 100mm and 125mm fabs. Dataquest's wafer consumption forecast expects just a slight decline in worldwide 150mm wafer consumption, and we believe that 1998 fab trends are in line with this forecast. 100mm and 125mm fabs were operating through the mid-1990s to fill analog and discrete device demand, but the transition to larger-diameter wafers began with the wafer shortages experienced during the 1994-to-1995 time period. Meanwhile, even though investments to expand fab capacity for MOS digital devices are on hold, investments in fabs to satisfy analog device requirements have continued. Specifically, these investments are aimed at responding to high-growth products such as mixed-signal ICs, power devices, and high-frequency devices, as well as to growing demand for linear ICs, which contain standard analog devices.

Trends by Product Type

Reviewing the situation by product type, it is evident that the number of DRAM-dedicated fabs has dropped sharply. Even when adding fabs that combine DRAMs with other devices, it is clear that the DRAM presence is declining. We believe this is happening for the following reasons:

- Even though volume demand is strong, chip shrink techniques enable production volume increases without expanding wafer processing capacity.

 ©1999 Dataquest

- Chip maker fab investments are being reduced by utilizing external resources such as foundries and OEMs.
- Acceleration of the chip shrink trend is making older-generation fabs outdated and unable to compete.
- There is already adequate capacity for other device types that might be used as a conversion alternative or for facility sharing.

As things currently stand, the primary focus in DRAM capacity strategies is on increasing production volumes through chip shrink techniques, and new investments are dominated by facility upgrades to accomplish this. Therefore, DRAM fab investments in 1998 are dedicated mainly to 0.18-micron design rule capabilities, moving forward with greater precision. Leading chip makers expect to have prototypes using the 0.18-micron process at the end of this year and intend to embark on volume production in 1999.

Logic fabs are also increasing design rule precision to 0.25 micron, and investments in 0.18-micron facilities are beginning to be made for system-level integration (SLI) devices. Looking at process technology line widths, logic fabs have caught up with DRAM fabs at the 0.25-micron mark. Furthermore, the facility investment burden for logic fabs is rising in order to introduce planar technology required for multilayer logic devices and process integration to deal with embedded memory and analog function elements.

This survey has confirmed the development of two distinct types of logic fabs. One is an application-specific standard products (ASSP)-oriented fab, and the other is a microcontroller (MCU)- and ASIC-oriented fab. For the former type, the main focus is on reducing costs by enhancing productivity, and for the latter type, productivity improvements are being accomplished by stabilizing yields with process integration. Considering the product technology and production technique, the expression "microcomponent core ASIC" can be applied.

These product-specific trends are creating clear distinctions among the fab construction investments of Japanese chip makers. Naturally, the restrictions on capital spending resources vary by company, and differences in earnings structures also produce differences in capital investment approaches. However, capital spending investments ultimately are guided by product strategies. Dataquest expects to see differences in the capital-to-application capital spending investment stances having a significant impact on the positioning of Japan's chip makers.

Capital Investments

Dataquest is currently in the process of conducting a survey on capital investments by chip makers, and it appears that changes in capital investment levels are linked to the fab survey results. We will report on the details in a separate document, but the gist of it is that leading chip makers are significantly reducing their investment levels.

 ©1999 Dataquest

The reductions in capital investments during 1998 are most prominent in the area of production-expansion investments primarily for DRAMs. Taking a slightly different angle, the downward trend is steepest for overseas plants (see Table 1). During the DRAM boom, chip makers moved aggressively to establish new overseas plants. However, under the current DRAM recession conditions, the impetus to secure overseas production capacity has subsided considerably as chip makers focused on improving the operating rates at domestic plants and on reducing the foreign exchange risk from yen depreciation. Also, because the chip makers are giving priority to the introduction of chip shrink techniques at domestic plants, in cases where the overseas plants are joint ventures or where production items are jointly developed, Dataquest believes that overseas plants will have considerable trouble staying competitive.

Table 1
Japanese Manufacturers' Overseas Plant Trends

Company Name	Fab Name	Date of Change	Prior to the Change	After the Change
Oki Electric	Oregon	September 1998	Back-end fab in operation	Back-end fab closed
Hitachi (joint venture with TI)	TwinStar	March 1998	16Mb DRAM	Hitachi's share sold to TI (afterward, TI sold the whole share to Micron Technology)
Hitachi	Irving	June 1998	4Mb DRAM, MCU	Fab closed
Fujitsu	Dahrum	December 1998	16Mb DRAM	Fab closed
Matsushita Electronic Industries	Matsushita Semiconductors America (MASCA)	December 1998	New 64Mb fab, suspension of 4Mb fab, continuation of 4/8-bit MCU fab	Operations halted
Mitsubishi Electric	Aachen	Early 1999	16Mb DRAM	Product types changed (embedded DRAM, SRAM, flash memory)
Mitsubishi Electric	Raleigh	March 1998	4Mb DRAM	Wafer fab stopped, packaging continued
Mitsubishi Electric	Raleigh	November 1998	Discrete assembly and test, memory module assembly	Packaging stopped (capabilities moved to Nagano packaging facility)

Source: Dataquest (December 1998)

At overseas plants where older-generation DRAM fabs are being converted to logic and analog device operations, it is becoming increasingly difficult to offer the functionality that customers demand as logic products rely more and more on advanced technologies. The value of these facilities has largely vanished as the benefits of supplying products that use existing technologies at a low cost and free of foreign exchange risk have diminished. Further, countries and regional governments that showed an active interest in attracting semiconductor plants with preferential measures during the strong

©1999 Dataquest

years are not wooing additional investments; this is because a larger number of plants require infrastructure upgrades, and tax revenue is down from the poor earnings performance.

Under these circumstances, there has been a string of overseas plant closures and freezes on additional investments. These appear to be appropriate business decisions for the current situation. However, a longer-term view shows a pattern of extremes in Japanese chip makers' overseas investments, with extremely aggressive investment during the good years and retreat and withdrawal strategies during the bad years. In fact, the passive posture of the Japanese chip makers in the early 1990s, following the rise in overseas plant openings in the latter half of the 1980s, can be cited as a factor in their slow start in the semiconductor boom, which materialized initially in the overseas markets. If the overseas plant strategies of Japanese chip makers are on the retreat merely as a by-product of a cutback in total capital investment levels, these companies run the same risk once again of missing future opportunities.

Dataquest's spring survey forecast a 20 percent reduction in capital investments by Japanese chip makers in 1998 compared to the previous year, but it appears that the actual rate of decline will exceed this level. This larger-than-expected decline in capital investments is a combination of large-scale cutbacks through the postponement of new fab investments and microadjustments to existing fab upgrade and production-expansion investments. The relative share of investment funds going to the packaging process is rising as new test equipment is introduced to handle the growing diversity in package types and higher device speeds. However, chip makers are working to reduce gross unit levels, the basis for determining investment amounts, by enhancing yields and thereby avoiding an excessive rise in investment costs, as has happened with the fab process.

The motivation to limit capital investment is twofold: restrictions on investment resources and a move to stem excess supply capacity. However, the real question is whether chip makers have lost a sense of direction in the industry's so-called focus on "system LSIs." Not only are chip makers unable to determine what facilities are necessary, how to best link products and technology development, and other key strategic points, but they also appear to be having trouble defining an appropriate road map for their own fab operations. This suggests that once economic conditions recover, the chip makers will simply re-start the supply capacity expansion approach to competition.

A less simplistic readying of supply capacity requires a well-reasoned capital investment strategy, which includes the following:

- A strategic narrowing of business areas based on systematic marketing
- A narrowing of production items for company fabs and the selective use of external resources
- Development of a company structure that utilizes external resources

 ©1999 Dataquest

At the same time, these strategies also involve the following risks:

- Trouble commercializing products if appropriate customers cannot be secured, even if the application-specific narrowing of products is performed in advance at the development stage through systematic marketing
- The need to develop a structure for assessing and minimizing the costs of utilizing external resources

Japanese chip makers are currently in the process of cautiously, but steadily, expanding production consignment to outside companies. However, in cases where the consignments are not for integrated production from the fab to final testing, it is necessary to develop know-how to avoid overlapping tests and understand how to utilize foundry services.

It is difficult to define clear income levels for custom logic production, which cannot assume the high yield levels of classic memory device production. Also, real operating rates are falling because of multiple-lot and mixed-lot production. Thus, facility plans must be worked out using lower yield and operating rate assumptions. This is reminiscent of the generational shift in DRAM production when facilities were allocated on the basis of low yield rates, but yields surprised everyone by rising sharply and then combined with chip shrink techniques to cause excess supply.

Although increasingly complex business management is required for SLI opportunities, given our outlook that restrictions on investment resources will continue, chip makers will be forced to make decisions from the perspective of their total semiconductor business rather than planning capital investments at the individual product or business unit level.

Dataquest Perspective

Far from the initial expectation for a recovery in the world semiconductor market in 1998, conditions worsened, and the overall market contracted, making this a year of serious challenges for chip makers. Meanwhile, the 1999 outlook foresees a return to a path of recovery, and high growth at 20 percent annual levels is expected again in 2000 and 2001. However, this growth pace is just an average for the total semiconductor market. Dataquest expects to see the market split into two segments: chip makers who achieve high growth rates and those who only receive a minor boost. There are two reasons for this departure of fortunes. From the demand side, there are signs that the market is moving from system diversity to integrated systems, and the success of chip makers enjoying the benefits of the SLI era, which hinges on system support, depends largely on whether they can secure suitable customers. On the supply side, investment strategies currently crippled with a variety of restrictions will define the course of chip makers' potential capacities.

Price stabilization is revisiting the DRAM market, beginning with PC100 specification, high-speed devices, and talk of long-term agreements (LTAs) has returned after a long interlude. Meanwhile, in 1999, leading chip makers will prepare 0.15-micron facilities and gear themselves up for the next phase of market growth. Dataquest believes that under these circumstances, semiconductor companies' capital investments require both bold and refined judgment, which ensures that an overall balance in the business and appropriate investment timing are maintained.

Market Analysis

Silicon Wafer Market in Transition: Moderate Growth Is Expected for the Japanese Market

Abstract: *The silicon wafer market seemed to be in a stage of recovery during the first quarter of 1997. However, the market is staggering again, partly because of the sluggishness of the device market late in 1997 and partly because of reduced wafer consumption caused by the accelerated pace of chip shrinkage in DRAM production. Now, two more forces, the expected changes in regional wafer consumption patterns in the future and a delay in migration to the 300mm wafer process, are working against a market that faces significant changes and turning points. This Perspective analyzes the current state of the Japanese wafer market as well as Japanese suppliers and offers a future outlook for the market.*

By Takashi Ogawa and Clark Fuhs

World Trends in Silicon Wafer Consumption

FILE COPY:
MARIA VALENZUELA

According to Dataquest's survey, worldwide consumption of silicon wafers in 1997 increased 7 percent from the previous year to 4,014 million square inches (MSI). This is the result of some recovery seen between late 1996 and early 1997, which was partially offset by a decline that began late in the second half of 1997. At present, the market is losing the momentum that was gained from the temporary recovery. Among the major factors causing the downturn, chip shrinkage is particularly noteworthy. It was accelerated by DRAM suppliers that desperately needed to improve profitability under pressure from the market slump, resulting in a significant drop in wafer consumption.

During the 1Mb and 4Mb DRAM era, the rate of chip shrinkage between the first and final versions was estimated to be in the range of 50 to 60 percent. Since last year, however, DRAM suppliers have accelerated the pace, and 60 to 70 percent reduction has already been achieved in shrink versions of 16Mb

DRAM. For 64Mb DRAM, for which volume shipments began only last year, shrink versions have been developed over a shorter period of time by using the deep ultraviolet (DUV) technology. As a result, even under the optimistic scenario where bit growth is assumed to reach 60 to 70 percent between mid-1997 through the end of 1998, wafer consumption for DRAM production will remain almost unchanged on a quarterly basis.

Given the effect of the rapid pace of chip shrinkage and the slack device market as a whole, wafer consumption in 1998 is expected to expand at a meager 3 percent to 4,113 MSI, according to Dataquest's July forecast. Furthermore, if device demand continues to wither beyond the current forecast, the wafer market will likely experience negative growth. It is expected to make a rebound in 1999 when the device market will show a modest recovery, but full-fledged recovery will have to wait until 2000 as the crossover of DRAM generations (on a unit basis) is completed. The market will then record two-digit growth in 2000 and 2001. Dataquest predicts that silicon wafer consumption will expand at a compound annual growth rate (CAGR) of 9 percent between 1997 and 2003, reaching 6,825 MSI in 2003.

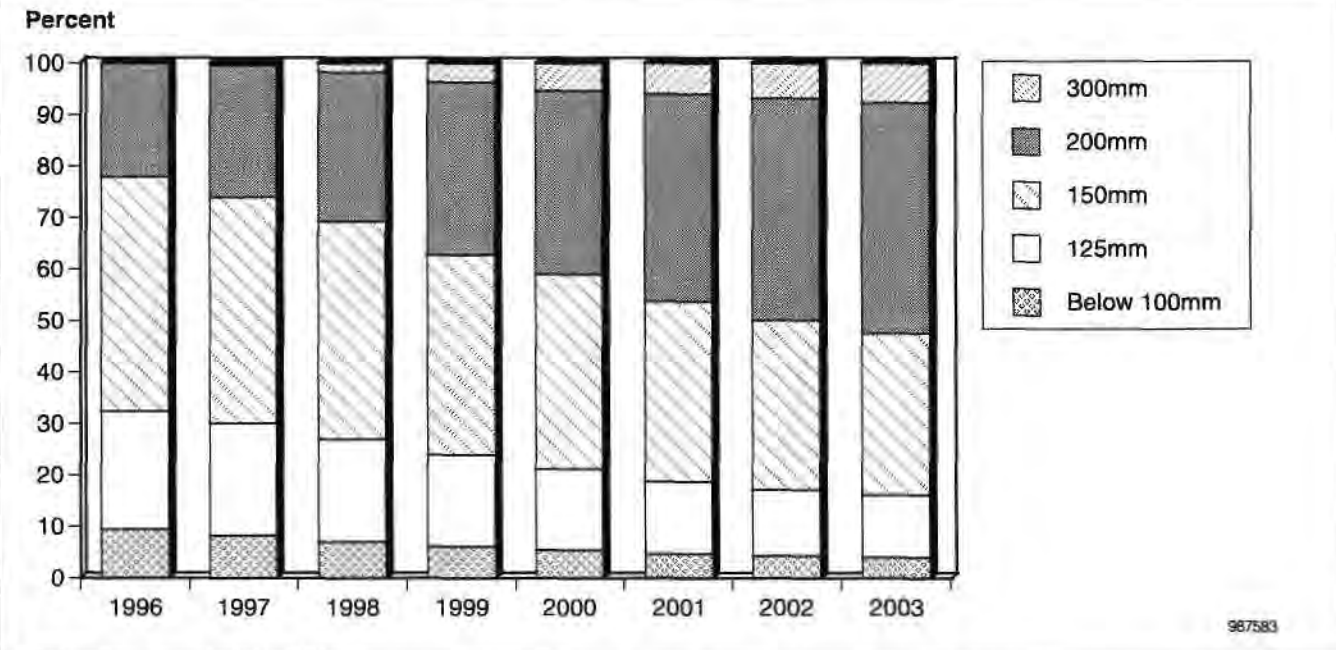
Japanese Trends in Silicon Wafer Consumption

In 1997, silicon wafer consumption in the Japanese market grew 2 percent to 1,527 MSI, reflecting its sensitivity to DRAM market conditions. Again, the sluggish DRAM market and the accelerated pace of chip shrinkage will continue to suppress wafer consumption in 1998. Although Dataquest expects, as of June 1998, that 1998 consumption will remain unchanged from 1997's growth rate of 2 percent, silicon wafer consumption may experience negative growth, depending on an actual recovery of DRAM demand in the second half of 1998. Recovery will occur in 2000 or afterward, accompanied by the revival of the DRAM market. In 2000, wafer consumption in Japan will reach 1,887 MSI, a 12 percent increase over consumption in 1999.

One of the notable characteristics of the Japanese wafer market is a high percentage of smaller-diameter wafers (150mm or less). This is evidenced by the 1997 distribution of water consumption by diameter: 75mm wafers accounting for 0.6 percent of total consumption in the market (on a wafer-area basis), 100mm accounting for 7.7 percent, 125mm accounting for 21.8 percent, 150mm accounting for 43.9 percent, and 200mm accounting for 25.6 percent (see Figure 1). Because Japanese semiconductor manufacturers have curtailed their capital spending in reaction to the murky market conditions in the past few years, the resulting modification or delay in the planned installation of 200mm fab lines will further delay the shift from 150mm to 200mm fabs in terms of percentage share of wafer consumption. In fact, if this trend of cautious investment continues to prevail in the industry, 200mm wafers will not become the mainstay of the Japanese market until 2001—a sharp contrast to the world market, where they will take over 150mm wafers in 1998.

 ©1998 Dataquest

Figure 1
Silicon Wafer Consumption by Wafer Size in Japan, 1996 to 2003



Source: Dataquest (November 1998)

Another important trend is the rapid growth of epitaxial wafer demand for 64Mb DRAM production, which is breaking away from the historical trend, where the Japanese market typically has been a relatively small consumer of epitaxial wafers, primarily using them for discrete and bipolar devices. According to Dataquest's survey, epitaxial wafer consumption for DRAM production (including R&D) jumped from 7.2 MSI to 56 MSI in 1997. Then, after a slowdown anticipated in 1998 because of the DRAM recession, it will grow at a CAGR of 13 percent between 1997 and 2003, amounting to 475 MSI in 2003. Thus, Japan will become the second-fastest-growing market for epitaxial wafers, following the Asia/Pacific market.

In the long run, growth in total wafer consumption in the Japanese market will turn into moderate growth for two reasons: continued investment cutbacks by Japanese semiconductor companies whose business is still highly DRAM-dependent and a decreased reliance on domestic production by Japanese companies as a result of increased procurement from foreign manufacturers through alliances. Dataquest predicts that the Japanese market will record a CAGR of 7 percent between 1997 and 2003, the lowest among four regions (Europe, Asia/Pacific, the Americas, and Japan), and it will lose share in the world wafer market in terms of consumption (see Figure 2).

Japanese Silicon Wafer Manufacturers: 1997 Market Review

Table 1 summarizes the world market share of Japanese silicon wafer suppliers in 1997 (on a revenue basis), and Table 2 lists their product focus. Share distribution in the world market has remained virtually unchanged during the past decade. In the world market, Shin-Etsu Handotai Co. Ltd. has maintained the leading position with a market share of 24 to 26 percent, and the next five companies, including non-Japanese, have generally stayed within the share range between 10 percent and 12 percent. Japanese companies control a dominant share in the world market. In 1997, they held a combined share of 63.8 percent, while U.S. companies held 15.5 percent, European companies held 13.3 percent, and Asia/Pacific companies held 7.4 percent. In particular, Japanese companies nearly monopolize the Japanese market with an outstanding 90.8 percent share.

Table 1
Japanese Silicon Wafer Makers' Market Share and Revenue in 1997

Maker	Revenue ($B)	Market Share (%)	Market Share Gain or Loss (%)
Shin-Etsu	1.65	23.4	-0.3
Sumitomo Sitix	0.96	13.5	0.7
Mitsubishi Materials	0.75	10.6	1.3
Komatsu Electronic Metals	0.61	8.7	-0.2
Toshiba Ceramics	0.35	4.9	-0.8
NSC Electron	0.16	2.3	0.2

Source: Dataquest (November 1998)

Table 2
Japanese Silicon Wafer Makers' Product Focus in 1997

Maker	DRAM	CMOS Logic Epitaxial	Power/Discrete Epitaxial
Shin-Etsu	X	Emerging	-
Sumitomo Sitix	-	X	X
Mitsubishi Materials	-	X	X
Komatsu Electronic Metals	Small	-	X
Toshiba Ceramics	X	-	X
NSC Electron	X	-	-

Note: The "X" indicates the products that each company makes.
Source: Dataquest (November 1998)

Shin-Etsu, controlling the dominant share, is a key supplier of silicon wafers to DRAM manufacturers, together with MEMC Electronic Materials Inc. (MEMC). Because Shin-Etsu gains most of its revenue from 200mm wafers in the DRAM market, it was directly hit by the slow market in 1997, which was accompanied by wafer price erosion, and its market share fell slightly (0.3 percentage points) from the previous year. Sumitomo Sitix Corporation, which recently merged with Sumitomo Metal Industries Ltd., is a major player in the epitaxial wafer market for CMOS logic applications. It is also a major supplier to Intel Corporation and maintains first place in the U.S. epitaxial market with a 22.7 percent share. The company is now boosting share in the power and discrete IC market.

Mitsubishi Material Silicon Corporation (MSIL) is another important supplier in the epitaxial wafer market for power and discrete devices. Although the market is still small, together with sales in epitaxial wafers for DRAM, MSIL registered strong growth in the Americas market in 1997, a 19.1 percent increase over the previous year, and increased its share by 1.3 percentage points. In the future, the company expects business expansion in the epitaxial wafer market for CMOS logic applications, to follow in the footsteps of Shin-Etsu. Komatsu Electronic Metals Co. Ltd. is a secondary supplier to the DRAM market and the major supplier in the power/discrete device segment. In 1997, it demonstrated healthy annual growth of 19 percent in the epitaxial

 ©1998 Dataquest

market but lost revenue in the polished wafer market by 13.6 percent, resulting in a 0.2 percentage point decline in its overall market share.

Toshiba Ceramics Co. Ltd. supplies epitaxial wafers for power and discrete devices and DRAM wafers, but the latter is limited to several customers, as is also the case with NSC Electron Corporation. Toshiba Ceramics now is focusing on hydrogen annealed, low-defect wafers and steadily is improving product quality in an attempt to expand its share. Finally, Showa Denko KK announced that it would withdraw from the silicon market entirely in fiscal year 1998.

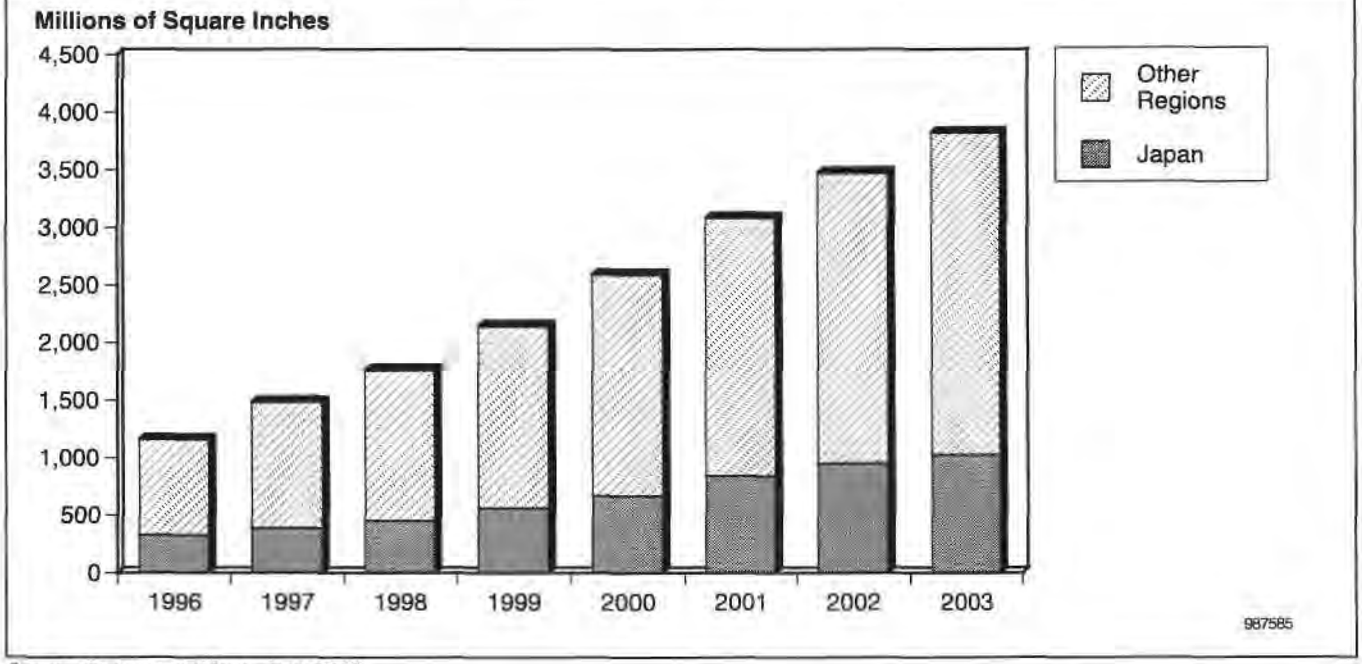
Global Trends in 200mm Wafer Consumption

In 1997, world consumption of 200mm wafers grew 26 percent to 1,485 MSI. In 1998, however, consumption inevitably will be affected by increased cases of phased-down or postponed construction of 200mm fab lines and a slowdown in consumption by the DRAM industry because of the chip shrinkage boom. In June 1998, Dataquest predicted that the 200mm wafer market would expand at a CAGR of 17 percent between 1997 and 2003, reaching 3,824 MSI in 2003 (see Figure 3). However, because the average monthly shipments during the first half of 1998 remained at around 2.6 million wafers, the short-term results may fall below the forecast. Given the many uncertainties about new fab construction plans—which are heavily dependent on the general economy, the timing of the much-awaited DRAM market recovery, and the development of shrink versions—consistent analysis and vigilant watching are essential. Dataquest expects that essentially all of the reduced levels of wafer consumption for 1998 will take place in the 200mm wafer segment.

It is also important to note that test wafer consumption is experiencing a significant decline, reflecting the maturing of production technology and the increased demand for cost reduction. In particular, consumption of 200mm test wafers in the Asia/Pacific region in 1997 decreased by around 30 MSI compared to the previous year. It is expected to decline further during the forecast period, and as a result, the test/process wafer ratio will change from 1:3 in 1998 (worldwide average) to 1:5 in 2003.

 ©1998 Dataquest

Figure 3
200mm Silicon Wafer Consumption Forecast, 1996 to 2003



Source: Dataquest (November 1998)

Japanese Trends in 200mm Wafer Consumption

In 1997, around 391 MSI of 200mm wafers were consumed in Japan, accounting for 26 percent of the world total; epitaxial wafers represented 26 percent of those (23 percent in the world market). Because demand for 200mm wafers in the Japanese market primarily comes from the DRAM industry, it will be adversely affected in the short run by the sluggish DRAM market and the increased efficiency in wafer use because of chip shrinkage. Dataquest's June forecast expected recovery in the second half of 1998 and double-digit annual growth, but the apparent delay in recovery will likely cause 200mm wafer consumption in Japan to remain flat or record negative growth compared to consumption in 1997. One exception is the demand for epitaxial wafers, which grows steadily because it is driven by demand for 64Mb DRAM production. As a result, epitaxial wafers will account for 30 percent of 200mm wafer consumption in the first half of 1998. In the long run, 200mm wafer consumption in the Japanese market will expand at a CAGR of 17.5 percent between 1997 and 2003.

300mm Wafer Trends and Fab Activity

Technological development efforts to commercialize the 300mm wafer are undertaken through two consortiums—Semiconductor Leading Edge of Technologies (SELETE) and International 300mm Initiative (I300I)—which have produced a number of achievements and deliverables. Nevertheless, semiconductor companies are forced to cut back investments in 300mm wafer

 ©1998 Dataquest

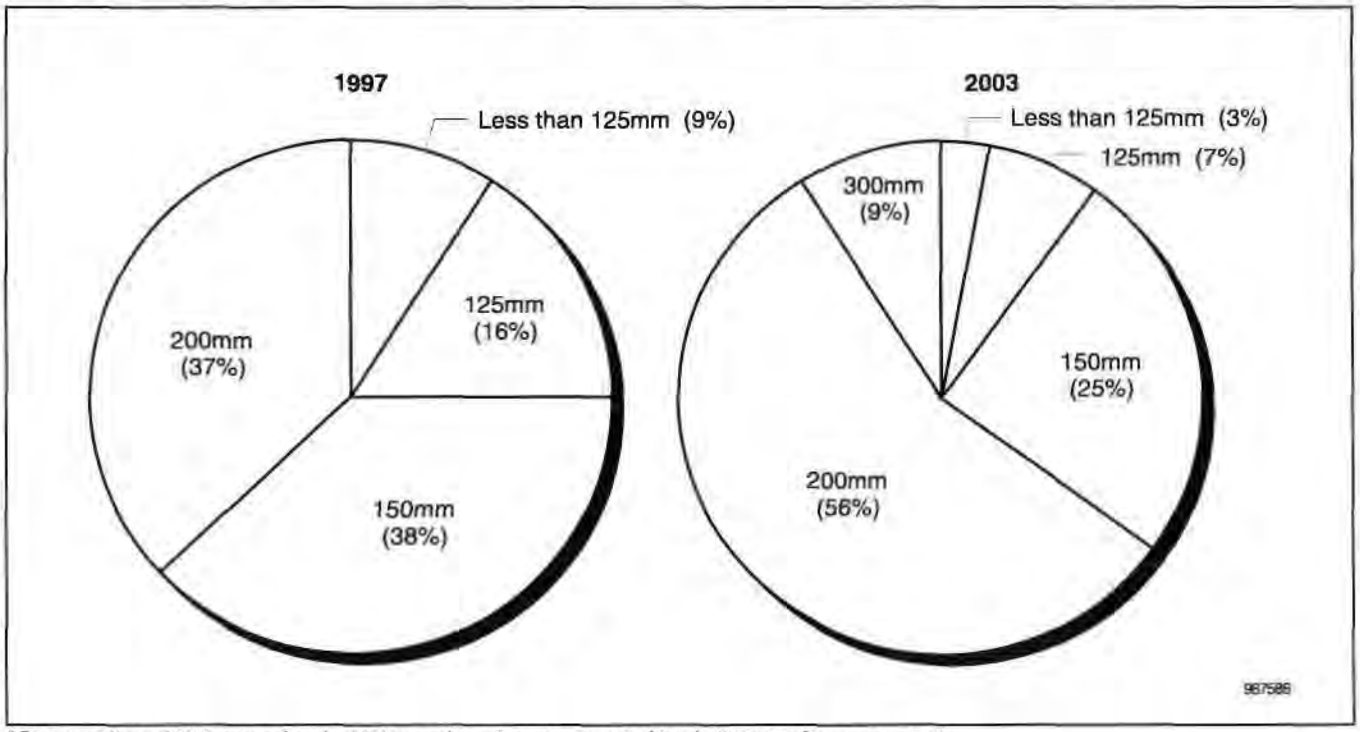
production in order to weather the unfavorable business environment—a grave, but logical consequence of the persistent slump in the device market. Dataquest believes that most of the movement toward 300mm fab construction will be postponed further by another year.

According to Dataquest's fab equipment market forecast, the share of semiconductor equipment for 300mm processes will grow to 2.4 percent in 1998 as the market for R&D and pilot production purposes emerges; it then will grow to 7.0 percent in 1999 and 9.0 percent in 2000, reaching a small peak. Then, after a temporary setback, the market for volume production will ramp up, and 300mm process equipment will boost its share to over 20 percent by 2003. It is assumed that eight to 11 pilot fab lines will be operating by the end of 2001, followed by volume production in 2002, with a substantial wafer volume ramp-up during 2004 and 2005.

In addition to the unfavorable investment climate, 300mm fab plans seem to have lost their impetus because most semiconductor manufacturers are still struggling to find the business case (viability) for the 300mm process in the changing semiconductor market environment. In particular, many Japanese semiconductor companies are striving to cultivate new market opportunities, such as system-level integration (SLI), in an attempt to become less dependent on the DRAM business; it is difficult for them to find proper positioning for the 300mm process technology in future business strategies. On the other hand, the 300mm process seems to be one possible choice for companies that have product offerings in the established monopolistic markets and that can find technical advantages from the new process. Dataquest believes that Intel, IBM, and Siemens AG will likely become early adopters of the 300mm process.

Historically, silicon wafer consumption has experienced the crossover of generations at an interval of six to seven years (on a wafer-area basis). The life cycle of 200mm wafers is expected to be much longer: probably ten to 11 years. The previous crossover occurred in 1998 when 200mm wafers took over 150mm products in terms of volume consumed. At that time, 300mm wafers accounted for less than 1 percent of total silicon wafers consumed and were mainly used for testing purposes related to the development of transportation systems (see Figure 4). The share will grow slowly to reach 9 percent in 2003, which would be almost the sixth year of the historical life cycle. This will be equivalent to 5.6 million wafers.

Figure 4
Worldwide Silicon Wafer Consumption Forecast by Wafer Size, 1997 versus 2003

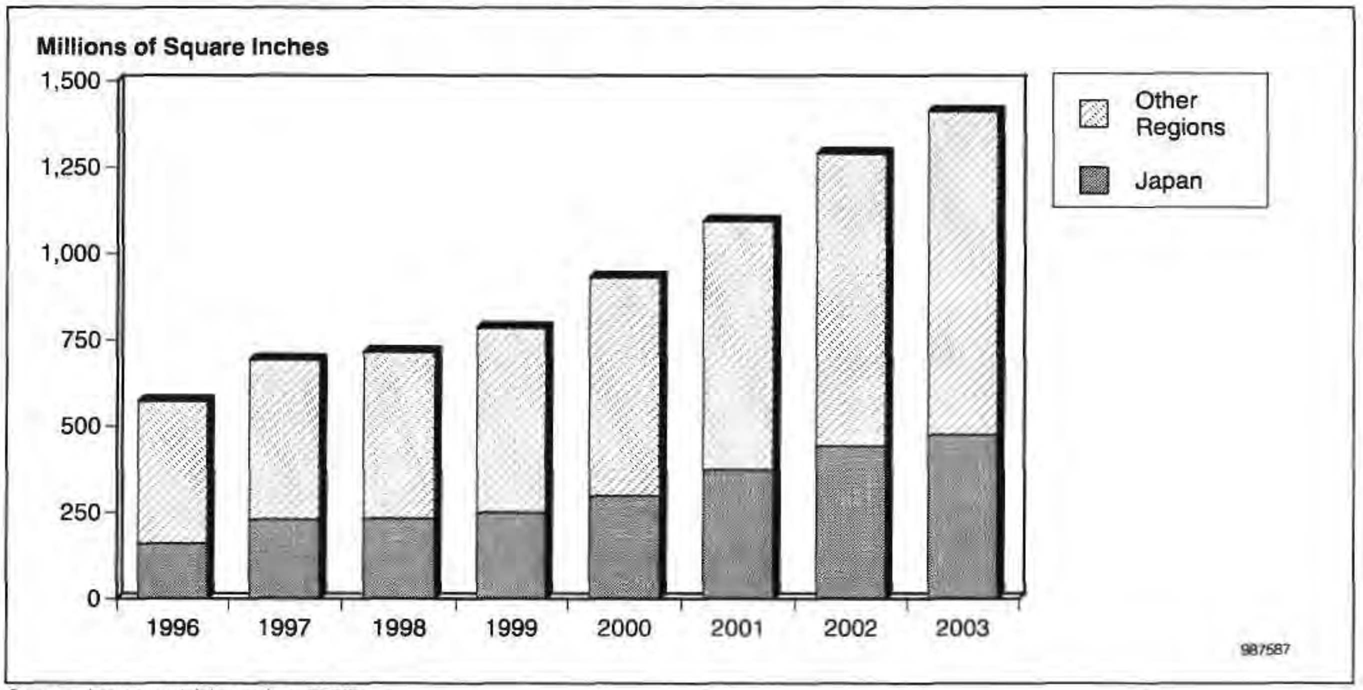


*Consumption of 300mm wafers in 1997 was less than 1 percent of total silicon wafers consumed.
Source: Dataquest (November 1998)

Epitaxial Wafer Consumption Trends

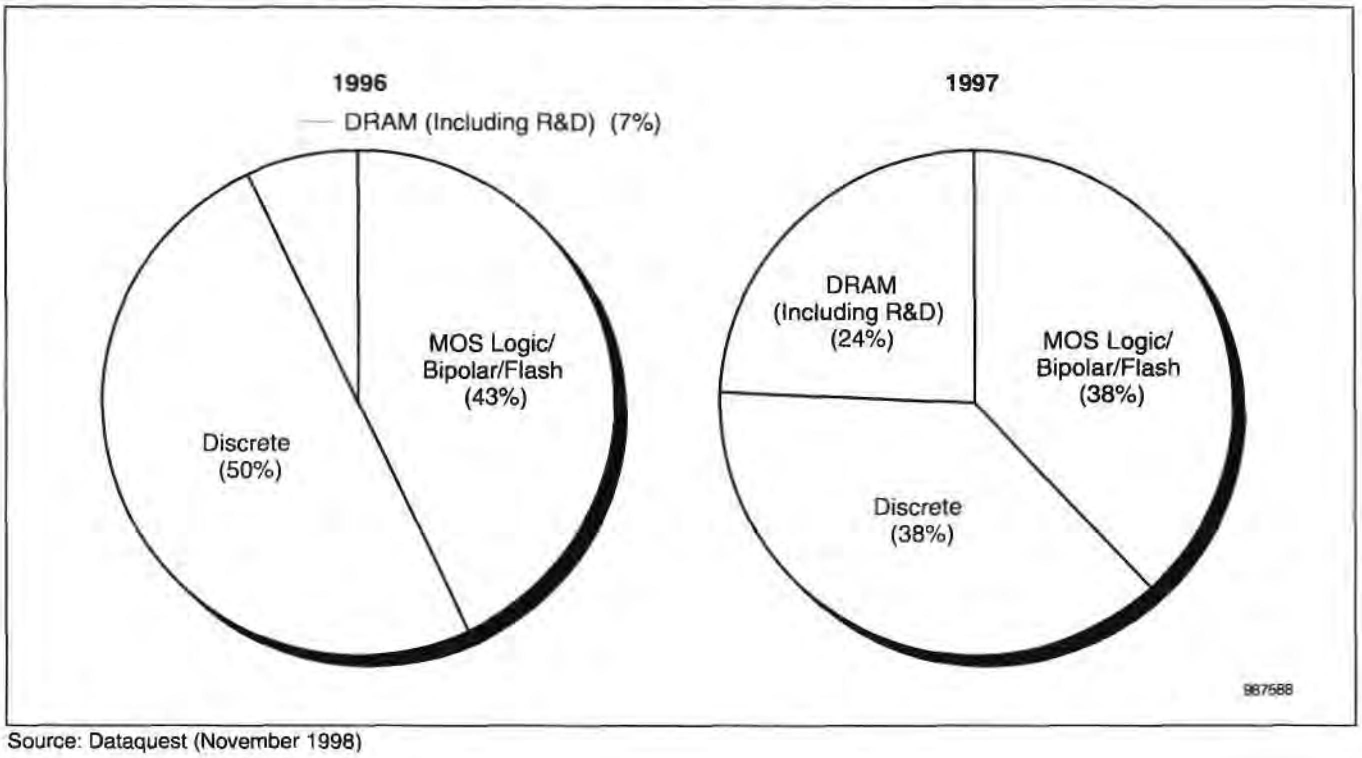
Worldwide epitaxial wafer consumption (merchandise sales only) in 1997 surged 21 percent to 693 MSI, far exceeding polished wafer consumption, which remained at a 5 percent growth rate. In particular, the Japanese market registered an impressive 42 percent growth rate to 230 MSI in 1997 (see Figure 5). In 1997, the breakdown of the world market by application was logic/bipolar/flash memory with 61.6 percent, discrete with 25.4 percent, and DRAM with 13.0 percent. (DRAM applications jumped from 3.0 percent in 1996.) The breakdown was far more conspicuous in 1997 in the Japanese market where the DRAM market still plays a major role: Logic/bipolar/flash memory represented 38.1 percent, discrete represented 37.6 percent, and DRAM represented 24.3 percent (see Figure 6).

Figure 5
Epitaxial Wafer Consumption Forecast, 1996 to 2003



Source: Dataquest (November 1998)

Figure 6
Epitaxial Wafer Consumption by Application in Japan, 1996 versus 1997



Source: Dataquest (November 1998)

Epitaxial demand for DRAM production has risen sharply since the end of 1996 because epitaxial wafers are an effective means of preventing grown-in defects, such as crystal-originated particles (COPs), on silicon wafers. These defects are known to cause a variety of device defects in 0.3-micron-or-finer processes, such as abnormal electric fields below the gate, the poor separation of features, and increased current leakage, depending on the actual position of the COPs.

Meanwhile, other factors that influence epitaxial demand have loomed over the past year. First of all, the persistent DRAM recession forces manufacturers to accelerate the development of shrink versions in a desperate attempt to reduce production costs by improving per-wafer yields. This suppresses wafer consumption while DRAM shipments increase in volume. Second, epitaxial technology was the first to receive industry attention due to its high levels of perfection and reliability. Also, the development of competing technologies—hydrogen annealed wafers and low-COP-type CZ wafers—has progressed steadily with improved performance, so that DRAM suppliers need to be cautious in their choice of wafer technology in consideration of price trends as well as technological advancement.

Nevertheless, Dataquest predicts that epitaxial wafer demand for DRAM production will grow firmly in the medium term at a CAGR of 30 percent between 1997 and 2003. Volume demand will reach 428 MSI in 2003, of which 46 percent will be consumed in Japan. This will fuel epitaxial demand, to achieve a CAGR of 13 percent during the same period, totaling 1,411 MSI in 2003. Similarly, consumption in the Japanese market will grow at an annual rate of 13 percent, bolstered by DRAM demand, and will amount to 475 MSI in 2003, of which the DRAM industry will consume a lofty 42 percent.

Dataquest Perspective

The silicon wafer market is about to experience some significant changes and turning points. The accelerated pace of process miniaturization since 1997, driven by the proliferation of DUV technology, has brought a wave of changes to the silicon wafer market. In particular, this has created a dilemma for the wafer industry because consumption does not grow side by side with increased DRAM shipments. The move is expected to prevail in the medium term, making it necessary for the industry to interpret the market trends on the basis of new criteria to reflect the future evolution of submicron processes (that is, its impact on wafer consumption). A regional consumption pattern will also change. In the past, most of the wafers produced in Japan were consumed locally to meet the gigantic appetite of the fast-growing DRAM industry. In the future, however, domestic consumption will slow down because of increased offshore production and the use of overseas foundries in the form of joint ventures, not to mention the sluggish DRAM market. As a result, domestic consumption market share will drop appreciably.

At the same time, the introduction of a larger-wafer generation will follow a new pattern. The delay in the commercialization of 300mm processes will break the historical pattern, and 200mm wafers will maintain the longest life

 ©1998 Dataquest

cycle among past generations since the start of product standardization by the Semiconductor Equipment and Materials Industry (SEMI). This means that the wafer industry will face difficulty in relying on its traditional strategy for market expansion, under which it has used larger wafers as a source of value add. In addition to the structural changes in factors affecting profitability, the industry is required to continue capital investment in 300mm wafers. Various moves have recently surfaced as clear signs of response to the situation—for example, the announcement that Showa Denko KK planned to pull out from the market and the merger between Sumitomo Sitix and Sumitomo Metal Industries, which was partly motivated by the need for strengthening the financial base to meet increasing R&D investment. Because wafer manufacturers are facing the same situation as that of chip makers and semiconductor equipment manufacturers, such moves are expected to intensify in order to spread investment risks and boost market share.

Regional wafer consumption trends largely reflect regional device market and production trends. In the Japanese markets that remain in a stage of moderate growth, wafer consumption seems to signify the stagnate semiconductor industry, which is still groping in the dark to find new market opportunities as alternatives to the sluggish DRAM market. Although the need to make a livelihood will likely force Japanese companies to rely on the DRAM business for the time being, there is no doubt that any new direction that they find will have important bearing on the future of the Japanese wafer market. In fact, Dataquest believes that the move for change by the semiconductor industry will not be felt directly by the wafer industry until 2003.

Semiconductors Japan

Market Analysis

Fall 1998 Forecast: Japanese Electronic Equipment Production and Semiconductor Market

Abstract: *Dataquest has brought down its forecast of the semiconductor market in Japan. Economic difficulties both in Japan and other parts of the world, including Asia/Pacific and the Americas, are hurting Japanese electronic equipment production, causing semiconductor consumption to remain below the 1997 level. Persistent oversupply is also a culprit, bringing revenue down even where unit demand is sound. From 1997 to 2002, the Japanese semiconductor market will experience only modest growth, with a 6.7 percent compound annual growth rate (CAGR). However, there will be changes and challenges in each product market, including product transitions in DRAM and an accelerated move toward system-level integration (SLI) ASIC. There are also a number of possible drivers to this semiconductor market forecast, as well as restraints, and the key for resuming growth lies in the overall recovery of Japanese electronics production in various categories, specifically leveraging on infrastructure development.*

By Yoshihiro Shimada, Motoya Ohgami, Masahiro Suzuki, and Yoshihisa Toyosaki

Overview of Electronic Equipment Production in Japan

Japan's economic slump is becoming increasingly severe, with practically no sign of a recovery. This is most starkly seen in the outlook for negative gross domestic product (GDP) growth. Although yen depreciation has improved the profitability of exports, Japan's export markets are drying up. Asian economies, a major destination for Japanese exports, are embroiled in the Asian financial crisis (AFC), and even the United States, Japan's other key trading partner, has begun to show signs of weakening since mid-1998. This economic environment has spelled trouble for Japan's electronic equipment production.

Electronic equipment production in Japan in 1997 rose by 9.7 percent against the previous year on a yen basis, but the real slowdown has taken hold since

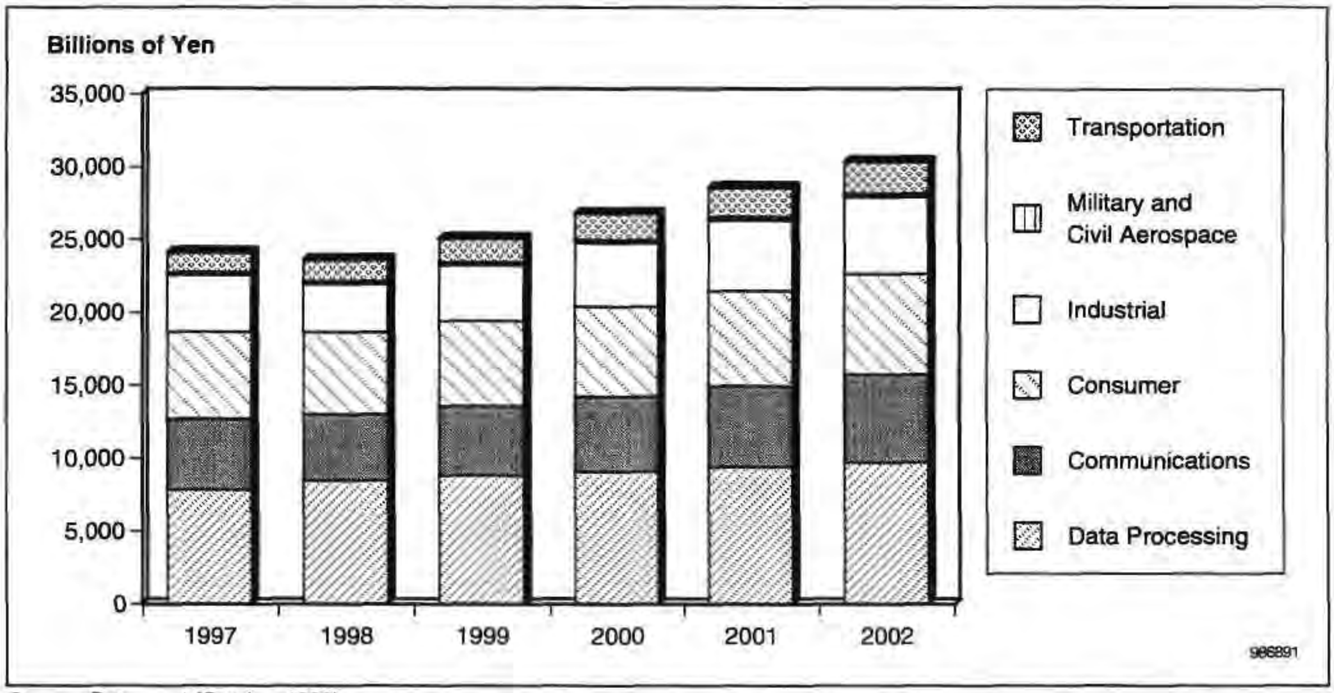
spring 1998. In our spring forecast, Dataquest estimated 3.1 percent growth in Japan's electronic equipment production for 1998. Based on the production results for the first half of 1998, which show a substantial decline in PC and other key electronic equipment production, Dataquest determined that it is necessary to adjust our outlook for 1998 downward. Dataquest expects electronic equipment production in Japan to achieve ¥23,579 billion in revenue in 1998, a 2.1 percent decline since 1997, and to maintain a compound annual growth rate (CAGR) of 4.7 percent during the 1997 to 2002 period (see Figure 1).

Figure 1
Japanese Electronic Equipment Production Forecast



Source: Dataquest (October 1998)

Slumping PC Market and EDP Equipment Production

With the release of Windows 98 delayed until July, PC shipments from January through June suffered a sharp turn for the worst, off 11.9 percent from 1997's shipments to 1.67 million units. Following the release of Windows 98, however, the market is rebounding, fueled primarily by individual demand. Hope is limited for an expansion of demand for PCs used by businesses, which account for nearly 70 percent of the domestic PC market, because of cutbacks in corporate capital spending in response to financial difficulties, including loans. At the same time, client/server systems are picking up as companies move to purchase computer systems to support the introduction of business applications such as enterprise resource planning (ERP) and supply chain management.

In the area of universal serial bus (USB)-compatible peripheral devices, designed to capitalize on the new Windows 98 USB feature, a steady stream of keyboards, mouse units, and other medium- and low-speed equipment is being marketed. Therefore, Dataquest is expecting increased demand not only for new PCs but also for peripheral devices. With the popularity of sub-$1,000 PCs, storage devices such as CD-ROMs, DVD-ROMs, and rigid disk drives (RDDs) are faced with rather difficult price metrics. As a result, CD-ROM drives continue to be primarily available in a 40x speed mode, while 2.5-inch-and-smaller RDDs are becoming the mainstream for thin, high-capacity notebook computers. From the perspective of added value, desktop computers are offering high-speed rotation at 7,200 rpm and faster. Dataquest expects scanners and printers to continue enjoying healthy demand in the input/output (I/O) device segment in Japan.

Dataquest estimates that data processing equipment production in Japan will increase by 7.7 percent, compared to 1997 production, to ¥8,462 billion in 1998. The CAGR for the 1997 to 2002 period is set at 4.4 percent.

A Breather for Communications Electronic Equipment Production

The total number of wireless phone subscribers including those subscribing to personal handyphone systems (PHSs) has surpassed 40 million, but new subscriber growth for personal digital cellular (PDC), the primary domestic digital cellular phone service, is slowing. In contrast to the steady pace of new subscriber growth for PDC service at 700,000 to 800,000 new subscribers per month, PHS, pager, and other service contracts continue their downward slide. Replacement demand for home phone terminals has been reinvigorated by the start of number display service. Nonetheless, the number of new contracts for fixed telephone service is declining as an increasing number of users are opting for mobile phones to satisfy their telephone requirements. In November 1998, regulatory changes are planned that will allow phone service rates to be set or changed through a reporting system rather than requiring permission in advance. Dataquest expects that this will increase the variety of low-cost services offered.

Investment in communications infrastructure in 1998 is tailing off following the completion of the digitization of all telephone office switching systems by the end of 1997. While demand for LAN and WAN systems is strong, the benefits are being discounted by sharply lower hub and router prices. In fact, the Japanese market is now considered to be more price-attractive than other Asian markets—even Taiwan, where Japanese companies used to go for a deal. Dataquest believes that demand for LAN-related equipment will expand at an annual rate of around 20 percent for the next few years.

Communications electronic equipment production in Japan is expected to decrease to ¥4,559 billion in 1998, which is 6.5 percent lower than production in 1997. The CAGR for 1997 to 2002 is forecast to be 4.3 percent.

Digital Systems—A Bright Spot for Domestic Consumer Equipment Production

Japan's consumer equipment market for audiovisual equipment is rapidly being digitized. In the audio equipment area, mini-disc (MD) shipments are posting solid gains. MD functionality is no longer only a portable phenomenon and can be found as a standard capability in minicomponent systems. As a result, its growth is expanding into all sectors, including replacement demand. Meanwhile, in the video equipment market, DV-C

©1998 Dataquest

shipments are sharply increasing. On a domestic shipment basis, DV-Cs account for 70 percent of all video camera volume, surpassing analog video cameras.

The digital still camera (DSC) market is discovering two distinct segments: a high-pixel-density version with over 1 million pixels and an economy version. With more than 30 companies participating in this market, excessive competition is a concern. Demand is also expanding in overseas markets for application as a simple image input device for Internet home page creation. However, this opportunity is being challenged by the expense of DSC compared to the recent emergence of flatbed-style scanners, which are selling in the ¥20,000 range. DVD player revenue growth is expected to exceed 100 percent in 1998, compared to 1997, but shipment volumes are still small. The conditions for further expansion of this market are in place as consumer prices for a stationary system are down to around ¥30,000, and DVD software offerings are being enhanced.

Domestic production in existing TV and VCR markets improved in 1998, spurred by the Nagano Olympics and World Cup Soccer, major sporting events that had a positive effect on the sales of wide-screen TVs. Upcoming opportunities in this market include receiver equipment for earth-based wave digital broadcasts and broadcasting satellite (BS) digital broadcasts scheduled to begin in 2000. Given these developments, Dataquest expects continued growth in demand for wide-screen TVs with high-image quality and multiple functions. In contrast, Dataquest expects negative growth for air conditioners, refrigerators, other consumer appliances, and VCRs.

Dataquest estimates that the value of consumer equipment production in Japan will be ¥5,624 billion in 1998, a 5.3 percent decrease from 1997 production. The CAGR is forecast to be 3.1 percent from 1997 to 2002.

Trends for Other Electronic Equipment Production in Japan

With the worsening economic situation, capital investments in manufacturing have substantially dropped off. Facility operating rates are also lower, and temporary operation halts have been introduced in some cases. The production of production-related and machining equipment is down across the board for the first half of 1998, with negative annual growth of 20 percent or more. Meanwhile, the necessity of monitoring equipment and other security applications in the safety and security alarm markets is expected to grow. For all industrial electronic equipment, Dataquest expects a 1998 production value of ¥3,316 billion, a 15.0 percent decline from 1997 production. A CAGR of 6.3 percent is forecast for the 1997 to 2002 period.

Although the number of new vehicles registered in Japan's domestic car market recorded a double-digit decline from 1997 in the first half of 1998, sales of car navigation sets continued posting steady growth. This market received a boost from the start of the Vehicle Information and Communication System (VICS) transportation information service, and currently more than 600,000 car navigation systems with VICS functionality have been shipped. There are also plans for evolving this system into an all-around information service with more sophisticated capabilities than

 ©1998 Dataquest

Intelligent Transport Systems (ITS). The value of transportation electronic equipment production in Japan is expected to be ¥1,428 billion in 1998, a 7.9 percent increase from 1997 production. The CAGR from 1997 to 2002 is forecast to be 10.4 percent.

The 1998 Semiconductor Market Disappoints

In a forecast update issued in July, Dataquest put forth a scenario of 1.4 percent growth in the 1998 worldwide market, compared to the same market in 1997. However, the market has continued to lose ground, and there is little doubt that even this scenario is no longer attainable. The following points can be cited as causes of this market's decline:

- Continuing downward slide in DRAM prices—Chip shrinking and other efforts to secure supplier-side profits are backfiring on the elimination of oversupply.
- Growing AFC impact—The AFC has spread on a worldwide scale and is causing an economic slowdown in the United States and other regions.
- Oversupply is spreading to the entire semiconductor market—Market conditions began weakening for microcomponents and logic devices late last year, and this trend has extended to analog and discrete devices. Foundry demand is also rapidly declining.
- Oversupply of electronic equipment—Production adjustments are starting for electronic equipment, and either demand for semiconductor volume is temporarily falling, or the pace of growth is slowing.

Eliminating Excess Supply Capacity

When setting forecasts for the semiconductor market, Dataquest formulates a supply/demand scenario and uses this as the basis for analyzing semiconductor consumption trends. The scenario adopted for this market forecast is outlined as follows:

- Shortages of PC100-specification DRAMs are already occurring, and facility investment cutbacks, factory closings, and other efforts to adjust supply capacity for the entire DRAM segment have started. In light of these circumstances, Dataquest believes that the DRAM supply/demand will balance in mid- to late-2000.
- A restoration of the supply/demand balance for the overall semiconductor market is expected to occur approximately one to two quarters after the DRAM supply/demand balance recovers.
- As a result, there will be a slight shortage in the semiconductor market in 2000, and market conditions will recover. The positive market conditions will continue through 2001, and this will prompt a reinstatement of capital investment.
- Supply capacity will expand because of the increasing capital investments, and another excess supply situation will occur in 2002. Affected by a mild worsening of market conditions, the peak in market

 ©1998 Dataquest

growth rates is expected to occur in 2001. Furthermore, negative growth is only expected for the DRAM segment. The rest of the semiconductor market will continue growing.

The main culprit behind the semiconductor market slump since the end of 1995 has been excess supply capacity. Since 1997, however, the market sentiment has shifted, and slowing demand has emerged as the key factor dragging the market. The phase during which adjustments of supply capacity had a significant impact on semiconductor market trends is approaching an end, and the primary question is whether demand can continue expanding. This is the scenario on which the current Dataquest forecast is based. Accordingly, in 1998, Dataquest expects a 5.9 percent decline for worldwide market growth and a 15.8 percent decline for Japan's market growth, compared to 1997. The main points of this forecast are as follows:

- 1998
  - The worldwide semiconductor market will again post negative growth (see Figure 2).
  - The DRAM market, following three consecutive years of negative growth, will contract to one-third of the historical peak reached in 1995.
  - The "non-DRAM" category, which previously managed to experience positive growth despite negative growth in the overall market, will also record negative growth this year.
  - The Japanese market, affected by yen depreciation, is turning in the weakest results and will be surpassed by the Asia/Pacific market (see Figure 3).
  - The only region likely to record positive growth in 1998, compared to 1997, is the European market.
- 1999 and later
  - The worldwide market in 1999 will begin to recover with double-digit growth.
  - Growth rates will be highest in the Americas and lowest in Japan. As a result, the Japanese market will be surpassed by Europe and will become the smallest of the four regional markets.
  - The supply/demand balance is expected to improve in 1999, and positive market conditions will be enjoyed in 2000 and 2001.
  - A mild adjustment period will occur in 2002 with DRAM revenue falling to negative growth and overall semiconductor market growth slowing to the single-digit level.

Drivers and Restraints

Dataquest's market forecasts are based on the "most likely scenario," as described previously. However, actual market trends will change depending on the manner in which various factors move, either upward or downward. The main elements that could affect market trends for the current forecast are the following:

- Drivers
  - Short-term (1998 to 1999)
    - Improvement in domestic economic trends (personal consumption trends and capital investment)
    - Early recovery of the Asian economies
    - Future Olympic demand and progress in audiovisual-related infrastructure projects
    - Stabilization of DRAM prices
  - Long-term (2000 to 2002)
    - Recovery in the domestic economy
    - Progress in infrastructure projects that link the digital consumer, communications, and data processing segments, and related increases in domestic electronic equipment production
- Restraints
  - Short-term (1998 to 1999)
    - Continuing economic weakness in the Asian and Japanese economies
    - Sluggish replacement demand as the level of mobile communications equipment dissemination rises
    - DRAM price stabilization limiting the pace of megabyte demand expansion
  - Long-term (2000 to 2002)
    - Delays in information communications infrastructure development
    - Falling prices because of intensified competition in system-level integration (SLI)

The forecast for growth of electronic equipment production in Japan is the lowest of the four regions. Likewise, the 6.7 percent dollar-based CAGR for Japan's semiconductor market for the 1997 to 2002 period is also the weakest (see Figure 4). Although from past experience Dataquest knows that growth in Japan's semiconductor market is accelerated during periods of yen strength, Dataquest's market forecast is based on a constant exchange rate in future years (see Figure 5).

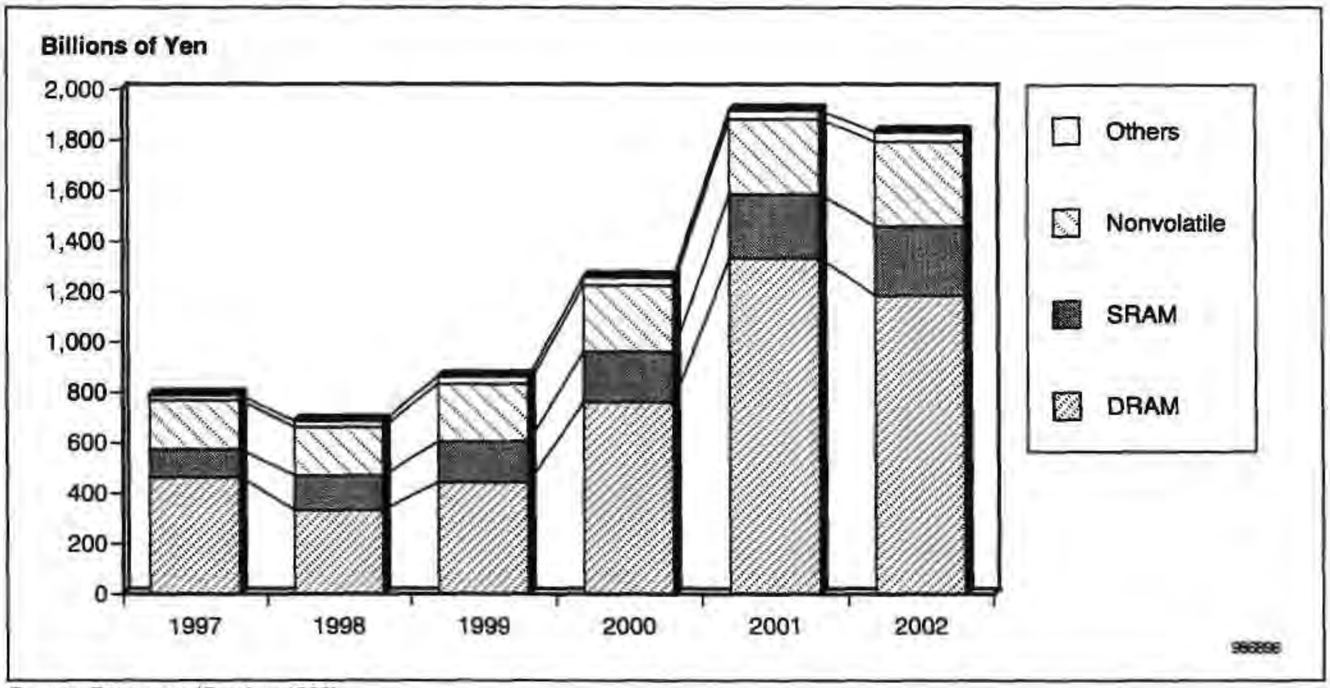
MOS Memory Market in Japan

Dataquest expects the MOS memory market in Japan to decline 13 percent (22.8 percent on a U.S. dollar basis) in 1998, compared to 1997 (see Figure 6). This represents a hefty downward adjustment of 20.0 points from the spring forecast. The primary factor behind this forecast revision is the rapid pace of DRAM price deterioration, which has been much faster than originally thought because of excess supply capacity, a similar pattern to what is happening in the worldwide MOS memory market. In the spring forecast, Dataquest stated that the activities of Korean manufacturers in 1998 would significantly affect DRAM prices and that plummeting 16Mb DRAM prices would also affect 64Mb DRAM prices. In fact, these worries have become a reality over the course of this year. Shipments of 16Mb DRAMs by Korean manufacturers in the first half of 1998 at levels far exceeding demand triggered a downward price slide for not only 16Mb DRAMs but also 64Mb DRAMs. In the 1998 MOS market, static RAM (SRAM) and other MOS memory devices will compensate for the negative DRAM factor.

Figure 6
Japanese MOS Memory Market Forecast



Source: Dataquest (October 1998)

From 1999 onward, Dataquest again expects the MOS memory market in Japan to follow the worldwide market trend, in which the DRAM and nonvolatile memory segments return to positive growth while solid SRAM performance continues. A full-scale expansion of the market will not happen until 2000, and this phase will peak in 2001 with a drop back to negative growth in 2002. The outlook also follows the worldwide market cycle. Dataquest believes that the dip in 2002 will occur when the colossal DRAM market takes a downturn from the negative effect of a generational transition from 64Mb to 256Mb memory devices. Japan's MOS memory market CAGR

 ©1998 Dataquest

for the 1997 to 2002 period is forecast to be 18.3 percent, a 2.9-point upward revision from the spring forecast's projected CAGR.

DRAM Market in Japan

On a product basis, Dataquest is forecasting a 28.2 percent decline in Japan's DRAM market in 1998 (36.3 percent on a U.S. dollar basis) compared to 1997. This is a sizable downward adjustment of our spring forecast. Just as in worldwide market forecasts, the dramatic reductions in DRAM prices at a pace way beyond original expectations are forcing lower forecasts. Even though DRAM-makers have taken steps to reduce capital investment plans, they also have adopted a strategy of maintaining shipment volumes at a certain level through the introduction of reduced-size chip technology and OEM procurement from Taiwanese manufacturers, while keeping capital investment budgets to a minimum. Moreover, DRAM-makers already have sufficient production capacity with existing 16Mb DRAM facilities, and it is this product area (16Mb DRAMs) that can be blamed for the DRAM price slide.

However, Dataquest sees the shift in PC DRAM demand from the 66-MHz type to the 100-MHz type picking up speed in the latter half of 1998 and believes that this will require more advanced production facilities. In 1999 and thereafter, DRAM-makers will need 0.2-micron-level production facilities to keep up with high-speed DRAM demand. Capital investments in 1998 and 1999 will be vital for maintaining production capacities based on such advanced facilities at a certain level. The implementation of finer process technology is moving forward at a faster pace than it did previously. Dataquest expects this trend to continue, and therefore, Dataquest foresees DRAM-makers having to shoulder an even heavier capital investment burden.

Dataquest's positive growth forecast for 1999 is based on an assumption that production capacity using advanced facilities will be introduced in balance with demand. Dataquest expects the DRAM market in Japan to enter a phase of full recovery in 2000, with a peak reached in 2001. Thereafter, in 2002, the market will be revisited by negative growth. Dataquest forecasts a CAGR of 20.6 percent for the 1997 to 2002 period.

Nonvolatile Memory Market in Japan

Dataquest's forecast for the nonvolatile memory market in Japan is a 1.5 percent decline (12.5 percent on a U.S. dollar basis) in 1998 compared to 1997. This represents a 1.8-point downward adjustment from the spring forecast. Dataquest's decision to lower the forecast was prompted by a change in the flash memory outlook from positive growth to slight negative growth. Over the next few years leading up to 2002, Dataquest expects that flash memory and EEPROM will turn in positive-growth performances, but it is worth emphasizing that the real driver in the nonvolatile memory market is flash memory. Dataquest is sticking to its view that the EEPROM market will shrink and the mask ROM market will be flat.

Portable equipment such as mobile phones is the primary application fueling growth in the flash memory market. Japan's semiconductor makers, in

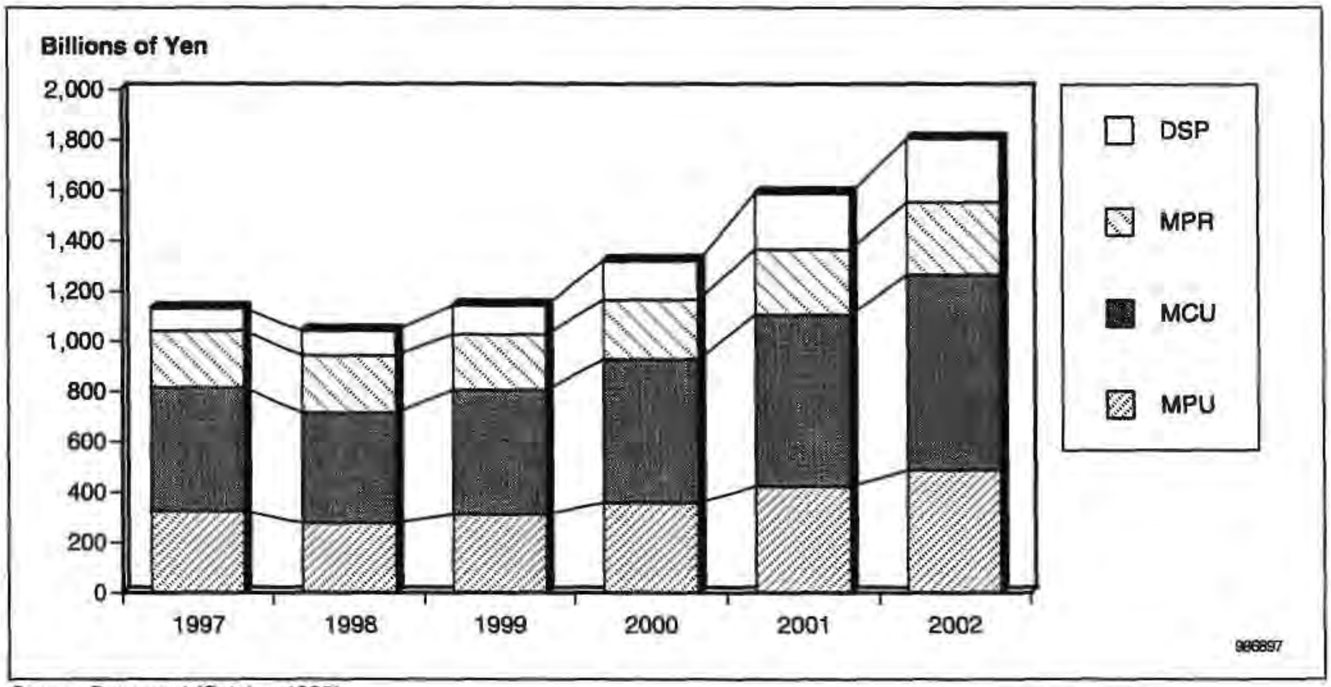
©1998 Dataquest

particular, rely heavily on mobile phones. In contrast, U.S. semiconductor makers depend on the communications equipment application. While the flash memory market currently is led by NOR-type devices, Japan's top semiconductor makers are making a move into the large-capacity flash memory arena in 1998. The main application for large-capacity flash memory is DSCs; however, this market is still rather small. The success of developing new market opportunities will be the primary determining factor for flash memory market expansion.

MOS Microcomponent Market in Japan

Dataquest has revised its 1998 forecast for the MOS microcomponent market substantially downward, compared to the previous forecast, to a 7.9 percent decline (18.2 percent on a U.S. dollar basis) since 1997. During the 1997 to 2002 period, a CAGR of 9.8 percent is expected (see Figure 7). Dataquest expects Japan's MPU market to record negative growth in 1998 because of weak demand in the domestic PC market and sliding MPU prices. Meanwhile, the microcontroller (MCU) segment, which accounts for the largest share of Japan's microcomponent market, is still posting higher shipment volumes, but revenue growth is being diluted by the decline in product prices. Feeling the effect of the disorder in the Asian economies caused by the AFC, Japanese makers' shipments of low-bit MCUs to the Asian market are experiencing even tougher circumstances than those of Asian competitors. Another factor hampering market growth is the stringent cost reduction demands of Asian system manufacturers.

Figure 7
Japanese MOS Microcomponent Market Forecast



Source: Dataquest (October 1998)

Looking at MCU market trends by product type, although the range of applications for 4-bit products has greatly broadened, this market entered a mature phase in 1997 from a growth perspective, and prices are falling. Revenue performance for 4-bit products is taking the brunt of slowing demand for portable game machines, a major market driver until last year. Meanwhile, Dataquest expects stable growth opportunities for 8-bit products, with the upper-layer compatibility shift from 4-bit products and growing demand for more complicated system control.

Although there is a possibility of 16-bit products experiencing a slight decline from the correlation between existing application shipments and unit prices, the first half of 1998 recorded high annual growth, benefiting primarily from strong demand for air conditioners caused by the strange weather. In other areas, as well, including VCRs, RDDs, telephones, digital mobile phones, CD-ROMs, printers, DSCs, automotive equipment, analog camcorders, and pachinko game machines, shipments are posting steady gains. On the technology front, a shift from mask ROM to flash technology is taking place, and the added value that this technology can deliver is expected to win 8-bit application business.

The main applications for 32-bit-and-higher MCUs, including 64-bit MCUs, are DSCs, DV-Cs, DVD players (including ROM), car navigation systems, next-generation home game machines, printers, digital mobile phones, and smart cards. Dataquest expects that demand for lower-power consumption features and cost reduction in the digital mobile phone category will drive a transition from 16-bit MCUs to higher-bit MCUs. Sharply higher growth is expected in the higher-bit MCU market, primarily in applications such as digital consumer equipment and mobile communications equipment, shored up by requirements for systems with sophisticated digital signal processing and advances in SLI technology. From 1999 onward, DVD player demand is expected to rise dramatically, mainly in the U.S. market, and Dataquest expects that this will also contribute to growth for higher-bit MCU products.

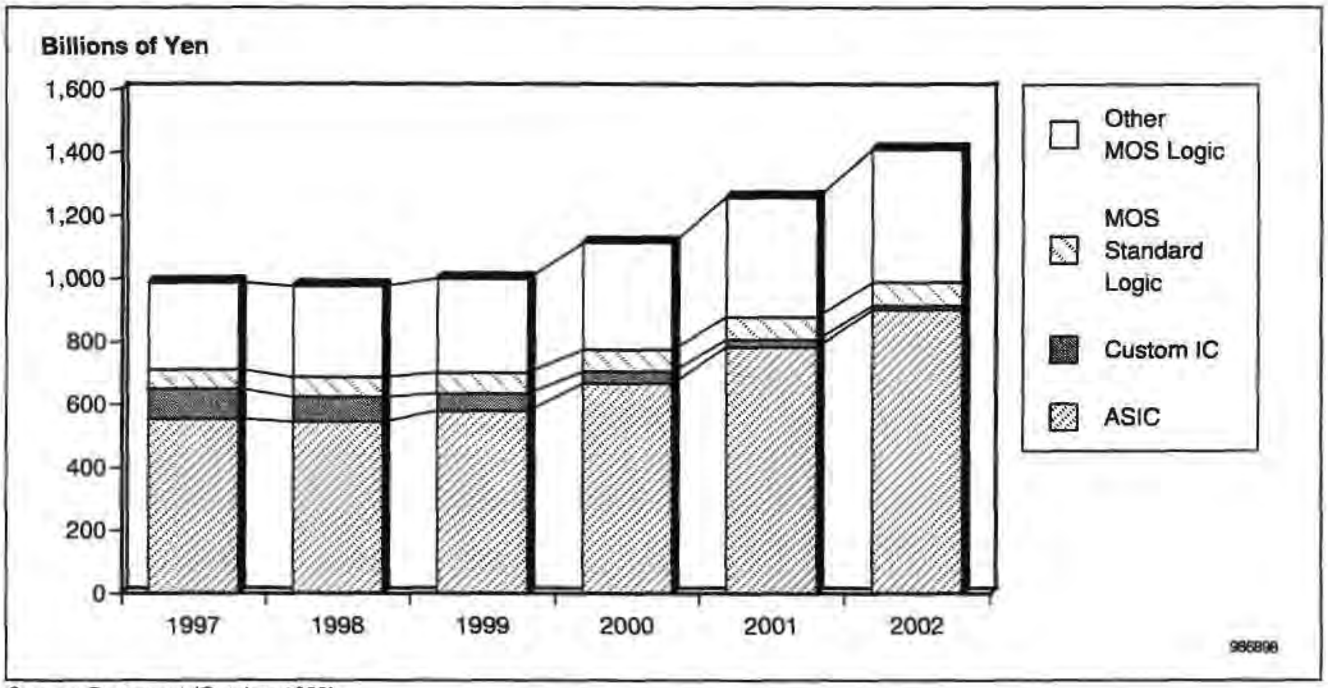
Demand for flash MCUs is showing steady growth in 1998. Applications driving the 8-bit, 16-bit, and 32-bit flash MCU market are memory cards, CD-ROMs, DVD-ROMs, RDDs, and automotive equipment. Also, Dataquest expects that custom LSIs, which combine an embedded ARM core with a flash core, will open up entirely new opportunities in the portable game machine market. Digital signal processors (DSPs) are finding demand in inverter-control and servo-control application areas, in addition to the existing market for mobile communications equipment.

MOS Digital Logic Market in Japan

Dataquest's forecast for the MOS digital logic market in Japan is a 1.2 percent (12.2 percent on a U.S. dollar basis) decline in 1998 compared to 1997. A CAGR of 7.4 percent is forecast for the 1997 to 2002 period (see Figure 8).

 ©1998 Dataquest

Figure 8
Japanese MOS Logic Market Forecast



Source: Dataquest (October 1998)

Japanese chipmakers excel in the gate array segment of the ASIC market and have shown impressive growth while Americas chipmakers have vanished from the top of the rankings for this segment. Essentially, while the Americas chipmakers are strategically focused on the SLI business and are staging a withdrawal from the gate array market, the Japanese chipmakers are stepping up to the plate in this segment and are winning orders from markets around the world that have been left open. Dataquest believes that this trend will continue.

The programmable logic device (PLD) market in Japan still has not demonstrated the expansion taking place in the Americas market. This is primarily because of internal system customer requirements that a stable supply of gate arrays and extensive support be provided. Chipmakers in Japan and the Americas are clearly operating in different business environments. In Japan, chipmakers are part of a vertically integrated organization that is dedicated to generating profits as a whole. This contrasts starkly with the situation in the Americas, where companies are divided into independent entities or independent business groups and have a mandate to return profitable results. The approach of Japanese chipmakers to the ASIC business is escalating the weakness of the market in Japan. A similar trend is observed across the full spectrum of logic products.

Although today ASIC and application-specific standard product (ASSP) devices incorporate nearly all of the functions offered by standard logic devices, Dataquest still anticipates demand for logic devices that satisfy special applications such as one-gate CMOS, ultrahigh-speed CMOS, and low-amplitude signal logic. Dataquest also believes that strong future

 ©1998 Dataquest

demand exists for LCD drivers, grouped in the "other logic" category, from the proliferation of portable systems with built-in LCD panels and flat panel display (FPD)-related products.

Dataquest Perspective

When the semiconductor market fell short of previous-year results in 1996, there was a pervasive recognition that this was the first negative growth in a decade. At the same time, while acknowledging that the market was in an adjustment phase, expectations were that once the adjustment was completed, the market would recover to a growth trajectory again. What has happened instead is that market conditions have not improved and are heading for a second dip in results. The DRAM market has contracted back to the level it was at before its last burst of growth, and joining this is negative growth for all other non-DRAM semiconductor products. The CAGR for the 1997 to 2002 period for the worldwide market is forecast to be 11.5 percent, indicating a long-term trend during which the semiconductor market will enjoy double-digit, stable growth, but not at the feverish pace of past years.

The semiconductor industry in Japan is in the process of transitioning supply capacity from DRAMs to other products as a response to the sharp cycles in market conditions characteristic of the DRAM segment. In fact, logic product offerings have been bolstered with each DRAM downturn. However, recent trends clearly underline the ineffectiveness of this approach for dealing with future market circumstances.

It is apparent from the domestic market's slip into the position of being the smallest of the four regional markets worldwide that Japanese chipmakers must make every effort to strengthen their approach to overseas markets. In doing so, the Japanese market cannot be the model for conceiving business strategies. This effort must be firmly rooted in applications and customer trends enjoying success in these overseas markets. From this perspective, Dataquest believes that the limits have been reached in the conventional approach, which treats the Asia/Pacific market as merely a site for the offshore operations of Japanese electronic equipment makers and puts this region in the same category as semiconductor business in Japan.

From a perspective of product evolution, the importance of SLI and other system-oriented products is growing. Success in this field requires further integration of product functions and manufacturing processes. The prolonged weakening of market conditions is increasing the losses incurred by Japan's semiconductor industry as a whole and thereby is limiting the resources available for expanding the scale of operations. However, Japan's chipmakers should consider the process of building an infrastructure to support system products as an opportunity to implement much-needed efficiencies. Dataquest sees growth in alliances and intellectual property business in the product design and development field. Meanwhile, foundry business is gaining force in the manufacturing area. Finally, for sales and customer support, alliances are being formed to ensure the proper response to application trends in regions throughout the world, and distributors with a global presence are accelerating their activities.

©1998 Dataquest

In a situation where mild semiconductor market growth is expected for the next few years, the focus has returned to the demand side. Given this current market outlook, Dataquest believes that the future evolution of the semiconductor industry hinges on the extent to which efficient resource use can be accomplished in all aspects of the semiconductor business.

CSP: Next-Generation High-Density Packaging Technology

Abstract: *Low-cost chip scale package (CSP) technology has entered a full-growth stage as the package for system-level integration (SLI) ASICs and memory, including flash memories and static RAMs (SRAMs) in the 0.25- to 0.35-micron arena. A major driver is the increased demand for more compact and lighter systems by mobile communications equipment and digital consumer equipment, which form fast-growing markets. This Perspective analyzes CSP technology, which holds the key to the successful implementation of device miniaturization.*
By Yoshihisa Toyosaki

Evolution of High-Density Mounting Packaging Technology

With the rapid growth of the information and communications equipment markets, such as personal digital assistants (PDAs), digital cellular phones, mobile computing devices, and subnotebook PCs, and with the swift expansion of digital consumer equipment markets, including digital video camcorders (DV-Cs), digital still cameras (DSCs), and portable digital video disk (DVD) players, packaging technology for high-density mounting is becoming a technological and commercial focal point. For IC packaging, leading-edge technologies such as chip scale package (CSP) and ball grid array (BGA) have been accepted by a number of applications at a faster pace than previously forecast. In the near future, flip chip (FC), direct chip attach (DCA), and known good die (KGD) are expected to follow suit as emerging technologies.

These leading-edge IC packaging technologies—as well as printed circuit boards (PCBs) accommodating multiple chips that represent buildup substrates, such as surface laminate circuits (SLCs)—are being widely used in a range of volume applications that demand system miniaturization, and new materials appear to be expanding into sizable markets. There are various issues to be addressed, however. First, buildup substrate suppliers continue

Publication Date: October 5, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

to be limited in number, keeping board costs at lofty levels. Also, the reliability of the materials for IC packaging still needs to be improved. Finally, there are differences in CSP package standards between the United States and Japan.

What Is CSP?

CSP is highly compact IC packaging, which almost equates to a die area. Many CSPs use terminals of a dense area array type on their rear side. CSP is considered to be the same as BGA, but it is not. CSP occupies a smaller area on the PCB (to reduce cost) and helps implement a variety of mobile applications. Also, its ability to reduce the IC package size leads to the improvement of electrical performance. Its market potential is being carefully examined by system manufacturers.

At present, volume markets using CSP are divided into digital consumer equipment, including DV-Cs and portable DVD players, and communications equipment, including digital cellular phones and pagers. Other promising markets are hard disk drives (HDDs), PC cards including modem cards, PDAs, DSCs, and portable audio equipment. These application markets are demanding system size and cost reduction, which can also be satisfied by CSP. These systems have relatively small pin counts (176 or fewer, as of 1998), and many of them are restricted in package height in addition to width and depth. At present, the CSP with the smallest form factor is primarily used to accommodate memories such as flash, static RAM (SRAM), and Rambus DRAM (RDRAM). These devices are relatively large in chip size with 50 or fewer pins, making them highly suitable for the package that is slightly larger than the die.

There are various obstacles to a wider market acceptance of CSP. One of them is establishing a small package with a narrow terminal pitch width. This increases the initial packaging cost, which is an important element of digital consumer equipment, and limits wiring patterns on the PCB. More precisely, to avoid "pin-out" in the area array type package with a narrow terminal pitch, a highly dense PCB needs to be used to secure a certain degree of freedom in the wiring pattern. Partly because the PCB industry must invest in costly equipment to meet the density requirements at a low cost for major applications, the cost issue related to CSP equipment is primarily governed by the PCB cost. As a result, Dataquest believes that an industrywide use of "true" CSP will take some more time.

Nevertheless, the industry must address package miniaturization requirements demanded by system manufacturers, which entails the development of an optimum solution to meet a specific cost target. The solution should include low-profile/thin quad flat package (L/TQFP) and BGA. In due course, the industry is expected to improve the ability to provide a matured technological infrastructure and will offer CSP with higher pin counts, which increasingly will be consumed by volume applications. In fact, system-level integration (SLI) ASICs in CSP are adopted in many DV-Cs, where buildup substrates consisting of an average of six to eight layers are used in PCBs.

 ©1998 Dataquest

Devices most suitable for CSP are those having a very large area of logic circuits compared to pin counts, namely "core-limited design," where an inner core is limited. This type of circuit design requires a relatively large die area to accommodate balls in the interconnection area, so that the ball terminal pitch can approach a standard grid arrangement. As for applications, CSP is optimum for those that must mount low-pin-count devices on a very small and highly dense PCB. These applications usually use 176 or fewer pin packages. For digital cellular phone and DV-C manufacturers, size and weight reduction of system products are of supreme importance; it is justifiable for them to use very costly SLC boards. In fact, SLC boards permit CSP to be used in the area array layout. In contrast, CSP is not suitable for computing or transmission/telecommunications applications that require high-pin-count packages.

The full-featured CSP, which increasingly is used for memory devices, is ready for volume production in 1998. This serves as the buildup of the technological infrastructure and will spur demand. At this point, chip makers and their subcontractors will provide "true" CSP technology. CSP technologies implemented by Sharp and Texas Instruments Japan are not technological breakthroughs, but they will build on top of proven technologies; their main goal is to minimize cost and risk. Technological advancement will occur in the reduction of ball pitch to less than 1.27mm, namely 1.0mm and 0.8mm. IC package size will continue to shrink until the chip itself becomes a limiting factor, because the improved infrastructure for PCB production and assembly will enable a smaller terminal pitch (the 0.5mm pitch used in DV-C, for example).

Current Status of CSP

Currently available chip packages are mostly shrink versions of existing packages—the results of gradual efforts. A typical example is seen in modified plastic BGA (PBGA) and L/TQFP versions with a 1.27mm or smaller ball pitch. CSP, having the same or a similar pin count, is smaller and lighter than these modified versions. In this sense, CSP can be defined as a low-cost, low-pin-count solution. The industry defines CSP as a package that does not exceed 120 percent of the chip area. The development of CSP was started around 1990, and a large number of semiconductor suppliers are currently working with diverse structures in their R&D efforts. From the density point of view, CSP is positioned midway between existing standard packages and FC, with technical issues to be cleared accordingly (see Figure 1). Given the industrywide trend toward increasingly high-density mounting, CSP is expected to provide a feasible solution for a wide range of applications; however, it is difficult to forecast when exactly it will win which share of which market.

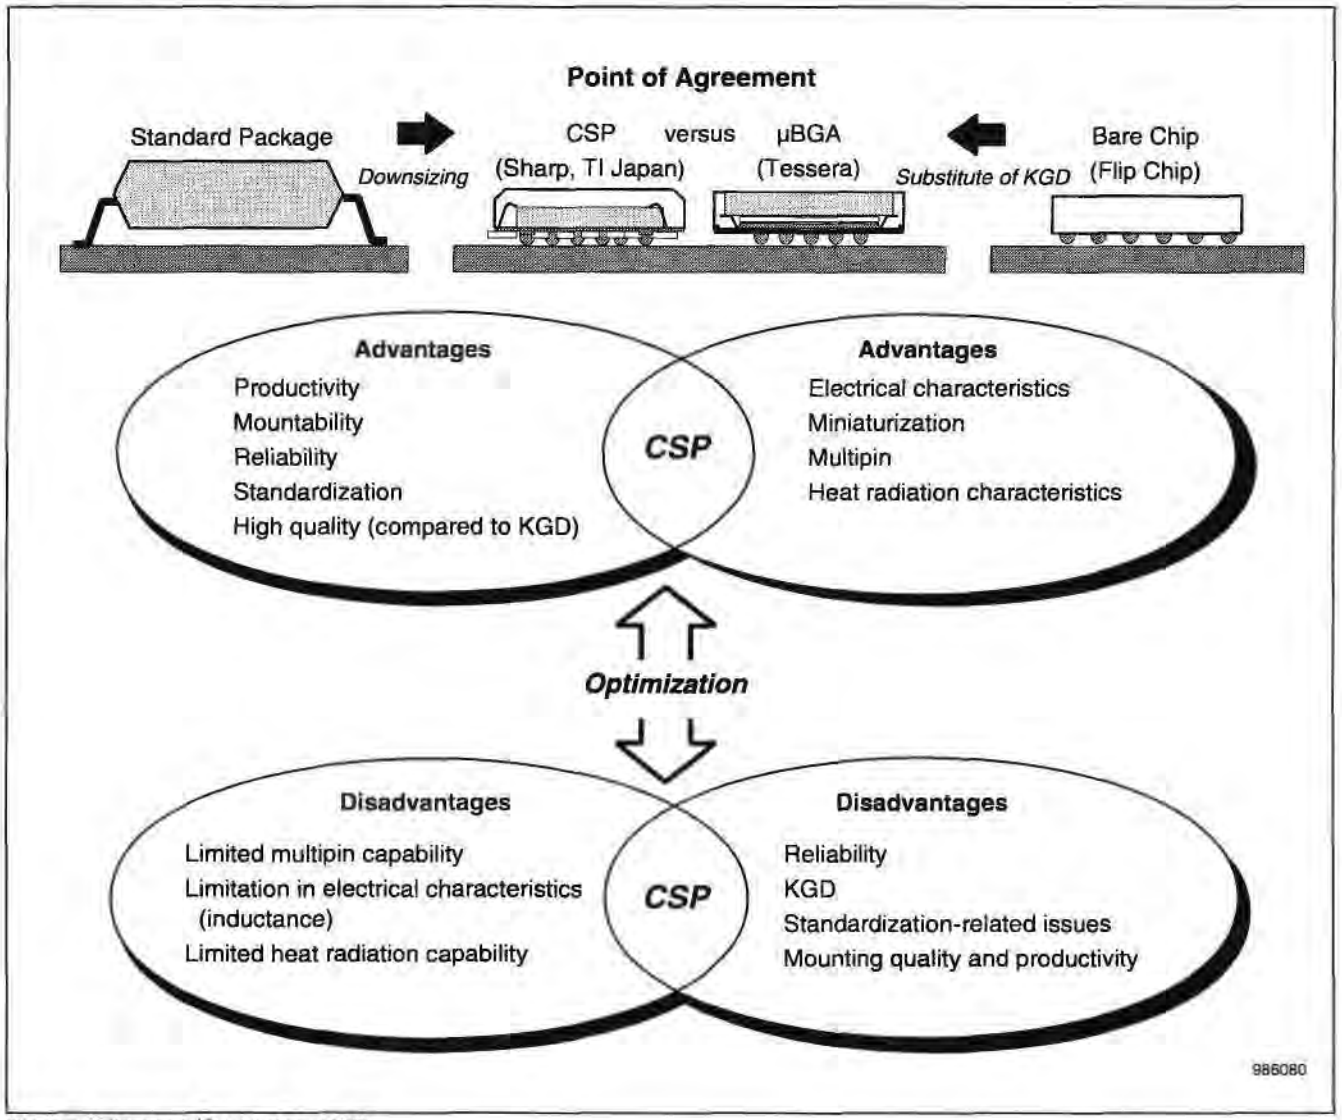
Figure 1
Advantages and Disadvantages of CSP



Source: Dataquest (September 1998)

CSP is undoubtedly a focal point of the PCB industry. Overall, the volume market for true CSP will be a bit slower than expected because of the immature technological infrastructure. Meanwhile, CSP technology capable of satisfying diverse applications will enable package miniaturization at the lowest cost. The CSP-enabled package size will be free from chip size limitation and can be reduced to address a wide range of terminal counts, required by system manufacturers according to a ball pitch allowed by wiring patterns on a PC. Regardless of the package type and name, the industry's goal is to supply small packages in volume and at low cost, as required by system companies.

 ©1998 Dataquest

Major Features and Advantages of CSP

The proliferation of CSP is driven by size and cost. In particular, applications subject to strict limitations in terms of size and weight will find the solution highly attractive. As the continued miniaturization of devices ends up in bare chips—the minimum practicable package size is no package—CSP will be compared to bare chips and KGD in addition to existing packages. CSP implementation methods commercially adopted in the industry are basically divided into chip-on-board (COB)—derived from wire bonding technology—and FC-on-board (FCOB)—derived from FC technology.

In terms of size, CSP is much smaller than standard packages and is larger than bare chips. A major advantage of package miniaturization, in addition to its space-saving, is its reduction of the accumulation of electricity and heat. CSP is a surface-mounting package and is mainly of area array type. As a result, its terminal pitch is more narrow than that of current BGA packages and wider than that of FC.

Figure 2 shows CSP structures developed by leading vendors. A few of them have already implemented CSP for ASICs and other devices. As for CSP used in the SLI ASIC business, Dataquest believes that the Sharp/Texas Instruments Japan type (a tape type that can be implemented at low cost by using existing equipment) and the Matsushita/Kyocera type (alumina ceramic) will become the mainstay for mobile communications equipment and digital consumer equipment with low system operation frequency. At present, other technologies still have yet to reach a volume production stage. Commercialization depends on several factors, including cost, technical feasibility, and infrastructure development.

In fact, applications suitable for CSP vary with each technology. For instance, the area array type is suitable for applications with a relatively high pin count (50 pins or more) designed by ASIC vendors because of a large terminal pitch. Table 1 compares specifications of the packaging technologies. Compared to bare chips (including KGD), CSP has the advantages that are usually available in packages. In terms of external appearance and terminal shape, CSP is a standard contact device, and it can help simplify the subsequent mounting of parts in the following respects:

- Ability to standardize sockets for cost reduction and simplified testing
- Ability to simplify PCB design regardless of chip design change or generation shift (silicon respin) by offering the same package solution (for bare chip, PCB design modification is often required)
- Ability to allow any semiconductor suppliers to reduce the mounting cost, as demanded by system companies, by standardizing packages' external appearance and terminal shape

It should be noted that system companies that adopted CSP at an earlier time intend to use it as a differentiating factor and to provide their own solutions before standards are established.

CSP Technology and Competitive Analysis

Diverse CSP technologies that are under development are all categorized by chip scale and include area array and peripheral packages. These technologies use substrates, flex inserters, wafer-level reallocation, and overmolding for interconnections to the PCB. Table 2 lists selected CSP technologies currently owned by vendors. Table 3 ranks currently offered CSP packages according to their estimated volume production costs. Note that the list ranks the packages that are similar to low-cost LQFP, which is already commercialized with a sufficient technological infrastructure. Sandia National Laboratories' technology is not included because it is closer to reallocated FC than to CSP.

Table 2
CSP Technologies under Development

Manufacturer	Terminal Structure	Interconnection/Substrate
Tessera	A	Tape inserter, TAB bonding, solder balls
TI MicroStar	A	Tape inserter, wire bonding, solder balls
Matsushita Electric/Electronics	A	Mounting of flip chip to ceramic LGA, underfill
Motorola SLICC	A	Mounting of flip chip to laminated substrate, underfill
NEC	A	Tape inserter, thermo-compression bonding, solder balls
Mitsubishi Electric	A	Reallocation to solder pads, transfer molding, ball bonding to pads
Sandia National Laboratories	A	Reallocation of polyimide to gold or solder balls
GE	A	Flex bonding to Si and bump formation using bear holes, development of HDI
Hitachi Densen	A	Derivative of leadframe technology arranging metal posts in perimeter, overmolding
IBM	A	Flip chip bonding to ceramic mini-BGA with cap, eutectic crystal solder balls
Nitto Denko	A	Tape inserter, thermo-compression bonding, solder balls
Toshiba	A	Flip chip bonding to ceramic LGA, underfill
Sharp	A	Wire bonding to flex substrate, molding
Hitachi Densen	P	Leadframe by small J lead, overmolding
ChipScale	P	Wafer reallocation to silicon post, expoxi-resin encapsulation to active face
Rohm	P	Flip TCP, resin sealing of die front side
Fujitsu	P	Die-size leadframe LOC, formation of LGA by one side overmolding
LG Semicon	P	Small leadframe, formation of LGA by overmolding
ShellCase	P	Sealing of Si between two glass plates, metallization of end contact

Table 3
Current State of CSP Packaging Development and Volume Production

Manufacturer	Volume Production Cost	Maturity Level	Advantage/Disadvantage
Matsushita Electric/Electronics	Low	Commercialized	Flip chip (SBB), ceramic substrate (mainly for captive users)
NEC	Low	Using two systems of sample level	Advantages/disadvantages vary with methods. The NEC system is similar to the one in Figure 1.
Fujitsu	Low	Prototype	TSOP's derivative technology
Kyocera	Low	Commercialized	Land-type ceramic substrate/PCB (supplied to semiconductor suppliers, SBB technology applied for partial connection)
Hitachi Densen (P)	Low	Commercialized	QFP's derivative technology
Nitto Denko	Medium to low (future)	Commercialized	Additional cost because of bold bonding on tape
Motorola SLICC	Medium	Sample level	Flip chip, for PowerPC
Mitsubishi Electric	Medium	Development level	Cost increase because of multistage process
Hitachi Densen (A)	Medium	Development level	Cost increase because of multistage "post" leadframe, no standard substrate assembly
Tessera	High to medium (future)	Partially commercialized	Equity participation by Amkor-Anam and a few licensing agreements have accelerated CSP development and capital investment; this is expected to result in cost reduction in the near future.
GE	High	Development level	Scrap cost increase because of the initial die mounting process
IBM	High	Development level	Flip chip, ceramic substrate
Toshiba	High	Development level	Flip chip, ceramic substrate

SBB = Stud bump bonding technology
P = Peripheral structure
A = Array structure
Source: Dataquest (September 1998)

Major factors affecting the CSP cost are the substrate cost, assembly techniques (FC and wire bonding technology, for example), the number of process steps, and yield. On the other hand, the price is ultimately governed by the level of market penetration. No technology can achieve the lowest possible cost unless it follows learning curves determined by very large volume production. Dataquest sees that any CSP technology involves a certain risk until official standards are established to depict a "technological winner."

 ©1998 Dataquest

An Analysis of Alternative Technologies

The introduction of CSP technology is hindered by interindustrial barriers that increase the initial cost. To meet short-term design requirements for cost and size, LSI Logic and other vendors propose the small form factor package (SFP)—mini-BGA—technology as a temporary substitute for CSP. This solution includes LQFP and BGA with a small terminal pitch. Table 4 compares existing products using these alternative technologies. It should be noted that the size difference between each IC package and the chip varies greatly among them. For instance, the large core-limited design allows a more efficient use of the package, so that the name "chip scale package" is not appropriate.

Table 4
Comparison of Existing Packages and Mini-BGA

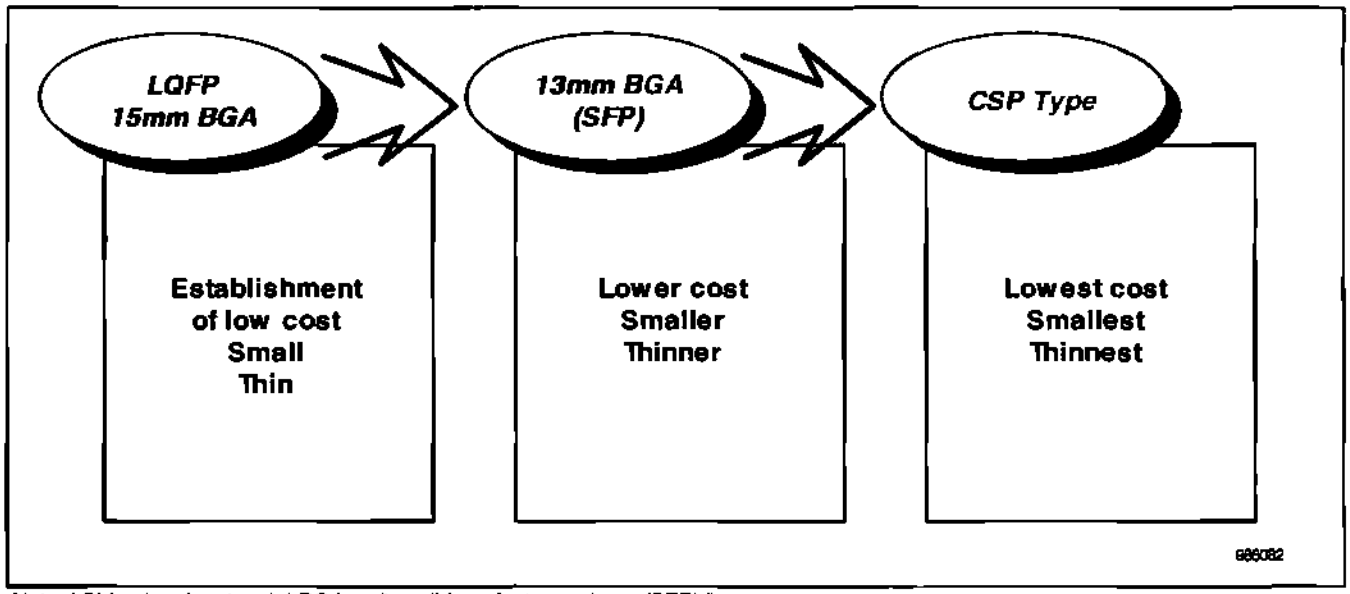
Package Item	LQFP	PBGA	1mm BGA/SFP
Package Total Width	7mm to 28mm	23mm to 35mm	15mm
Package's Relative Size (Compared to Chip Size)	2.5 to 28 times	3.7 to 25 times	3 to 10 times
Height	1.0mm to 1.4mm	2.3mm	1.6mm
Package's Relative Cost in 1997 (Compared to PQFP)	1.2 times	1.5 times	1.5 times
Terminal Width	0.4mm to 0.5mm	1.27mm to 1.8mm	1mm to 0.8mm
Pin Count	44 to 208	169 to 456	100 to 176

Source: Dataquest (September 1998)

Because the package size is primarily governed by size requirements for the system and PCB, it is more appropriate to standardize the package size relative to an available area on the PCB rather than the chip area. In the future, as the CSP cost declines and capabilities related to PCB production and assembly improve, the high-density, area array package will be promoted. The possible evolution of these technologies is analyzed by taking the example of LSI Logic: how the company will implement SFP technology for the 100-to-200-pin markets (see Figure 3).

 ©1998 Dataquest

Figure 3
SFP to CSP Road Map at LSI Logic



Note: LSI Logic refers to mini-BGA as "small form factor package (SFP)."
Source: Dataquest (September 1998)

Not all of the currently available CSP-alternative technologies, such as COB, FCOB, chip-on-flex (COF), and LQFP, are suitable for the ASIC market. They basically consist of many bare chip technologies and several types of packages. Many ASIC suppliers have not weighed bare chip sales, because there are pros and cons on the use of the bare chip. The bare chip can be less costly than packaged devices if all the tests are eliminated; however, it must sacrifice many of the advantages offered by the package solution, while suffering the following drawbacks:

- Testing—Testing techniques on the bare chip still have to be matured.
- Standardization—Chip design changes or the commercialization of a new-generation chip often lead to various changes in external appearance and pad shape. Unless a standard package to absorb such changes is used, the PCB needs to be reconfigured and then tested.
- Risk and reliability related to handling—Without physical protection provided by the package, the bare chip can be damaged by various causes, including corrosion and a mechanical or physical shock. Also, the production process to mount bare chips to systems, similar to a semiconductor assembly line, is required.
- Exchange of chips (rework)—The exchange of chips is more difficult for the bare chip than for CSP.

Barriers to Commercial Implementation of CSP

Major obstacles to the commercial implementation of CSP are an immature technological infrastructure and high equipment costs. The major technical issue facing CSP is how to maintain the terminal pitch and array required to implement cost-effective interconnection patterns at a PCB level. The infrastructure refers to the technological capabilities of the PCB industry in supporting assembly and testing operations. In particular, infrastructure development should address the following areas:

- Standard lead and package shapes to support compatibility
- Test socket connection
- Testing process
- Standard tapes and reels
- Assemblies handling equipment
- Visual aid systems for assembly
- Assembly process and thermal distribution, including adequate soldering materials and their geometries

These areas require extensive development efforts, and the use of a standard BGA is considered to be the first step toward the development of CSP.

Also, the total system cost poses a major challenge. Following the learning curve for volume production, the CSP package cost will fall to a very low level because small amounts of materials are used and existing assembly techniques can be used with some modifications. On the other hand, the PCB cost as the basis of the above technologies, particularly Tessera's BGA, is much higher than the cost of standard PCBs.

Figure 4 lists routing issues related to small-pitch, area array packages. As shown in this figure, the escape route is established in one layer, representing the worst case. In a small 7 x 7 array, the maximum number of traces escaping between two balls in the array is three. Generally, the required routing density is proportional to the number of ball rows; the routing issue becomes more serious as the array becomes larger. In practice, the required routing density is secured by using a multilayer PCB. Basic rules related to the PCB are governed by the terminal pitch of the package array, the number of balls, and the size of the capture pads. The PCB's cost impacts vary with markets and are generally determined by PCB size and the number of CSP devices mounted on it.

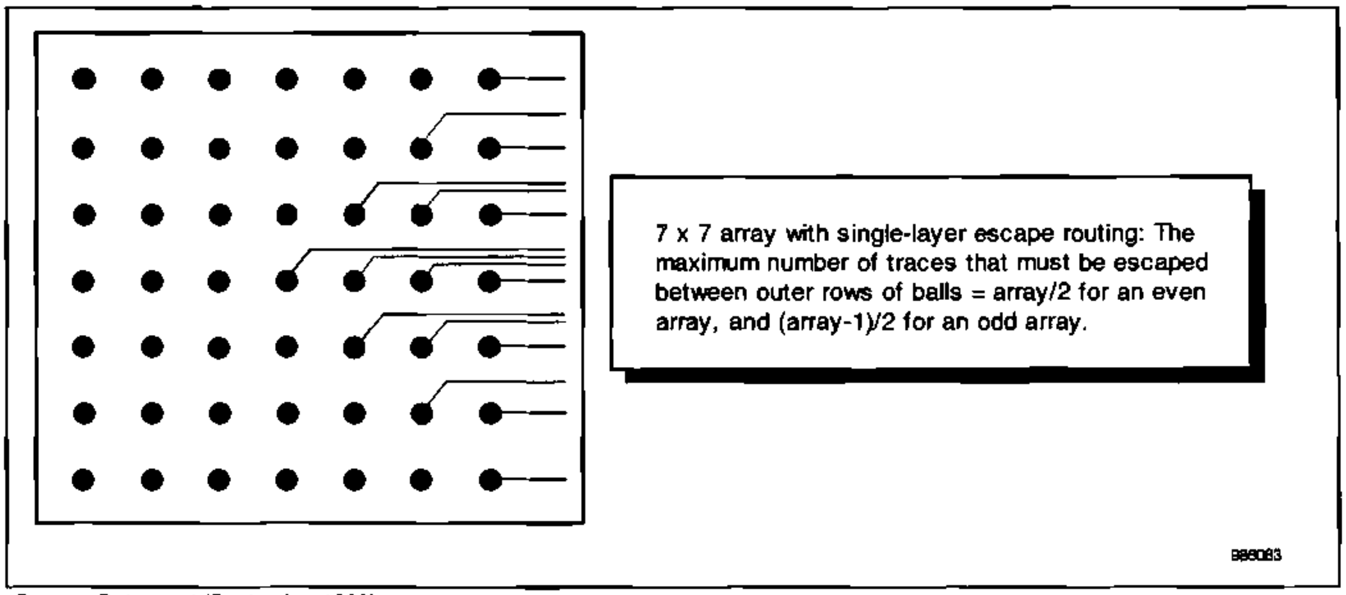
Figure 4
Routing Rule in Area Array Layout



Source: Dataquest (September 1998)

Dataquest Perspective

In the conventional ASIC process development, each manufacturer has established its basic process and packaging technology that are then incorporated into products. Also, in many cases, the memory process, such as DRAM, has been adapted to the ASIC process as a technology driver. Historically, Japanese semiconductor companies have developed products on the basis of "the supply-side logic" and have palmed them off to system companies. This reflects that the product development process lacks the marketing concept—efforts to grasp and serve market needs. In recent years, Americas ASIC suppliers seem to have established a clear competitive edge over Japanese competitors. The difference comes from not only a technology gap in the basic process and packaging but also the lack of market analysis and marketing strategy to address users' needs on the Japanese side.

Because the ASIC industry has already entered the SLI ASIC age, where large-scale LSI development efforts are required, it has become imperative for ASIC suppliers to respond effectively to the needs of application users. Future challenges for establishing the product concept of SLI ASIC include optimizing application requirements by semiconductor technologies, including packaging, process, libraries, and IP core. Dataquest believes that CSP will be one of the critical factors for success.

Semiconductors Japan

Market Analysis

A Comparative Analysis of Wafer Fab Equipment Markets in 1997: The Japanese Market Was Down 23 Percent

Abstract: *In 1997, the worldwide wafer fab equipment market declined 7 percent from the year before to $20.2 billion. The regional breakdown showed mixed results, however. While the Americas and Taiwan maintained double-digit growth, Europe, Japan, and Asia/Pacific (excluding Taiwan) recorded negative growth. From the first quarter through the third quarter, leading-edge equipment, led by excimer laser and equipment used for MPU and logic production, expanded and bolstered growth of the entire market. In the fourth quarter, however, a lingering slump in the DRAM market put a drag on market growth because of capacity expansion, resulting in negative growth on an annual basis.*
By Takashi Ogawa

1997 World Market Trends

In 1997, the wafer fab equipment market recorded negative growth for the first time since 1992 with a 7 percent decrease from 1996. Of $20.2 billion, the Americas accounted for $6.7 billion and maintained a double-digit growth of 15 percent. In contrast, the Japanese market decreased by 23 percent (to $5 billion), Asia/Pacific decreased by 7 percent (to $6 billion), and Europe decreased by 15 percent (to $2.4 billion). Within the Asia/Pacific market, Korea plunged 37 percent (to $1.9 billion), whereas Taiwan expanded 30 percent (to $3.3 billion). The polarized results between regions as well as individual markets (see Figure 1) seem to reflect their semiconductor product mix. Japan and Korea, which are heavily dependent on DRAM, showed sharp declines, while the Americas maintained firm growth, fueled by the expansion of the MPU, ASIC, and logic markets. Taiwan benefited from the booming foundry business, which was increasing capacity.

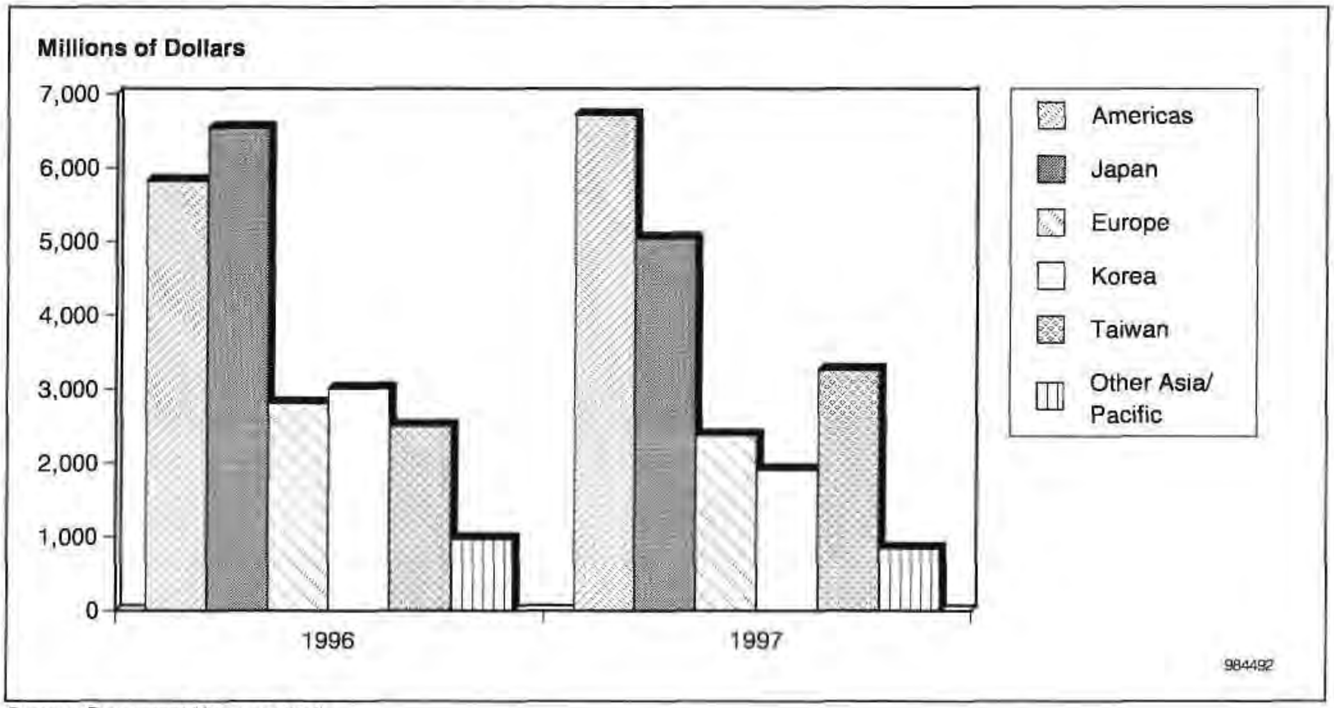
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Figure 1
Wafer Fab Equipment Market Trends by Region

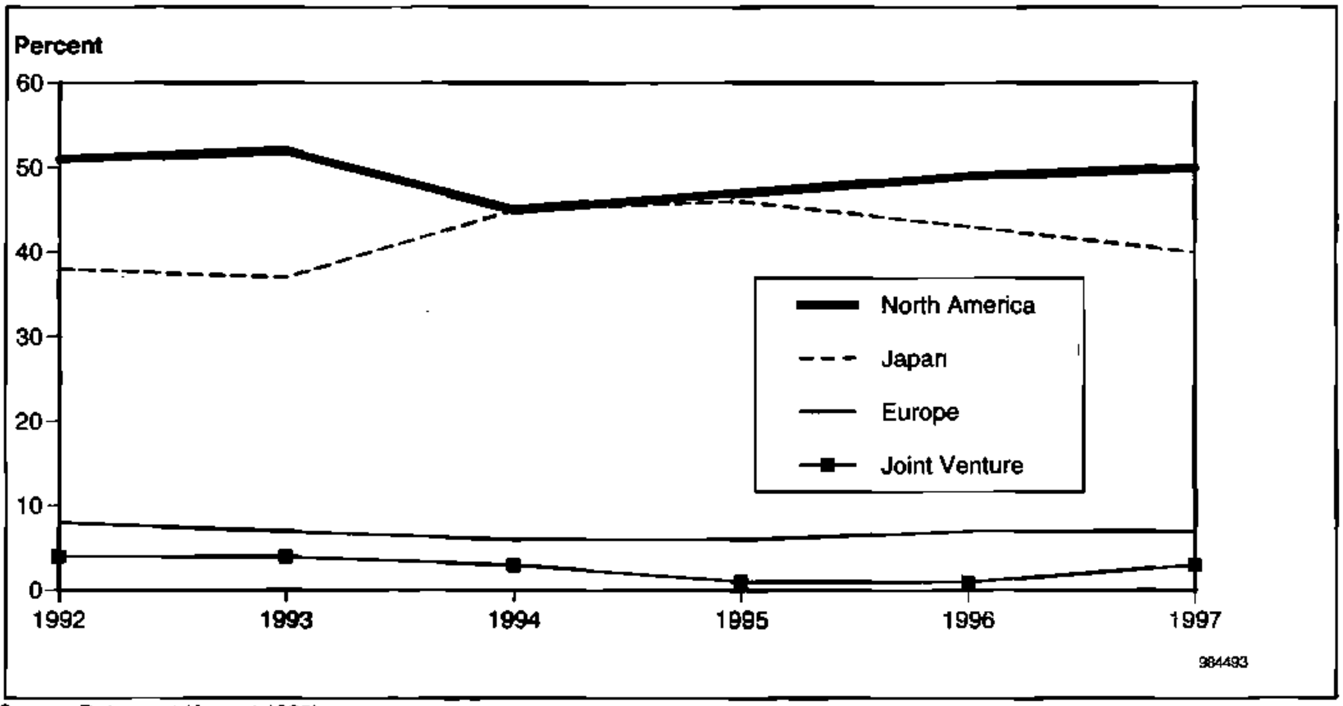


Source: Dataquest (August 1998)

The market breakdown by segment also showed mixed results. Major winners were leading-edge equipment markets, including excimer steppers, chemical mechanical polishing (CMP), rapid thermal processing (RTP), and high-density plasma chemical vapor deposition (CVD). On the other hand, the segments relying on capacity expansion, such as auto wet stations and diffusion equipment, suffered a defeat. By ownership, North American companies increased their share to 50 percent, widening a lead over Japanese competitors, whose share declined to 40 percent. This shift was mainly because U.S. companies had a stronger lead in the logic-oriented technologies, which grew relative to the DRAM-oriented equipment segments. Also, the Japanese companies were weaker than average in 1997. European companies maintained their share of 7 percent with their strength in the lithography segment (see Figure 2).

 ©1998 Dataquest

Figure 2
Recent Trends in Wafer Fab Equipment Market Share by Ownership



Source: Dataquest (August 1998)

1997 Japanese Market Trends

After Korea, in terms of losses, the Japanese fab equipment market suffered a major decline of 23 percent. Notably, as shown in Table 1, all of the categories recorded double-digit negative growth. Resist processing equipment plummeted 44 percent to $256 million, ion implantation equipment was down 41 percent to $202 million, and RTP and diffusion equipment declined 29 percent to $208 million. The major downturns reflect the direct impact of curtailed capital spending by Japanese semiconductor companies because of the sluggish DRAM market. As a result, the Japanese market's world share dropped from 30 percent in 1996 to 25 percent, a sharp contrast to the Americas market, which increased its share from 27 percent to 33 percent.

 ©1998 Dataquest

Table 1
Breakdown of Wafer Fab Equipment Market in 1997

Equipment	Japan's Revenue ($M)	Worldwide Revenue ($M)	Japan's Market Share (%)	Japan's Growth Rate (%)
Lithography	1,058.5	3,904.2	27	-14
Resist Processing	255.5	1,205.9	21	-44
Etching, Cleaning, and Planarization	1,285.4	5,194.8	25	-23
Deposition	1,186.1	4,551.5	26	-21
RTP and Diffusion	207.7	805.9	26	-29
Ion Implantation	202.3	912.2	22	-41
Process Control	570.7	2,212.9	26	-14
Manufacturing and Control	196.1	1,056.1	19	-28
Others	84.2	327.6	26	-21
Total	**5,046.5**	**20,171.0**	**25**	**-23**

Source: Dataquest (August 1998)

The breakdown by ownership reveals a similar pattern. Japanese companies lost revenue by 13 percent to $7.9 billion, compared to moderate performances of North American companies (down 1 percent) and European companies (up 1 percent). Of Japanese companies' total revenue, lithography equipment accounted for 31 percent, and resist processing accounted for 11 percent, indicating a continued dominance of exposure technology in terms of revenue. In contrast, North American companies, which are strong in the MPU and logic (including ASIC) markets, earned 59 percent of the revenue from equipment related to interconnection technology, such as etching, cleaning, and planarization and deposition.

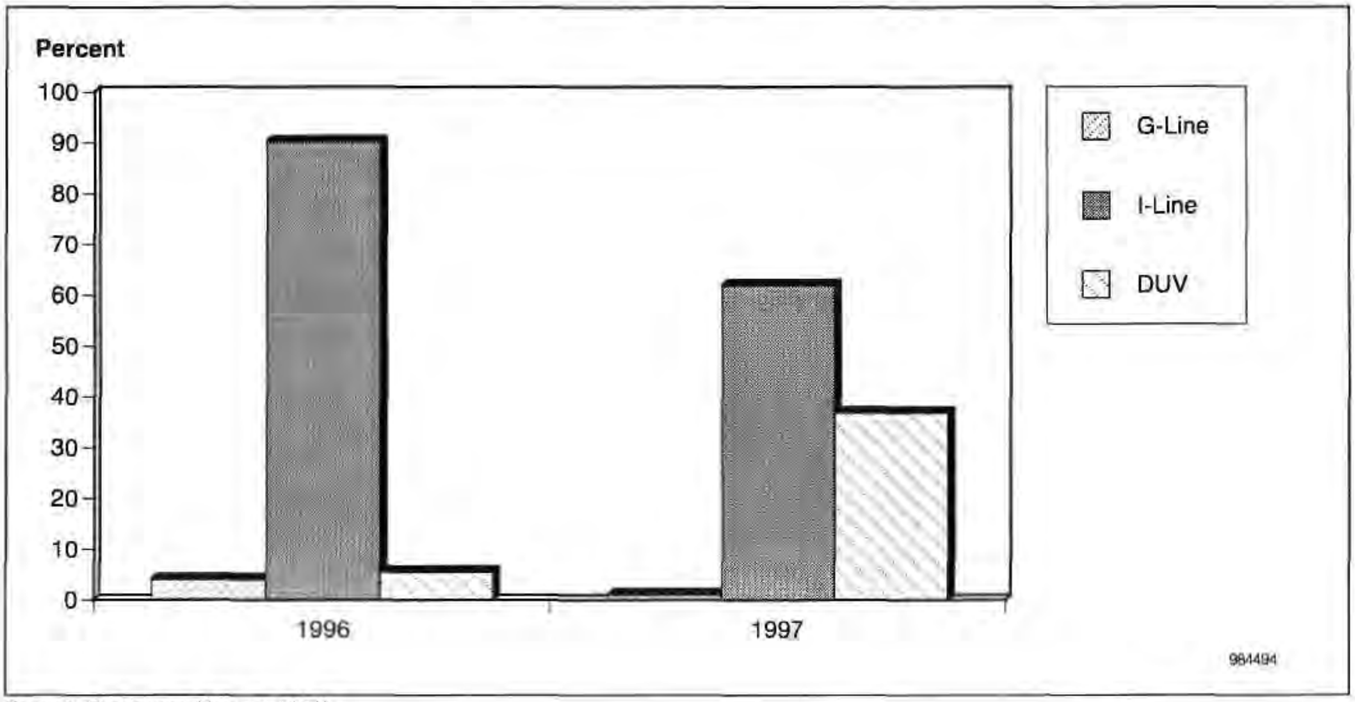
The following sections analyze major trends, reflecting the Japanese fab equipment market and manufacturers by the type of equipment.

Steppers

Steppers form a major element of wafer fab equipment investment. In 1997, the world stepper market remained almost flat from the previous year, totaling $3.6 billion. The Japanese market dropped 16 percent to $938 million. Notably, while shipment revenue (on a dollar basis) maintained more or less the previous year's level, unit shipments declined from 1,321 to 1,043. This reflects the fact that the shipment of conventional i-line steppers declined significantly because of cutbacks in capital spending for capacity expansion, whereas sales of higher-priced krypton-fluoride (KrF) excimer laser steppers grew considerably because of the commercial rollout of 0.25-micron technology. Dataquest's survey indicates that unit shipments of excimer steppers surged from about 8 percent in 1996 to 30 percent in 1997.

The breakdown by region and technology indicates that the Americas and European markets previously held high shares of deep ultraviolet (DUV) stepper shipments, but in 1997, unit shipments to the Japanese and Korean markets grew rapidly as 0.25-micron technology was introduced to 64Mb DRAM production (Figure 3). The increased use of excimer steppers for volume production has affected each vendor's share as well; while no significant change was seen in unit shipment ranking, companies that dominated the excimer stepper segment on a revenue basis increased their shares. Following Nikon Corporation, which maintained first place with a 43 percent share in 1997 (47 percent in 1996), ASM Lithography Holding N.V. advanced to second place by expanding its share from 20 percent to 25 percent and replaced Canon Inc., whose share dropped from 25 percent to 23 percent. In the second-tier group, Silicon Valley Group Inc. raised its share from 4 percent to 7 percent.

Figure 3
Recent Trends in Stepper Shipments to the Japanese Market by Technology (Units)



Source: Dataquest (August 1998)

Auto Wet Stations

The world auto wet station market totaled $954 million in 1997, an 18 percent decrease from the previous year. The highest rates of decline were seen in Europe (down 43 percent) and Korea (down 25 percent). The Japanese market also experienced a 17 percent decrease, totaling $247 million. All of these regions were adversely affected by a major setback in capacity expansion investment, particularly in the DRAM area.

The market shares by company underwent some reshuffling. While Dainippon Screen Corporation continued to hold the leading position with a 20 percent share, Sugai Corporation advanced from fourth to second place (13.3 percent), and Tokyo Electron Ltd. fell from second to third place (12.6 percent), followed by Kaijo Corp. (from fifth to fourth) and STEAG

MicroTech Inc. Japanese companies command a combined share of around 70 percent of the market. Interestingly, different companies have established dominant positions in different regions. Dainippon takes a lead in the Americas, Japan, and Korea; Kaijo takes a lead in Taiwan; Tokyo Electron takes a lead in other countries in Asia/Pacific; and STEAG MicroTech takes a lead in Europe. While there is no global winner, Sugai and Sankyo Engineering Company Ltd. are moving toward a merger, and the new company is expected to emulate Dainippon's 1997 market share. Much more consolidation is expected in the market.

Resist Processing

The resist processing market was by no means immune to the sluggish capital spending triggered by the DRAM recession. As a result, the worldwide resist processing market declined 28 percent in 1997 to $1.2 billion. The momentum of the equipment for DUV lithography, market-driven by the proliferation of excimer steppers, was dwarfed by a major decline in the conventional equipment segment. The Korean market was hit hardest, and value shipments decreased 45 percent to $105 million, followed by the Japanese market, which dropped 44 percent to $256 million. Again, high dependency on the DRAM business was a determinant factor.

As for vendor ranking, Tokyo Electron dominated the market (59 percent share), followed by SVG (15 percent) and Dainippon (13 percent). Fairchild Technologies GmbH was the only company reporting high growth (50 percent increase over the previous year) and advanced to fifth place by winning a 4 percent share. Its significantly increased presence in the Korean market served as a major impetus for this.

The DUV equipment market is expected to grow consistently with expansion of the excimer stepper market. Vendors are vying for higher performance by focusing on several areas: the controllability of atmosphere inside equipment by means of chemical filters and increased durability of the filters, accurate temperature control in the oven, and the reduction of footprint for the 300mm wafer process.

Dry Etching

In 1997, the worldwide dry etching market declined 13 percent from the previous year to $3.0 billion. Segment-wise, the low-density plasma etching equipment market was down 26 percent to $1.6 billion, while the high-density segment reported an impressive 9 percent increase to $1.4 billion. High-density plasma etching equipment has gained popularity with the pervasiveness of the 0.25-micron process, on account of profile characteristics accompanying the pattern's high-aspect ratio, selectivity, and adaptability to pattern shape. It has now reached a market size similar to that of low-density plasma etching equipment.

Regionally, the high-density plasma etching markets in the Americas and Taiwan recorded high growth, 62 percent and 61 percent over the previous

©1998 Dataquest

year, respectively, whereas the Japanese market plunged 17 percent to $333 million. As for each company's share in the high-density plasma etching markets, Applied Materials Inc. boosted revenue by 208 percent to hold a 27 percent share and get closer to the leader, Lam Research Corporation (43 percent). Hitachi Ltd. came in third. Applied Materials increased sales in the Americas, European, and Japanese markets.

Chemical Mechanical Polishing

Compared to the dreary condition of the wafer fab equipment market, which recorded a 7 percent decline, the worldwide CMP market grew 75 percent in 1997 to $518 million. In addition to the traditional strongholds in the Americas and Europe, the CMP market underwent rapid expansion in Asia/Pacific, particularly in Taiwan (up 352 percent) and Korea (up 303 percent). In all of the regions, CMP technology expanded its applications from the production of leading-edge logic devices to DRAMs. The Japanese market grew 56 percent to $134 million. As a result, regional shares changed to 41 percent for the Americas, 26 percent for Japan, 10 percent for Europe, and 23 percent for Asia/Pacific, with the Japanese and Asia/Pacific markets ahead of the European market.

In terms of system configuration, integrated CMP equipment that incorporates post-cleaning equipment has expanded its market, a 227 percent increase over 1996, to total $179 million and a 35 percent share. In particular, the Japanese market accounted for 53 percent of the entire segment.

Each company's share showed notable changes as well. IPEC/Planar managed to hold the No. 1 position, although its share dropped to 26 percent, and Ebara Corporation came in second by boosting its share to 22 percent. Applied Materials also gained a 15 percent share and followed SpeedFam Corporation, which was in third place (21.5 percent). Japanese companies together registered a considerable gain from 36 percent to 49 percent. With more Japanese companies (for example, Mitsubishi Materials Corporation, Tokyo Seimitsu Co. Ltd., and Sony Corporation) looking for market share, coupled with expanded applications (such as shallow trench isolation and the dual damascene process), the market should become more competitive.

Chemical Vapor Deposition

In 1997, the worldwide vertical- and horizontal-tube CVD system market totaled $603 million, down 24 percent from a year ago. Two markets recorded healthy growth: the Americas with 22 percent and Taiwan with 18 percent. On the other hand, the Korean and European markets declined sharply, with 64 percent and 47 percent, respectively. Similarly, the Japanese market recorded a negative growth of 25 percent, totaling $190 million. The regional disparity clearly reflects the different conditions of individual device markets.

The distinctive patterns in different segments are more pronounced in the nontube CVD system market. Low-pressure CVD (LPCVD) and

 ©1998 Dataquest

atmospheric/subatmospheric CVD (APCVD/SACVD) maintained the same revenue levels as the previous year, as bolstered by the first growth of the markets in Taiwan, the Americas, and Europe. In these markets, primary film demand comes from logic-oriented products such as blanket tungsten and gap-fill dielectric depositions. The worldwide nontube CVD market grew 6 percent to $610 million, and the worldwide APCVD/SACVD market was up 1 percent to reach $657 million. In contrast, the Japanese market recorded double-digit negative growth in the both segments—the nontube CVD market totaling $180 million, and the APCVD/SACVD market totaling $138 million—as these markets depended on the DRAM-sensitive films of tungsten silicide and higher-temperature deposited dielectric materials.

In the plasma CVD market, the low-density segment reported a 13 percent decline to $609 million, while the high-density segment recorded an outstanding gain of 88 percent, totaling $202 million. Strong market expansion was seen across the regions: The Americas grew 77 percent, Europe grew 144 percent, and Asia/Pacific grew 144 percent. The Japanese market also grew 10 percent to $12 million.

In the future, further market expansion is expected in the 0.25-micron-and-finer processes where high-density plasma CVD systems expand applications such as dielectric layers below metal films and trench isolation, in addition to the formation of dielectric layers between metal films. Leading the high-density plasma CVD market is Novellus Systems Inc., which managed to maintain first place with a 49 percent share, closely followed by Applied Materials, which increased revenue by 246 percent to gain a 48 percent share. Thus, the market is almost equally divided between the two vendors.

Silicon Epitaxial Reactors

The worldwide silicon epitaxial reactor market recorded a 25 percent growth in 1996 that was driven by DRAM demand; this turned into a negative growth of 13 percent in 1997, totaling $226 million. While it grew somewhat in the first half of 1997, it seemed to cool down in the second half. A major cause was the delay or cutback in the expansion of 200mm wafer production capacities by silicon wafer manufacturers because of the sluggish DRAM market and the lackluster outlook for wafer demand as a result of accelerated chip shrinkage. The falloff from investment in power/discrete capacity was another major cause. Regionally, the Japanese market recorded a 20 percent growth ($99 million), while other regions suffered declines: the Americas by 26 percent ($79 million), Europe by 26 percent ($39 million), and Asia/Pacific by 50 percent ($9 million). This reflects the continuous efforts of Japanese companies to explore the DRAM market as design rules fall below 0.3 micron.

In the world of 0.3-micron-or-finer linewidth, it is well known that crystal defects such as crystal-originated particles (COPs) impede yield in DRAM production. DRAM suppliers take varied approaches, which primarily reflect the maturity and economics of their processes. At present, most Japanese companies address the issue by using epitaxial wafers. At the same time, some continue to use CZ wafers (wafers created using the Czochralski

Method), adopt hydrogen-annealed wafers (Hi wafers), or consider low-COP CZ wafers.

In terms of share by company, Applied Materials continued to lead the market by holding a 57 percent share, followed by ASM International N.V. (24 percent), whose position also did not change. In third place, however, Concept Systems Design was replaced by Moore Epitaxial Inc. with a 12 percent share.

Rapid Thermal Processing

In 1997, the worldwide RTP equipment market grew strongly at 49 percent and reached $273 million. Double-digit growth was recorded in all of the regions except Europe. The Americas market was up 60 percent (totaling $106 million), Japan was up 69 percent ($69 million), and Asia/Pacific was up 69 percent ($71 million), while Europe was down 19 percent ($28 million). Entering the 0.25-micron age that requires ever finer and thinner devices, precise temperature control in the thermal treatment process becomes increasingly critical, and RTP finds new applications in ion implantation and annealing of source drains, silicide formation, and the formation of gate oxide films.

In terms of vendor ranking, Applied Materials, in first place, recorded a 139 percent increase in revenue to $162 million and gained a 59 percent share. While the company boosted sales in all of the regions, major contributions came from the Japanese market, where its sales skyrocketed by 1,640 percent over the previous year and its share grew to 58 percent. As a result, Dainippon slid from the top position in 1996, and its share plummeted to 17 percent in Japan. In the worldwide market, STEAG AST Elektronik maintained second place with a share of 18 percent. AG Associates came in fourth with a 15 percent share. Future technological challenges in the market include uniform temperature control, the improvement in temperature reproducibility because of variation in wafers' emissivity, and the improvement in the maintainability and reduction of running costs associated with the use of 300mm wafers. Various vendors are establishing volume production capabilities.

Ion Implantation

The ion implanter market is one of the markets primarily governed by individual device market trends and new fab construction. In 1997, the worldwide ion implanter market declined 18 percent to $912 million. Regionally, the Americas and Taiwan reported double-digit growth, whereas other regions suffered negative growth in double digits. Looking at individual segments, high-current ion implanters used in the source drain process and medium-current ion implanters used in the field threshold voltage control process recorded negative growth of 27 percent and 23 percent, respectively, to reflect new fab investment cutbacks by most companies, except for those in the Americas and Taiwan. On the other hand, the high-energy ion implanter market (used for the formation of barrier

 ©1998 Dataquest

layers and retrograde wells) recorded a 12 percent growth. A regional breakdown, however, unveils mixed results. While the DRAM-dependent Japanese and Korean markets declined 8 percent and 47 percent, respectively, the Americas and European markets reported appreciable growth of 59 percent and 31 percent, respectively, because they rely on logic processes where high-energy ion implantation expands applications. Overall, the Japanese market declined in all of the segments, resulting in a 41 percent decrease and $202 million.

Share by company has remained unchanged for the top three vendors: Eaton Corporation (45 percent), Varian Associates Inc. (30 percent), and Applied Materials (13 percent). However, because Varian acquired the ion implanter division of Genus Incorporated and vendors are introducing products with wider applications, market reshuffling is expected among the segments.

CD-SEM

In 1997, the worldwide critical dimension scanning electron microscope (CD-SEM) market decreased 1 percent to $327 million. Again, a regional breakdown shows polarized results. Two markets recorded strong growth: the Americas (up 21 percent) and Taiwan (up 46 percent). Two markets suffered declines: Korea (down 50 percent) and Japan (down 16 percent and totaling $79 million). The wafer testing and inspection systems industry went through major consolidations between 1996 and 1997, including the merger of KLA Instrument with Tencor Instrument and the market entry of Applied Materials. These moves have already affected market share. Hitachi continued to dominate the 1997 market with a 60 percent share, followed by KLA-Tencor Corporation (18 percent) and Applied Materials (13 percent). In the future, performance improvement efforts will focus on measurement accuracy and reproducibility at low acceleration voltage and on higher throughput. Recently, the need has arisen to implement defect analysis capabilities and evaluation capabilities in the form of data processing utilities through a graphical execution manager (GEM) interface.

Manufacturing Automation and Control

This year, Dataquest newly defined a segment in the factory automation equipment market, called semiconductor manufacturing automation and control (SMAC), for a full-scale market study. The SMAC market is further divided into automation software systems covering system integration and similar functions, transport and storage automation covering wafer handling and transportation, lithography management systems, transition environmental control systems such as standard mechanical interface (SMIF), and process environmental control systems such as cluster tool platforms.

Generally, the SMAC market is expected to be directly affected by fab investment, which was clearly seen in 1997. The entire market showed a slight increase of 2 percent to $1,209 million. Regionally, three markets showed firm growth: The Americas grew 10 percent, Europe grew 36 percent, and Taiwan grew 19 percent. The Korean and Japanese markets, on the other

 ©1998 Dataquest

hand, declined 22 percent and 23 percent, respectively. Again, the market contrasts are evidence of the impacts of major cutbacks in DRAM-related capital spending on some markets. However, in the Japanese market, to which total shipments in 1997 amounted to $237 million, the transition and process environmental control segments registered positive growth, albeit a small size, and systems adaptive to the next-generation production environment, including SMIF and cluster tool platforms, showed some signs of market expansion.

In terms of share by company, Japanese and North American manufacturers dominate the market, controlling 30 percent and 64 percent, respectively. North American companies hold high shares in Taiwan, other Asia/Pacific countries, and Europe, in addition to their home ground. On the other hand, Japanese companies take the lead in the Japanese and Korean markets. In the 1997 market share ranking, PRI Automation came first with a 15 percent share, followed by Daifuku Company Ltd. (14 percent), Asyst Technologies Inc., and Digital Equipment Corporation. Among the Japanese companies, Shinko Electric Company Ltd. ranked sixth (6 percent).

Equipment Vendor Ranking

Table 2 lists the top ten semiconductor equipment manufacturers in 1997. Clearly, Japanese companies decreased their revenue, whereas U.S. companies recorded firm growth. While no change is seen in the top three, KLA-Tencor ranked fourth because of the merger, and Canon fell from fifth to seventh place because of slow sales in the stepper market. In contrast, ASML maintained sixth position by gaining share in the excimer stepper market and boosting revenue by 21 percent. SVG was also driven by increased revenue from excimer steppers and achieved ninth place. On the other hand, Dainippon stepped down from seventh to tenth place because of the slump in the resist processing and auto wet station markets.

Table 2
Semiconductor Equipment Vendor Ranking

1996 Rank	1997 Rank	Vendor	1996 Revenue ($M)	1997 Revenue ($M)	1997 Growth (%)	1996 Market Share	1997 Market Share
1	1	Applied Materials	3,350.5	3,669.3	9.5	15.9	18.7
2	2	Tokyo Electron	2,591.2	2,145.1	-17.2	12.3	10.9
3	3	Nikon	1,721.2	1,565.2	-9.1	8.2	8.0
-	4	KLA-Tencor	-	1,027.2	-	-	5.2
4	5	Lam Research	1,091.9	915.6	-16.1	5.2	4.7
6	6	ASML	726.0	875.9	20.6	3.5	4.5
5	7	Canon	956.0	862	-9.8	4.5	4.4
8	8	Hitachi	631.9	609.2	-3.6	3.0	3.1
10	9	SVG	551.2	560.6	1.7	2.6	2.9

Source: Dataquest (August 1998)

©1998 Dataquest

The wave of consolidation in 1997—including the mergers, acquisition of divisions, and alliances—seems to have subsided in 1998. Nevertheless, Sugai and Sankyo Engineering plan to merge for the sake of survival in the auto wet station market to form a new company, SES, and Varian has announced the acquisition of the ion implanter division of Genus. Thus, market reorganization is expected to continue through mergers or acquisitions, and market share in various segments will change accordingly.

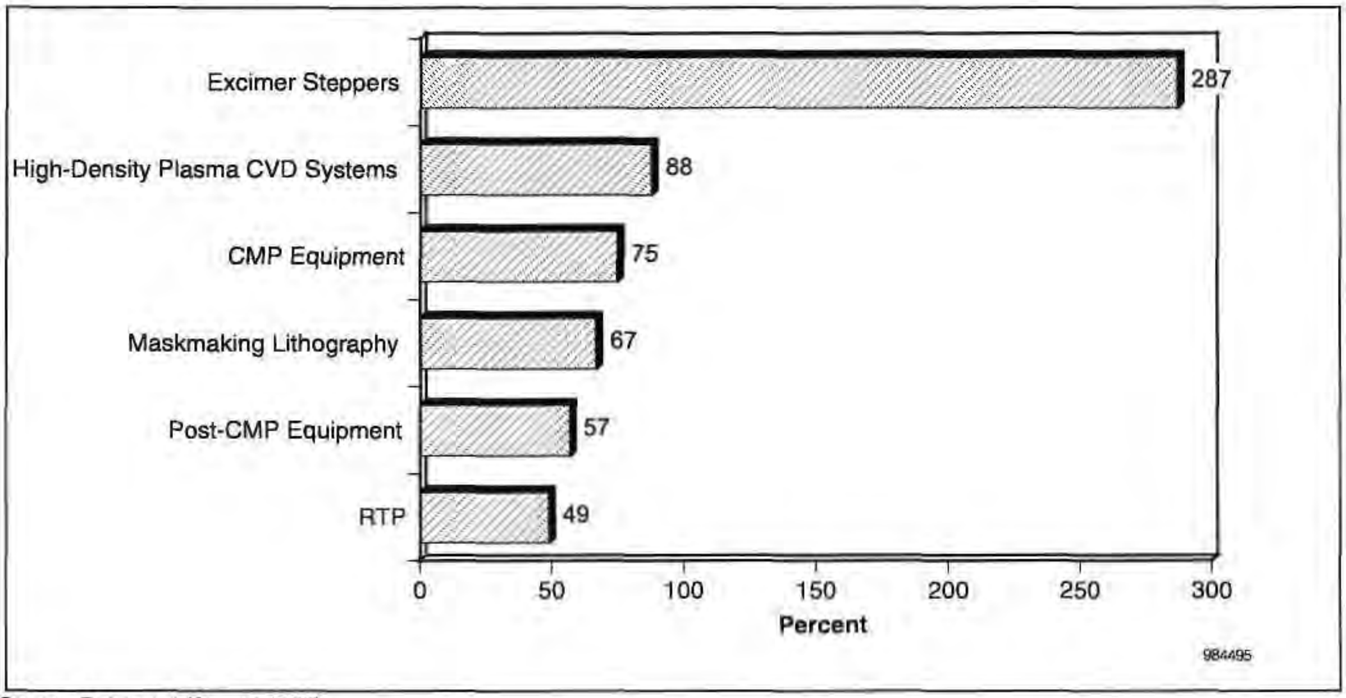
Dataquest Perspective

The 1997 fab equipment market trends can be summarized in several ways. Generally, the Japanese and Korean markets contracted dramatically as they relied heavily on DRAM investment, and, therefore, equipment companies selling their products primarily in these two markets suffered significant revenue loss. In contrast, the Americas market, whose lifeblood lies in logic (including ASICs) and MPUs, and Taiwan, where foundry investment is rampant, enjoyed expansion, and equipment manufacturers holding share in these markets recorded healthy growth. Thus, the fab equipment market in 1997 was directly linked to the local characteristics of device production, which resulted in a notable regional gap.

Parallel to the widening regional disparity, technology-driven market expansion continues, as seen in 1996. Figure 4 lists segments that recorded high growth in 1997. While the fab equipment market recorded a negative growth of 7 percent, several segments related to 0.25-micron and later process technologies, led by excimer steppers, grew strongly. While the entire market is expected to remain sluggish for another year or two, these high-end segments that hold the key to the commercialization of leading-edge process technology—particularly, sputtering equipment that forms copper interconnections (seed layers) and the formation of electroplated films—will follow a path of solid growth.

 ©1998 Dataquest

Figure 4
Fast-Growing Segments in 1997 (Worldwide)



Source: Dataquest (August 1998)

In the future, regional equipment market trends will further be differentiated according to the development of leading-edge technology and according to their local device markets and growth patterns. At present, Japanese semiconductor companies are struggling to pursue and nurture high-value-added businesses, such as system-level integration (SLI). In the short run, however, they still have to depend upon DRAM. Dataquest predicts that the DRAM market will make a sufficient recovery after the end of 1999, allowing suppliers to resume full-scale capacity expansion. In the meantime, the Japanese wafer fab equipment market will have to rely on leading-edge equipment such as excimer steppers, CMP, RTP, and high-density plasma CVD as market drivers.

Semiconductors Japan
Market Analysis

Time to Think about the Marketability of 128Mb DRAM

Abstract: *Traditionally, DRAM has quadrupled its integration level. In 1998, however, the grand tradition has been broken with the introduction of 128Mb DRAM. The industry considered the development of 32Mb DRAM in 1996 to be a bridge between 16Mb and 64Mb DRAM, although the 32Mb DRAM failed to materialize as marketable, generic DRAM. Likewise, many view the newly rolled-out 128Mb as a short-lived stopgap between 64Mb and 256Mb DRAM. Whether the quadrupling pattern will continue to dominate or the industry will undergo a paradigm shift in DRAM evolution where the doubling becomes the norm is a critical issue for both DRAM users and suppliers in their product development. This Perspective analyzes 128Mb DRAM from the marketability point of view and examines differentiating factors for 64Mb, 128Mb, and 256Mb DRAM with opportunities for market segmentation.*

By Masahiro Suzuki

Market Forecast for 128Mb DRAM

FILE COPY:
MARIA VALENZUELA

In 1998, the DRAM market is in transition from 16Mb to 64Mb, the demand for which has yet to ramp up. However, some leading Japanese and Korean DRAM vendors have unveiled the start of volume production of 128Mb products, which is to take place at the end of this year, and other companies seem to be following suit. To add complexity or choice, some Japanese and Korean suppliers have announced commercial shipments of 256Mb DRAM, starting in early 1999. If these plans proceed according to schedule, 64Mb will become the mainstay in the 1998 DRAM market, and three generations of leading-edge DRAM—64Mb, 128Mb, and 256Mb—will coexist in 1999.

In making forecasts for various device markets, Dataquest refers to past trends and demand forecasts for electronics. In our extensive database, however, there is no comparable case like this one—three generations of leading-edge devices competing in the same market. It is therefore important

Dataquest
Program: Semiconductors Japan

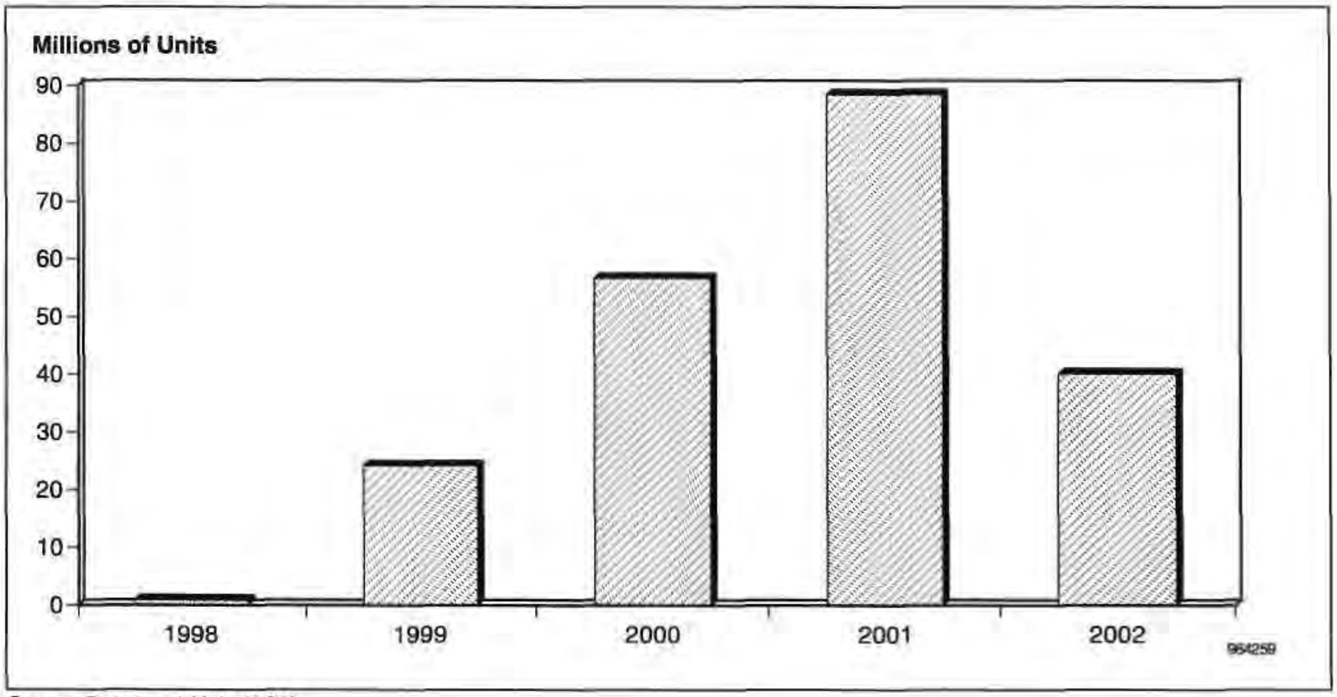
PublicationDate: August 3, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

to analyze the 128Mb DRAM market in our May 1998 forecast by focusing on the demand-side, system vendors and their products.

Figure 1 shows unit shipment forecasts for 128Mb DRAM between 1998 and 2002. Note that the 1998 shipments are rather limited, around 900,000, as the forerunners are expected to start up volume production in the third quarter of 1998. To encapsulate the 128Mb chip in the 400-mill package required by DRAM users, semiconductor companies must use the leading-edge production process of 0.23-micron or finer, the capacity of which will inevitably be limited in 1998.

In 1999, other leading vendors will enter the market, and unit shipments will grow steadily. The market is expected to peak in 2001 and then plummet in 2002 to one-half the level of 2001, under the assumption that volume production of the 256Mb version will start to trigger the bit price crossover with 64Mb in that year. Some believe that 128Mb will be further short-lived as volume production of 256Mb ramps up earlier than expected. However, if this happens and 256Mb starts to replace 128Mb at an earlier time, suppliers will face price erosion of the leading-edge device, which will make it difficult for them to reap major investment and secure sufficient profitability for the DRAM business.

Figure 1
Total 128Mb Unit Demand



Source: Dataquest (July 1998)

 ©1998 Dataquest

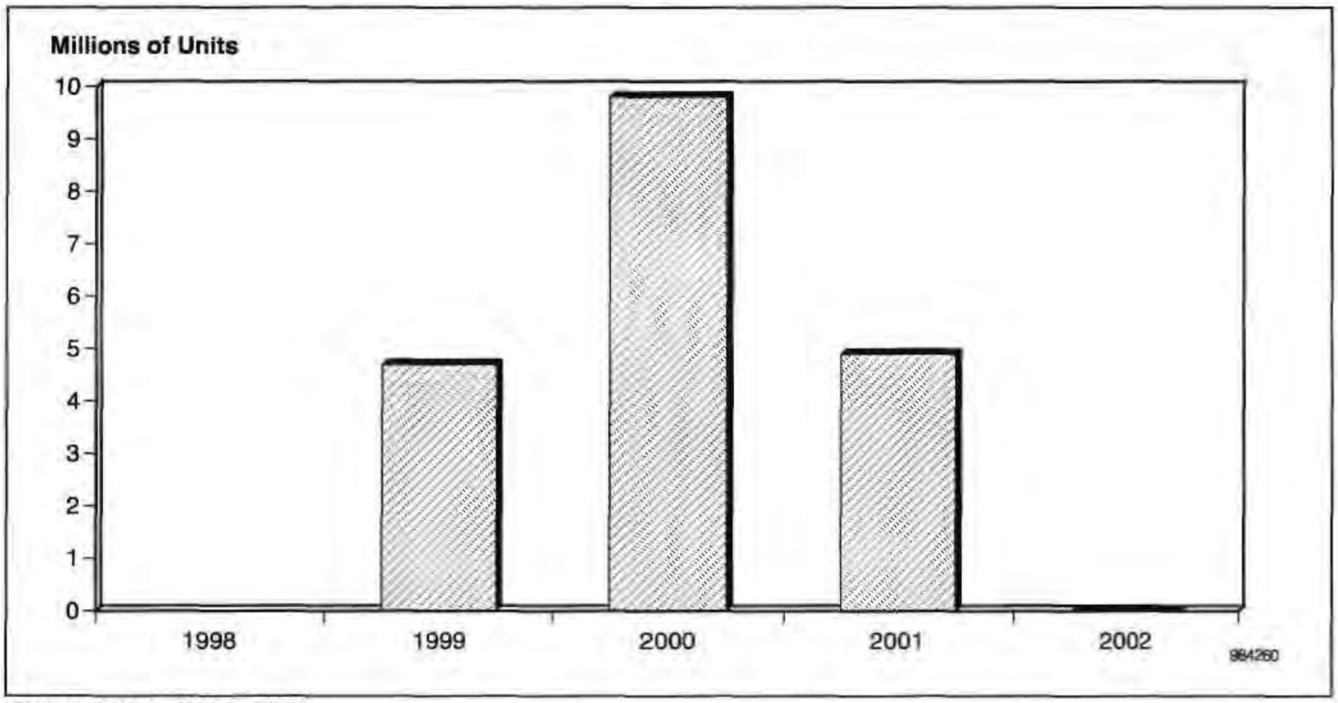
Demand Forecast for 128Mb DRAM

Major target applications for 128Mb DRAM include midrange computers, workstations, PC servers, and high-end notebook PCs. Generally, high-end computers require a larger main memory, which consumes DRAMs of larger capacity, resulting in a higher price premium. On the other hand, semiconductor companies are focusing their efforts on the development of 128Mb synchronous DRAMs (SDRAMs). Generally, when SDRAMs are packaged in a buffer-type dual inline memory module (DIMM), the number of slots available on the motherboard is limited to eight. Thus, supercomputers and mainframes, which require a very large main memory, tend to use extended data out (EDO)-type DRAMs rather than SDRAMs by maximizing performance through the interleave approach.

Midrange Computers

Midrange computers are classified as one class above workstations and thus have relatively large main memory requirements. 128Mb DRAMs will be an attractive choice for low-end machines with a smaller memory size, but they will soon be replaced with 256Mb DRAMs according to the price decline. As a result, 128Mb DRAM demand in the midrange market will reach its peak level in 2000 (see Figure 2).

Figure 2
Midrange Computers: 128Mb Unit Demand



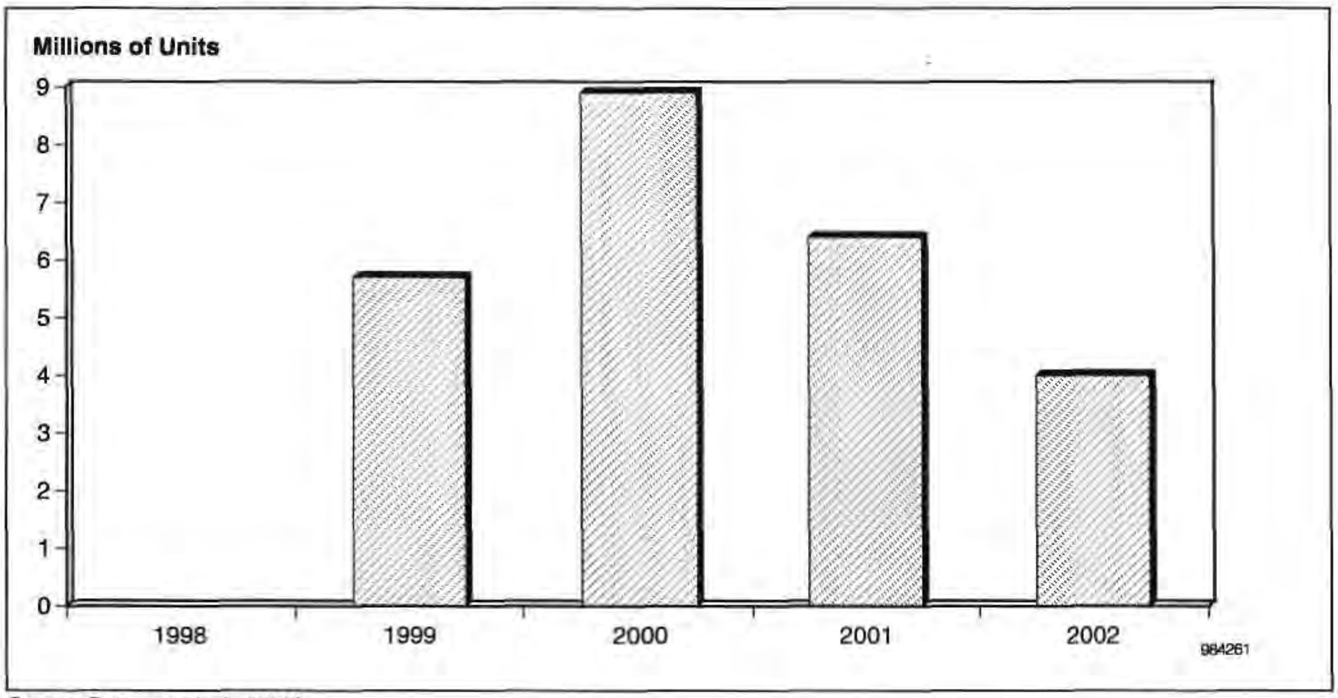
Source: Dataquest (July 1998)

Workstations

This is the segment where replacement of 128Mb by 256Mb is not certain. When the market is divided into three parts—high-end, midlevel, and low-end—the replacement process will be sure to occur in the high-end segment. On the other hand, in midlevel and low-end machines, it will be conditional to the 256Mb price, which must decline to a level triggering the crossover. Furthermore, the low-end segment should be preceded by the proliferation of 128Mb products as their bit price becomes closer to that of 64Mb products.

Interestingly, high-end workstations account for less than 1 percent of the total annual unit shipments, whereas low-end machines represent more than 70 percent. This means that unless the 256Mb price falls significantly, the rate of replacement is not likely to accelerate. In the low-end segment, the 256Mb nonbuffered DIMM will be mainly used for cost saving. In contrast, high-end machines with large memory will demand the buffer DIMM version. The main memory size of 1GB seems to be a threshold. Dataquest predicts that demand for 128Mb DRAM in the workstation market will peak in 2000 and then will gradually be replaced by 256Mb DRAM with a declining price (see Figure 3).

Figure 3
Workstations: 128Mb Unit Demand



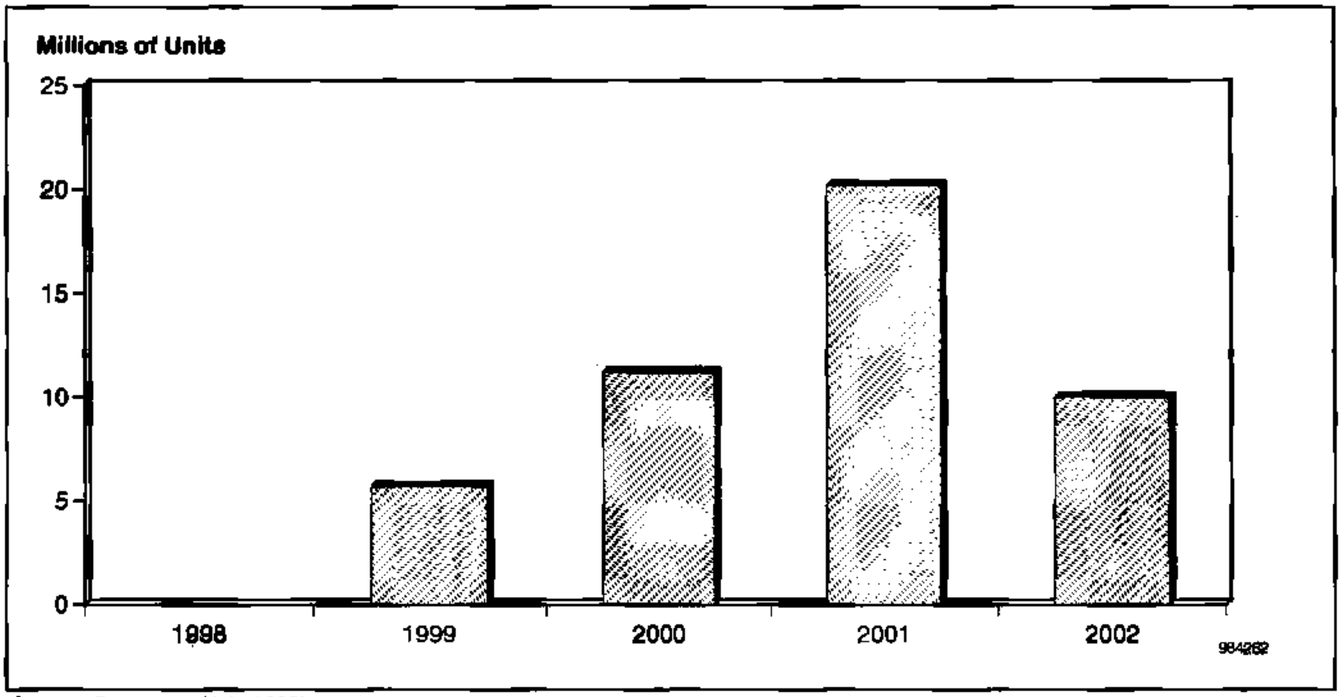
Source: Dataquest (July 1998)

 ©1998 Dataquest

PC Servers

As also seen in the low-end workstation segment, PC servers will become a major application market for 128Mb DRAM that can replace 64Mb DRAM if a parity is reached for the bit price. Between 1998 and 1999, unit demand for 128Mb will expand so much that it will prompt DRAM suppliers to launch strategic pricing for market share. Again, PC servers will opt for the nonbuffered DIMM type. Market demand for 128Mb will reach the highest level in 2001 (see Figure 4), during which time 128Mb will still keep price competitiveness against 256Mb on a bit-price basis.

Figure 4
PC Servers: 128Mb Unit Demand



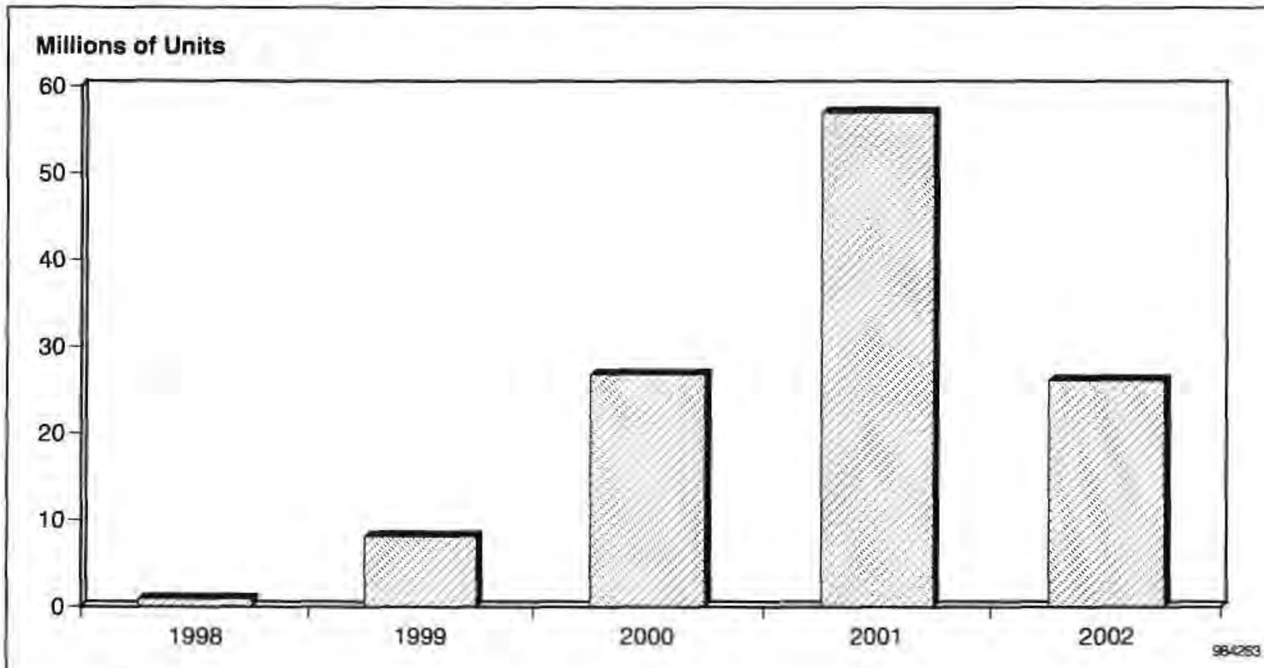
Source: Dataquest (July 1998)

Notebook PCs

The seemingly relentless drive for a thin form factor makes the packing of parts into less space an increasingly critical issue. The use of 64Mb DRAMs in high-end notebook PCs in early 1997 is evidence that vendors can afford to select costly, large-capacity DRAMs if main memory is to be expanded. The 64MB main memory will increasingly become a standard feature of 1998 models with the release of Windows 98. 128Mb DRAMs will be able to easily configure a thin 64Mb module by allowing four units to be mounted on the single side of the small-outline DIMM (SODIMM). Dataquest believes that high-end models will start to incorporate 128Mb DRAMs in the second half of 1998. The 128Mb price is expected to enter a downward path in 1999, pushing the pervasiveness of notebook PCs. Demand in the notebook PC market will reach its peak in 2001 (see Figure 5).

©1998 Dataquest

Figure 5
Notebook PCs: 128Mb Unit Demand



Source: Dataquest (July 1998)

As demand forecast for 128Mb DRAM in four major target applications indicates, actual market acceptance is governed by price levels and the timing of model changes in each segment. Another factor is the generation shift from 64Mb to 256Mb, which is expected to occur in 2002. Once the bit price crossover takes place between 64Mb and 256Mb products, it will entail accelerated replacement of 128Mb DRAM by 256Mb DRAM. Table 1 lists 128Mb DRAM shipment schedules of eight leading DRAM suppliers in Japan and Korea.

Table 1
128Mb DRAM Shipment Schedules of Leading Suppliers in Japan and Korea

	Hitachi	NEC	Samsung	Toshiba	Hyundai	LG Semicon	Mitsubishi	Fujitsu

Volume Production	Q2/98	Aug 98	Q3/98	Q4/98	Q4/98	Q4/98	Q1/99	H1/99

Source: Dataquest (July 1998)

Dataquest Perspective

In 1998, the previous hype about 128Mb DRAM is beginning to subside among leading Japanese and Korean DRAM suppliers, as they can afford less and less R&D expenditure. At present, the highest priority is given to the development of a 64Mb shrink chip, for which leading-edge fabrication processes are starting up at an accelerated pace. The next priorities will be

 ©1998 Dataquest

the 64Mb version that is adaptive to column address strobe (CAS) Latency 2 for PC100, which will take up much time toward the end of 1998, and the next-generation high-speed DRAM in 1999. Future development points to cost reduction, high speed, and large capacity. In particular, the first two areas are already subject to intensive competition. Under these situations, 128Mb DRAM, which is doomed to serve as a stopgap between 64Mb and 256Mb, inevitably lags behind in the R&D priority list.

128Mb DRAMs come in two types: the stack type to integrate two 64Mb chips into one package and the single-chip type. The stack type, already marketed by a Japanese manufacturer, is more costly than the single-chip version. Also, the use of two chips doubles input capacitance, which results in larger dynamic power loss because of charge/discharge with the switching operation, making it unsuitable for notebook PCs. Korean suppliers, originally working on the stack type, are now focusing on the single-chip version. Dataquest believes that the single chip will become the mainstay in the 128Mb segment.

Because there is a limited number of Japanese and Korean DRAM suppliers who can start volume production in 1998, the forerunners will be able to maintain leadership in the 128Mb pricing. The use in PC servers is spurred when the bit price of 128Mb becomes 1.5 to two times that of 64Mb. Dataquest expects that the total shipments of 128Mb DRAMs will reach 24.2 million units in 1999, which translates to a moderate number of 2 million per month. Thus, the initial target is set for midrange computers, workstations, PC servers, and notebook PCs; the market can be sufficiently served by the three forerunners. However, as shown in Table 1, more entrants are expected, and oversupply is highly likely in 1999.

In conclusion, the general impact of 128Mb products on the entire DRAM market can be described by two possible scenarios:

- Scenario 1: When the bit price of 128Mb DRAM constantly exceeds that of 64Mb DRAM, target markets for 64Mb, 128Mb, and 256Mb become highly distinctive: 128Mb for midrange computers, workstations, PC servers, and notebook PCs; and 64Mb for supercomputers, mainframes, and PCs. Then, once 256Mb DRAM is introduced, migration will start from the high-end segments. In this case, DRAM suppliers, particularly the three forerunners, will be able to reap profits from the business.
- Scenario 2: Generally, the semiconductor business relies on volume production for profitability. However, unless semiconductor companies listed in Table 1 discipline themselves in curtailing their output, a supply glut is hard to avoid, and price erosion will follow. The question is how far the price will decline. As the bit price of 128Mb becomes closer to that of 64Mb, desktop PC manufacturers will be enticed to use it, which will push the 64Mb price downward to trigger the price decline cycle between the two products. In this case, manufacturers having volume production capabilities of both 64Mb and 128Mb on the 0.23-micron-or-finer process will be able to have a cost advantage in 128Mb fabrication, if the production yield is more or less the same for the two products. In other words, 128Mb DRAM will be a lucrative product for companies that have

a competitive edge in leading-edge process technology. On the other hand, those without it will have to suffer a blow.

Dataquest believes that the significance of 128Mb DRAM is found not only in the fact that it breaks from the traditional quadrupling but that this device will determine the profitability of DRAM suppliers entangled in persistent excess capacity.

Perspective

Semiconductors Japan

Market Analysis

A Changing Landscape for the Japanese Foundry Business

Abstract: *This Perspective analyzes foundry business trends for Japanese semiconductor companies on the basis of Dataquest's latest foundry shipments survey results. The prolonged recession of the Japanese semiconductor market increases the capital investment burden, and alliances are needed to build the ability to produce system LSIs—the wave of the future. In the changing environment, foundry business plays a much different, increasingly active role in the industry. Foundry business is gaining new meaning for Japanese semiconductor manufacturers, which are becoming foundry users themselves rather than foundry providers as in the past.*
By Yoshihiro Shimada

Start of Dataquest's Official Foundry Survey

Dataquest has been tracking semiconductor companies' brand shipment revenue trends in the annual market share survey. In 1997, we added a new item, foundry shipments and purchase, covering gross revenue from foundry business, as well as users and technology trends. Since foundry demand is continuously on the rise, the new survey focus is designed to shed light on this demand from the foundry company's perspectives and analyze the overall impact of foundry business on the semiconductor industry.

Most Japanese semiconductor companies have their own fabs and are generally referred to as integrated device manufacturers (IDMs). Japanese IDMs characteristically ramped new fabs producing the most advanced DRAMs, and as new fabs with more advanced technology are built, the old fabs are converted to produce other devices, including MOS logic, MOS microcomponents, and later, even analog. This has been regarded as the most efficient method of fab utilization and has actually been the most typical method. This traditional conversion cycle, however, has been changing recently. Instead of converting DRAM fabs to production of other

Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

devices, companies are required to build new fabs with logic capabilities. The change is partially driven by the notable success of dedicated foundry providers led by Taiwan Semiconductor Manufacturing Company (TSMC), together with the high profitability they have demonstrated.

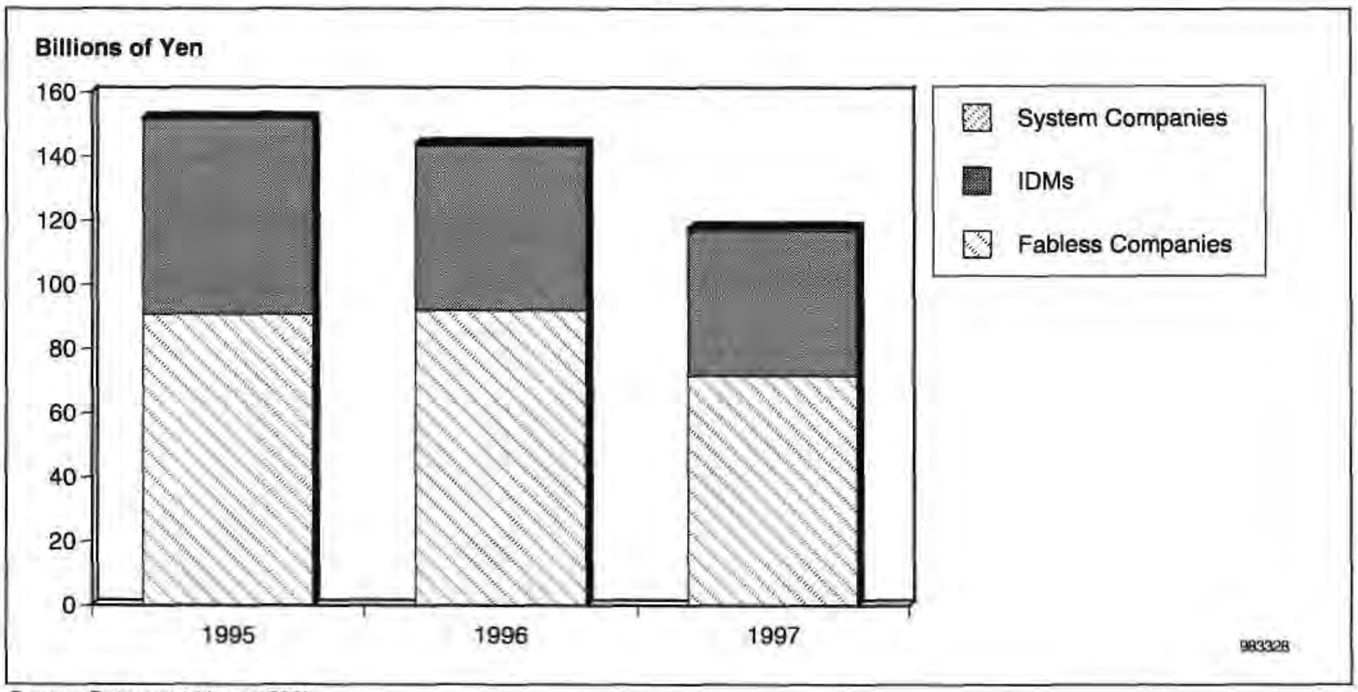
Foundry production as referred to throughout this Perspective includes the OEM production observed among Japanese and Korean companies.

Declining Foundry Shipments from Japan

In the 1997 semiconductor brand shipments ranking, Japanese companies again lost share in the worldwide market. At the same time, their total foundry shipments declined while the worldwide foundry market was expanding (see Figure 1). This makes a sharp contrast to the increasing commitment by Japanese semiconductor companies to foundry business. To put it simply, their decision came long after that of their competitors, especially dedicated foundry providers in Taiwan, who established technical leadership and developed close relationships with U.S. fabless companies.

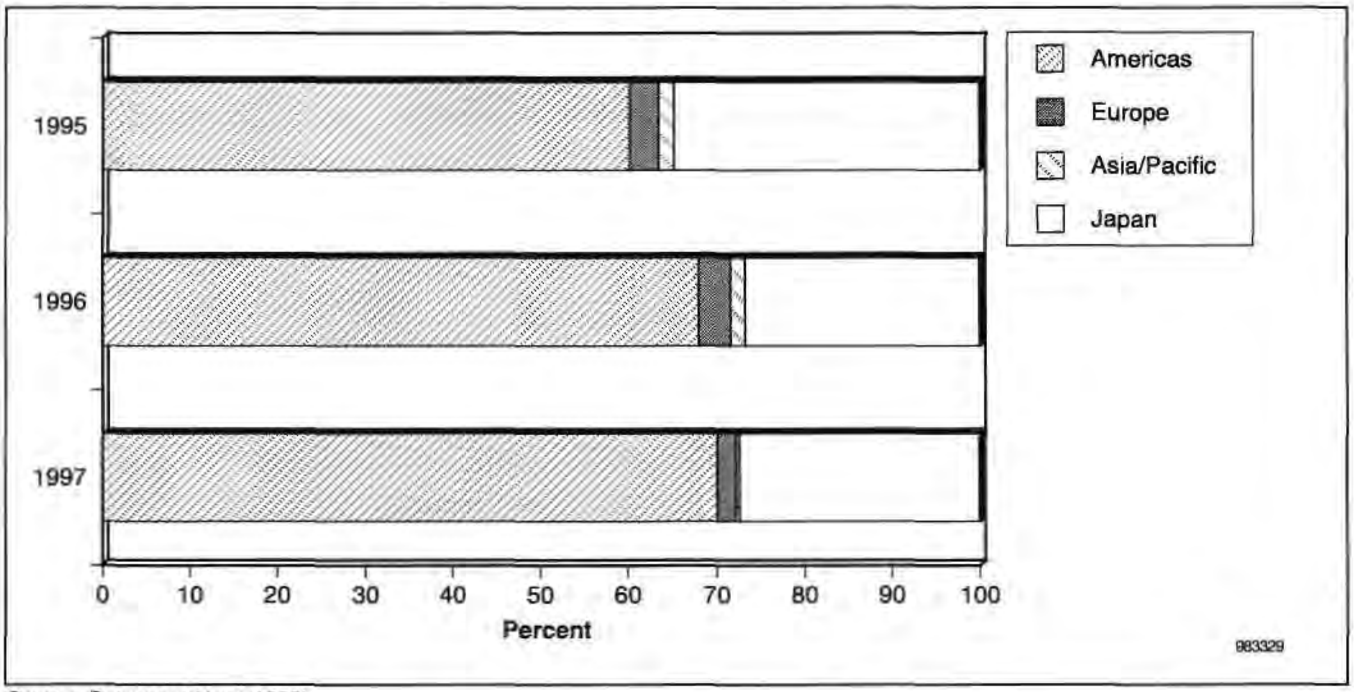
A major destination of foundry shipments by Japanese companies is the Americas market, which accounts for 70 percent of the total (see Figure 2). While the share of the Americas region has been on the rise since 1995, the absolute figure shows slight declines. This reduction in shipments comes mainly from reduced foundry business with U.S. fabless companies. At the same time, the value of shipments to the Japanese market has been declining, which reflects not only sluggish foundry contracts among Japanese companies, but also a decline in domestic delivery to foreign foundry users.

Figure 1
Japanese Companies' Foundry Shipments by User Type



Source: Dataquest (June 1998)

Figure 2
Japanese Companies' Foundry Shipments by Destination



Source: Dataquest (June 1998)

The downward trends are clearly evident in an analysis of revenue by product. The market share of logic and microcomponents, which accounts for a major portion of foundry shipments to Americas fabless companies, has dropped significantly compared to two years ago (see Figure 3). Instead, flash memory foundry has increased, with shipments from Japanese companies such as Sharp Electronics Corporation and SANYO Electric Company Ltd. to U.S. partners.

Technology trends are visible in the change in share by wafer size, down for 150mm and up for 200mm (see Figure 4). The major reasons for these changes include the following, given that 200mm fabs:

- Account for a large chunk of excess capacity because they were built during the previous boom
- Need to be operated to their capacity to vie effectively for the increasingly competitive foundry business
- Are more advanced than their 150mm counterparts in terms of design rule

The third point is substantiated by the fact that 0.5-to-0.8-micron processes using 150mm wafers lost share, while 0.5-micron or finer processes, which can be translated to 200mm fab technology, have gained sharply (see Figure 5). Finally, products with one to two metal layers lost share, while three-layer designs grew to 17 percent of the total in 1997. No contract has been won for four or more layers (see Figure 6).

 ©1998 Dataquest

These technology trends suggest that Japanese foundries are focusing on higher capacity utilization for 200mm fabs, while they still have to establish capabilities to support U.S. fabless companies.

Foundry Orders on the Rise

Showing a clear contrast to declining foundry shipments, foundry orders by Japanese companies have been increasing steadily, although their worldwide share is still fairly small. While Japanese IDMs have not yet utilized their DRAM capacity fully, their logic fabs are not meeting customer demand, either in volume capacity or in technological capability. Rather than converting memory fabs to logic, which requires additional capital spending, Japanese IDMs are trying to leverage the low production cost of dedicated foundry providers. Alliances and foundry deals involving Japanese companies can be classified into the following models.

Evolution from Joint Development to Foundry Production

Primary examples are Sharp, producing flash memory for Intel Corporation, and Hitachi Ltd. and Mitsubishi Corporation, which share development and production efforts for their own brands of flash products. The intent is to reduce the R&D burdens on circuit design, process technology development, and product planning, while optimizing a production system where partners are responsible for production resources that they can provide with a comparative advantage.

Generally, the manufacture of a product developed by a partner leaves a foundry (an OEM) with relatively little value added. Still, the foundry provider can benefit by gaining experience with a product that it would be difficult to develop or market on its own, not to mention the infusion of new technology, which may enable it to develop proprietary products. This type of partnership can be mutually beneficial as long as each partner has a key technology to license. By sharing the development process from the outset, the production process can be made more reliable. At the same time, it allows the partners to maximize flexibility and efficiency in marketing their own products.

Capacity Supplementation

Traditionally, Japanese companies have seen foundry contracts as a means of using their excess capacities and keeping fabs highly utilized. In particular, when companies are hit by recession just as fabs invested in during a booming market come on line, foundry use is considered to be the "last resort" to avoid idling capacities. Companies often accept orders that are far below the ordinary break-even point for brand shipments.

Foundry deals in the form of such capacity supplementation are typically limited to a specific period, especially in the case of an IDM, that is, until the IDM's own fab is ready for start-up. In the case of an OEM deal, foundry production may be a temporary relief for the customer until it has the ability to develop and manufacture its own products. On the other hand, the OEM may rely on the foundry deal as a strategic instrument that effectively prevents the manufacturer from making inroads into the market.

At present, Japanese companies that order foundry production to supplement their capacities are primarily doing so in the DRAM field, such as Hitachi/LG Semicon, Fujitsu/TSMC, and Toshiba/Winbond Electronics.

 ©1998 Dataquest

The Hitachi/LG Semicon deal is unique in that the two companies—major players in the DRAM market with their own established brands—have entered an alliance in the form of a joint production arrangement. Hitachi also maintains a long-term relationship with Texas Instruments Inc. and operates diverse DRAM processes. This framework allows Hitachi to disperse burdens and risks related to product development and manufacture, but at the same time, Hitachi has presumably been loaded with the management of those diversified masks and processes. For LG Semicon Co. Ltd., the alliance is intended to ensure a jump-start of its new business thrust by leveraging technology and production capacities.

The other two deals differ from that of Hitachi and LG Semicon. TSMC and Winbond Electronics Corporation do not intend the first step of entering the DRAM market for foundries. The decision by TSMC to start a DRAM foundry with Fujitsu seems to represent a point of confluence for TSMC's strategy to establish "0.35-micron and beyond DRAM cell" technology, which was included in its technology road map. On the other hand, Fujitsu intends to disperse risks related to capital spending. These two companies' strategies match, which has led to their foundry deal. The Toshiba/Winbond alliance, which follows a similar pattern to the TSMC case, is characterized as part of their broader partnership, including LCDs.

Strategic Alliance

The Toshiba/Motorola alliance has served as a model for a constructive relationship between Japanese and U.S. semiconductor industries facing much-publicized trade friction. This broad-based, long-term (seven-year) relationship embraced a number of models and paved the way for a myriad of subsequent alliances. Among these were joint product development initiatives uniting the strengths of the partners, committed assistance in increased access to the Japanese market, wafer fab production at a joint venture (for instance, Tohoku Semiconductor), and factory-based collaboration in production efforts.

Nevertheless, the relationship seems to have matured to a stage requiring redefinition as the Japanese semiconductor market is losing its attractiveness in the global context and semiconductor production in the country is waning in terms of comparative advantage. The Hitachi/TI alliance faces a similar situation. Under the long-term relationship, the two companies chose a U.S. joint venture rather than a foundry contract. However, the joint venture was discontinued this March. In this sense, foundry is becoming a less desirable option for IDMs, which have traditionally used it as part of a strategic alliance. Foundry business itself increasingly makes sense on the basis of its flexible, low-cost production.

Evolution from Joint Production

Mitsubishi Electric Corporation has established Powerchip Semiconductor Corporation with UMAX Group of Taiwan to reduce financial burdens from capital spending, use the Taiwan semiconductor industry and its increasingly credible resources, and explore a new DRAM user (since UMAX is a PC motherboard manufacturer). The deal includes a new attempt to reduce the workload for marketing efforts through the joint venture, as

 ©1998 Dataquest

opposed to the traditional approach that foundries are solely responsible for production. Powerchip is authorized to ship its own products in excess of a certain production level under its own brand. If this happens, shipments to Mitsubishi Electric will be on a partial foundry basis that goes beyond the traditional, narrow definition.

The Powerchip case relied on UMAX's high expectations for profits from the booming DRAM business as well as Mitsubishi's expectation of securing users for its products. In this sense, this type of alliance cannot be positioned as a general model. Nevertheless, it certainly suggests one of the feasible directions for the industry, which is seeking a way to reduce capital investment requirements by leveraging the technological prowess of each company.

This categorization seems to depict, among other things, the versatile roles of Taiwan companies. Backed by rich financial resources, they have successfully developed semiconductor production into the broad relationships shown here. Japanese PC manufacturers have accelerated procurement from Taiwan companies on an OEM basis since the mid-1990s. The viability of these complementary roles is based on the fact that semiconductor companies in the two countries are both primarily vertically integrated electronics manufacturers. This long-term relationship seems to lay the foundation for diverse alliances in semiconductor production and can serve as the core of a strategy.

Dataquest Perspective

Japanese semiconductor companies largely assume foundry business to be less than profitable, which clearly reflects the "opportunistic" nature of the Japanese foundry business model. Foundry business is forced to assume this less-than-exalted position for several reasons. First, obsolete fabs, rather than leading-edge ones, are used for foundry. Second, the primary purpose of foundry production lies in maximizing utilization. Finally, foundry production is considered a part of complementary or diverse alliances between IDMs. However, with the emergence of TSMC, which has proven the high profitability of the dedicated foundry business, Japanese companies are looking for opportunities to improve the profitability of their own foundry contracts. Many are expecting foundry deals to fill a growing gap between demand and supply capacity stemming from the prolonged recession of the semiconductor market. However, this expectation is no longer feasible, as evidenced by declining foundry revenue. Clearly, the tide has turned. The foundry market continues to establish itself by offering lucrative opportunities for specialized manufacturers. It cannot be viewed as the last resort for IDMs to replenish idling capacities.

Dr. Morris Chang of TSMC, in his recent speech at Dataquest's Semiconductor Conference 98, stated, "It is not correct to think of foundry as a manufacturing issue. Rather, foundry is a service business, and without that notion, you cannot be successful in the business." Foundry service as a reliable and viable business becomes feasible only when there is no need for

 ©1998 Dataquest

the manufacturer to adjust a process conflict with its own products, which strongly suggests the need for the specialized company.

For dedicated foundry providers, Japanese semiconductor companies can be primary customers because of their broad product lines and business structure, which require ever-growing capital spending. The benefits they offer, that is, elimination of the need for capital investment, including broad process development and optimization toward volume production, are highly attractive for Japanese companies. Not many Japanese companies, however, have a clear, corporatewide foundry strategy; only a handful of them are prepared to deploy foundry business by keeping the optimum balance with brand businesses. What Japanese companies need is to establish core competence in the semiconductor business, which entails a redefinition of "strategic domains" in many cases. Dataquest believes that it is increasingly becoming a critical management issue for Japanese companies to utilize foundry providers (especially Taiwanese companies) effectively as an integral part of the redefinition process.

Perspective

Semiconductors Japan
Dataquest Predicts

Spring 1998 Forecast: Japanese Electronic Equipment Production and Semiconductor Market

Abstract: *Dataquest's spring forecast shows downward adjustments for electronic equipment production and the semiconductor market in Japan and worldwide, reflecting a clear slowdown in the electronics industry following the end of the PC boom. In the long run, however, growth of the industry will continue, along with expansion of the semiconductor market. When will we see the market bottom out from the present recession, and in what form will this occur? In particular, will the DRAM market reach its bottom this year? Will system LSI become the key to market recovery? With a focus on Japan, this Perspective analyzes electronics production and semiconductor consumption trends up to 2002, on the basis of Dataquest's latest forecast. Unless otherwise specified, world market data is indicated in U.S. dollars, and Japan market data is in yen (exchange rates: ¥121.10/$1.00 in 1997 and ¥129.73/$1.00 from 1998 through 2002).*
By Yoshihiro Shimada, Motoya Ohgami, Masahiro Suzuki, and Yoshihisa Toyosaki

Electronic Equipment Production in Japan

The Japanese economy in 1997, after a temporary surge in domestic demand prior to the consumption tax hike in April, was beleaguered by turmoil in the financial system, a decline in consumer expenditure, and a slowdown in capital spending, which was amplified by the Asian financial crisis toward the year-end. Against the backlash, electronic equipment production showed stronger growth than expected, 7.8 percent over 1996, reaching ¥23,715 billion. Cellular phones contributed greatly as fueled by a series of price cuts and the shift in demand from personal handy phone (PHS) models. Electronic data processing (EDP) equipment also outgrew the forecast, despite a slowdown in domestic PC shipments, and consumer equipment added some momentum that came from video game systems and digital equipment.

FILE COPY:
MARIA VALENZUELA

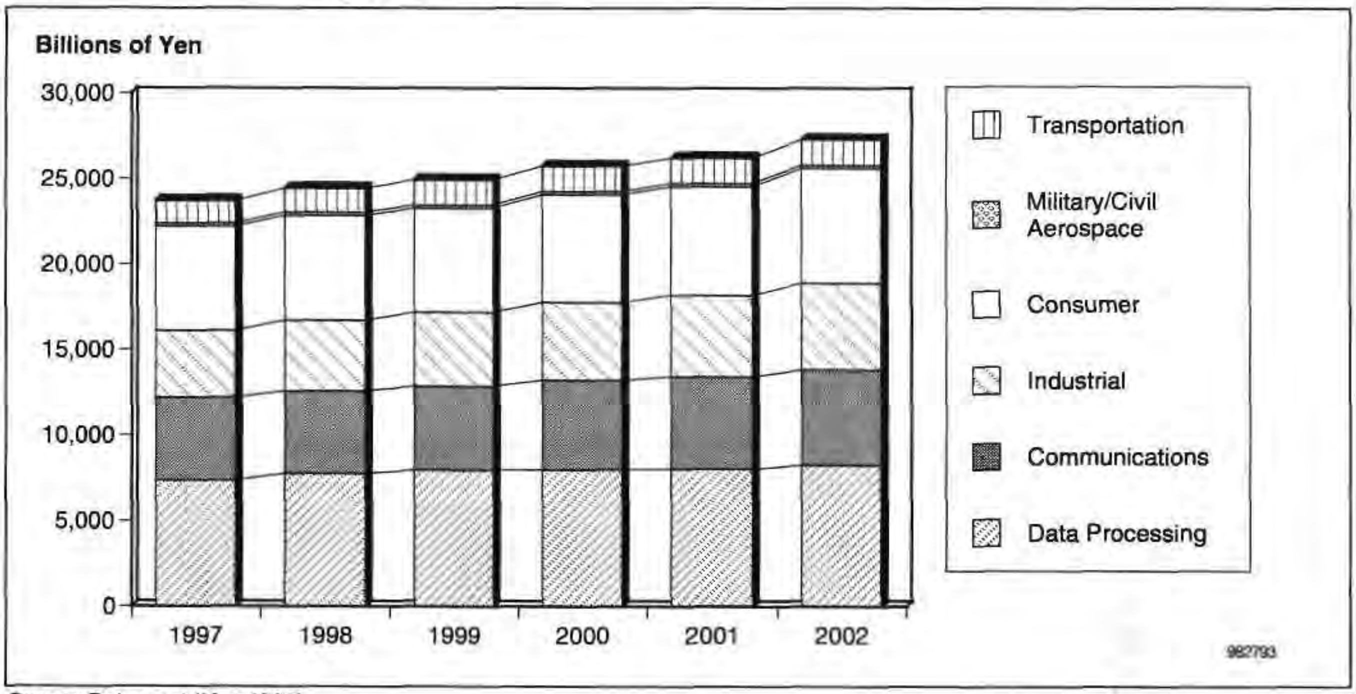
Dataquest
Program: Semiconductors Japan
Product Code: SEMI-JA-DP-9805
Publication Date: June 8, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

In 1998, communications equipment will no longer serve as a major impetus, as the cellular phone market reaches a high level of penetration and digitization of backbone networks completes its first round. Thus, Dataquest predicts that electronic equipment production in Japan will grow at a moderate 3.1 percent to ¥24,459 billion, down 1.5 percentage points from the fall forecast. Similarly, the compound annual growth rate (CAGR) between 1997 and 2002 will settle at 2.8 percent (see Figure 1).

Future growth opportunities must come from a surge in PC demand stimulated by introduction of low-cost models, and increased implementations of plug-and-play interfaces such as Universal Serial Bus (USB) and Institute of Electrical and Electronics Engineers (IEEE) 1394. While Windows 98 will not have much impact on the PC market, evolution of PCs to a new platform for WebTV and other media-mix services will hold the key to growth of demand for personal equipment.

The following section provides a detailed analysis of electronic equipment production in Japan, by major segment.

Figure 1
Japanese Electronic Equipment Production Forecast



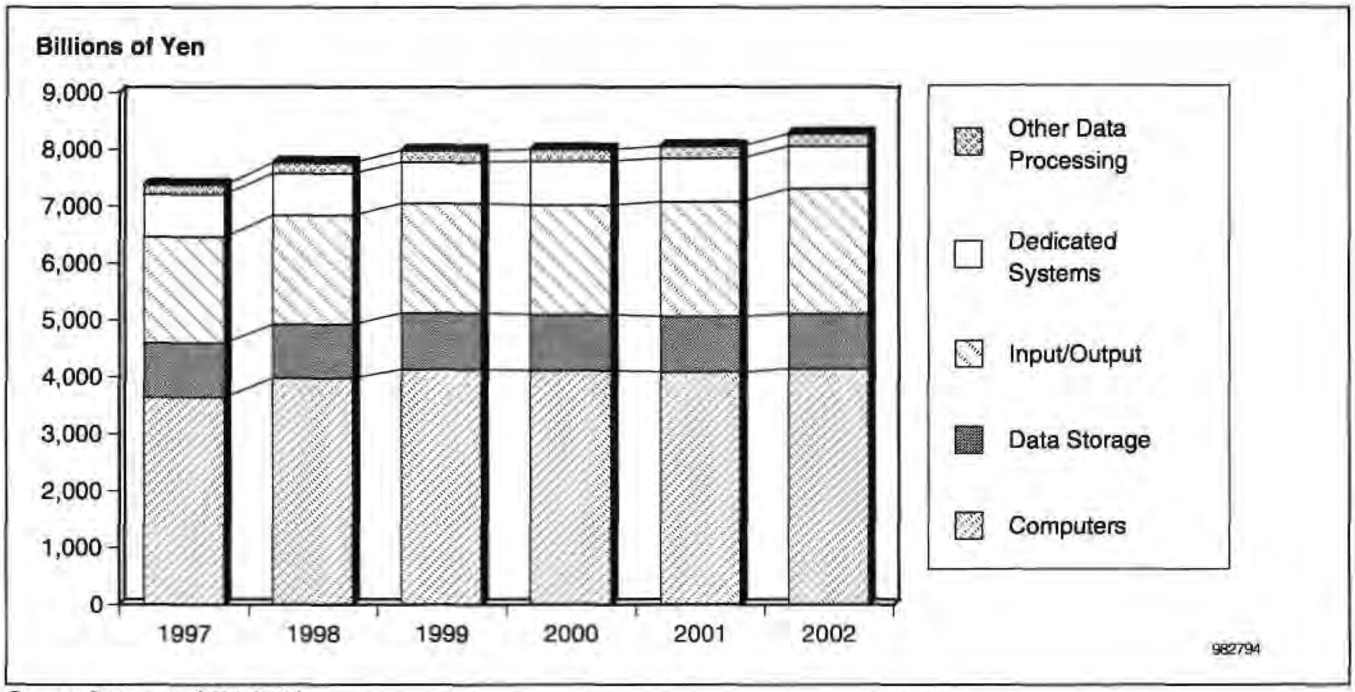
Source: Dataquest (May 1998)

EDP Equipment

In 1997, EDP equipment production in Japan soared 8.3 percent to ¥7,380 billion (see Figure 2). While PC shipments to the domestic market slowed down to less than 5 percent on a unit basis, the price decline spurred the purchase of peripherals such as printers and display units. Also, storage devices led by high-speed optical disk drives, for example, 32x CD-ROM drives and DVD-ROM drives, enjoyed strong growth. The segment is expected to drive the market in the forecast range.

 ©1998 Dataquest

Figure 2
Japanese Data Processing Production Forecast



Source: Dataquest (May 1998)

IT investment will continue to be a major driver in 1998 while Japanese financial institutions are exposed to global competition as a result of the "Big Bang," which urges them to strengthen information systems. Therefore, more than compensating for the general economic slump, computers will drive EDP equipment production, growing 5.3 percent in 1998 with a CAGR of 2.3 percent during the next five years. Gradual recovery of the Japanese economy will continue to fuel EDP equipment production after 1998, which should exceed ¥8 trillion in 2001.

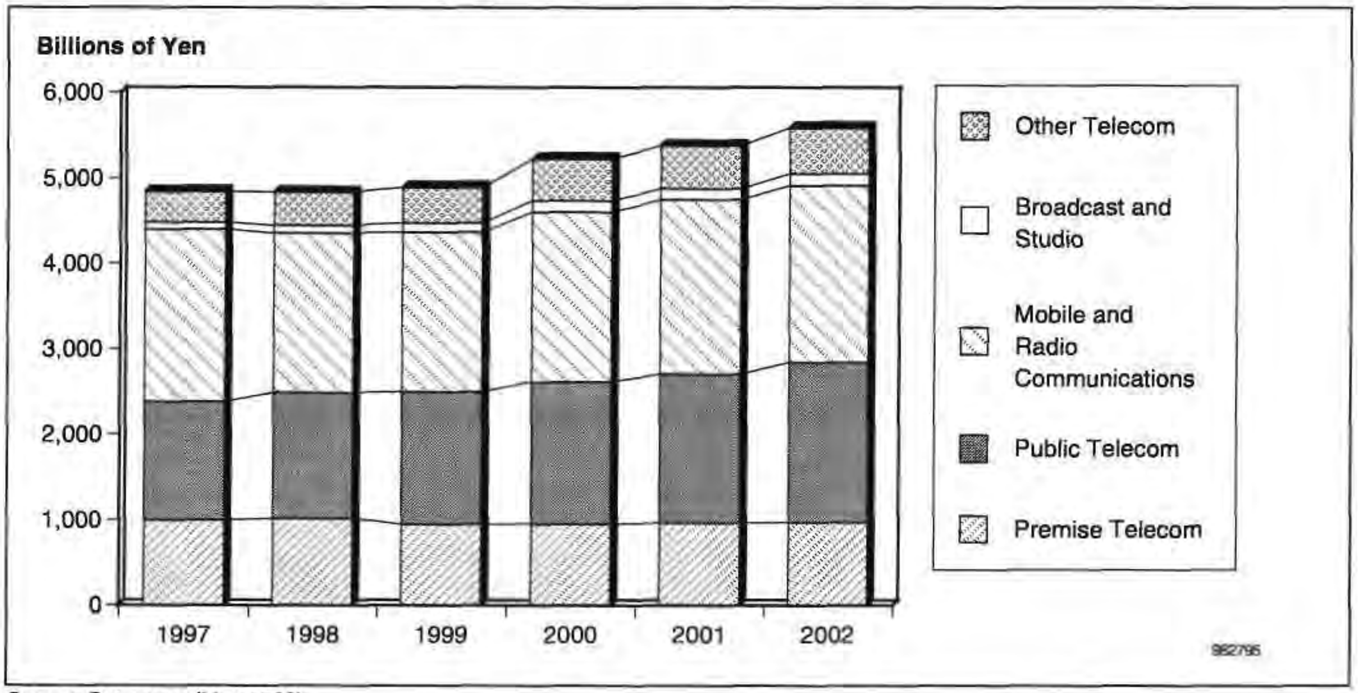
Communications Equipment

Communications equipment production in 1997 jumped 19.8 percent to ¥4,844 billion (see Figure 3). A prime driver was mobile communications equipment; subscribers grew much faster than expected, recording a net increase of 10 million in 1997. While PHS production decelerated at 7 million units, the market is expected to expand as its focus shifts from personal to office use.

Nevertheless, the penetration of mobile phones combining PHS and cellular phones has surpassed 50 percent, and continuation of previous high growth will become inevitably difficult. Meanwhile, digitization of infrastructure facilities by Nippon Telegraph and Telephone (NTT) was completed by the end of 1997. These factors will consequently put a brake on communications equipment production, which will turn into negative growth of 0.2 percent. On the other hand, network equipment, including LANs, will experience healthy growth at a CAGR of 15 percent or above. All in all, communications equipment production will grow at a CAGR of 2.9 percent between 1997 and 2002.

 ©1998 Dataquest

Figure 3
Japanese Communications Equipment Production Forecast



Source: Dataquest (May 1998)

Industrial Equipment

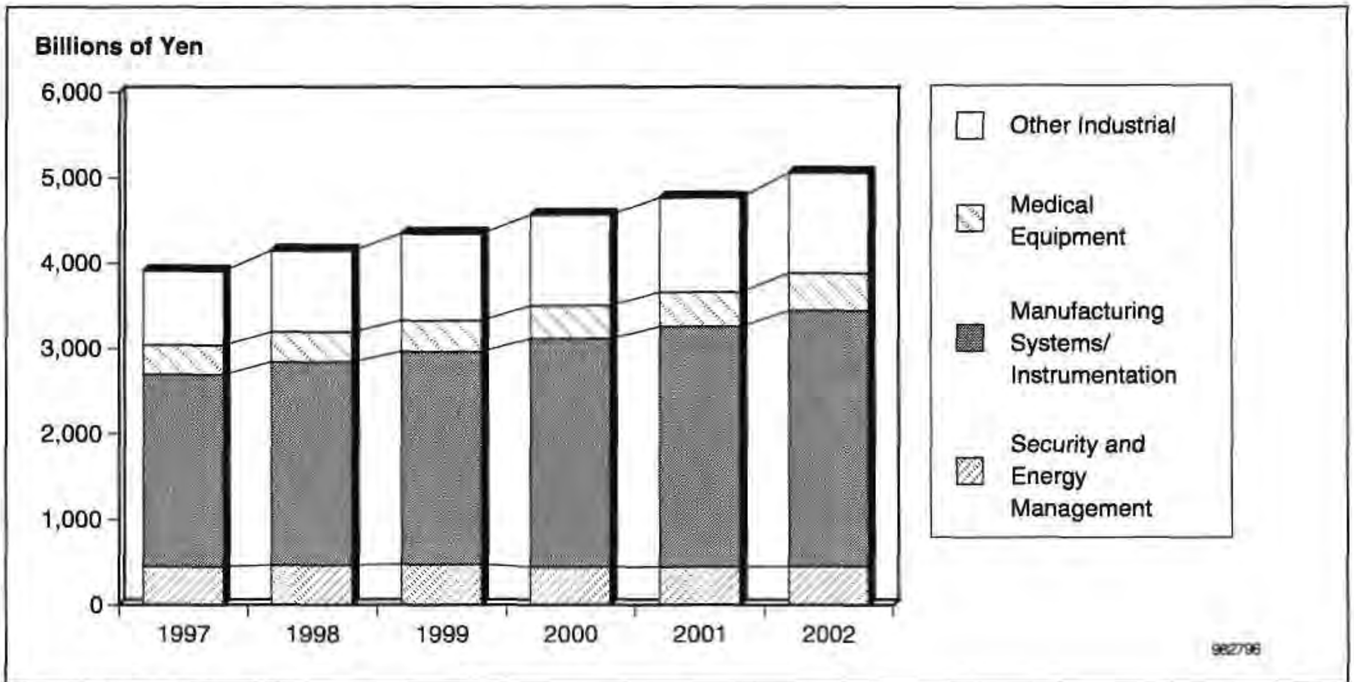
Industrial equipment production in 1997 was up 7.2 percent, totaling ¥3,908 billion (see Figure 4). Of the total, manufacturing systems and instruments recorded the highest growth rate of 14.9 percent. As the wave of relocation of production sites to Asia/Pacific countries subsides, the focal point of the market will shift to computerization and sophistication for value addition and further automation. In particular, medical equipment will show strong growth, with increasing demand for advanced systems to meet the needs of the aging society, resulting in the CAGR of 5.2 percent between 1997 and 2002. Overall, Dataquest predicts a CAGR of 5.3 percent, the highest among the six segments.

Consumer Equipment

Consumer equipment production recorded a 1.3 percent increase in 1997, reaching ¥6,098 billion (see Figure 5). In the video equipment segment, where TVs and VCRs sold in the domestic market are mostly made overseas, it was the replacement demand for wide-screen TVs produced at domestic sites that contributed greatly. In the digital consumer equipment market, digital video cameras (DV-Cs) recorded notable growth, and unit shipments up to the end of 1997 were estimated at slightly below 1 million. The DV-C will become pervasive quickly, driven by price declines and improved availability of key components. Similarly, digital still cameras (DSCs) will ramp up rapidly as they can be easily connected to PCs or TVs via a flash memory card or IEEE 1394 interface. On the other hand, commercialization of digital TVs will have to wait until after 2000 as infrastructure construction has been delayed.

 ©1998 Dataquest

Figure 4
Japanese Industrial Equipment Production Forecast



Source: Dataquest (May 1998)

The current recession will hit household appliance production directly, leading to negative growth in 1998. Video game systems will continue to be a fierce battlefield for a 32-bit hegemony, but production will remain mostly unchanged in 1998, until the next-generation products are introduced in 1999. Dataquest predicts that consumer equipment production as a whole will grow at a CAGR of 1.9 percent between 1997 and 2002.

Japanese Semiconductor Market

In 1997, the Japanese semiconductor market recorded negative growth on a dollar basis, becoming the only market to shrink among the four world regions. Although the yen depreciation diluted the dollar-based figure, the fact remains that the Japanese market is the weakest of the four regions. While electronic equipment production grew faster than previously forecast, semiconductor consumption was sluggish. This indicates that a major source of growth in electronics production came from the segments with little semiconductor content. Also, PC shipment lost momentum in Japan, exerting negative impact on consumption of a variety of semiconductor products, including memory, microprocessors (MPUs), and logic.

The Japanese semiconductor market in 1998 will grow at 9.8 percent (2.5 percent on a dollar basis), down from the fall forecast (see Figure 6). While this reflects the anticipated slowdown in electronic equipment production and the hovering market conditions for DRAMs, a recovery is expected in the second half, leading to double-digit growth. Nevertheless, the CAGR between 1997 and 2002 will be the lowest among the four regions, at 12.4 percent (10.9 percent on a dollar basis).

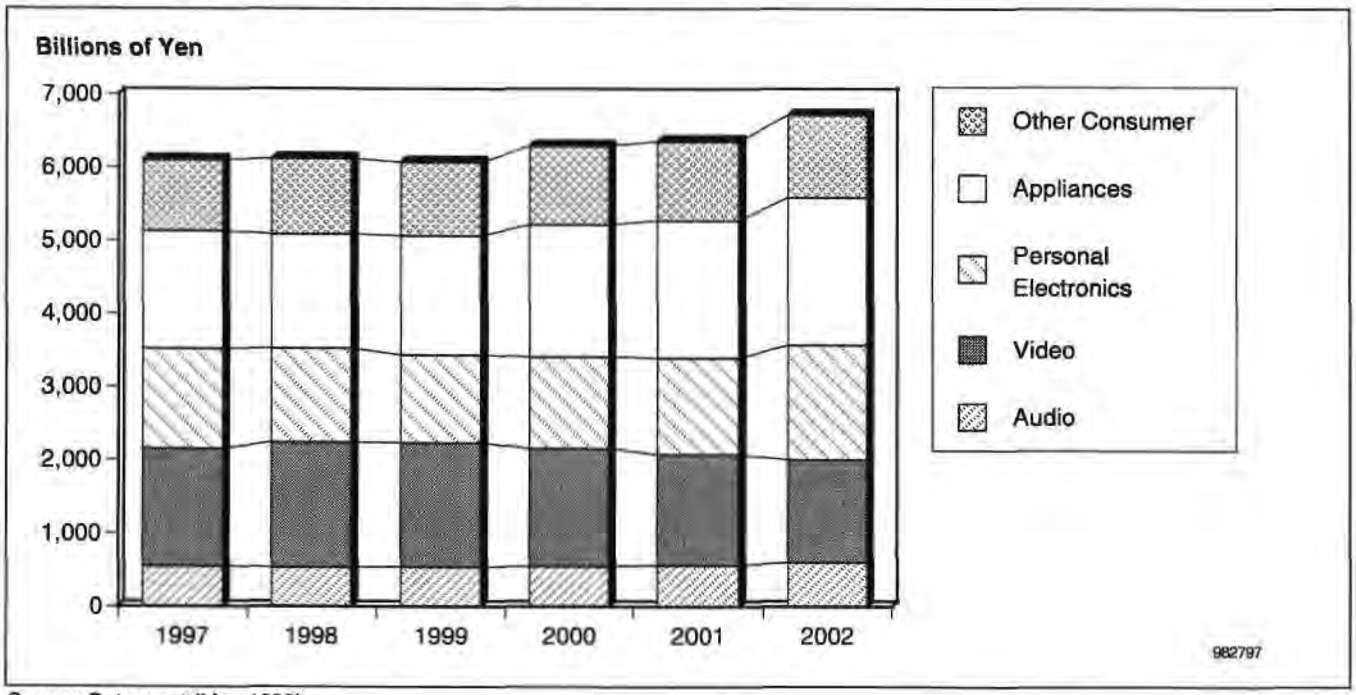
The following section analyzes the future outlook for the Japanese semiconductor market by device.

MOS Memory

In 1997, the Japanese MOS memory market suffered a 14.5 percent decline (23.1 percent on a dollar basis) (see Figure 7). Dataquest predicts that the 1998 market will grow 7.0 percent (a 0.1 percent decrease on a dollar basis), which represents a downward adjustment of 6 percentage points compared to the fall forecast. Again, DRAM price decline because of supply glut is the major culprit. While increased 16Mb production by U.S. companies triggered the price fall in 1997, the aggressive moves of Korean suppliers will dictate DRAM prices. At present, 16Mb prices continue to fall below $3 on the spot market, which pulls 64Mb prices downward.

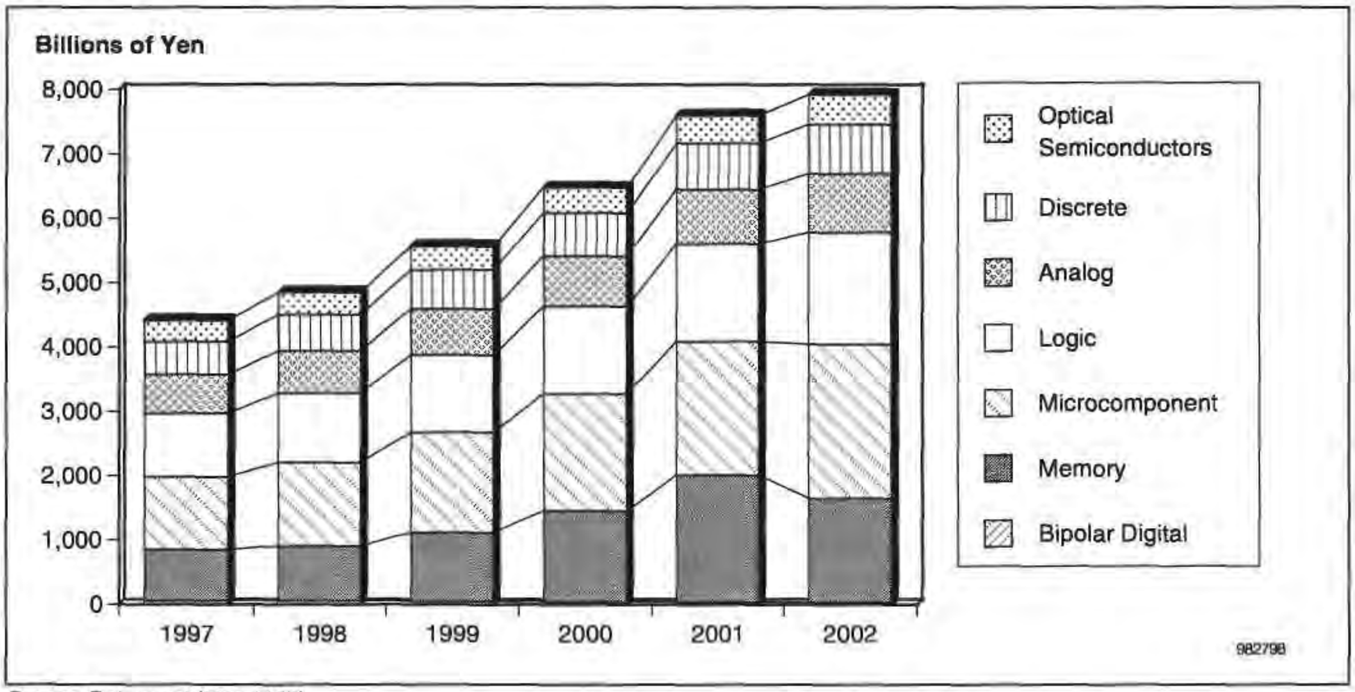
The Japanese MOS memory market in 1998 will be driven by SRAM, EEPROM, and flash memory. In particular, after 1999, the DRAM market will expand at an accelerated pace, while SRAM and nonvolatile memory markets will maintain healthy growth. In 2002, however, the DRAM market will experience negative growth as the generation crossover from 64Mb to 256Mb occurs. Dataquest predicts that the market's CAGR between 1997 and 2002 will be 15.4 percent (13.8 percent on a dollar basis).

Figure 5
Japanese Consumer Equipment Production Forecast



Source: Dataquest (May 1998)

Figure 6
Japanese Semiconductor Consumption Forecast



Source: Dataquest (May 1998)

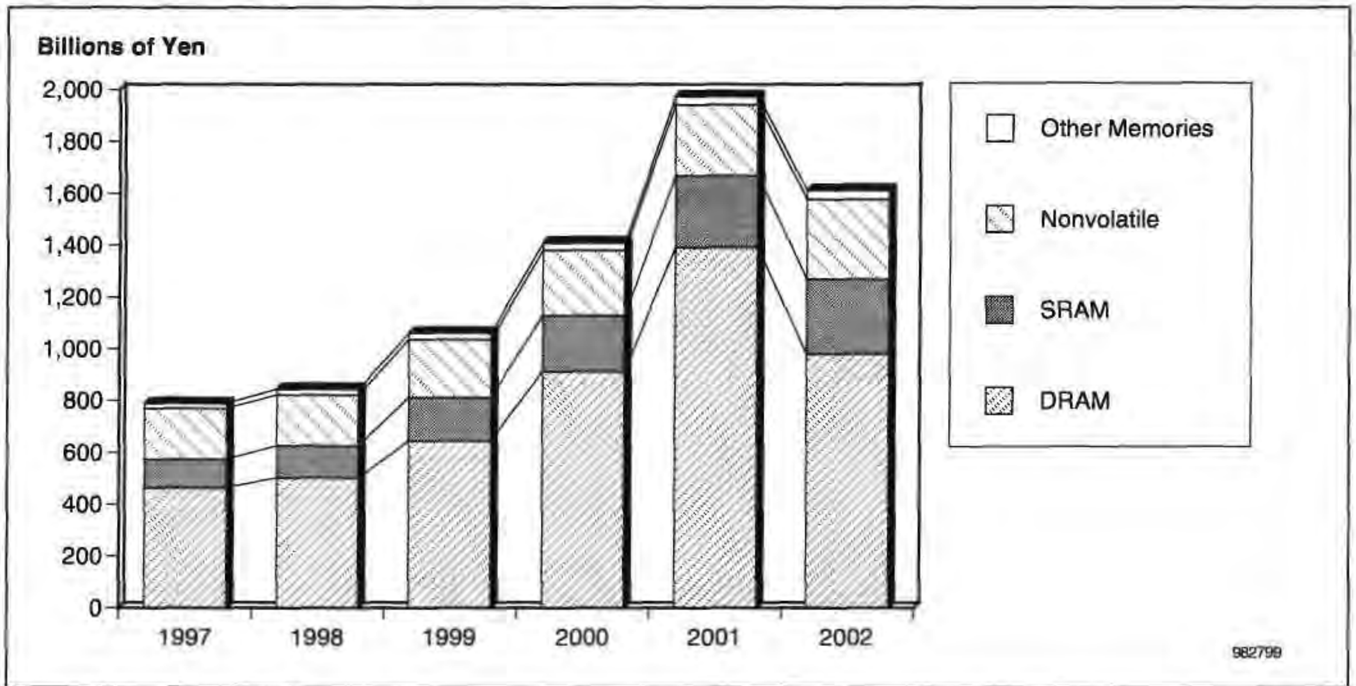
While the fall forecast assumed that DRAM companies would curtail capital spending in 1998, they are currently moving to minimize the rate of investment cutbacks where possible. In particular, Korean companies are considering maintaining capital spending as close as possible to the 1997 level (on a won basis), despite the DRAM recession and the pain from the AFC. Dataquest pointed out in the fall forecast that a major reduction of 64Mb-production capacity would be required to regain revenue growth in 1998. However, DRAM companies are not reducing capital spending as much as expected, which necessitated the downward adjustment of the DRAM market growth forecast.

In 1998, a major event in the DRAM market will be a full-blown shift from extended data out (EDO) to synchronous DRAM (SDRAM). During the first half of 1998, 100-MHz SDRAMs for PC100 will keep a price premium against 66-MHz versions, which will significantly narrow in the second half as DRAM companies roll out 0.25-micron fab lines. After 1999, the Japanese DRAM market will be driven by better-managed capacity expansion by DRAM suppliers, recording a CAGR of 16.1 percent (14.6 percent on a dollar basis) between 1997 and 2002.

The Japanese nonvolatile memory market will be up slightly 0.3 percent (6.3 percent down on a dollar basis) in 1998 because of double-digit declines in EPROM and mask ROM, which will more than offset the 20 percent growth of EEPROM and flash segments. The CAGR between 1997 and 2002 will be 9.6 percent, as the market will be driven by EEPROM and flash memory.

 ©1998 Dataquest

Figure 7
Japanese Memory Consumption Forecast



Source: Dataquest (May 1998)

The Japanese flash memory market recorded negative growth of 9.8 percent in 1997, but it is expected to resume growth in 1998. Major applications include mobile communications equipment, led by cellular phones as well as IC cards. In particular, smart phones are expected to ramp up early in Europe, becoming an important consumer of flash memory. This is expected to a have a positive impact on the Japanese mobile communications and flash memory market.

In the MOS memory market, Japanese semiconductor companies still strive to become less dependent on DRAM business. Large suppliers will increasingly shift their strategic focus to flash memory. The 1997 flash market saw price declines in 8Mb-or-less products. Dataquest expects that the move will spread to 16Mb-or-larger segments in 1998 and after.

MOS Microcomponents

The Japanese MOS microcomponent market will expand 15.2 percent (7.5 percent on a dollar basis) in 1998 (see Figure 8). The CAGR between 1997 and 2002 will be 16.2 percent (14.6 percent on a dollar basis) with firm growth expected for each year.

The Japanese MPU market in 1998 will fail to meet the previously forecast level because of the slowdown in the PC market. The market should grow at 12.6 percent (5.1 percent on a dollar basis). The market will see a wider variety of products besides Intel's X86 families (Pentium with MMX technology, PentiumPro, and MMX Pentium II). Products will include non-Intel, high-speed MPUs, MPUs for low-cost PCs, and MPUs designed for

 ©1998 Dataquest

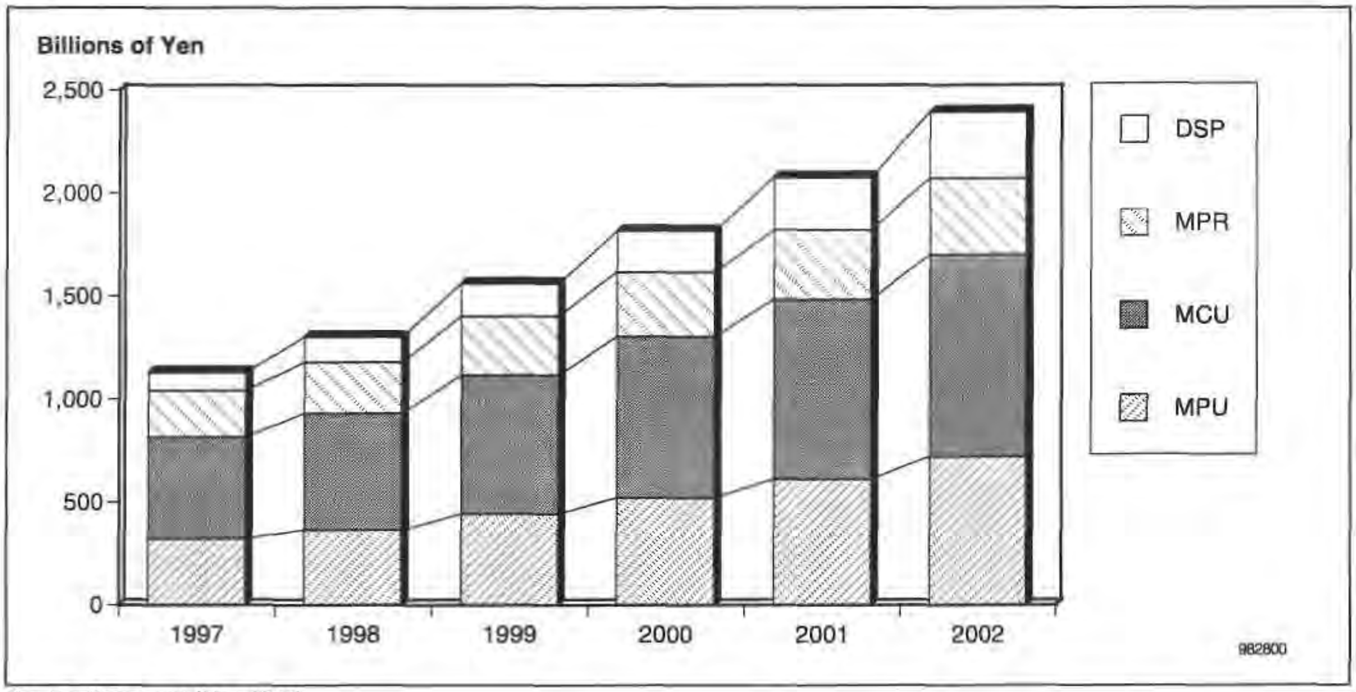
portable applications, including mobile computing (embedded MIPS, SH, Strong ARM), for example, Tillamook, Mobile Pentium II, and Windows CE2.0.

Microcontrollers (MCUs), the largest of the Japanese microcomponent segments, are expected to surge 15.1 percent (7.4 percent on a dollar basis) in 1998. They are incorporated into a variety of electronic equipment. Low-bit versions are embedded into household appliances for system control purposes, many of which are implemented on a 4-bit or 8-bit basis. Japanese companies still hold a dominant share in the 4-bit segment.

Four-bit MCUs are used in diverse products ranging from toys to analog cordless telephones, and companies are still exploring new applications. Nevertheless, the market size will grow only moderately, partly because of the weakening demand from portable game systems, which have been a major driver, and partly because of increased migration to 8-bit products. In particular, revenue growth will be minimal because of low prices, although unit growth may continue.

On the other hand, the 8-bit MCU market will enjoy strong growth as a result of upgrading from 4-bit applications and the need to address the increasing complexity of system control. Development of MCUs embedding flash-memory technology is under way, and the competition has heated up among U.S., European, and Japanese companies for market share.

Figure 8
Japanese Microcomponent Consumption Forecast



Source: Dataquest (May 1998)

In 1997, 8-bit MCUs were used in most electronic equipment, including the following range of products:

- Video and audio equipment
- Computer-related equipment, including keyboards and display units
- Communications equipment, including analog cordless telephones and digital portable telephones
- Antilock braking systems (ABSs)
- *Pachinko* game systems
- Household appliances

Applications expected to emerge in 1998 and afterward include smart cards, minidisc (MD) players, USB controllers (8-bit basis), and MCUs incorporating Infrared Data Association (IrDA) communications features. Encouraged by potential demand for contact/noncontact IC cards, semiconductor companies will opt for alliances to consolidate technological resources and vie for industrial standards. Finally, MCUs integrating ferroelectric memory technology will be introduced to the noncontact IC card market to invigorate the 8-bit MCU market.

Sixteen-bit MCUs, on the other hand, will be increasingly used for digital processing applications, particularly digital cellular phones, PHS phones, hard disk drives (HDDs), and CD-ROM drives. Applications expected in 1998 and afterward include DVD, fixed and on-board audio MD players, and DV-C. Again, flash memory technology will be increasingly incorporated to address system requirements in terms of flexibility, and semiconductor companies will focus on enhancement of their offerings.

As for 32-bit and 64-bit MCUs, system-level integration (SLI) based on ASIC technology will become the mainstay. Promising applications that will be developed after 1998 by using a leading-edge process and an embedded MPU include vehicle information and communication system (VICS)-based car navigation systems incorporating DVD-ROM drives, next-generation home/portable video game systems, and set-top boxes (STBs). Sixteen-, 32-, and 64-bit MCUs will enjoy strong growth next to 8-bit products, driven by price declines resulting from SLI, the emergence of digital consumer equipment, and digitization of systems. Dataquest expects solid profitability.

In 1997, rapid growth was seen in the flash MCU market. Major applications include memory cards for video game systems, CD-ROM drives, and HDDs, spurring consumption of 8- and 16-bit MCUs. As for multibit, embedded MPU (MCU) architectures, ARM will be rapidly accepted in 1998 and afterward. Diverse architectures offered by vendors (MIPS, M Core, SH, SPARC, PowerPC, and X86) will be optimized for different applications according to their SLI strategy.

In 1998, the Japanese microperipherals (MPR) market is expected to grow 9.6 percent over the previous year (2.3 percent on a dollar basis). A variety of PC peripherals based on PC98 standards will become pervasive, and different

 ©1998 Dataquest

application-specific standard product (ASSP) segments (chipset, USB, IEEE 1394, and MPACT1/2) will grow in relation to different applications.

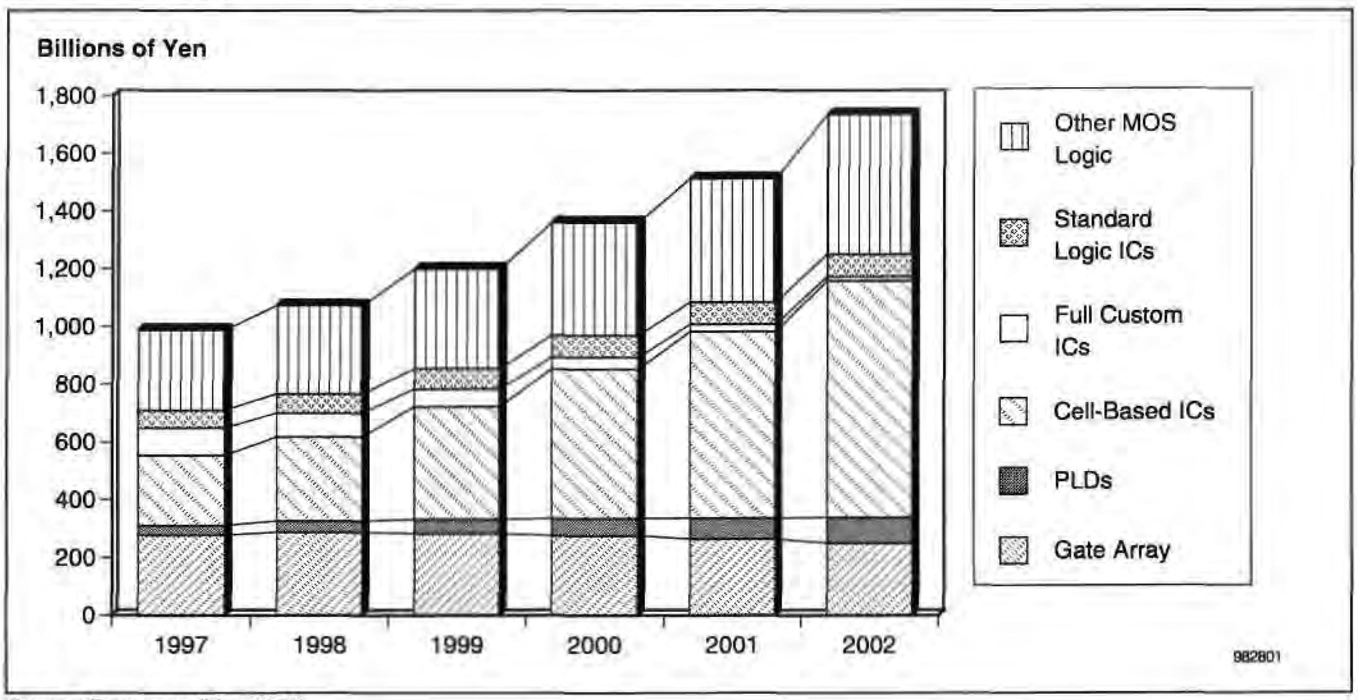
The Japanese digital signal processor (DSP) market will continue strong growth of 39.8 percent (30.5 percent on a dollar basis) in 1998. With the increasingly shortened development cycle for system products, DSPs and media processors will undoubtedly become core technologies as they offer flexibility in development of digital consumer equipment with the ability to reconfigure themselves by replacing middleware/microcode. By 2002, 0.18-to-0.12 micron processes will be commercialized. As a result, the DSP market will grow strongly at a CAGR of 29.7 percent (27.9 percent on a dollar basis) between 1997 and 2002.

Finally, embedded DSPs are increasingly incorporated into servo controllers for CD and MD players as well as codec processing for cellular phones. Generic DSPs including media processors are primarily used in high-speed analog modems (56Kbps) for PCs and sound source processing. New applications emerging in 1998 and afterward include digital cellular phones, which use a single chip integrating a 16/32 bit MCU and DSP, HDD controllers containing DSP/MCU and DRAM for buffer memory, and high-speed disk drives such as DVD-ROM/RAM, incorporating partial response maximum likelihood (PRML) technology and DSP.

Logic/ASICs

In 1998, the Japanese total logic market will grow 8.7 percent (1.5 percent on a dollar basis). The total ASIC market will expand 11.8 percent (4.3 percent on a dollar basis) (see Figure 9).

Figure 9
Japanese Logic Consumption Forecast



Source: Dataquest (May 1998)

In 1997, high-performance systems, as seen in digital consumer equipment, were implemented to incorporate multiple, large-scale circuits by using intellectual property (IP) core and leading electronic design automation (EDA) tools. We also saw a rapid increase in volume production of ASSPs and SLI ASIC products in single-chip implementation by using a highly integrated ASIC process and SLI technologies. A future challenge lies in reducing the cycle time for system development to minimize turnaround time (TAT) and R&D investment, reduce development-related risks, and support early LSI implementation.

Traditionally, the "core-limited design" issue, derived from large-scale internal cores, was a major obstacle in designing ASICs. Recently, however, as the ASIC process reached submicron levels, the shrink ratio of the internal core has been improved. This, in turn, has resulted in an increase in the "I/O pad-limited design," where I/O pads set the limit rather than cores. Also, flexibility in ASIC design to result in small-lot production adversely affects the profitability of business.

Many leading ASIC vendors in the Americas region started to de-emphasize gate array business by 1997. This move is favorable for the programmable logic device (PLD) market and accelerates the collapse of the U.S. gate array market. Technically, PLDs have already integrated 250,000 to 500,000 gates on a commercial basis by using process technology based on 0.25-micron, five-layer interconnect, and shallow trench structure. Dataquest believes that 1 million gates will be integrated by using a 0.18-micron process technology by 2000.

In 1998, the Japanese PLD market will show a strong growth of 15.6 percent (7.9 percent on a dollar basis). In Japan, the gate array business still dominates because of high captive demand. Nevertheless, as SLI will lead ASIC business in the future, the Japanese PLD market will grow to an appreciable size compared to the Americas market. Dataquest expects that the market will register the second-highest growth rate, following cell-based ICs (CBICs), with a CAGR of 21.3 percent between 1997 and 2002.

The Japanese CBIC market (including mixed signal) will grow 20.7 percent (12.7 percent on a dollar basis) in 1998. The ramp-up of 0.35- to 0.25-micron process manufacturing and the increasing need for design optimization in various applications have been driving the market for CBICs, which are regarded as the key infrastructure factor in SLI technologies such as embedded MPUs/DSPs, IP core, embedded memories, and mixed-signal designs. At the same time, the establishment of CBIC technology has caused the custom IC market to shrink rapidly, resulting in the negative CAGR of 15.2 percent (20.8 percent on a dollar basis) between 1997 and 2002.

At present, standard logic features such as small-scale integration (SSI), middle-scale integration (MSI), and large-scale integration (LSI) are mostly incorporated into ASICs, but demand for standard logic still exists in the area of super high-speed CMOS- or BiCMOS-based standard logic, such as CMOS-based one-gate logic products and wide bus products. Thus, the Japanese standard logic market will continue to grow steadily at a CAGR of 5.1 percent (3.7 percent on a dollar basis).

 ©1998 Dataquest

Finally, LCD drivers classified as other MOS logic will be driven by increased market acceptance of LCD-equipped systems as well as exploration of new application markets. As a result, the Japanese market's CAGR will be 11.8 percent (10.3 percent on a dollar basis) during the five-year period.

In 1998, ASIC suppliers announced a number of next-generation 0.18-micron processes, and some of them in Japan and the United States started volume production. Also development efforts are under way to commercialize a "unified process" that represents a "dream process integration." Dataquest believes that portable applications in the Japanese market will contribute to technological progress in the areas of ultralow operating voltage below 1.0V, embedded flash memory, mixed-signal designs, and high-density packages such as chip-scale packaging (CSP) and direct chip attach (DCA), thereby driving the SLI ASIC market.

Other Devices

The outlook for analog, discrete, and opto markets has been adjusted downward from the previous forecast. It should be noted that the analog market was partially affected by reclassification of linear array and mixed signal ASICs (although small in size) into total ASICs.

Dataquest sees that strong demand growth for analog ICs in the past few years has caused the industry to hold unduly high expectations. With the rapid progress of system diversification, accompanied by LSI implementations over several generations, demand for analog ICs and discrete devices experiences a momentum surge. Nevertheless, expansion of mixed-signal analog IC markets will ultimately lead to CBICs absorbing analog functions, so that suppliers tend to overestimate long-term demand by extrapolating the recent high-growth trends. Also, sluggish electronics production causes demand for generic analog devices to slow down.

In the first quarter of 1998, suppliers do not seem to be accelerating analog capacity, partly because of heavy constraints on investment resources. If supply capacity expands abruptly, prices will plummet to result in unit growth without revenue growth. Given this cap for capacity expansion, Dataquest believes that it is difficult for the Japanese analog market to continue double-digit growth.

Dataquest Perspective

After the rapid progress of production site relocation to the Asia/Pacific countries, electronic equipment production in Japan has increasingly depended on the domestic market by building high-value-added production capacities. Given the economic slump and curtailed personal spending in response to the gloomy outlook, digital consumer equipment incorporating advanced technologies fails to create a market opportunity, despite its great potential. Thus, strong growth of electronics production hinges highly on whether the ongoing attempt to reinvigorate domestic consumption can spur demand for new digital consumer equipment and personal information equipment.

©1998 Dataquest

The slack state of electronic equipment production is directly reflected in softened semiconductor demand. At present, Japanese semiconductor companies sell about 50 percent of their products to the domestic market, even though Japan is expected to show the weakest growth trends in the forecast range years. If slow growth persists, overseas strategies cannot help being affected seriously. If the foreign exchange rate does not change significantly, and manufacturers opt to site production capacities near their markets, the increasing weight of overseas markets will cause Japanese companies to boost overseas production. Manufacturers lacking distribution channels other than Japan and the Asia/Pacific region will not be able to survive under the traditional strategy. This may create a dramatic change in the industrial landscape, including semiconductor equipment and materials.

The industry seems to expect a paradigm based on a new market driver: the development of digital consumer equipment by offering SLI-based solutions. Before that, it must answer a question raised in relation to the development of 300mm wafer fabs: "Will there be a market large enough to absorb the explosive growth of supply capacity?" Unless the industry finds an answer, it cannot rely on the domestic market as it has in the past. While Japanese companies have to streamline their business from nontechnological perspectives, such as the introduction of supply chain management, they may have to redefine their global operations and business structure. Dataquest believes that the industry's future lies in its ability to determine whether the redefined business structure serves the overall interest of maintaining business efficiency and whether it can adapt to the change derived from the redefinition process.

Perspective

Semiconductors Japan

Market Analysis

The Present and Future of the Japanese Semiconductor Equipment Industry

Abstract: *The Japanese semiconductor device industry thrived on its DRAM business, but it is now being threatened by the Korean and Taiwanese competitors. The prosperity of the device industry led to the eminence of the wafer fab equipment industry. Today, Japanese equipment suppliers share the world market equally with U.S. competitors, with different industry structures that reflect the characteristics of the device industries of the two countries. This Perspective discusses the position of the Japanese wafer fab equipment industry on the basis of the two clearly distinguishable semiconductor markets and discusses opportunities and issues facing the industry.*

By Takashi Ogawa

The Japanese Semiconductor Equipment Industry Is Prosperous

According to Dataquest's survey, the world wafer fab equipment market in 1996 reached $21.68 billion, of which Japanese companies earned $8.75 billion and held a 40 percent share. Figure 1 shows the total semiconductor revenue of Japanese companies between 1982 and 1996, together with revenue from DRAM and wafer fab equipment. During that period, Japanese companies' semiconductor revenue recorded a compound annual growth rate (CAGR) of 17.4 percent. As is already widely known, Japanese companies earn a higher percentage of their semiconductor revenue from DRAM sales (the DRAM ratio) than U.S. companies. In 1996, the average DRAM ratio among U.S. chipmakers was 7 percent, while that of Japanese companies was a lofty 23 percent. This is closely associated with the development history of the Japanese device industry, which is equated with the DRAM business that has recorded such phenomenal success.

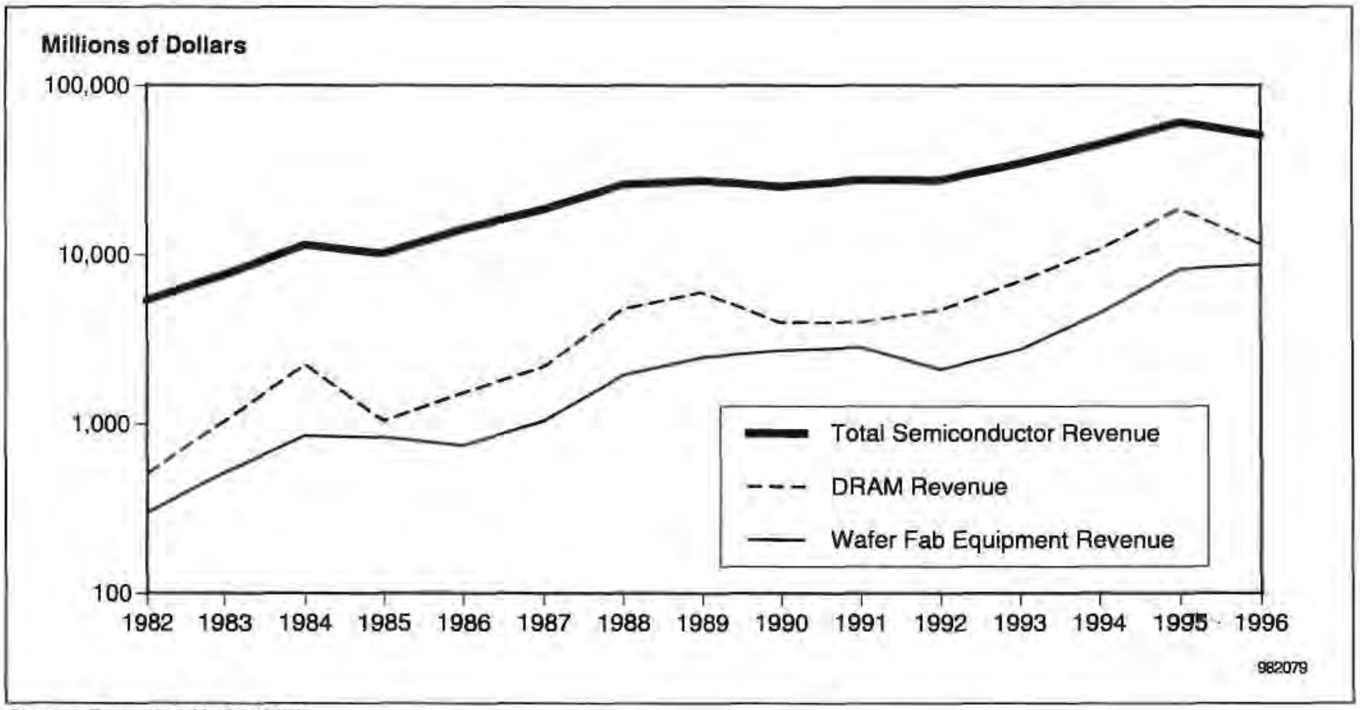
Publication Date: May 11, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Between 1982 and 1996, the Japanese DRAM industry maintained strong growth at a CAGR of 25 percent. The growth path virtually synchronized with growth in sales of wafer fab equipment supplied by Japanese companies, which grew 30 times from $298 million to $8.75 billion during the period, at a CAGR of 27 percent. Semiconductor manufacturing technologies share common ground with device process technologies, so the emergence of a new process technology or the enhancement of existing technology spurs the birth of new production technology and equipment. Adoption of the new technology then leads to the emergence of a market.

Analyzing the history of semiconductor device development reveals a complementary relationship between wafer fab equipment technologies and device process technologies; both served to support the remarkable growth of the semiconductor industry. In other words, the device market and the equipment market have been evolving in closely related patterns that reflect their specific characteristics.

Figure 1
Changes in Japanese Companies' Semiconductor and Wafer Fab Equipment Revenue, 1982 to 1996

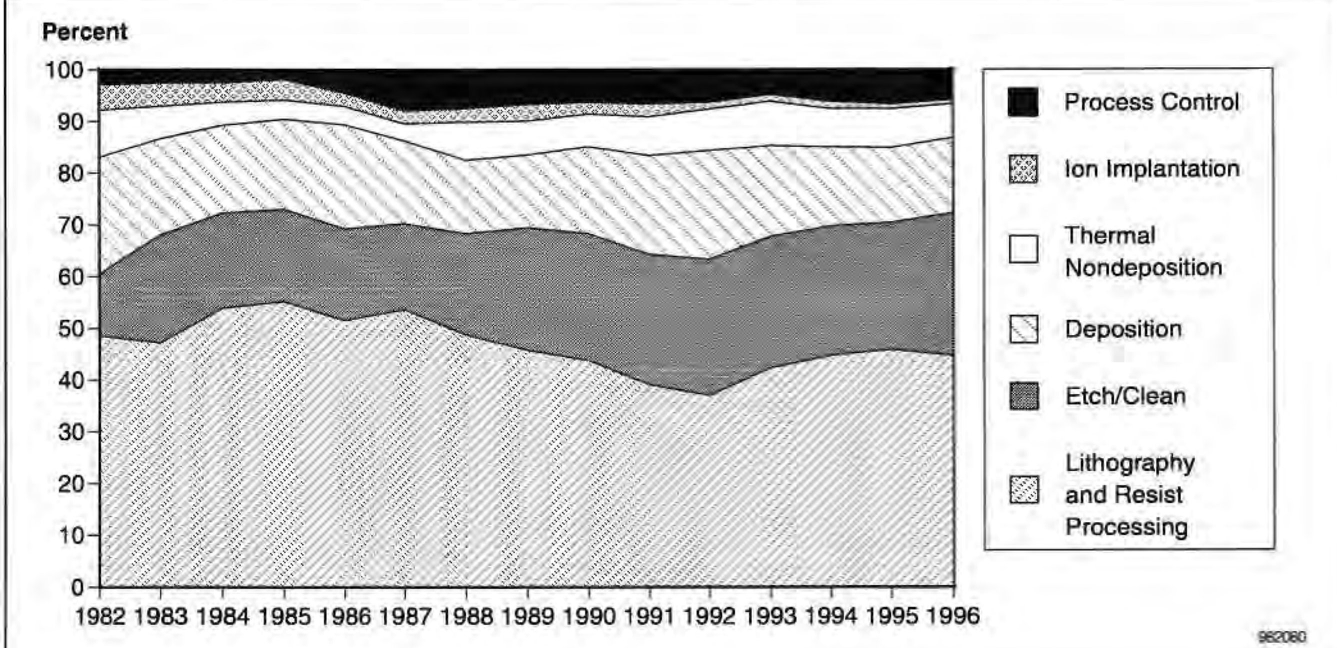


Source: Dataquest (April 1998)

Why Is the Japanese Wafer Fab Equipment Market the Way It Is?

In Japan, semiconductor production technology has evolved in close association with development of DRAM process technology. In the 1970s, Japan, under a near-national consensus to develop the semiconductor industry as a strategic sector, established several consortia, such as the VLSI Technology Research Association, which aimed to develop key process technologies. The industry used these projects to build a technological infrastructure in key areas such as exposure, deposition, and wafer fabrication. In the development process, a number of semiconductor equipment makers worked together with device makers. As they entered the nascent market, industrial leaders such as Nikon Corporation, Canon Inc., Kokusai Electric Co. Ltd., and Ulvac Japan Ltd. prepared themselves for success. More important, certain characteristics emerged and cemented the market. Figure 2 shows a breakdown of wafer fab equipment revenue by Japanese companies between 1982 and 1996 by segment.

Figure 2
Changes in Japanese Companies' Wafer Fab Equipment Revenue, by Segment, 1982 to 1996



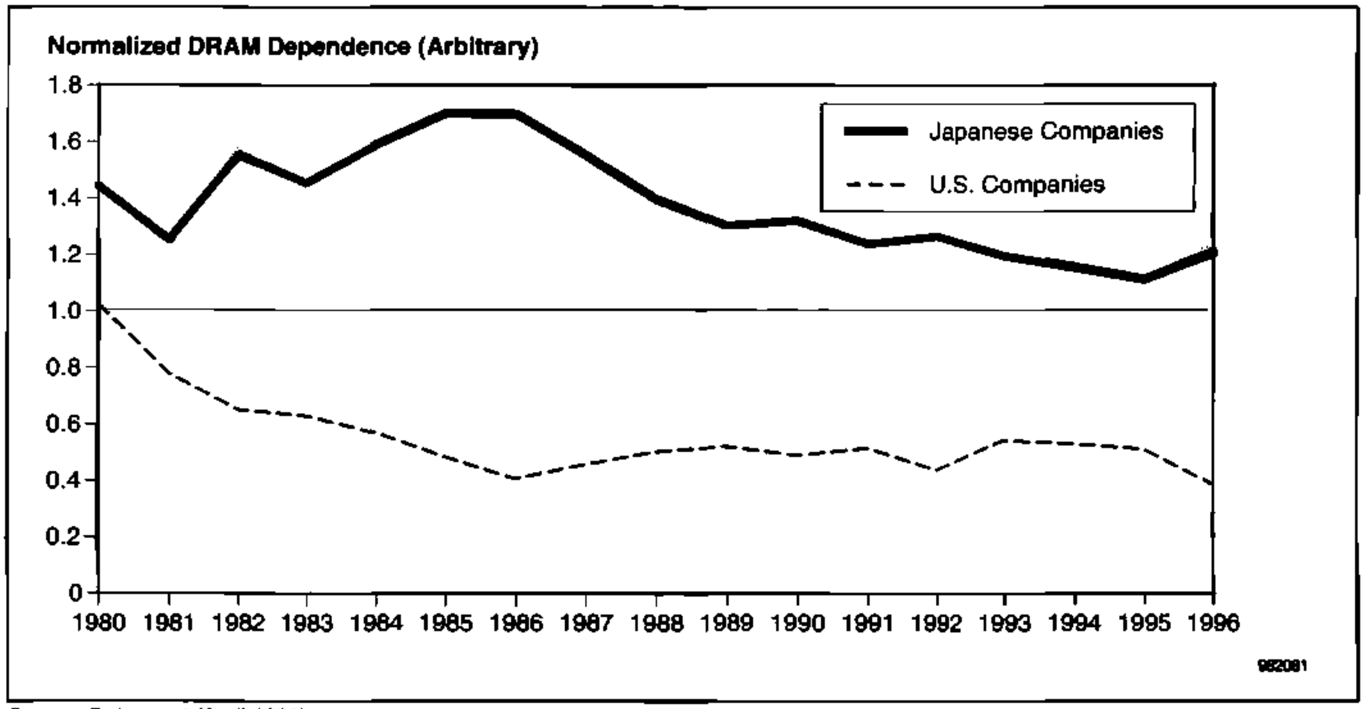
Source: Dataquest (April 1998)

Lithography and resist processing equipment has consistently held a very high share, around 45 percent, except for some turmoil during downward phases of the silicon cycles. Of the DRAM process technologies, lithography equipment, led by steppers and developers, constitutes a critical element. To survive in the highly competitive and volatile DRAM market, manufacturers must keep up with a relentless cost-cutting race, boosting integration levels through chip shrinkage, adoption of increasingly fine design rules, and increasing the number of die from each wafer. Japanese semiconductor manufacturers, armed with superb production technologies, centered on lithography. Through joint development initiatives and quality control practices, they gained share in the worldwide DRAM market until the 1980s. Explosive device market growth has, in turn, spurred the equipment market. Japanese makers virtually monopolized the lithography and resist processing equipment market. This was during the time when the market was highly skewed toward lithography, and the resist processing segment was born.

 ©1998 Dataquest

Figure 3 shows normalized DRAM dependence in semiconductor revenue. "Normalized" means that the worldwide average of DRAM dependence is standardized as 1.0. After 1986, Japanese companies gradually decreased their dependence on DRAM; however, their ratio remains at 1.2, higher than the worldwide standard of 1.0. Meanwhile, Japanese equipment makers, which have grown under the umbrella of the device makers, are pursuing global business deployment strategies, including targeting Korean chipmakers, but the market structure originally shaped by the DRAM industry during the dawn of the market has shown little change.

Figure 3
Changes in Normalized DRAM Dependence in Semiconductor Revenue, 1980 to 1996

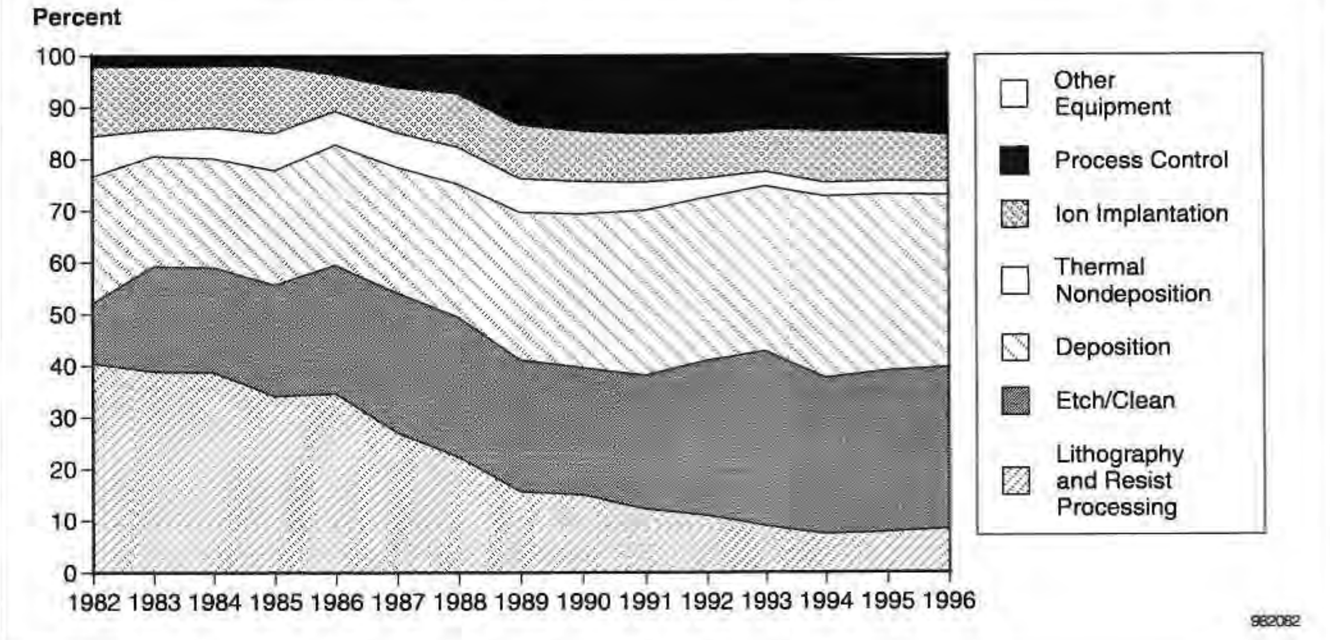


Source: Dataquest (April 1998)

The U.S. Wafer Fab Equipment Industry

The wafer fab equipment market in the United States has also shown distinctive characteristics. In 1996, the wafer fab equipment revenue of U.S. companies totaled $9.73 billion. The world market was more or less divided between U.S. companies and Japanese companies. The U.S. market's CAGR from 1982 through 1996 was 21 percent, about in parity with the Japanese market. Figure 4 shows a breakdown of revenue for U.S. equipment manufacturers between 1982 and 1996 by segment, which reveals a noticeable change. In 1982, lithography and resist processing equipment accounted for about 40 percent of the U.S. equipment market. The share dropped sharply, to 8.5 percent, in 1996. In contrast, the share of the deposition and etch/clean segments grew steadily, from 24.4 percent to 33.3 percent and from 11.7 percent to 31.2 percent, respectively, during the period. In 1996, the combined share of the two segments amounted to 65 percent. Clearly, the U.S. equipment market transformed itself from a structure centered on lithography and resist processing to one centered on deposition and etch/clean during this period. Again, this structural change reflects the evolution of the U.S. device industry.

Figure 4
Changes in U.S. Companies' Wafer Fab Equipment Revenue by Segment, 1982 to 1996



Source: Dataquest (April 1998)

In the U.S. semiconductor industry, DRAM served as a starting point and springboard for prosperity. Before 1980, U.S. semiconductor companies wielded the power in the DRAM market. According to a Dataquest survey, they controlled more than 40 percent of the market before 1980. At that time, they relied on domestic suppliers for wafer fab equipment, including lithography and other key technologies. In fact, the stepper market was dominated by U.S. companies until the mid-1980s, including such companies as GCA, Perkin-Elmer Corporation, and American Semiconductor Equipment Technology, with a combined share exceeding 50 percent. Thus, the U.S. fab process equipment market was originally dominated by lithography and resist processing segments. However, U.S. companies faced aggressive competition and lost share to Japanese DRAM manufacturers. At the same time that the market landscape changed, Nikon and Canon made inroads into the stepper market, and U.S. companies were driven out or lost substantial share.

Intel Corporation, which withdrew from the DRAM market, established new turf, the microprocessor market. Following this bellwether, the U.S. semiconductor industry successfully converted its structure to microcontroller (MCU) and application-specific IC (ASIC) production. In the process, it adopted the consortium approach seen in Japan in the 1970s; the SEMATECH consortium was born in 1987. This initiative focused originally on developing device processes, but this was later replaced by efforts to strengthen semiconductor manufacturing technology.

It is important to understand what the strategic shift in the U.S. semiconductor device industry has meant for the equipment industry. Although DRAMs demand state-of-the-art lithography technologies and have acted as a technology driver for device miniaturization, production of ASICs and MPUs calls for technology to form multiple layers for interconnection, including metallization and formation of contact holes. This entails refinement of deposition, etching, and planarization technologies. The United States maintained an advanced technological base in this field, particularly within the military and aerospace industries, and semiconductor equipment companies capitalized on this and expanded their share of these segments through vigorous R&D efforts.

Comparing of Figure 4 with Figure 3 shows that, as DRAM dependence dropped, starting in the early 1980s, U.S. market share from the lithography and resist processing segment declined as well, in contrast to the rise in share of the deposition and etch/clean segments. In 1996, these two segments held a combined share of more than 60 percent. Clearly, the U.S. semiconductor equipment market has completed a structural transformation, moving from the original market focus in response to the changing device market.

Another Strategic Shift?

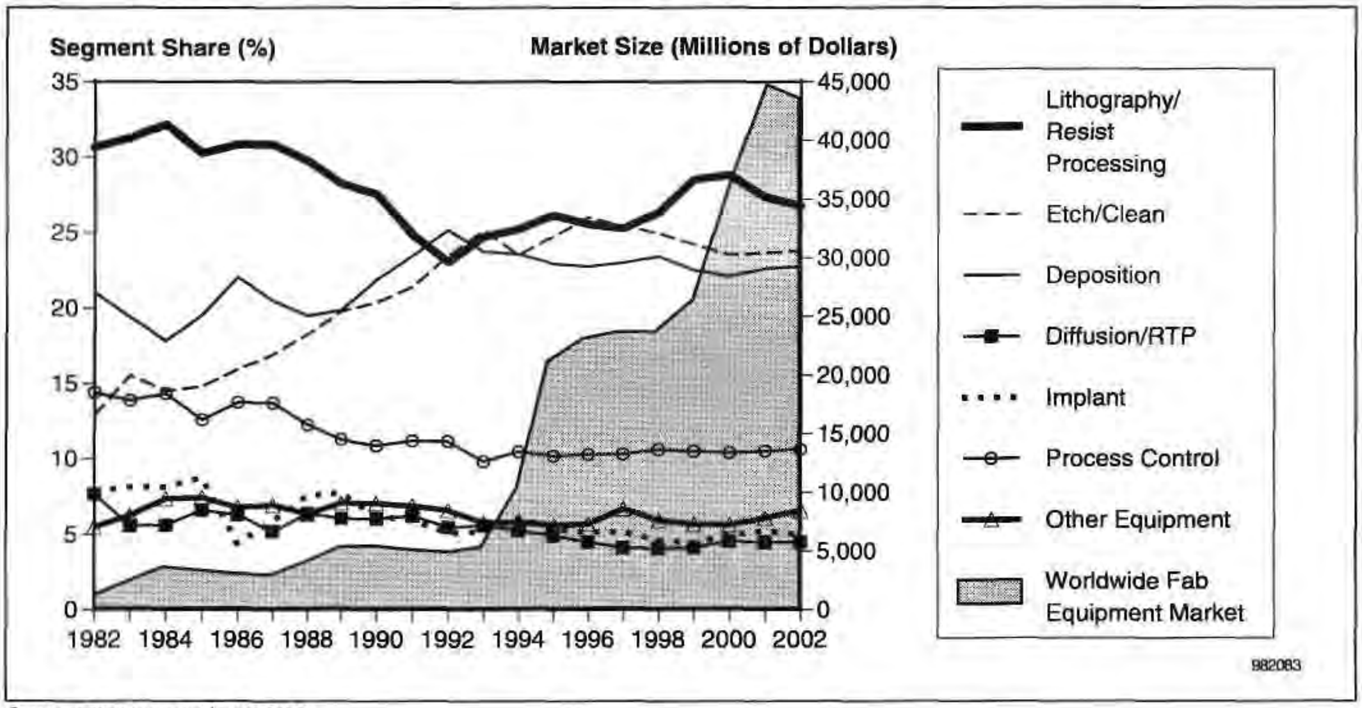
It is reasonable to ask how the semiconductor device market will evolve to understand how the equipment market will evolve. Dataquest predicts that the world semiconductor market will grow at a CAGR of 16 percent between 1996 and 2001, reaching $300 billion in 2001. The DRAM market's CAGR will be 19 percent for the same period, and in 1999, it will achieve major growth, reaching $620 billion in 2001. The DRAM market's share of the total semiconductor market will grow slowly in the next few years and will ramp up in 1999. As a result, DRAM market share is expected to go from 14 percent in 1997 to 16 percent in 1998, to 19 percent in 1999, and to 25 percent in 2000. How will this trend be reflected in the fab process equipment market? Figure 5 summarizes the changes in the world equipment market size and in the percentage breakdown by segment between 1982 and 2002. In short, the semiconductor equipment market is expected to expand at a CAGR of 12 percent up to 2002, when the total market will reach $43 billion. The change in segment composition reveals the following two trends:

- Lithography/resist processing segment will take an increasing share because of the shift to deep-UV laser-based technologies.
- Three markets, lithography/resist processing, deposition, and etch/clean, will polarize.

Year 1 for excimer technology at volume production levels was clearly 1997. According to the results of Dataquest's preliminary surveys, the excimer equipment market in 1997 grew at 240 percent over the previous year. As 0.25-micron or finer processes are adopted for ASICs as well as for DRAMs, deep-UV equipment will become a driver for expansion of the lithography and resist processing equipment market. Because the unit price of the krypton-fluoride (KrF) excimer equipment is higher than that of traditional i-line products (about 70 percent higher at present), the deep-UV segment will gain share, with deep-UV applications expanding after 1998. Therefore, in the lithography and resist processing equipment market, in which Japanese companies have been showing dominance, the ability to gain share in the excimer market will hold the key to success. In fact, the landscape is already changing with the emergence of ASM Lithography.

The lithography and resist processing segment's share eroded gradually from the late 1980s through the early 1990s, while the deposition and etch/clean segments expanded share. In the future, the three segments will divide the market nearly equally. In other words, the deposition and etch/clean market size will increase to approach that of the lithography/resist processing market. Also, new technologies , including the use of such new materials as copper in interconnection and the addition of metal layers, will make deposition and etching technologies more prominent in the ASIC market. Moreover, in DRAM technology, which has traditionally been driven by lithography, mainstream technologies for ASIC/MCU production such as chemical mechanical polishing (CMP) are increasingly being adopted for stack-structured 64Mb and higher devices using 0.25-micron design rules. Again, the deposition and etch/clean segments will be critical in the equipment market.

Figure 5
Trends in the Wafer Fab Equipment Market and in Segment Share, 1982 to 2002

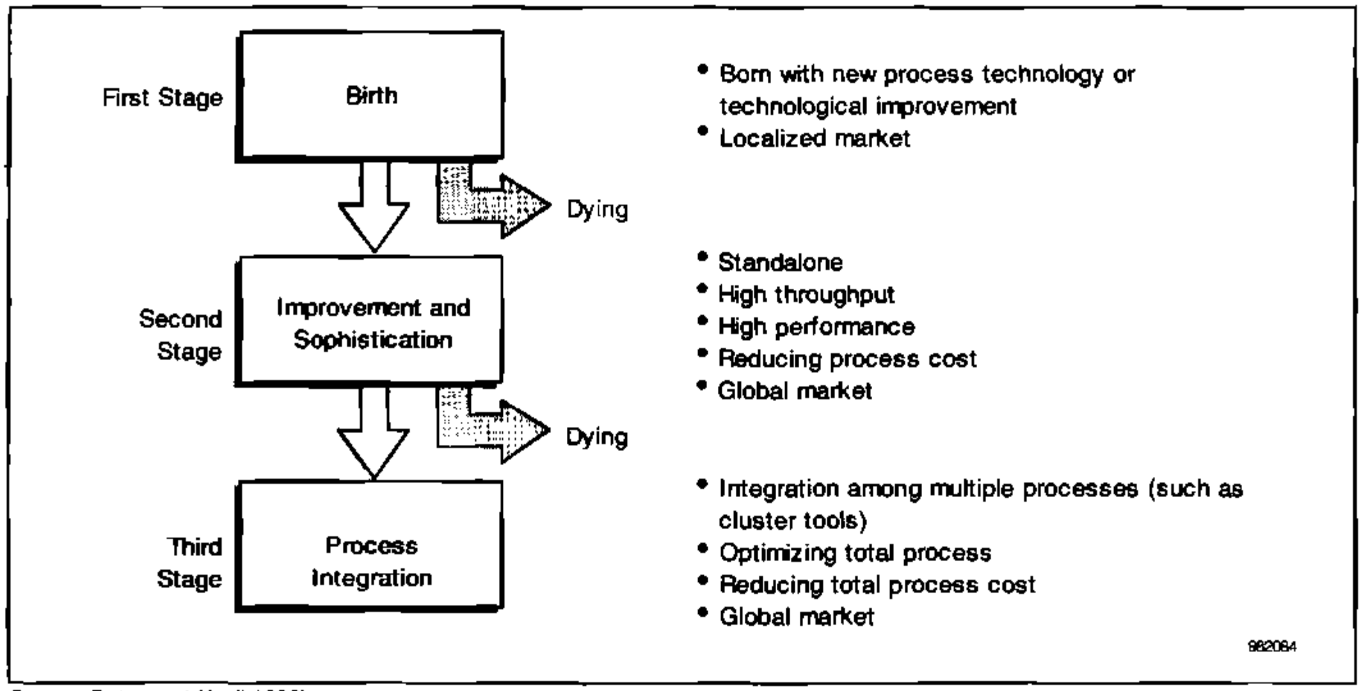


Source: Dataquest (April 1998)

Moving to Process Integration

In addition to market changes, wafer fab equipment is about to enter a new era. Figure 6 shows a conceptual view of the evolution of wafer fab equipment. As discussed earlier, most equipment has been developed for a particular semiconductor process technology. As a new process technology comes on stream, it is incorporated into equipment that will be marketed widely later. At this first stage, the market is still localized; that is, the technology is used by a handful of manufacturers, or the market is limited to a specific country or industrial area.

Figure 6
Development of Semiconductor Manufacturing Equipment



Source: Dataquest (April 1998)

Eventually, the process technology and its advantages become widely recognized, and the equipment is widely accepted, expanding the market. At this level, the market becomes global and attracts new customers. Competition increases, and equipment manufacturers are busy developing variants that extract maximum performance by improving throughput and yield and by reducing process costs, as well as enhancing the original process technology. Now the market is at the second level. Most equipment that incorporates field-proven process technology and has entered the world market is considered to be in this stage.

What's next, then? In the next stage, multiple processes are integrated and a new development concept pursues maximum performance. More precisely, cluster tools and other equipment will be adopted to integrate various process steps, and equipment manufacturers will be required to help optimize performance, including costs. This concept has already been proposed by a U.S. manufacturer. At this stage, equipment vendors must

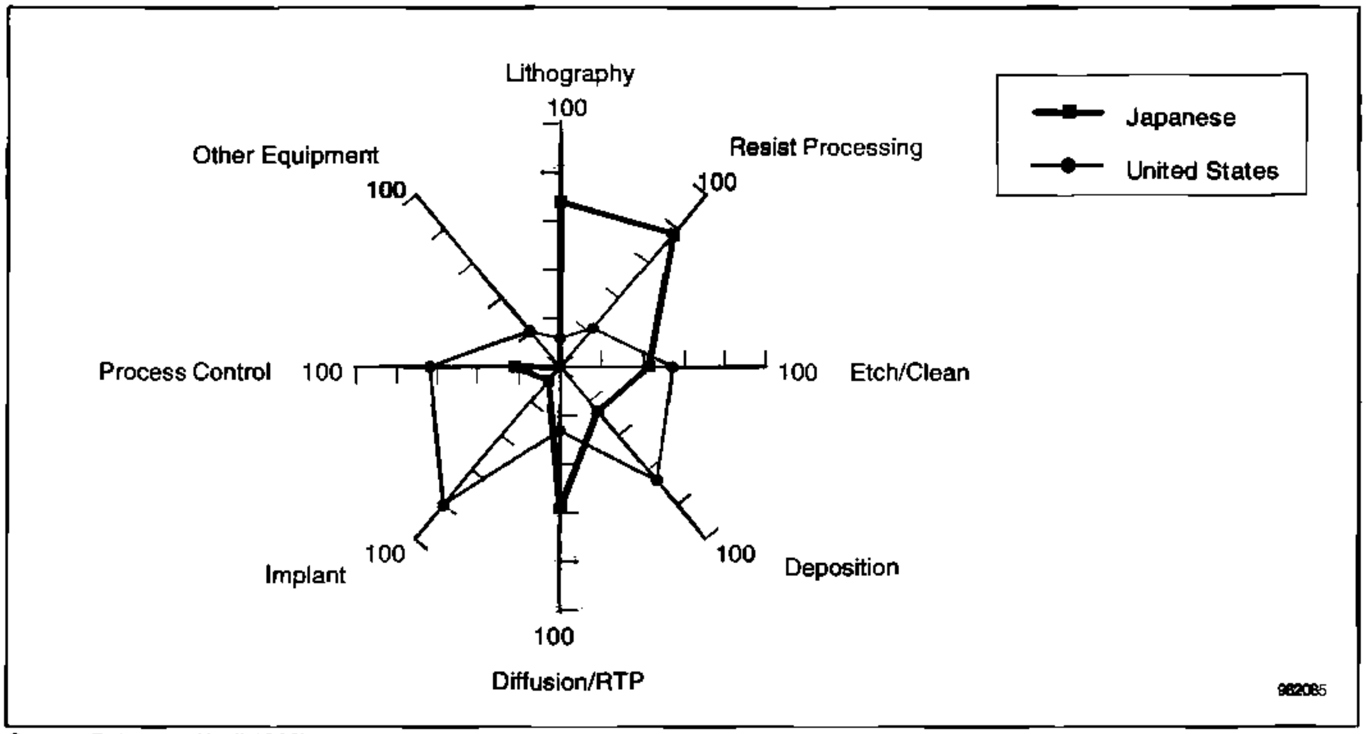
 ©1998 Dataquest

provide know-how related to process conditions, in addition to upgrading hardware technology, such as improving the reliability of existing equipment. In fact, the ability to provide such expertise will increasingly become a key factor in the success of semiconductor equipment makers, which will be required to address "software aspects" of market needs—they will need to cover the entire semiconductor production process.

Dataquest Perspective

Figure 7 shows the share of Japanese and U.S. companies in the semiconductor equipment market by segment. As noted earlier, Japanese companies dominate the lithography and resist processing segment, which has been nurtured in the DRAM market, but they are weak in other segments of the market, except for diffusion and rapid thermal processing (RTP). If market share reflects strength, including technological and management capabilities, then the lopsided share structure of the Japanese wafer fab equipment industry suggests unbalanced allocation of abilities and resources.

Figure 7
Comparison of Wafer Fab Equipment Market Share of Japanese and U.S. Companies by Segment, 1996



Source: Dataquest (April 1998)

A similar pattern is found in the diffusion/RTP segment, in which Japanese companies hold a high share of traditional diffusion equipment. They are being overwhelmed by U.S. companies in the RTP area, which is considered to be essential in advanced control of the thermal process. Given the technological significance and market potential of the deposition and

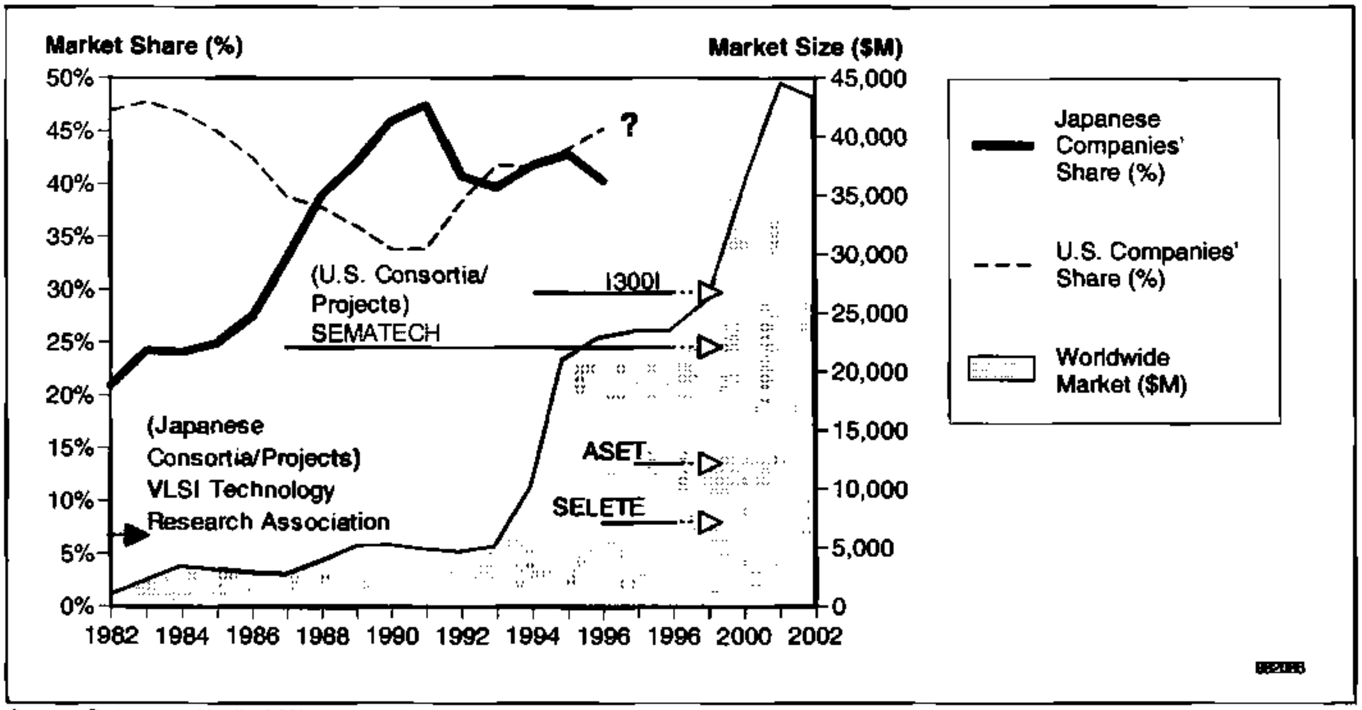
 ©1998 Dataquest

etch/clean segments, the Japanese wafer fab equipment industry needs to refocus on these areas. At the same time, the irreversible move toward process integration will require a broad range of technical capabilities and know-how in a variety of segments. The prosperity of the Japanese wafer fab equipment industry will hinge on its ability to foster companies or consortia that can offer such capabilities, including cost reduction.

It is very important for semiconductor equipment vendors and device makers to work together in developing new process technologies, which lead to new equipment and market opportunities. In retrospect, national projects and consortia have been the most effective means of producing results for the wafer fab equipment industries in both Japan and the United States.

Figure 8 shows the changes in market share of Japanese and U.S. wafer fab equipment companies and the progress of joint development projects in the two countries. Market share positions reversed five to six years after the start of a joint development project in either country. These projects have developed tangible technologies that have helped strengthen the equipment industries and have produced measurable results. In fact, the enhancement of key technologies has proven to play a critical role in periods when a major technology change occurs.

Figure 8
Semiconductor Technology Development, Wafer Fab Equipment Market Size and Share, 1982 to 2002



Source: Dataquest (April 1998)

Today, the industry is in the midst of technology change as various novel technologies, including deep UV and 300mm wafer processing, are about to enter a commercial stage. It is a technology change that will significantly alter the market's structure, and the winners of the race will become the next-generation market leaders. The Japanese wafer fab equipment industry is aware of the imminent change and seems to be determined to meet the challenge by initiating joint development projects—Semiconductor Leading-Edge Technology (SELETE) and Association of Super-Advanced Electronics Technologies (ASET). Dataquest believes that the time has come for Japanese equipment companies to make concerted efforts to refine and enhance key technologies by setting aside their own interests, just as they did in the 1970s—which remains the best course of action to ensure the industry's growth.

Semiconductors Japan

Market Analysis

Analyzing the 1998 DRAM Market

Abstract: *The DRAM market has been plagued by oversupply since 1996, and there are no clear signs of its moving toward a balance. The persistent glut has been squeezing profits for DRAM suppliers, who must relentlessly restructure their DRAM business. Predicting the timing of the market recovery has become urgent. This Perspective analyzes the 1998 DRAM market, focusing on synchronous DRAMs, which are expected to become central in the market. The DRAM shipment and demand data used in this Perspective is based on Dataquest's DRAM supply/ demand quarterly statistics survey in December 1997.*

By Masahiro Suzuki

The General Outlook for the DRAM Market in 1998

The 1998 Japanese DRAM market will be characterized by three distinct trends: increased 64Mb production, 16Mb production cutbacks led by Japanese companies, and rapidly growing share of synchronous DRAMs (SDRAMs).

First, 1998 will be a year of a generation shift from 16Mb to 64Mb. Volume production of 64Mb, led by Samsung Electronics Company Ltd. and NEC Corporation, is steadily on the rise, with other leading suppliers having started commercial production from the second half of 1997. As of February 1998, both 16Mb and 64Mb products were in oversupply, except for 100-MHz, 64Mb SDRAMs, of which a slight shortage is being felt. Dataquest estimates that DRAM demand measured by total bits will reach about 7.5 billion megabytes in 1998, while total supply will amount to 7.7 billion megabytes, resulting in a sufficiency ratio (supply/demand ratio) of around 102. Dataquest believes that, even if DRAM suppliers curtail capital spending significantly, the glut will prevail in 1998.

FILE COPY:
MARIA VALENZUELA

Dataquest
Program: Semiconductors Japan
Product Code: SEMI-JA-DP-9803
Publication Date: March 30, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

Meanwhile, 1998 will see another major shift, an accelerated technology shift from EDO DRAMs to SDRAMs. SDRAM emerged in the third quarter of 1997, when it was rapidly adopted in 16Mb products. Nevertheless, development of 64Mb SDRAMs, particularly PC-100 versions, is somewhat behind schedule. PC-100-enabled and 100-MHz versions will therefore be in slightly tight supply during the first and second quarters. A stable supply of PC-100 versions can be expected in the third quarter of 1998.

DRAM Demand in 1998

The total DRAM demand forecast for 1998, about 7.5 billion megabytes, translates to 3,760 million 16Mb DRAMs, representing a 56 percent increase over 1997. The major driver continues to be PCs, with shipments expected to surge 16.7 percent in 1998, reaching 98.4 million units. At the same time, the average system memory size of PCs will grow to 56.3MB (including the aftermarket). Two factors are important here: The market environment will still work against DRAM prices, which are unlikely to rise rapidly in 1998, and the release of Windows 98 and NT 5.0 will prompt a further increase in system memory size.

Meanwhile, the use of SDRAMs on PCs has accelerated since the third quarter of 1997, and SDRAMs are increasingly outpacing EDO DRAMs in share of design wins. This trend is expected to continue throughout this year. It should be noted that the adoption of SDRAMs for notebook PCs is a bit slower than for desktops, mainly because current SDRAMs consume more power than EDO products. In fact, SDRAMs consume much less power than LCD backlighting and mechanical components, but notebook suppliers continue to use power-saving versions of SDRAMs. DRAM companies are apparently being slow to develop low-power 64Mb SDRAMs.

DRAM Demand Outlook by Integration Level

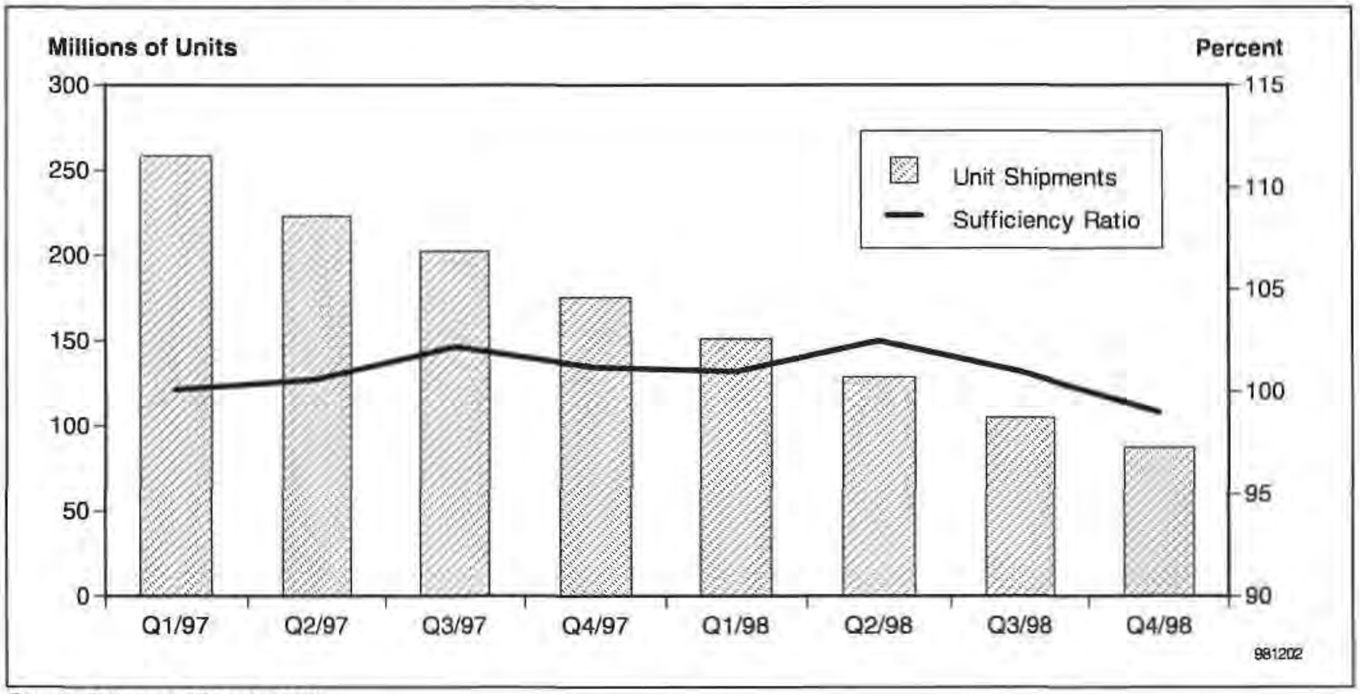
Figures 1, 2, and 3 show Dataquest's worldwide supply and demand forecast for 4Mb, 16Mb, and 64Mb DRAMs, respectively. Note that a sufficiency ratio of over 100 represents a market glut.

4Mb DRAM

Major systems consuming 4Mb DRAMs include PCs, rigid disk drives (RDDs), printers, facsimile machines, network routers, set-top boxes, and video game systems. Note that total consumption has entered a declining trend. One exception is 4Mb, which is now replacing 1Mb in RDDs. Similarly, the supply of 4Mb DRAMs is on the decline, as shown in Figure 1; unit shipments in 1998 are expected to plunge 45 percent to 472 million from 859 million in 1997. The shipment forecast data for leading manufacturers indicates that most of them will proceed with production cutbacks throughout 1998. In particular, leading suppliers have already switched to order production. The sufficiency ratio will be at about 100 throughout 1998, meaning that the market will be near balance this year. One variant scenario would be further acceleration of production cutbacks by major suppliers, which would spur second-tier companies to boost their production.

 ©1998 Dataquest

Figure 1
Supply/Demand Forecast for 4Mb DRAMs



Source: Dataquest (March 1998)

16Mb DRAM

Major application markets for 16Mb DRAMs, in addition to PCs, include printers, network routers, DVD players, set-top boxes, and video game systems. Of these, laser printers are the largest consumer. Supply was on the rise in 1997 but flattening in 1998 (see Figure 2). Total shipments of 16Mb DRAMs in 1998 will reach 2,128 million, a 10 percent increase from 1,982 million in 1997.

Analysis of shipment trends by individual manufacturers indicates that leading Japanese and Korean suppliers have already launched production cutbacks. Leading DRAM companies have changed the plans made in mid-1997 and now plan to make the actual cutbacks one or two quarters earlier, to the third or fourth quarter of 1997. However, second-tier companies will generally increase their production throughout 1998, which reflects their delay in developing 64Mb products. Depending on price trends, they may boost 4Mb production while curtailing 16Mb output.

Conspicuous 16Mb DRAM players in the 1998 market are Micron Technology Inc., Texas Instruments Inc., Siemens AG, and Nan Ya Technology Corporation. All of them plan to continue to expand production in 1998. Micron has announced plans to boost 16Mb production while it has the ability to expand 64Mb production. Micron's annual 16Mb shipments reached 224 million units in 1997, ranked second in the world next to the 244 million units shipped by Samsung Electronics. Micron plans a further increase to 416 million units in 1998. Nevertheless, Dataquest believes that Micron will cut back 16Mb capacity and ramp up 64Mb production once

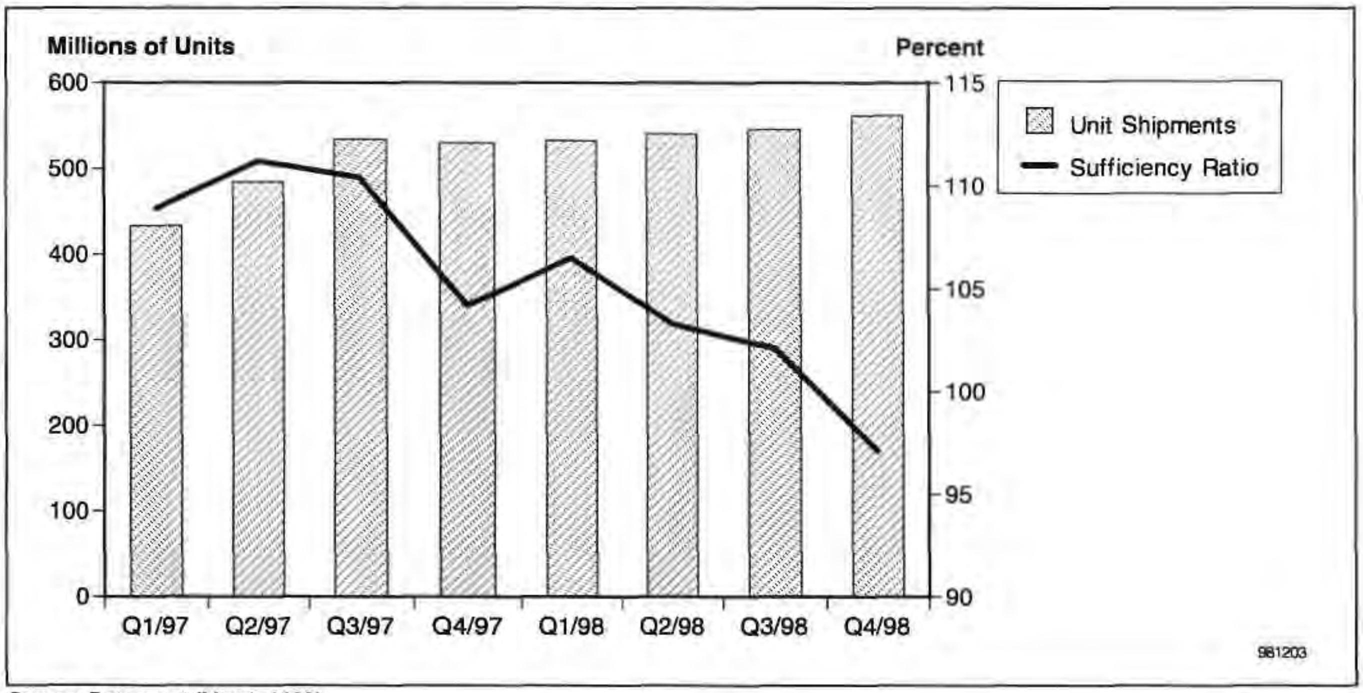
 ©1998 Dataquest

64Mb DRAMs begin proliferating in desktop PCs. In that case, the total supply in 1998 might be reduced from 2,128 million.

TI follows Micron in a major production expansion plan. The company's 16Mb shipments in 1997 totaled 205 million units, ranked No. 3, next to Micron, and it is expected to churn out 278 million units in 1998. However, Siemens and Nan Ya, although they plan to increase production, will ship a combined total of 243 million units in 1998, far below TI's shipments. Thus, Micron and TI will have major clout in the 16Mb market in 1998.

As shown in Figure 2, the oversupply will remain pervasive in the 1998 market if these companies act on their plans to increase production, which will compensate for the production cutbacks planned by other companies. One note of caution—a temporary shortage is possible if so many suppliers cut back production so quickly. More important, Micron's move needs to be watched because it plays a key role in the group intending to boost production. The company may adjust the production ratio between 16Mb and 64Mb according to 64Mb demand. By doing so, it would be a decisive factor in supply and demand trends in 1998.

Figure 2
Supply/Demand Forecast for 16Mb DRAMs



Source: Dataquest (March 1998)

64Mb DRAM

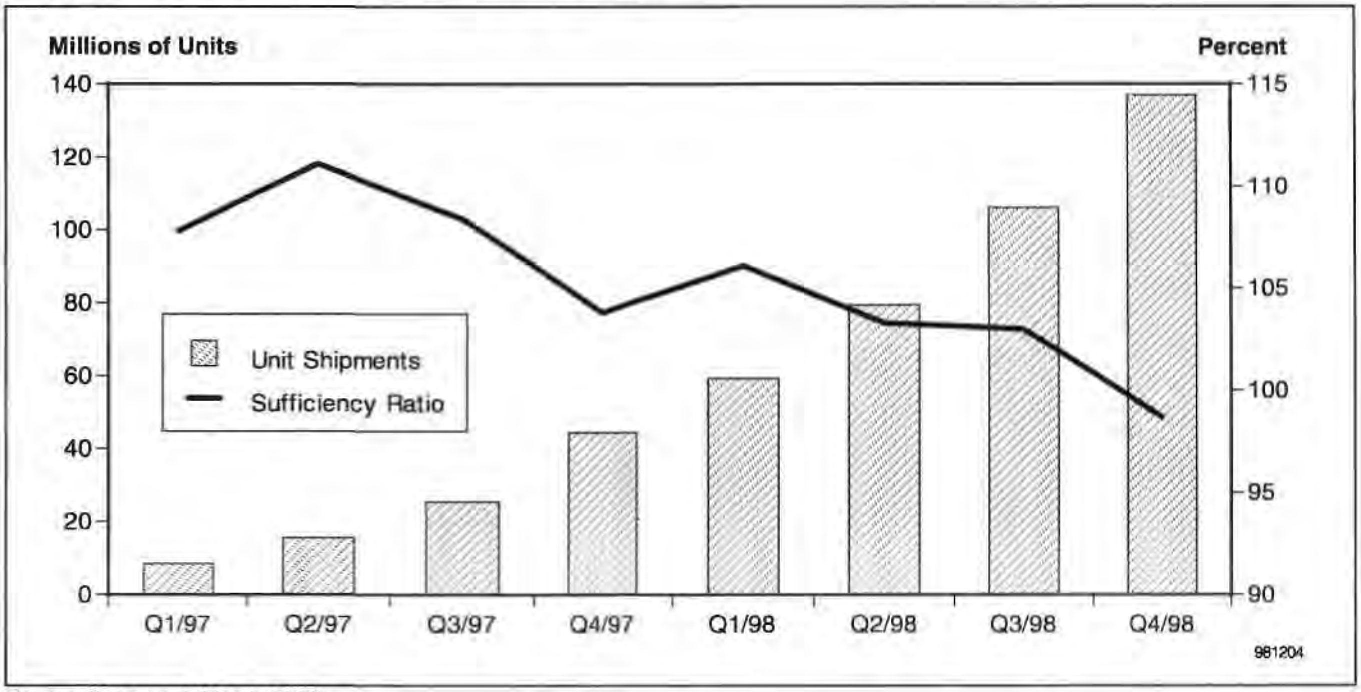
Again, PCs and other higher-end computers are a major consumer of 64Mb DRAMs. In fact, computer main memory seems to be the only application requiring 8MB capacity in the memory device. In addition to PCs, workstations, with a relatively short product cycle, are fast adopting high-integration DRAMs. In 1997, major demand came from workstations in the first half and from some notebook PCs in the second half.

 ©1998 Dataquest

In 1998, 64Mb DRAMs will make inroads into desktop PCs to replace 16Mb products. As shown in Figure 3, 64Mb production will ramp up steadily, and oversupply will be seen in 1998. Korean and Japanese DRAM suppliers have been forced since 1996 to curtail capacity expansions in the wake of the recession. However, Dataquest believes that their cutbacks alone will not lead to the long-awaited balance unless other DRAM companies follow suit by substantially reducing capital spending.

Samsung Electronics shipped an estimated 32 million units in 1997 and will ship 79 million units in 1998. NEC followed Samsung with 21 million units in 1997 and 63 million units in 1998. Micron, however, in 1997 produced 2.8 million units and plans production of 10 million units this year, although the company will likely adjust its plans when 64Mb demand ramps up.

Figure 3
Supply/Demand Forecast for 64Mb DRAMs



Source: Dataquest (March 1998)

Shipment Trends and Forecast by DRAM Type

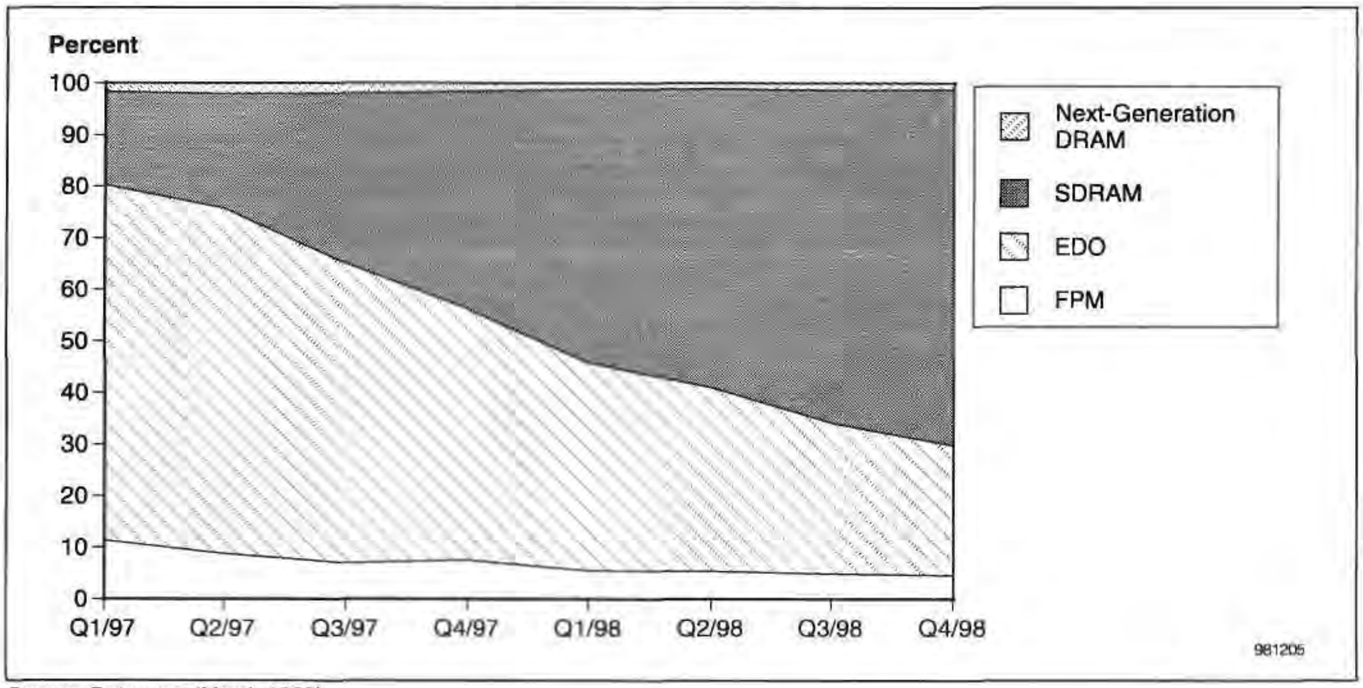
Figures 4 and 5 show shipment trends and the forecast for 16Mb and 64Mb DRAMs, respectively. (The category "next-generation DRAM" refers to Rambus DRAMs, or RDRAMs).

For 16Mb, the shift to SDRAMs has accelerated since the third quarter of 1997. In 1997, Intel released the 430TX and the 440LX for supporting SDRAMs. The increase in SDRAM shipments coincided with Intel's release of the 440LX in the third quarter. Nevertheless, it is well known that replacement of EDO with 66-MHz SDRAM does not improve the performance of the memory system. Thus, the increasing use of SDRAMs

 ©1998 Dataquest

seems to reflect the intention of systems companies to gain know-how about use of the future mainstream device by adopting early. SDRAM shows little difference in price over EDO DRAMs, and using it as a replacement early reduces the kinds of products that require inventory control as early as possible.

Figure 4
Breakdown of 16Mb DRAM Shipments by Device Type



Source: Dataquest (March 1998)

Figure 5 shows that the shift to 64Mb SDRAMs will speed up during the first quarter of 1998. A major driving force is Intel's 440BX, a chipset supporting 100-MHz SDRAMs slated for release in the first quarter. At present, 64Mb SDRAMs are primarily 66 MHz, and 100-MHz versions are available from only a few vendors. For SDRAMs to operate at a system clock speed of 100 MHz on PC motherboards, they must operate at 100 MHz as they are mounted on the dual in-line memory module (DIMM), which is equivalent to a speed of 125 MHz for an SDRAM device alone. (Note that 100-MHz SDRAMs are usually used at the system clock frequency of 66 MHz.) Volume production of 125-MHz SDRAMs requires a 0.25-micron type of process technology.

Dataquest Perspective

The Japanese DRAM market in 1998 will be still characterized by oversupply, judging by analysis of total bid-based supply and demand as well as of supply capacities of DRAM suppliers and their likely changes. One exception is 125-MHz 64Mb products, which may face some shortages, accompanied by price premiums. The 125-MHz versions will be required for the 440BX, which operates at a clock frequency of 100 MHz, as well as for 350-MHz

Pentium II or later MPUs. If volume production of these MPUs is substantially delayed, DRAM suppliers will focus on building up 0.25-micron process capacities, and a shortage of the 125-MHz products will become less likely.

Many development challenges are waiting for DRAM companies. In addition to the traditional race for higher integration, they are expected to commercialize high-speed SDRAMs, low-power SDRAMs, and next-generation DRAMs, including RDRAMs, double-data-rate (DDR) DRAMs, and SLDRAMs. In particular, next-generation products, for which specifications have still not been finalized (except for RDRAMs), have a long way to go. Dataquest believes that the most important challenge for DRAM makers is to identify which device type will become mainstream and to allocate their resources effectively to allow timely introduction of suitable products to the market.

Semiconductors Japan
Market Analysis

The Impact of the Asian Financial Crisis on Japanese Semiconductor Companies

Abstract: *The impact of the Asian financial crisis is beginning to be felt on a wider basis. The loss in GDP in the areas hit by the crisis has started to affect local demand for goods, including electronics, affecting both exports to those countries and local production. This Perspective analyses the impact of the crisis on Japanese electronic equipment production and Japanese semiconductor suppliers and offers possible scenarios.*
By Yoshihiro Shimada

The Asian Financial Crisis

The arrival of the Asian financial crisis in 1997 shook Asia/Pacific countries, including Thailand, Korea, Indonesia, Malaysia, Philippines, Singapore, and Hong Kong. The crisis is a financial phenomenon, but its widespread impact is beginning to be felt in the overall economies of those countries.

In Korea, as in Japan in the early 1990s, production of low-end model shifted to Association of Southeast Asian Nations (ASEAN) countries because of their lower costs, and the domestic production remaining in Korea showed a profile similar to domestic production in Japan. The yen depreciation that preceded the Asian financial crisis, however, strengthened Japanese exports of consumer equipment, and production of that equipment in Korea was adversely affected. Semiconductors had already become a major contributor to nationwide exports in Korea, but weak pricing over the past two years or so has hurt Korean exports and the country's foreign exchange reserves. At the same time, rapid expansion of DRAM production capacity required vast capital spending, but most manufacturing equipment and manufacturing materials had to be imported. This is one of the most serious impacts of the Asian financial crisis for Korean semiconductor companies.

Publication Date: March 9, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

In countries such as Singapore, Malaysia, Thailand, and Indonesia, the production shift from Japan, the United States, and Europe has contributed to a rapid growth in electronic equipment production. Because products have been exported back to those advanced countries, as well as to other regional markets, the economies of those countries have benefited, on the whole. This scheme, however, made those countries heavily dependent on imports as more manufacturing equipment and materials were required, making them vulnerable to the effects of the financial crisis.

Hong Kong, too, has been exposed to the Asian financial crisis, and a financial blow has been unavoidable. In Hong Kong, a large portion of imported semiconductors are re-exported to other parts of the mainland China, and the impact of the crisis must be measured in relation to equipment production sites supported by imported semiconductors. The Chinese government has been making every effort to maintain the value of renminbi, but if the currency should be hit directly by the Asian financial crisis, the impact could be felt throughout the whole Asia/Pacific region.

Taiwan has seen only a minimum impact and has proven its excellence in managing industries and finance. Major industries such as PCs, peripherals, and semiconductors are still growing fast in Taiwan, and Dataquest expects Taiwan to remain comparatively unaffected by the Asian financial crisis.

As the Asian financial crisis's adverse impact widens, Japanese export of industrial equipment is starting to show a decrease. Asia/Pacific countries have been forced to scale down utilization of production sites for equipment to be marketed within Asia/Pacific, and Japanese companies have been no exception.

Impact of the Crisis on Japanese Electronics Production in Asia/Pacific

Dataquest is conducting in the first quarter of 1998 a detailed survey of 1997 semiconductor revenue. The final results are scheduled to be released in the second quarter of 1998, but a preliminary look at Japanese companies has already shown that 1997 revenue has been influenced by the crisis. It should be noted, however, that a discrepancy between company plans and actual revenue in Asia/Pacific does not necessarily come from the Asian financial crisis alone —some equipment had been plunged into a painful correction when oversupply followed a period of robust production.

In the first half of 1997, consumer equipment production in Asia/Pacific on the whole saw recovery from an extended slump that started in mid-1995. There were doubts about PC peripherals' continued production growth, but an adjustment phase had not started yet.

By mid-1997, the winds of change had started to blow. Video CD players, which had enjoyed a sudden increase in production because of a rapid rise in demand from mainland China, began to show sluggishness, and production plummeted. CD players, portable audio equipment, rigid disk drives, and CD-ROMs also saw a decrease in production.

 ©1998 Dataquest

So far in 1998, there has been no clear sign that production levels of this equipment are recovering, and semiconductor orders for those applications continue to be slow.

The Impact on Japanese Semiconductor Companies

The impact of the Asian financial crisis on semiconductor companies is not necessarily negative. The following factors need to be considered:

- Demand side
  - Negative—Reduction in orders from Asia/Pacific users
  - Negative—Price pressure from users
  - Positive—Increase in orders because of improved competitiveness of electronic equipment manufactured in Asia/Pacific
- Supply side
  - Negative—Asia/Pacific semiconductor companies' drive to export
  - Positive—Improvement in short-term semiconductor supply and demand because of production constraints stemming from difficulties in importing materials
  - Positive—Improvement in long-term supply and demand because of limited capital spending by Asia/Pacific semiconductor companies

In this analysis, Dataquest attempts to estimate the impact of the Asian financial crisis on Japanese companies' revenue, using metrics such as revenue by country and semiconductor revenue share of local users in Asia/Pacific.

Naturally, actual problems that semiconductor vendors face will be affected also by the application involved and, eventually, each user. This analysis, however, attempts to show trends in the impact of the crisis on semiconductor orders. Dataquest classifies Asia/Pacific into the following five countries or areas: Korea, Taiwan, China/Hong Kong, Singapore, and Rest of Asia/Pacific (ROA). In this analysis, it is assumed that the higher the revenue in Korea, Singapore, and ROA and the higher the ratio of local users, the higher the risks in semiconductor orders.

Although there has been industry input into these estimates, this analysis is not based on a rigorous survey, and therefore Dataquest chooses to avoid using specific company names. Metrics have, however, been estimated based on each company's characteristics as perceived by Dataquest. The companies analyzed are the top 11 Japanese companies included in the ranking of the top 30 worldwide Asia/Pacific companies: NEC Corporation, Toshiba Corporation, Hitachi Ltd., Fujitsu Ltd., Mitsubishi Corporation, Matsushita Electric Industrial Co. Ltd., SANYO Electric Company Ltd., Sharp Electronics Corporation, Sony Corporation, Sanken Electric Company Ltd., and Rohm Company Ltd.

©1998 Dataquest

These 11 Japanese companies combined hold a 33 percent share of the revenue of the top 30 companies in Asia/Pacific (see Table 1), and their sales into Korea, Singapore, and ROA together account for 60 percent of their total revenue in Asia/Pacific (see Figure 1). In Korea, most of the sales come from business with local users, while in Singapore and ROA, the major portion of their revenue comes from Japanese users or Americas and European users. Among those 11 companies, consumer applications-oriented companies tend to show higher dependence on local users, but they also benefit from their internal user divisions' Asia/Pacific production sites. For those 11 Japanese companies combined, 55 percent of the revenue comes from local users in Asia/Pacific (see Figure 2).

Figure 3 shows the results of estimating the risks that Japanese companies face in semiconductor orders because of the crisis. The first risk scenario is for Korea, Singapore, and ROA combined, and the second risk scenario is for Korea and ROA only. There are some companies whose sales to local users are significantly high but whose risks from the Asian financial crisis are small. Those companies' users are associated with either Japanese, Americas, or European electronics vendors. DRAM companies show similar trends. On the other hand, there are companies whose risks may be high not only because of the Asian financial crisis but also because of sluggishness in certain application markets worldwide. Japanese companies' semiconductor sales in Asia/Pacific are generally characterized by high dependence on Japanese users.

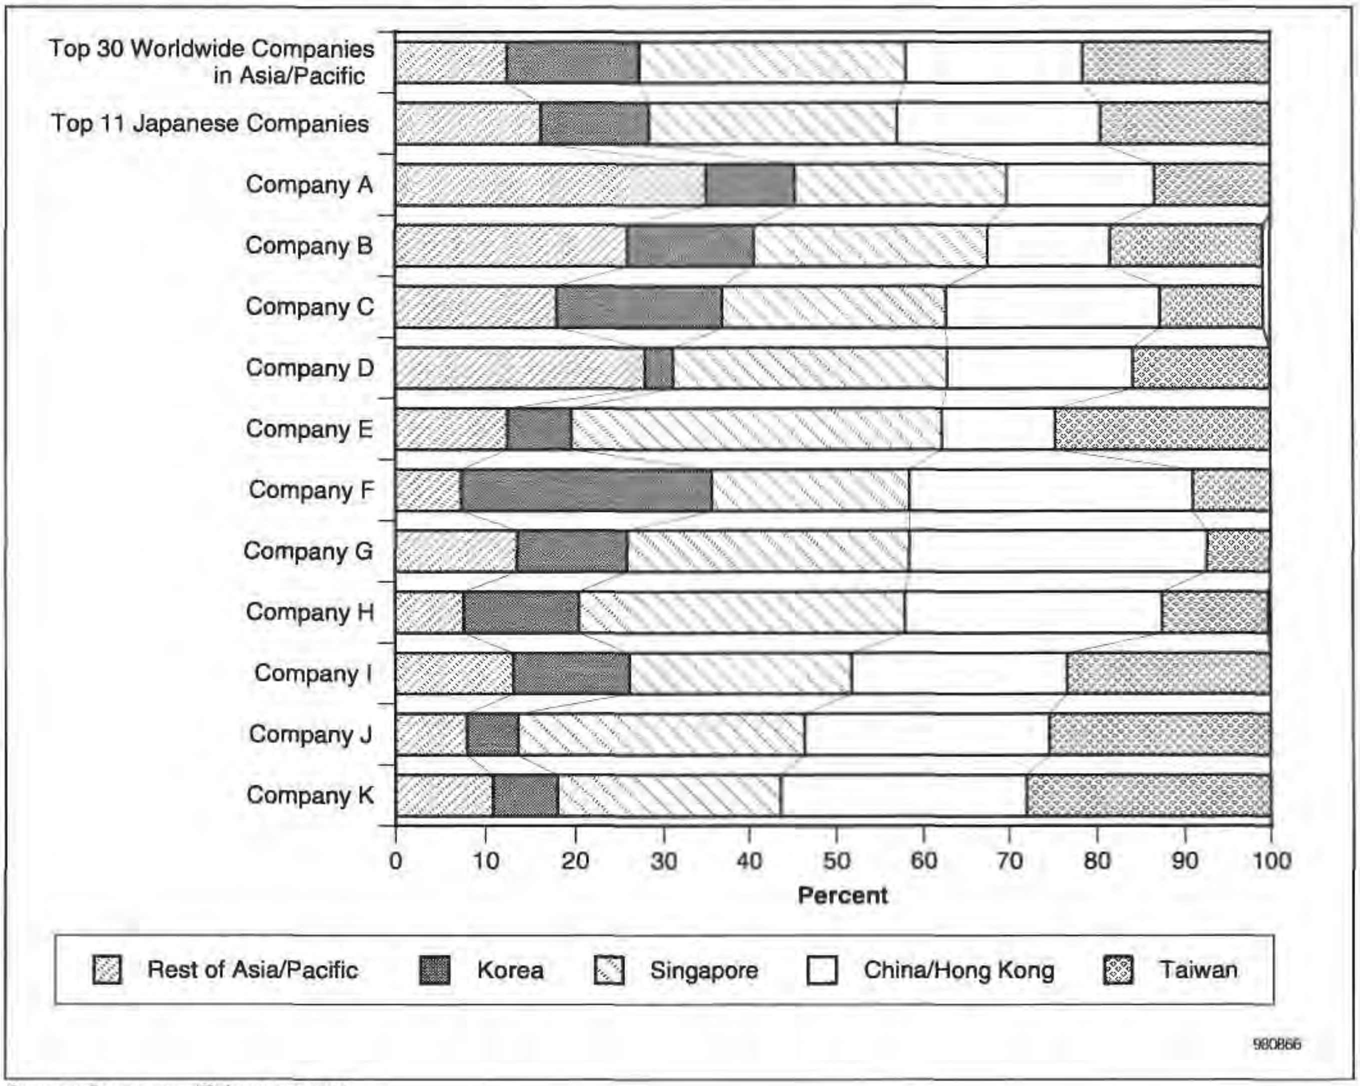
Table 1
Revenue of Selected Japanese Semiconductor Companies in Asia/Pacific, 1996 (Millions of Dollars)

1996 Rank	Company	1996 Revenue	Percentage of Top 30 Companies' Revenue
3	Toshiba	1,804	7.3
7	NEC	1,283	5.2
9	Hitachi	1,169	4.7
11	SANYO	913	3.7
13	Mitsubishi	729	3.0
15	Matsushita	500	2.0
16	Fujitsu	476	1.9
17	Rohm	471	1.9
20	Sharp	406	1.6
23	Sony	286	1.2
29	Sanken	215	0.9
	Top 11 Japanese Companies	**8,252**	**33.4**
	Top 30 Worldwide Companies in Asia/Pacific	**24,699**	**100.0**

Source: Dataquest (February 1998)

 ©1998 Dataquest

Figure 1
Japanese Companies' Sales into Major Countries in Asia/Pacific

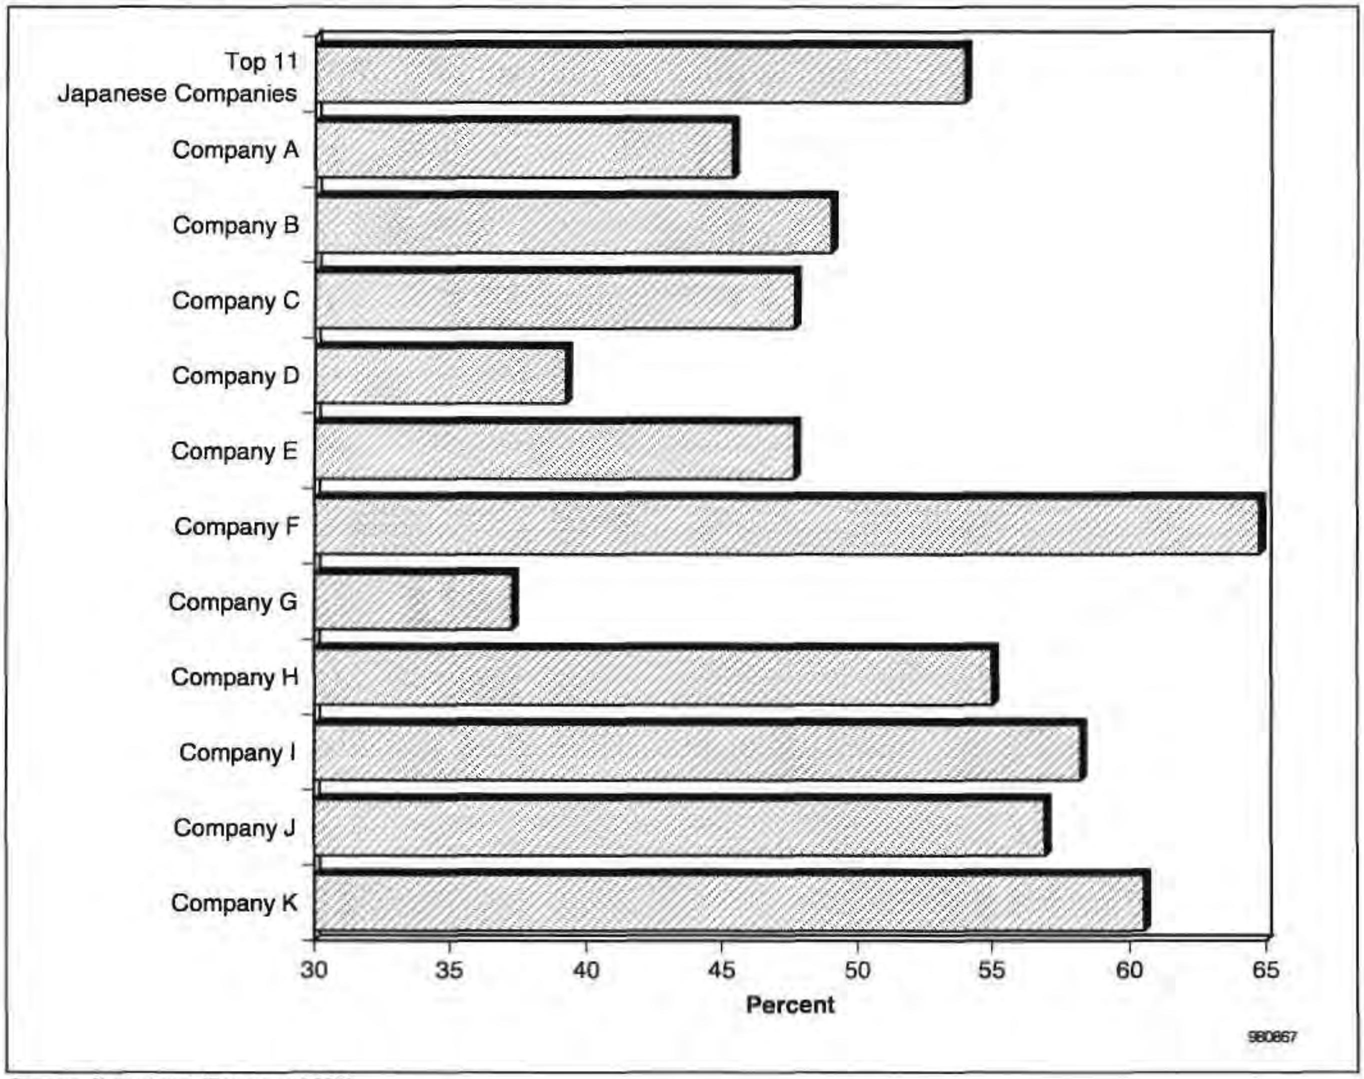


Source: Dataquest (February 1998)

One trend shown in this estimate of risk is that the element of risk added by the Asian financial crisis increases as the total revenue in the crisis-hit areas increases, but at a certain point, the crisis-based risk saturates. This again reflects low dependency on purely local users.

True, semiconductor orders from Asia/Pacific had started to decline even in 1997, and companies with a stronger emphasis on the Korean market were exposed to direct and immediate losses in orders. Dataquest has not heard of any Japanese companies officially attributing lower sales forecasts in Asia/Pacific solely to the Asian financial crisis.

Figure 2
Japanese Companies' Sales to Local Users

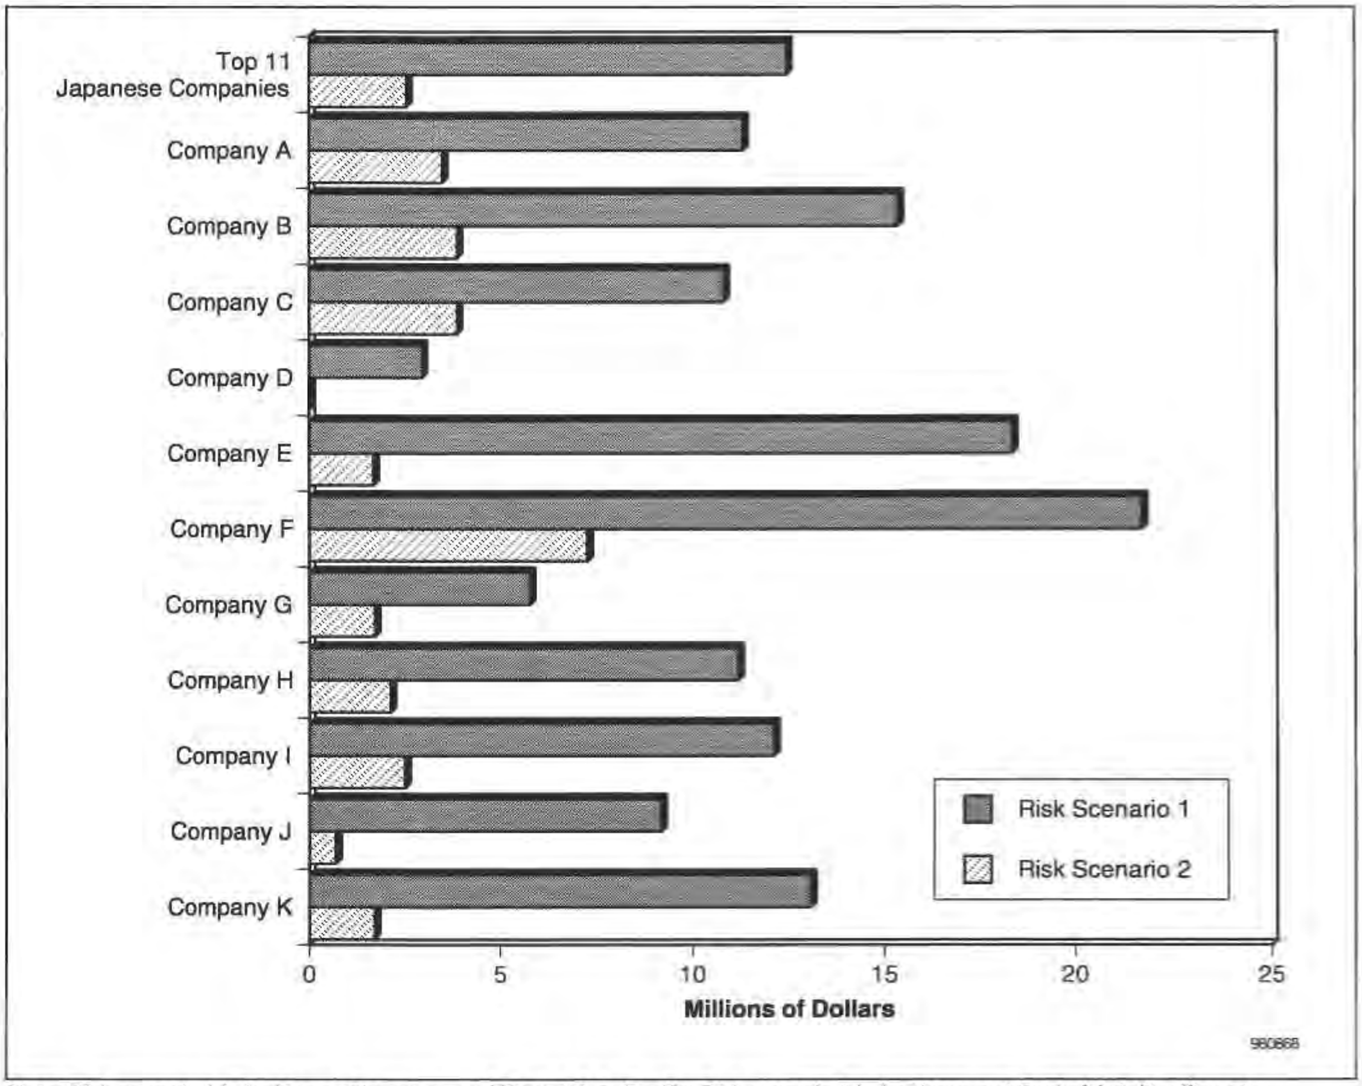


Source: Dataquest (February 1998)

This analysis has focused on semiconductor orders and revenue, and manufacturing issues have intentionally been put aside. There has been no immediate change to Japanese companies' wafer fab plans in Asia/Pacific. Test and assembly, or back-end, operations also remain unaffected, because most of the materials are still imported from Japan and the only visible change would come from labor costs.

 ©1998 Dataquest

Figure 3
Impact of the Asian Financial Crisis Japanese Companies' Sales into Major Countries in Asia/Pacific



Note: Risk scenario 1 is for Korea, Singapore, and Rest of Asia/Pacific; Risk scenario 2 is for Korea and Rest of Asia/Pacific only.
Source: Dataquest (February 1998)

Possible Scenarios

The future impact of the Asian financial crisis should be measured and analyzed from several aspects, including time frame, origin of demand (whether domestic or export) for application equipment, production of equipment in Asia/Pacific or in other parts of the world, high-end models versus low-end models, availability of semiconductor materials and manufacturing equipment, and semiconductor capital spending.

In the short term, confusion in orders is unavoidable as suppliers and users try to reach new terms of trade incorporating lower exchange rates for local currencies. Local users are putting pressure on local semiconductor sales

 ©1998 Dataquest

offices to decrease prices, while prices of imported devices now translate into higher value in local currencies.

In the mid- to long term, after new terms of trade have been settled on, Asia/Pacific countries will see changes in their basic economic structures in terms of electronic product categories as Japanese electronics companies rearrange production sites to take advantage of lower costs. Lower exchange rates will also encourage foreign companies to acquire local companies, and the increase in direct investment will contribute to re-establishing and renewing manufacturing facilities in the region.

In terms of demand for electronics manufactured in Asia/Pacific, domestic demand-oriented production will suffer an immediate and direct loss while export demand remains strong. Because overall demand for electronics in Americas and Europe seems to remain firm, the key factor here would be demand in Japan and China.

Lower exchange rates for local currencies will improve the export competitiveness of electronics produced in Asia/Pacific countries, but this could happen at the expense of production in other parts of the world. There is a possibility that some electronics equipment could see lower prices in export markets, and that may increase demand for those products. Whether electronics production in Asia/Pacific increases or decreases affects industrial equipment companies in Japan, because they have benefited from the Japanese electronics companies' production shift, which brought manufacturing equipment to those new sites. One other factor to be considered in electronics manufacturing is the possible shift in product class—in the past few years, ASEAN countries have shifted to middle-range products from low-end models, while China, with its low labor costs, took up production of low-end products. Depreciation of currencies in the ASEAN countries could enable them to resume production of low-end models, especially when they are motivated to increase exports to acquire foreign currency reserves.

Industrial equipment and manufacturing equipment are the areas hit hard by the Asian financial crisis because local companies find imported equipment too expensive. Along with the impact on the purchase of imported materials, this may motivate Asia/Pacific countries to secure industry autonomy.

Dataquest Perspective

The Asian financial crisis in its early stages was a set of financial phenomena. It should be noted that in countries whose gross domestic product (GDP) was not already damaged, economic fundamentals were not necessarily ailing, but the impact of the crisis is already being felt in various industries both inside and outside Asia/Pacific.

It should also be noted that, in Japan, the bursting of the bubble economy several years ago and the yen appreciation that followed continue to drag the Japanese economy down. If the effects of the crisis are managed poorly, there

 ©1998 Dataquest

could be similar aftereffects in Asia/Pacific countries; if better managed, those countries' economies and industries could become more efficient.

One important factor that this Perspective has not covered is the impact of the Asian financial crisis on semiconductor production by Asia/Pacific companies and Japanese semiconductor companies' reactions to it. Although there is a general expectation in semiconductor industry circles that the crisis will bring the supply and demand into equilibrium sooner than predicted, the actual effects are yet to be seen. If the Asian financial crisis proves to provide an effective adjustment period, electronics industries may find it an opportunity instead.

Perspective

Semiconductors Japan

Market Analysis

A First Look at 1997 Semiconductor Market Share from the Japanese Perspective

Abstract: *Dataquest has conducted phase one of the annual market share survey for the worldwide top 20 and regional top 10 semiconductor company rankings. This Perspective analyzes the Japanese ranking trends observed in the 1997 survey, trends related to Japanese companies in foreign markets, and the top 10 topics of conversation in the semiconductor industry, from the Japanese perspective.*
By Yoshihiro Shimada

Scope of Survey

Dataquest's annual 1997 market share survey was conducted in November and early December 1997, and the results were published in an earlier Perspective ("Intel, NEC, and Motorola Remain atop the Worldwide Semiconductor Market," SCND-WW-DP-9706, January 1998). We limited our information request to total worldwide semiconductor revenue plus revenue in four regions. We structured the survey to capture the top 20 worldwide plus the top 10 in each region. We did not survey every company worldwide, which explains why the published tables do not have a market total or "other companies" category. Also, we did not survey at detailed product levels.

FILE COPY:
MARIA VALENZUELA

The Top 10 in the Japanese Market

In the 1997 spring forecast, the Japanese market was expected to show clear signs of recovery by growing at an annual rate of more than 10 percent. By the time Dataquest started work on the fall forecast, this initial expectation had started to look too optimistic. The fall forecasts states that the Japanese

Dataquest
Program: Semiconductors Japan
Product Code: SEMI-JA-DP-9801
Publication Date: February 9, 1998
Filing: Perspective
(For Cross-Technology, file in the Semiconductor Regional Markets and Manufacturing binder)

market will grow annually only 9.5 percent on a yen basis, and 1.0 percent on a dollar basis. As mentioned, total market trends will be analyzed in the detailed survey to come, but the qualitative information obtained in this semiconductor revenue survey suggests deteriorating revenue trends, basically because of weak pricing of products such as DRAM and application-specific ICs (ASICs). Production of application equipment showed a slowdown in some areas, such as PCs, peripherals, and consumer equipment. Putting aside the shift of demand from PHS to cellular phones, mobile communications, on the whole, was the only area in which the industry outpaced initial forecasts that predicted weak or negative growth.

In such a market, the top 10 rankings of semiconductor shipments into Japan changed little during 1997 (see Table 1). Hitachi Ltd. suffered a major loss in revenue because of its high ratio of DRAM to total semiconductor revenue, but managed to maintain its No. 2 position. The only change in ranking was between Intel Corporation and Mitsubishi Corporation. Mitsubishi, with the second-highest DRAM ratio of major Japanese companies, recorded a contraction, while Intel's revenue continued to grow, even though Japanese PC markets turned sluggish in the second half of the year.

Japanese Companies in Foreign Markets

Table 2 shows Japanese companies in the worldwide top 20 ranking. NEC Corporation leads Japanese companies at No. 2 in the worldwide rankings. Hitachi's revenue exceeded Toshiba Corporation's in 1996, but its lead did not last long. Other than that, because revenue changes were comparatively small for most companies, the rankings among Japanese companies did not change much.

Table 1
Revenue of Top 10 Companies Worldwide from Shipments of Semiconductors to Japan (Millions of U.S. Dollars)

1996 Rank	1997 Rank	Company	1996 Revenue	1997 Revenue	Growth (%) 1996-1997
1	1	NEC	5,756	5,830	1.3
2	2	Hitachi	4,252	3,749	-11.8
3	3	Toshiba	3,838	3,562	-7.2
4	4	Fujitsu	2,645	2,912	10.1
5	5	Matsushita	2,268	2,340	3.2

19	20	Sharp	2,124	2,059	-3.1

Source: Dataquest (January 1998)

In the Americas region, three Japanese companies were listed among the top 10. NEC, with flat growth, gave way to Texas Instruments Inc. to become No. 4, while Toshiba and Hitachi switched places. In a market in which weak DRAM pricing eroded revenue, Japanese companies as well as Korean companies suffered two-digit reductions in total semiconductor revenue.

In the European market, only two Japanese companies made their way into top 10, NEC and Fujitsu. NEC maintained its No. 8 position, while Fujitsu jumped into No. 9.

In the Asia/Pacific region, three Japanese companies, again, appeared in the top 10 ranking. In this region, Toshiba has traditionally been strong, but it gave way to Texas Instruments and became No. 4. NEC, with comparatively strong growth of 7.9 percent over 1996, maintained its No. 7 position. The third Japanese company was SANYO, which has also had advantages in the Asia/Pacific region. SANYO's historical strength has been in consumer applications, and it was a beneficiary of the recovery in consumer equipment production in this region. None of these three Japanese companies' revenue showed any significant or immediate impact of Asia's financial crisis for 1997.

Starting in January 1998, Dataquest will conduct a detailed survey of all semiconductor companies' 1997 product revenue plus memory unit shipments and microprocessor (MPU), microcontroller (MCU), and digital signal processor (DSP) unit shipments. We will release that detailed information during the second quarter of 1998. Those detailed results will provide information on companies that enjoyed product successes in 1997 that are not listed in this document's tables.

The 10 Most Popular Topics in 1997 from the Japanese Perspective

Dataquest has put together a list of the top 10 news in the 1997 semiconductor industry from the perspective of the Japanese semiconductor industry, based on interviews with Dataquest's contacts in the industry, as well as from various Dataquest analysts' input.

Table 3 lists 10 ubiquitous topics of industry conversation. The top three topics, characteristically, centered around DRAMs. DRAM consumption was expected to resume a recovery path, but the actual trends betrayed this expectation. Although the shift from 16Mb to 64Mb started to make substantial progress and overall bit demand was more than steady, the delay in the shift from extended data out (EDO) to synchronous DRAM (SDRAM), weak pricing trends, and the PC slowdown in Japan and Asia/Pacific brought revenue growth down.

Micron Technology Inc. became the third most frequent topic. Micron Technology increased production and shipments of 16Mb DRAM while Japanese and Korean companies were seeking ways to stabilize the supply/demand balance. Its production trends and pricing and the profit Micron secured in 1997 revealed a totally new strategy in the DRAM business. True, Micron has been known for its unique strategy, but the fact that the company has finally become the top producer of 16Mb DRAM was a shock to many in industry circles—especially Japanese industry circles.

PC shipment trends were the fourth most frequent topic of discussion. In 1997, the Japanese PC market started to show sluggishness, and peripherals such as CD-ROMs finally started to show signs of production constraint. There is some indication that 1997 PC market trends can be characterized by language—in two-byte language regions such as Japan and Asia/Pacific, PC shipment growth weakened. This stems from the fact that, with PC penetration becoming high, additional demand for PCs lies in the growth of networking. In two-byte language areas, where English is not necessarily spoken as a native language, access to cyberspace is limited while Web sites in the native language may appear to be less attractive than those in English, especially those with American origins. Needless to say, the turbulence in Asian economies is playing a role, too.

Table 3
The 10 Ubiquitous Topics, from a Japanese Perspective

Rank	Topic
1	Contraction in the DRAM market for the second consecutive year
2	Continued fall of DRAM prices
3	Micron Technology's production increase and marketing strategy
4	Winds of change in the regional PC markets
5	Sluggishness in equipment production and semiconductor consumption in Asia/Pacific
6	Construction of quarter-micron fabs
7	Increase in flash memory market players
8	Visibility of Taiwanese manufacturers in the DRAM business
9	Disappointment in worldwide semiconductor consumption growth
10	Continued sound growth in mobile communications applications

Source: Dataquest (January 1998)

 ©1998 Dataquest

The Asian financial crisis ranked fifth as a topic. In 1997, the real impact was yet to come and influenced Japan very little. Japanese equipment companies with production sites in Asia/Pacific maintained their levels of production, especially in cases where products were destined to be shipped out of the region. Currently, the strongest interest lies in assessing the magnitude of the impact of the crisis on Korean semiconductor companies' capital spending. A major impact is anticipated, however, on various aspects of electronics industry in 1998.

The construction of quarter-micron fabs and their production starts is one of the few positive topics. Contrary to the initial expectation of improvements in profits, quarter-micron fab output was immediately exposed to harsh pricing competition, both in memories and in logic areas.

Flash memories drew interest as a substitute for DRAM in filling fabs as the fast-growing digital still camera market diversified the applications. MCUs with flash memory have also started to show strong growth. With prices lower than originally planned, flash MCUs are finding their markets quickly.

Ranked eighth is Taiwanese companies' penetration into the DRAM market. Over several generations, the winners in the DRAM business have shifted first from American companies to Japanese companies, then to Korean companies. Now the focus of interest is the question of whether Taiwanese companies will become the next leaders in the DRAM market. Taiwanese companies have already started to produce 64Mb DRAMs to seriously penetrate into the DRAM market, which they initially planned to with 16Mb. Whether their product and technology transfers with foreign partners can contribute to the success of Taiwanese companies is yet to be determined.

Ninth on the list is the disappointment in worldwide semiconductor market growth. The industry expected 1997 to be the year of recovery, but the signs of recovery ended up being very modest. In fact, it became the year when applications that had driven the semiconductor market for the past several years failed to bring about strong demand. Although Dataquest's fall forecast was lower than the spring forecast, actual market trends toward the end of the year suggest even further reductions in growth rates.

Last comes a topic in the communications. While the emphasis of the worldwide semiconductor market is shifting from standalone PCs to communications-related applications such as networks and mobile phones, the Japanese electronics industry is still dwelling on PCs and peripherals. Network-related equipment is yet to come into focus, but mobile phones have come to be recognized as one driver of semiconductor demand. In fact, at the beginning of the year, a slowdown in the production of mobile phones was expected, especially for PHS. It is true that PHS subscriptions suffered contraction in the last few months of 1997, but cellular phones remained steady.

Outside the top 10 are other topics, including:

- Applications: Windows 97/98, CD-ROM production, Windows CE machines, and cyberpets

 ©1998 Dataquest

- Semiconductors: SDRAM, embedded memories, Pentium MMX and Pentium II, clone chips, media processors, and analog ICs
- Manufacturing: fab construction trends, Korean companies' capital spending, and 300mm fab technology and construction

A pleasant surprise was seen among analog companies. As electronic equipment production rose on a worldwide basis, it was only natural for demand for analog ICs to grow steadily. But this is an area in which capital spending and engineering staffing have been underestimated, and the actual growth in demand for analog took companies by surprise. Lack of capital spending brought tight supply, even allocation in some cases, as well as constraint in product development because of the lack of analog engineers. This is expected to continue for some years, but the industry is trying to evaluate the actual demand that remains for independent analog devices, as opposed to analog functions incorporated into system-level integration (SLI) ASICs.

Topics of 300mm fab technology kept conversation going throughout the year and will continue to in the coming several years. The collaboration agreement between the International 300mm Wafer Initiative (I300I) and SELETE groups is expected to bring efficiency into the scheme through global standardization, but actual technology development and fab construction are dependent on each company. Semiconductor companies must face issues such as the cost comparison between 300mm and 200mm technologies, technology and equipment development, the long-term semiconductor supply/demand outlook, and semiconductor companies' product development.

Dataquest Perspective

The results of Dataquest's 1997 market share survey show a sharp contrast between strengthening American and European vendors and weakening Japanese and Korean companies.

This, however, does not result solely from a difference in their emphasis on DRAM but also from a difference in their successful systems-oriented marketing and product development. Even among major Japanese and Korean companies, there are companies that have managed to minimize the negative impact of the DRAM price drops by expanding nonmemory MOS digital products, such as microcomponents and logic. Even in DRAM, which has long been considered a typical commodity product category, a systems orientation can be seen, including development of SDRAM and certain companies' marketing efforts focused on PC companies and memory module companies.

The 1997 Japanese market share results, as well as the top 10 topics of interest to the semiconductor industry from a Japanese perspective, seem to pose one question: Has the Japanese semiconductor industry really become global, selective, and diversified? In 1998, systems-oriented product

Chapter 1
Executive Summary

Scope of This Report

This Market Trends report analyzes the following trends in Japan from 1997 through 2002:

- Electronic equipment production market trends
- Semiconductor market trends
- Semiconductor companies' capital spending trends

Chapter 1 sets the stage for the analysis in this booklet. Chapter 2 discusses electronic equipment production trends, focusing on four major categories: electronic data processing (EDP), communications, industrial, and consumer. Chapter 3 covers the overall semiconductor market trends in Japan, analyzing 1997 market share results and forecasting the market for five years to come. Chapters 4 through 7 discuss detailed product market trends for MOS memories; MOS microcomponents; MOS logic; and analog, discrete, and optical semiconductors, respectively. Those chapters also cover 1997 market share results and forecast market trends for 1998 through 2002. Chapter 8 sheds light on the Japanese semiconductor industry, focusing on the capital spending trends of the Japan-based semiconductor companies during 1997 and 1998.

Research Methodology and Definitions

This Market Trends report follows standard Dataquest market share and forecasting methodologies, but several points may need to be noted.

Numbers are expressed in Japanese yen to make the analysis of time series trends free from fluctuations in the yen/dollar exchange rate. Where necessary, numbers on a dollar basis are mentioned, using the exchange rates shown in Table 1-1.

Table 1-1
Yen-per-Dollar Exchange Rate, 1992 to 1998

Year	Yen (¥)
1992	126.45
1993	111.20
1994	101.81
1995	93.90
1996	108.81
1997	121.10
Preliminary 1998	129.73

Source: Dataquest (August 1998)

The preliminary 1998 exchange rate estimate incorporated in this report uses actual exchange rates through December 1997 and assumes that the December rate applies to all future months. For the years 1999 through 2002, the preliminary 1998 exchange rate is assumed to apply.

Dataquest has made some minor changes to the product definitions in the 1997 market share survey and analysis and is considering a major shift to a new set of definitions in the future; these future changes will be in conjunction with those made in 1997, aiming at the best analysis of system-oriented market trends.

The following are the changes that have been made:

- The hybrid ICs category has been erased from 1997 revenue. Revenue from the shipment of hybrid ICs is counted on the basis of component chips produced by the same vendor in the product categories that those chips belong to, such as analog and discrete. 1996 revenue remains as it was.
- Linear array revenue has been moved from analog to ASIC in 1997 revenue, while 1996 revenue remains the same. Mixed-signal ASIC revenue has also been moved from analog to ASIC, both in 1996 and 1997 revenue. As a result of those changes, analog and ASIC revenue in 1996 is different from previously published numbers for vendors of those products. Also, as a result, the ASIC category is now called "Total ASIC," and what was formerly called "MOS Digital Logic" is now called "Total Logic."

These changes do not appear explicitly in this book, because it describes top-line trends for each product category, but for any comparison of 1997 trends—as well as future trends—with the past trends, including 1996 and before, these changes may need to be noted in some cases.

Major points discussed in this document include the following:

- Japanese electronics production is forecast to grow 3.0 percent in 1998, and the compound annual growth rate (CAGR) for the coming five years will be 2.8 percent. These growth rates have been brought down from the level previously forecast, and Japan still needs to identify strong drivers of electronics production.
- The Japanese semiconductor market is forecast to grow 9.8 percent in 1998, and the CAGR for the coming five years will be 12.4 percent. In a downside scenario, however, 1998 growth could go down to 1.5 percent. The lack of a strong electronics driver is affecting semiconductor consumption in Japan, and the prolonged oversupply in various semiconductor products is affecting pricing trends negatively.
- Japanese semiconductor companies' capital spending in 1998 will see a major drop from the previous year. Reduction in spending is mostly seen in memories, and Japanese companies are placing more emphasis on preparing supply capacity for advanced logic products to serve SLI markets.

- The Japanese semiconductor market is forecast to grow at the slowest pace among the four regional markets worldwide. Along with prolonged weakness in the DRAM market and the acceleration of the SLI move, the changes in regional market size and application trends will force domestic vendors to restructure their operation toward improved support of global customers. Whether digital consumer applications can revive the Japanese market, and whether it is the Japanese vendors or overseas vendors that benefit from emerging applications, depend on each company's efforts to restructure semiconductor operation and transform from commodity vendor to system-level integrator.

Chapter 2
Japanese Electronic Equipment Production Trends

The Japanese economy in 1997, after a temporary surge in domestic demand prior to the consumption tax hike in April, was beleaguered by turmoil in the financial system, a decline in consumer expenditure, and a slowdown in capital spending. The economic hardship was amplified by the Asian financial crisis (AFC) toward the year-end.

In 1997, against all the backlash in the Japanese economy and in Asia/Pacific, electronic equipment production showed stronger growth than expected: 7.8 percent over 1996, reaching ¥23,715 billion (see Tables 2-1 and 2-2). Cellular phones contributed greatly, fueled by a series of price cuts and the shift in demand from personal handy phone (PHS) models. EDP equipment also outgrew the forecast, despite a slowdown in domestic PC shipments, and consumer equipment added some momentum that came from video game systems and digital equipment.

In 1998, communications equipment will no longer serve as a major impetus, as the cellular phone market reaches a high level of penetration and the digitization of backbone networks completes its first round. Thus, Dataquest predicts that electronic equipment production in Japan will grow a moderate 3.0 percent to ¥24,425 billion, down 1.6 percentage points from the fall forecast. Similarly, the CAGR between 1997 and 2002 will settle at 2.8 percent.

Future growth opportunities must come from a surge in PC demand stimulated by the introduction of low-cost models and increased implementations of plug-and-play interfaces, such as universal serial bus (USB) and Institute of Electrical and Electronics Engineers (IEEE) 1394. While Windows 98 will not have much of an impact on the PC market, the evolution of PCs to a new platform for WebTV and other media-mix services will hold the key to growth in demand for personal equipment.

The following section provides a detailed analysis of electronic equipment production in Japan for the four major categories, namely, EDP, communications, industrial, and consumer.

EDP Equipment

In 1997, EDP equipment production in Japan soared 8.3 percent to ¥7,380 billion. While PC shipments to the domestic market slowed down to less than 5 percent growth on a unit basis, the price decline spurred the purchase of peripherals such as printers and display units. Also, storage devices led by high-speed optical disk drives—32x CD-ROM drives and DVD-ROM drives, for example—enjoyed strong growth. This segment is expected to drive the market during the forecast period.

IT investment will continue to be a major driver in 1998 while Japanese financial institutions are exposed to global competition as a result of the "Big Bang," which urges them to strengthen information systems. Therefore, more than compensating for the general economic slump, computers will drive EDP equipment production, growing 5.1 percent in 1998 with a CAGR of 2.3 percent during the next five years. The gradual recovery of the Japanese economy will continue to fuel EDP equipment production after 1998, which should exceed ¥8 trillion in 2001.

Communications Equipment

Communications equipment production in 1997 jumped 19.8 percent to ¥4,844 billion. A prime driver was mobile communications equipment; subscribers grew much faster than expected, recording a net increase of 10 million in 1997. While PHS production decelerated at 7 million units, the market is expected to expand as its focus shifts from personal to office use.

Nevertheless, the penetration of mobile phones combining PHS and cellular phones has surpassed 50 percent, and the continuation of the previous high growth will become inevitably difficult. Meanwhile, the digitization of infrastructure facilities by Nippon Telegraph and Telephone Corporation (NTT) was completed by the end of 1997. These factors will consequently put a brake on communications equipment production, turning into a negative growth of 0.3 percent. On the other hand, network equipment, including LANs, will experience healthy growth at a CAGR of 15 percent or above. All in all, communications equipment production will grow at a CAGR of 2.9 percent between 1997 and 2002.

Industrial Equipment

Industrial equipment production in 1997 was up 7.2 percent, totaling ¥3,908 billion. Of the total, manufacturing systems and instruments recorded the highest growth rate, with 14.9 percent. As the wave of production site relocation to Asia/Pacific countries subsides, the focal point of the market will shift to computerization and sophistication for adding value and further automation. In particular, medical equipment will exhibit strong growth, with the increasing demand for advanced systems to meet the needs of an aging society, resulting in a CAGR of 5.2 percent between 1997 and 2002. Overall, Dataquest predicts a CAGR of 5.3 percent, the highest among the six segments: data processing, communications, industrial, consumer, military/civil aerospace, and transportation.

Consumer Equipment

Consumer equipment production recorded a 1.3 percent increase in 1997, reaching ¥6,098 billion. In the video equipment segment, where TVs and VCRs sold in the domestic market are mostly made overseas, the replacement demand for wide-screen TVs produced at domestic sites contributed greatly. In the digital consumer equipment market, digital video cameras (DV-Cs) recorded notable growth, and unit shipments up to the end of 1997 were estimated at slightly below 1 million. The DV-C quickly will become pervasive, driven by price declines and the improved availability of key components. Similarly, digital still cameras (DSCs) will ramp up rapidly because they can be easily connected to PCs or TVs via a flash memory card or IEEE 1394 interface. On the other hand, the commercialization of digital TVs will have to wait until after 2000 because infrastructure construction has been delayed.

The current recession will hit household appliance production directly, leading to negative growth in 1998. Video game systems will continue to be a fierce battlefield for a 32-bit hegemony, but production will remain mostly unchanged in 1998, until the next-generation products are introduced in 1999. Dataquest predicts that consumer equipment production as a whole will grow at a CAGR of 1.9 percent between 1997 and 2002.

©1998 Dataquest

Chapter 3
Overall Japanese Semiconductor Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese semiconductor market recorded a growth rate of 5.7 percent over the previous year on a yen basis, which was the only negative growth rate on a dollar basis among the four regional markets in the world. As discussed in the previous chapter, the production of electronics equipment in 1997 grew faster than what was forecast, but this growth was not directly translated into faster growth in semiconductor consumption. The difference in trends was caused by two factors: An increase in electronics production took place in categories with lower semiconductor contents, such as industrial equipment, and the price erosion of semiconductor devices betrayed the increase on a unit basis. Also, PC shipments lost momentum in Japan, exerting a negative impact on the consumption of a variety of semiconductor products, including memories, microprocessors (MPUs), and logic.

As a result, the Japanese semiconductor market has become less than one-fourth of the worldwide market for the first time since 1980. It is still the second-largest regional market following the Americas, but both European and Asia/Pacific markets are close behind. In fact, there were months within 1997 when the Japanese semiconductor market fell behind those two markets.

Affecting this is the sluggishness in the domestic market as well as the fast growth in other regions, especially in the Americas and Europe. Semiconductor procurement to support Japanese electronics companies' Asian production sites has moved to each site or to international purchasing offices (IPOs) outside of Japan, and the yen depreciation observed in 1997 did not reverse the trend.

Ranking Trends

The Japanese semiconductor market is characteristically led by domestic vendors, but their market share has been on a constant decline. In 1997, non-Japanese companies together had 26.4 percent of the Japanese market, and Americas companies alone had a more than 20 percent share, while Asia/Pacific companies lost share because of the weak DRAM market. European companies hold a meager 1.5 percent share but are increasing visibility by focusing on selected product areas for the target applications of digital consumer and automotive. Needless to say, the decline of the Japanese companies' combined market share was largely caused by the DRAM price fall, but it should be noted that non-Japanese companies no longer need strong side support in penetrating the Japanese market. Successful non-Japanese companies have come to enjoy close ties with Japanese system companies with their expertise in system-oriented devices in the areas of microcomponents, logic, and analog.

©1998 Dataquest

NEC Corporation continued to lead the Japanese market in 1997 (see Table 3-1). While many other major domestic vendors suffered from sluggishness in various product areas, NEC managed to secure positive growth in all of the major product areas except for memories—ranging from microcomponent, logic, analog, discrete, and optical—on a yen basis. Dataquest estimates that utilization at NEC's fabs remained higher than at those of most other Japanese vendors, helping it to maintain a comparatively healthy income profile. Toshiba Corporation and Hitachi Ltd. switched places in 1997. While Toshiba became the beneficiary of design wins in the digital consumer, mobile communications, and mass storage applications, Hitachi could not fully enjoy the fruit from the increased number of design wins for its proprietary architecture microcomponent product lines. Fujitsu Ltd. and Matsushita Electronics Corporation remained at the same positions of No. 4 and No. 5, respectively. Fujitsu increased market share, with contributions from digital consumer and mass storage applications. Matsushita Electronics also benefited from those two application areas, having system manufacturing companies inside the corporate group. Although PC shipments slowed, Intel Corporation still enjoyed a sound growth of over 20 percent and became No. 6, replacing Mitsubishi Electric Corporation.

Among the non-Japanese companies that gained market share in 1997, LSI Logic Corporation, Analog Devices Inc., Macronix International Company Ltd., and Lucent Technologies stand out with their high growth rates. The growth of LSI Logic was a result of the design wins of its SLI ASIC product line in digital consumer applications, while Lucent took advantage of its communications expertise. Analog Devices was a beneficiary of healthy analog market trends, and Macronix benefited from the mask ROM business, from which Japanese companies are exiting.

Forecast through 2002

The Japanese semiconductor market in 1998 will grow at 9.8 percent (2.5 percent on a dollar basis), down from the fall forecast (see Tables 3-2 and 3-3). This reflects the anticipated slowdown in electronic equipment production and the hovering market conditions for DRAMs, and it also exemplifies the expectation for a recovery in the second half. Underlying assumptions include a mild DRAM price decline, the small direct impact of AFC, and the firming up of the PC market with the introduction of Windows 98. With this growth, however, the Japanese market will lose its share in the worldwide market, while the other three regional markets will gain share.

The CAGR between 1997 and 2002 is forecast to be 12.4 percent, or 10.9 percent on a dollar basis, which is the lowest among the four regions, making the Japanese market the smallest, with a 20 percent share in the worldwide market. With the electronics production CAGR at 2.8 percent, this slow increase in semiconductor consumption is unavoidable, but the long-term trends will pose a major challenge to Japanese vendors.

Source: Dataquest (August 1998)

After Dataquest put together the spring forecast and announced the results in April, several major changes in the electronics industry and semiconductor market have been observed. In view of those factors, Dataquest has added another scenario to the forecast, a downside of the trends described earlier.

In this scenario, worldwide electronics production, which was forecast to show 6.9 percent annual growth in 1997, is assumed at 4.4 percent, or slightly above. Affecting this scenario is the slowdown in unit production in several electronics categories, which have suffered oversupply and reduced unit demand caused by the AFC as well as downturn in the factory average selling price for various electronic equipment.

On the other hand, price erosion in the semiconductor market accelerated, not only in DRAMs but also in various product categories, including flash memory, MPUs, and ASIC; this gloomy wave has come to affect analog and discrete devices that have enjoyed healthy markets even after MOS digital products fell victim to the oversupply-ridden market.

Incorporating these factors, the new scenario sees the worldwide semiconductor market growth this year decreasing to 1.4 percent, a sharp drop from the 8.2 percent scenario in the spring forecast. In Japan, this scenario can be translated into a growth of 1.5 percent, as opposed to the 9.8 percent growth discussed above. A detailed scenario will be illustrated in Dataquest's fall forecast.

Challenge to the Vendors

Once, the Japanese semiconductor vendors grew to enjoy the largest market share in the worldwide market by focusing on two factors: DRAM and consumer applications in the domestic market. The sales into the domestic market represented over 80 percent of Japanese vendors' worldwide revenue in the 1980s, but in 1997, this decreased to 56 percent. As discussed in the long-term forecast, however, the Japanese application markets are not likely to offer major drivers for semiconductor consumption growth.

With this demand-side outlook, vendors that have focused on the Japanese market are facing two major challenges:

- Emphasize and strengthen application-oriented marketing to identify growth segments
- Increase support capability for overseas customers

In fact, not only the consumption of semiconductors, but also the system design, has begun to show signs of overseas shift. This shift is inevitable when the localization of the system is required to best serve local markets, but another factor that is prompting this shift in design capability is the realization of limitations in engineering resources, not only within Japan but on a worldwide basis as well.

 ©1998 Dataquest

At the same time, with the DRAM market forecast to remain at around 15 percent of total semiconductors, Japanese companies need to accelerate the shift of business focus on other product areas. Already, the realization of SLI trends has prompted Japanese companies to initiate the restructuring of their businesses in all aspects of semiconductor operations, ranging from customer support and product design to process development and manufacturing capital spending. This "SLI Shift" also requires marketing power reinforcement.

With reduced profits because of weak pricing trends, major players in the Japanese market face the challenge of making all those changes with minimal resources. It is not sufficient to assume that Japanese semiconductor vendors can automatically benefit from the digital consumer just because the development and production of digital consumer equipment are taking place in the backyard. The efforts to best capture the SLI trends and reform the semiconductor operation will enable them to enjoy a reasonable share and profits in the semiconductor business.

Chapter 4
Japanese MOS Memory Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese MOS memory market recorded negative growth of 14.5 percent over the previous year. On a dollar basis, the decline reached 23.1 percent, worse than that of the world market, which registered an 18.6 percent decrease. The major factor for the MOS memory decline was the relentless erosion of DRAM prices, which hit the Japanese market hard, and Japanese companies relying on the domestic market were severely damaged. As a result, the world share of the Japanese market declined slightly, from 22.3 percent in 1996 to 21.1 percent in 1997.

A breakdown of the 1997 Japanese market by device indicates major slumps in the DRAM and static RAM (SRAM) segments, which shrunk by 15.6 percent and 17.8 percent, respectively. While the two devices grew in unit shipments, price declines caused the overall market decline on a value basis. In particular, the DRAM market has been suffering a supply glut and is still experiencing a seemingly unstoppable price erosion. The sluggish DRAM market affected SRAM prices that continued to plummet. The nonvolatile memory market was not immune to the dreary market conditions, recording a 12.2 percent decrease in 1997. Clearly, the entire memory market is satiated with excess supply capacities. Even flash memory, one of the few big hopes in the market, reported a negative growth of 9.8 percent on a value basis, although unit shipments grew strongly, as bolstered by cellular phone demand. In the 1997 flash memory market, prices of 8Mb-or-smaller products dropped sharply, to bring the entire market down. In 1998, as Japanese companies are expected to shift part of their production capacity to flash-with-view to reduce dependency on DRAMs, 16Mb flash will likely be a target for another round of price decline.

Ranking Trends

In the 1997 Japanese MOS memory market, NEC ranked first with a 16.4 percent share (see Tables 4-1 through 4-4). The company managed to keep revenue downturns at a single-digit level (7.7 percent) among leading semiconductor companies that heavily rely on the DRAM business. Hitachi held second place, just as it did in 1996, even though it reported a 14.8 percent decline. Fujitsu was the only company in the top five that recorded an increase (8.6 percent); it advanced from fifth to third place. The major contributing factor was the strong growth of 16Mb flash sales, up 53.7 percent from 1996. In contrast, Toshiba fell from third to fifth place as its revenue from flash memory declined 75.7 percent.

MOS Memory Forecast through 2002

Dataquest predicts that the 1998 market will grow 7.0 percent (an 0.1 percent decrease on a dollar basis), which represents a downward adjustment of 6 percentage points compared to the fall forecast (see Tables 4-5 and 4-6). Again, DRAM price decline because of supply glut is the major culprit. While increased 16Mb production by U.S. companies triggered the price fall in 1997, the aggressive moves of Korean suppliers will dictate DRAM prices. At present, 16Mb prices continue to fall below $3 on the spot market, which pulls 64Mb prices downward.

The Japanese MOS memory market in 1998 will be driven by SRAM, EEPROM, and flash memory. In particular, after 1999, the DRAM market will expand at an accelerated pace, while the SRAM and nonvolatile memory markets will maintain healthy growth. In 2002, however, the DRAM market will experience negative growth as the generation crossover from 64Mb to 256Mb occurs. Dataquest predicts that the market's CAGR between 1997 and 2002 will be 15.4 percent (13.8 percent on a dollar basis).

While the fall forecast assumed that DRAM companies would curtail capital spending in 1998, these companies are currently moving to minimize the rate of investment cutbacks where possible. In particular, Korean companies are considering maintaining capital spending as close as possible to the 1997 level (on a won basis), despite the DRAM recession and pain from the AFC. Dataquest pointed out in the fall forecast that a major reduction of 64Mb production capacity would be required to regain revenue growth in 1998. However, DRAM companies are not reducing capital spending as much as expected, which necessitated the downward adjustment of the DRAM market growth forecast.

In 1998, a major event in the DRAM market will be a full-blown shift from extended data out (EDO) to synchronous DRAM (SDRAM). During the first half of 1998, 100-MHz SDRAMs for PC100 will keep a price premium against the 66-MHz versions, which will significantly narrow in the second half of 1998 as DRAM companies roll out 0.25-micron fab lines. After 1999, the Japanese DRAM market will be driven by better-managed capacity expansion by DRAM suppliers, recording a CAGR of 16.1 percent (14.6 percent on a dollar basis) between 1997 and 2002.

The Japanese nonvolatile memory market will be up slightly 0.3 percent (6.3 percent down on a dollar basis) in 1998 because of double-digit declines in EPROM and mask ROM, which will more than offset the 20 percent growth of the EEPROM and flash segments. The CAGR between 1997 and 2002 will be 9.6 percent, as the market will be driven by EEPROM and flash memory.

The Japanese flash memory market recorded negative growth of 9.8 percent in 1997, but it is expected to resume growth in 1998. Major applications include mobile communications equipment, led by cellular phones, as well as IC cards. In particular, smart phones are expected to ramp up early in Europe, becoming an important consumer of flash memory. This is expected to have a positive impact on the Japanese mobile communications and flash memory markets.

In the MOS memory market, Japanese semiconductor companies still strive to become less dependent on DRAM business. Large suppliers will increasingly shift their strategic focus to flash memory. The 1997 flash market saw price declines in 8Mb-or-less products. Dataquest expects that the move will spread to the 16Mb-or-larger segments in 1998 and after.

Challenge to the Vendors

To analyze the current state of memory vendors, they should be divided according to their DRAM dependency. This analysis focuses on DRAM-dependent companies. At present, DRAM vendors continue to be beleaguered by serious oversupply conditions with a deteriorating profitability that shows no signs of improvement. Cutthroat competition among vendors accelerates the race for next-generation process technology and higher integration, requiring them to engage in an endurance contest to keep high capital spending. As a result, three generations of leading-edge devices—64Mb, 128Mb, and 256Mb—will coexist in 1999.

Up until 1995, the rapid advance of process technology drove the commercial development of smaller DRAM chips by applying a linear shrink approach. At present, however, cost reduction becomes a primary reason for shrinking the chip size, while the same processing technology is applied. This means that the present supply glut is a combination of excess capacities—as the aftermath of the previous capital spending spree—and an increased number of chips taken from each wafer because of the advance of shrink technology.

Needless to say, the DRAM supply capacity must be cut down drastically to bring the market back to parity. However, a reduction of production capacity would be a hard blow to Korean companies and some U.S. manufacturers that heavily depend upon the DRAM business. Compared to them, Japanese DRAM vendors are less dependent and have alternative products to offer. It is thus a reasonable option for them to convert DRAM capacities to other devices on a continuous basis. Although the large-scale production shift will adversely affect prices of other products, such as flash, it makes better sense than desperately insisting on DRAM production under the present no-win situation. While reducing DRAM capacities, even on a temporary basis, it is desirable for them to continue R&D efforts on finer process technology. Because the DRAM market is increasingly driven by higher integration and faster speeds, vendors that lead in design rules are beginning to enjoy early profits. Dataquest predicts that the current oversupply condition will continue until the end of 1999. Vendors should cut down their own DRAM capacities in consideration of capital spending by the end of the century, allowing them to establish leading-edge process technology.

Chapter 5
Japanese MOS Microcomponent Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese microcomponent market saw a sound 18.1 percent growth over the previous year (6.1 percent on a dollar basis). The major source of the increase was in the MPU and microcontroller (MCU) markets, both of which recorded two-digit growth rates.

PCs drove the MPU market, and the introduction of clone MPUs compatible with Pentium MMX helped the formation of the low-end PC and subnote PC markets. MCUs were boosted by the expansion of digital consumer equipment production, mobile communications equipment, and mass storage devices. In the emerging markets, such as the digital consumer and next-generation markets, ECU/euro areas consumed value-added 32-bit MCUs, which contributed to MCU vendors' profits. The Japanese digital signal processing (DSP) market shows a trend different from other regional markets because of Japanese application markets and the Japanese vendors' strategic technology. Notably, in mobile communications and in mass storage, Japanese system manufacturers tend to use semiconductor products developed by internal semiconductor divisions. This tendency has limited the penetration of foreign-made DSPs into the equipment and has created Japanese proprietary trends.

Ranking Trends

Intel increased its share to 22.8 percent, securing the No. 1 position in the Japanese MOS microcomponent market, as well as in other regional markets in 1997 (see Tables 5-1 through 5-5).

Following Intel was NEC, which led the worldwide MCU market as the No. 2 vendor, with a wide MCU product offering ranging from 4-bit to 64-bit. Its growth came mainly from 8-bit, proprietary 32-bit with proprietary architecture, and 64-bit million of instructions per second (MIPS) MCUs.

Ranked No. 3 was Hitachi, which lost market share in 1997 in spite of two-digit growth. Its growth in the previous year was boosted by 32-bit MCUs and MPUs used in video game applications. As its share in that application lowered in 1997, it penetrated into other applications, such as mass storage devices, but it could not make up the loss in other applications fast enough.

Toshiba, ranked No. 4, also grew in two digits, helped by mass storage and mobile communications applications. Fujitsu, with the contribution of 16-bit MCUs in mobile communications and 32-bit MCUs in storage and digital VCR applications, grew at an astonishing 49 percent, to be ranked at No. 5, surpassing Mitsubishi Electric. Mitsubishi Electric has traditionally been strong in VCR applications, and its revenue grew at a sound 13 percent, helped by 16-bit MCUs in storage applications and 32-bit proprietary MCUs with embedded DRAM for digital VCRs.

MOS Microcomponent Forecast through 2002

The Japanese MOS microcomponent market will expand 15.2 percent (7.5 percent on a dollar basis) in 1998. The CAGR between 1997 and 2002 will be 16.2 percent (14.6 percent on a dollar basis), with firm growth expected for each year (see Tables 5-6 and 5-7).

The Japanese MPU market in 1998 will fail to meet the previous forecast level because of the slowdown in the PC market. The market should grow at 12.6 percent (5.1 percent on a dollar basis). The market will see a wider variety of products besides Intel's X86 families (Pentium with MMX technology, Pentium Pro, and MMX Pentium II). Products will include non-Intel, high-speed MPUs; MPUs for low-cost PCs; and MPUs designed for portable applications, including mobile computing (embedded MIPS, SH, and StrongARM)—for example, Tillamook, Mobile Pentium II, and Windows CE2.0.

MCUs, the largest of the Japanese microcomponent segments, are expected to surge 15.1 percent (7.4 percent on a dollar basis) in 1998. They are incorporated into a variety of electronic equipment. Low-bit versions are embedded into household appliances for system control purposes, many of which are implemented on a 4-bit or 8-bit basis. Japanese companies still hold a dominant share in the 4-bit segment.

Four-bit MCUs are used in diverse products, ranging from toys to analog cordless telephones, and companies are still exploring new applications. Nevertheless, the market size will grow only moderately, partly because of the weakening demand from portable game systems, which have been a major driver, and partly because of the increased migration to 8-bit products. In particular, revenue growth will be minimal because of low prices, although unit growth may continue.

On the other hand, the 8-bit MCU market will enjoy strong growth as a result of upgrading from 4-bit applications and the need to address the increasing complexity of system control. The development of MCUs embedding flash memory technology is under way, and the competition has heated up among U.S., European, and Japanese companies for market share.

In 1997, 8-bit MCUs were used in most electronic equipment, including the following range of products:

- Video and audio equipment
- Computer-related equipment, including keyboards and display units
- Communications equipment, including analog cordless telephones and digital portable telephones
- Antilock braking systems (ABSs)
- Pachinko game systems
- Household appliances

Applications expected to emerge in 1998 and afterward include: smart cards, minidisc (MD) players, USB controllers (8-bit basis), and MCUs incorporating Infrared Data Association (IrDA) communications features. Encouraged by potential demand for contact/noncontact IC cards, semiconductor companies will opt for alliances to consolidate technological resources and vie for industrial standards. Finally, MCUs integrating ferroelectric memory technology will be introduced to the noncontact IC card market to invigorate the 8-bit MCU market.

Sixteen-bit MCUs, on the other hand, will be increasingly used for digital processing applications, particularly digital cellular phones, PHSs, hard disk drives (HDDs), and CD-ROM drives. Applications expected in 1998 and afterward include DVD, fixed and on-board audio MD players, and DV-C. Again, flash memory technology will be increasingly incorporated to address system requirements in terms of flexibility, and semiconductor companies will focus on enhancing their offerings.

As for 32-bit and 64-bit MCUs, SLI based on ASIC technology will become the mainstay. Promising applications that will be developed after 1998 by using a leading-edge process and an embedded MPU include: vehicle information and communication system (VICS)-based car navigation systems incorporating DVD-ROM drives, next-generation home/portable video game systems, and set-top boxes (STBs). Sixteen-, 32-, and 64-bit MCUs will enjoy strong growth next to 8-bit products, driven by price declines resulting from SLI, the emergence of digital consumer equipment, and the digitization of systems. Dataquest expects solid profitability.

In 1997, rapid growth was seen in the flash MCU market. Major applications include memory cards for video game systems, CD-ROM drives, and HDDs, spurring consumption of 8- and 16-bit MCUs. As for multibit, embedded MPU (MCU) architectures, ARM will be rapidly accepted in 1998 and afterward. Diverse architectures offered by vendors (MIPS, M Core, SH, SPARC, PowerPC, and X86) will be optimized for different applications according to their SLI strategy.

In 1998, the Japanese microperipheral (MPR) market is expected to grow 9.6 percent over the previous year (2.3 percent on a dollar basis). A variety of PC peripherals based on PC98 standards will become pervasive, and different application-specific standard product (ASSP) segments (chipset, USB, IEEE 1394, and MPACT1/2) will grow in relation to different applications.

The Japanese DSP market will continue a strong growth of 39.8 percent (30.5 percent on a dollar basis) in 1998. With the increasingly shortened development cycle for system products, DSPs and media processors will undoubtedly become core technologies because they offer flexibility in the development of digital consumer equipment with the ability to reconfigure themselves by replacing middleware/microcode. By 2002, 0.18- to 0.12-micron processes will be commercialized. As a result, the DSP market will grow strongly at a CAGR of 29.7 percent (27.9 percent on a dollar basis) between 1997 and 2002.

Finally, embedded DSPs are increasingly incorporated into servo controllers for CD and MD players as well as codec processing for cellular phones. Generic DSPs, including media processors, are primarily used in high-speed analog modems (56-Kbps) for PCs and sound source processing. New applications emerging in 1998 and afterward include digital cellular phones, which use a single chip integrating a 16/32-bit MCU and DSP; HDD controllers containing DSP/MCU and DRAM for buffer memory; and high-speed disk drives such as DVD-ROM/RAM, incorporating partial response maximum likelihood (PRML) technology and DSP.

Challenge to the Vendors

In order to meet technology requirements from a wide range of applications, 32-bit MPUs with embedded RISC have been rapidly expanding their market since 1996. Major applications include mobile equipment, such as cellular phones and personal digital assistants (PDAs); digital video systems, such as digital camcorders (DVC) and digital still cameras; and systems that require real-time graphical processing, such as in-car navigation and video game machines.

It is difficult to accomplish the real-time processing of large volumes of data such as graphic and/or sound in multimedia systems without high-performance MPUs. DSPs are one solution, but they could increase the number of large-scale integrators (LSIs), which poses a threat to overall system cost and/or size. This can be solved with an embedded RISC MPU solution with multimedia processing by middleware, which enables system makers to save cost and circuit board space.

User needs for graphical user interface (GUI) increases in MPU-driven systems and for high-performance embedded MPUs will be growing, expanding demand for embedded MPUs with advanced SLI ASIC technology, such as MIPS, ARM, SH, SPARC, V853(E), M32R/D, and Shark.

Complex-instruction-set computing (CISC) MPUs that can be represented by x86 architecture have expanded their market mainly in PC applications. Currently, this segment of the market is served with products that are developed and manufactured with 0.25-micron process technology, aiming at production efficiency, cost competitiveness, and high performance, such as high frequency and low-power dissipation. System makers can take advantage of existing resources such as development technology and environment.

Thus, progress in SLI ASIC technology, electronic design automation (EDA) technology, and the development of high-performance 32-bit and 64-bit RISC embedded MPUs and 32-bit CISC MPUs are enabling system companies to develop new systems and subsystems, enjoying benefits in specification optimization, shortening turnaround time, and lowering system cost.

In the microcomponent market, SLI has arrived. No longer are system designers using standalone microcomponents such as MPU, MCU, and DSP; rather, they are increasing their dependency on SLI LSIs. This trend has made the choice, alliance, and development of architecture ever more important in meeting requirements in applications.

These trends are also making the border obscure between ASIC and microcomponent, forcing microcomponent vendors to incorporate various factors, such as supply support, technology support, development environment, and future marketability, when planning microcomponent business for processor architecture. This planning should include the understanding of system technologies so that the architecture can best support system memory, cost management, system size optimization, power, and noise management.

 ©1998 Dataquest

Achieving those technology targets alone cannot bring success in the MPU/MCU or DSP business. Microcomponent vendors will be required to focus more on factors such as technology support, risk evaluation, marketability and launch timing, business opportunity evaluation, and cost of ownership (COO) evaluation. Also included is marketing power, which previously may not have been a strength, especially for Japanese microcomponent vendors. Dataquest believes that those factors are the key to choosing processors in optimizing systems.

Chapter 6
Japanese Total Logic Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese total logic market grew at 16.2 percent over the previous year (4.4 percent on a dollar basis), while the total ASIC market showed a solid growth of 15.7 percent, driven by cell-based ICs (CBICs), including mixed-signal ASICs. This sound growth in total ASICs is supported by the SLI market expansion, where CBIC technology is the key for developing ASIC and ASSP products that can meet competitive cost targets.

The Japanese ASIC market has followed its own trends, and 1997 was no exception. The worldwide ASIC market saw the following three changes:

- LSI Logic slipped from No. 2 to No. 4 in the total ASIC market.
- IBM and Lucent moved up to No. 2 and No. 3, respectively.
- Programmable logic device (PLD) makers made it to the top 10, but Xilinx Incorporated gave way to Altera Corporation, which has become the top PLD vendor.

These worldwide trends are clearly seen in the Americas market; however, in 1997, Japanese ASIC vendors were not affected. In Japan, where ASIC market growth depends on limited applications in digital consumer equipment and mobile communications, these trends can hardly be observed.

Japanese vendors in the ASIC market are very unique in that they continue to grow in the gate array market, where Americas companies are disappearing from top rankings. Americas companies are choosing to de-emphasize gate arrays so that they can focus on SLI business, while Japanese vendors are filling the void in the market, resulting in their positive growth in gate array revenue in 1997.

In the longer run, however, this trend will turn out to be a burden rather than a market opportunity, because Japanese companies will have to allocate their resources in process technology development, library development, designing power, and profitability to this low-growth segment of the ASIC market.

The PLD market in Japan has not grown to be a major segment as it is in the Americas market. A major cause of this is the persistent demand among system makers for gate array products in supply and in technology support. Japanese ASIC companies are at the same time vertically integrated companies, where overall corporate-level profit comes before profits in product segments such as semiconductors, while at Americas companies, profit maximization as well as the independence of each business unit is clearly defined.

As a result, in an effort to meet domestic customer requirements, small to medium-size designs, which could be optimized with PLDs, are still developed with gate arrays, limiting the growth of the PLD market. Gradually, however, this inefficient design practice is being improved in areas such as communications infrastructure systems, which helped the PLD market in Japan in 1998 to show a sound growth of 15.6 percent over the previous year.

Ranking Trends

As the determinant factor in the total logic market, ASICs played a key role in ranking trends (see Tables 6-1 through 6-5). In the 1997 Japanese ASIC market, NEC ranked No. 1, capturing one-quarter of the market. NEC is actually the worldwide leader in ASICs, having strength in a wide range of applications, including industrial, communications, consumer, and data processing. In the Japanese market, it was the consumer area that contributed to NEC's two-digit growth.

Following NEC was Fujitsu, also with a more than 20 percent market share, which it increased by revenue growth in digital consumer and communications applications. The third company in Japan was Hitachi, which grew in the number of designs, leveraging on its SLI strategy based on SH architecture, but was not free from the competitive pricing trends. LSI Logic ranked at No. 4, growing an overwhelming 64.6 percent over the previous year. LSI Logic leads the SLI trends, and in Japan, its growth comes from successes in ASSP and ASIC business in digital consumer applications, as well as custom LSI for video game machines based on a MIPS architecture embedded MPU core. Ranked as No. 5, Toshiba dropped one notch, recording a negative two-digit growth—the only negative growth among the top 10 Japanese companies.

Total Logic Forecast through 2002

In 1998, the Japanese total logic market will grow 8.7 percent (1.5 percent on a dollar basis). The total ASIC market will expand 11.8 percent, or 4.3 percent on a dollar basis (see Tables 6-6 and 6-7).

In 1997, high-performance systems, as seen in digital consumer equipment, were implemented to incorporate multiple, large-scale circuits by using intellectual property (IP) core and leading EDA tools. We also saw a rapid increase in the volume production of ASSPs and SLI ASIC products in single-chip implementation by using a highly integrated ASIC process and SLI technologies. A future challenge lies in reducing the cycle time for system development to minimize turnaround time and R&D investment, reduce development-related risks, and support early LSI implementation.

Traditionally, the "core-limited design" issue, derived from large-scale internal cores, was a major obstacle in designing ASICs. Recently, however, as the ASIC process reached submicron levels, the shrink ratio of the internal core has been improved. This, in turn, has resulted in an increase in the "input/output (I/O) pad-limited design," where I/O pads set the limit rather than cores. Also, flexibility in the ASIC design, resulting in small-lot production, adversely affects the profitability of business.

Source: Dataquest (August 1998)

By 1997, many leading ASIC vendors in the Americas region had started to de-emphasize the gate array business. This move is favorable for the PLD market and is accelerating the collapse of the U.S. gate array market. Technically, PLDs have already integrated 250,000 to 500,000 gates on a commercial basis by using process technology based on 0.25-micron, five-layer interconnect and shallow trench structure. Dataquest believes that 1 million gates will be integrated by using an 0.18-micron process technology by 2000.

In 1998, the Japanese PLD market will show a strong growth of 15.6 percent (7.9 percent on a dollar basis). In Japan, the gate array business still dominates because of high captive demand. Nevertheless, because SLI will lead ASIC business in the future, the Japanese PLD market will grow to an appreciable size compared to the Americas market. Dataquest expects that the market will register the second-highest growth rate, following CBICs, with a CAGR of 21.3 percent between 1997 and 2002.

The Japanese CBIC market (including mixed-signal) will grow 20.7 percent (12.7 percent on a dollar basis) in 1998. The ramp-up of 0.35-to-0.25-micron process manufacturing and the increasing need for design optimization in various applications have been driving the market for CBICs, which are regarded as the key infrastructure factors in SLI technologies such as embedded MPUs/DSPs, IP core, embedded memories, and mixed-signal designs. At the same time, the establishment of CBIC technology has caused the custom IC market to shrink rapidly, resulting in a negative CAGR of 31.0 percent (31.9 percent on a dollar basis) between 1997 and 2002.

Among other logic products, standard logic features such as small-scale integration (SSI), middle-scale integration (MSI), and LSI are mostly incorporated into ASICs, but demand for standard logic still exists in the area of super-high-speed CMOS- or BiCMOS-based standard logic, such as CMOS-based one-gate logic products and wide bus products. Thus, the Japanese standard logic market will continue to grow steadily at a CAGR of 5.1 percent (3.7 percent on a dollar basis).

Finally, LCD drivers will be driven by increased market acceptance of LCD-equipped systems as well as by the exploration of new application markets. As a result, the Japanese market's CAGR for the "Total other MOS Logic" category is expected to be 11.8 percent (10.3 percent on a dollar basis) during the five-year period.

In 1998, ASIC suppliers announced a number of next-generation 0.18-micron processes, and some of them in Japan and the United States started volume production. Also, development efforts are under way to commercialize a "unified process" that represents a "dream process integration." Dataquest believes that portable applications in the Japanese market will contribute to technological progress in the areas of ultra-low operating voltage below 1.0V, embedded flash memory, mixed-signal designs, and high-density packages, such as chip-scale packaging (CSP) and direct chip attach (DCA), thereby driving the SLI ASIC market.

Challenge to the Vendors

Traditional ASICs were mainly single-function products that integrated glue logic. With the introduction of a new business model in 1990 based on intellectual property cores, the whole ASIC industry has been moving toward SLI, and ASIC vendors have been in the process of restructuring their businesses. Japanese companies are no exception.

In this new ASIC business model, vendors first prepare a large number of IP cores, based on each vendor's own research, either developed internally or acquired from the outside. Then, in the development environment of IP cores, description languages such as Verilog Hardware Description Language (Verilog-HDL) and VHSIC HDL Roger's Interface Language (VHDL-RIL), for standardization, enable vendors to provide the appropriate set of IP cores at the request of ASIC users, which enables the design of a large, complex system with a short turnaround time. This SLI business model is advantageous to users because they can develop and market their new systems with minimum investment and risk, and within a short range of time. For ASIC vendors, users' recognition of IP cores as value-added will help differentiate them from competitors. In the ASIC business, where differentiation has been difficult, this SLI move is expected to help improve profitability.

In putting system-level functions on a single chip, traditional ASIC process technology is not sufficient. Also required are an understanding of requirements from each target application and the most advanced EDA, IP core development environment, and analog/mixed-signal technologies for designing embedded MPUs. Those are the key factors for ASIC vendors to be successful in the SLI business.

In this sense, the Virtual Socket Interface (VSI) Alliance, in which worldwide semiconductor vendors as well as system makers and EDA vendors participate, will standardize IP cores, establish their distribution system, and dramatically change the ASIC industry.

In the current market, continuing DRAM oversupply and pricing weakness have prompted semiconductor companies to shift emphasis from memories to logic, resulting in a crowded market in the latter half of 1997. This supply/demand situation has caused the price fall of logic products, and expectations about the profitability of the SLI business are being questioned. The needs for embedded DRAM and flash are increasing from the application side, and, leveraging on profitable applications such as graphics and mobile equipment, embedded memories will contribute to the market growth of SLI ASIC.

Another factor that poses challenges to vendors is the development of process technology. The main technology has shifted from 0.5 micron to 0.35 micron, and now it is shifting toward 0.25 micron and 0.18 micron concurrently. This trend may cause Japanese ASIC vendors currently investing in 0.25-micron process technology and manufacturing capacity to lose competitiveness.

The semiconductor industry has observed silicon cycles many times, but in this round, ASIC technology progress, in centering on graphics, data processing, and communications, may change the market positioning for various ASIC vendors. Americas companies have enjoyed high market share, leveraging on embedded MPU and DSP core technology. Korean companies are aiming to catch up with the forerunners by focusing on DRAM as a technology driver. Taiwanese companies have established a business model of dedicated foundry, supporting fabless companies. Japanese companies have an advantage in overall SLI technology, with their embedded technology and IP cores, based on MCU business experience. The SLI ASIC market will be more competitive with all of these vendors, and all SLI companies will be required to equip themselves with the necessary ASIC technologies, an understanding of various technical requirements for each target application, and a strategic analysis of competitors.

Chapter 7

Japanese Analog IC, Discrete Device, and Optical Semiconductor Market Trends

1997 Market Share

Market Trends

In 1997, the Japanese market saw healthy growth for analog, discrete, and optical semiconductor products. Among those, the analog market recorded a more than 20 percent increase over the previous year for the first time in the 1990s. Contributing to this strong growth were factors such as strong unit demand because of improved electronics production, stable pricing trends, and an increase in mixed-signal products with higher average selling prices than conventional linear products.

At a time when new systems are emerging, system designers resort to discrete function chips, such as general-purpose analog ICs and discrete semiconductor devices, until system designs become stable and circuits become integrated into larger devices, including ASSP and ASIC. The year 1997, which can be marked when the shift to digital consumer systems becomes a solid move, was another example of this trend. The increase in demand for analog and discrete semiconductor products has been observed since 1995, but the acceleration in 1997 was more than the industry expected, and the tightened supply/demand balance helped to keep the prices stable, contributing to profits for vendors.

Major contributions came from segments such as telecom analog, disk-drive analog, special-function analog, and power-management analog products. Among discrete semiconductor products, it was power transistors—not only the emerging isolated gate bipolar transistors (IGBTs) but also MOS field-effect transistors (FETs) and even bipolar transistors—that marked two-digit growth over the previous year. The increase in those products was supported by PC and peripheral equipment as well as mobile communications applications. The driver for the growth in optical semiconductors in Japan was the laser diode, whose consumption was pumped by optical storage devices and audio players such as CD-ROM drive and MD players.

Ranking Trends

In the 1997 Japanese analog market, Texas Instruments Inc. continued to lead while all the rest of the top 10 companies were domestic vendors (see Table 7-1). However, other Americas and European vendors, too, increased their sales rapidly, and as a result, the combined share of non-Japanese vendors has become one-third of the market. TI's revenue growth came both from general-purpose products and ASSPs such as disk drive and automotive. Toshiba, ranked No. 2, also enjoyed growth in general-purpose product revenue as well as an increase in applications in consumer and automotive. Matsushita Electronics switched places with NEC, helped by increases in telecom and disk drives. SANYO Electric Company Ltd. and Sony remained in their respective positions of the previous year, although they recorded growth rates that were higher than the market average.

The Japanese discrete and optical semiconductor markets have traditionally been dominated by domestic vendors, and 1997 was no exception.

In the 1997 Japanese discrete semiconductor market, Toshiba maintained the lead by growing faster than the market, leveraging on its coverage in all three power transistor areas (see Table 7-2). NEC replaced Hitachi as the No. 2 vendor in Japan, showing two-digit growth rates in most of the product areas except for thyristors. Companies such as Rohm Company Ltd., Mitsubishi Electric, and SANYO kept their respective positionings, but they have a marked difference in product coverage—Rohm benefits from bipolar, SANYO from MOSFET, and Matsushita Electronics from both bipolar and MOS.

In the optical semiconductor market in Japan, Sharp Electronics Corporation widened the lead by growing at 24 percent (see Table 7-3). Contributions came from a wide range of segments, including couplers, charge-coupled devices (CCDs), and laser diodes. Companies following Sharp maintained their respective positions, with Rohm and SANYO each showing over 20 percent growth and both benefiting from the demand increase for laser diodes. Included in the survey from 1997 is Stanley Electric, which jumped in at No. 8 with its focused product coverage of LED lamps and displays.

Analog IC, Discrete Device, and Optical Semiconductor Forecast through 2002

The outlook for the analog, discrete, and optical semiconductor markets has been adjusted downward from the previous forecast. It should be noted that the analog market was partially affected by the reclassification of linear array and mixed-signal ASICs (although small in size) into total ASICs.

The strong demand growth for analog ICs in the past few years has caused the industry to hold unduly high expectations. With the rapid progress of system diversification, accompanied by LSI implementations over several generations, demand for analog ICs and discrete devices has been experiencing a surge in momentum (see Tables 7-4 and 7-5). Nevertheless, the expansion of mixed-signal analog IC markets will ultimately lead to CBICs absorbing analog functions, so that suppliers will tend to overestimate long-term demand by extrapolating the recent high-growth trends. Also, sluggish electronics production causes demand for generic analog devices to slow down.

In the first quarter of 1998, suppliers do not seem to be accelerating analog capacity, partly because of heavy constraints on investment resources. If supply capacity expands abruptly, prices will plummet, resulting in unit growth without revenue growth. Given this cap for capacity expansion, Dataquest believes that it will be difficult for the Japanese analog market to continue double-digit growth. (In the downside scenario mentioned in Chapter 2, analog price erosion has been incorporated into the Japanese market growth.)

Challenge to the Vendors

Japanese analog vendors have enjoyed two advantages in the domestic market: IC demand and system technology from Japan-based consumer electronics makers. Now that even Japan-based consumer companies have shifted a large portion of their equipment production overseas and non-Japanese markets are growing much faster, Japanese analog vendors can no longer expect the same pattern. Also, the system technology required in digital consumer applications derives from basic technologies developed by non-Japanese system makers in the Americas and European markets. As system-oriented semiconductor suppliers, Japanese analog companies need to strengthen their design support capability in markets outside of Japan, focusing on target applications in each region.

Chapter 8
Japanese Companies' Capital Spending Trends

Overall Spending Trends

In 1997, capital spending in Japan saw a decline over the previous year, for the first time since 1992 (see Table 8-1). This was caused mainly by the Japanese companies, whose worldwide spending shrank by 1.7 percent. The outlook for 1998 is even gloomier because the capital expenditure in Japan is expected to be cut by 30 percent on a dollar basis—the largest reduction among all four regions. In the section below, the spending trends of Japanese companies are analyzed, as Japanese companies represent the majority of spending in Japan.

The regional distribution of Japanese companies' spending this year shows a clear preference: Domestic investment declines by one-third, while spending in the Americas and Europe is being reduced by one-half. The only region to show an increase is Asia/Pacific. This does not actually mean that Japanese companies on the whole are focusing on that region. Rather, the increase comes from a large commitment by NEC to the Shanghai joint venture.

During the boom years, Japanese companies took an aggressive approach to high-growth markets overseas by increasing the supply capacity near the markets, just like they did in the past boom years, and, just like they did after the past boom years, they are reducing overseas spending again. This trend can be attributed first to a big reduction in funds caused by lessened profits or increased loss from the semiconductor business in recent years. Realizing the need to focus on next-generation investments, Japanese companies have given up on the idea of enforcing local supply capacity. The second reason can be found in exchange rate trends, where the Japanese yen has depreciated to the level it saw about seven years ago when Japanese companies were less motivated to produce outside of Japan.

Spending trends by product also show a sharp contrast. Investment into memories is to be cut by one-third, while the microcomponent and logic segments combined show a much milder reduction of 7.6 percent. As a result, memories' share of Japanese companies' capital spending is to be surpassed by those two other categories for the first time since DRAM has become a major segment of business for Japanese semiconductor companies. The focus on microcomponent and logic clearly shows their determination to pursue SLI trends. Analog and discrete, two major product categories that represent a large portion of the profits, are given ample share in the investment this year. This, however, poses a threat to the near-future supply/demand of those categories, because the progress of SLI may imply a reduced rate of growth in demand—not reduced demand—for analog and discrete products.

Looking at facilities, the expenditure in property and land is being cut in half, while wafer fab equipment spending is to be reduced by 20 percent, and back-end facilities show only a 6 percent reduction. In view of the continuing overcapacity in the market, Japanese companies are discouraged about increasing overall supply capacity; once again they are carefully filling the shells that they build during the boom years. Most of the wafer fab equipment is aimed at upgrades to 0.25-micron technology, while in a limited number of cases, investments in deep submicron fab equipment are included. The efforts in 300mm wafer technology have been slowed for several reasons, including reduced overall spending, technology/equipment problems, and a market condition of prolonged overcapacity. The ultimate question for semiconductor manufacturers in pursuit of large wafer technology is whether they will really need production capacity of that magnitude. Not many companies can fully enjoy the increased efficiency in production of commodity products including DRAMs, but not many companies are ready to offer SLI products that can utilize 300mm wafer fab capacity. Shifting product preference is seen in back-end investment trends, where the focus on microcomponent and logic requires additional equipment for the interconnect/metal layer.

In the past down-cycle years, Japanese companies sought to increase foundry shipment to improve fab utilization. Ever since the emergence of dedicated foundry providers equipped with advanced logic technology, however, that "opportunistic foundry shipment" practice has become a less easy choice. Dedicated foundries are well prepared to cope with fabless companies' requirements. Foundry providers in Taiwan have a strong tie with the U.S. semiconductor industry, and the tie—especially with fabless companies—has brought them ample orders, taking away business opportunities from other companies. Thus, the decrease in foundry shipments has been another reason for Japanese companies' reduction in additional supply capacity.

The current weak revenue and pricing trends, and consequential dwindling profits, hardly justify strong spending in manufacturing equipment. The question then lies in deciding how much spending is the appropriate amount. There has been a general, empirical belief in the industry that capital spending of over 20 percent of revenue is not necessarily a safe practice unless a company has good reasons to do so and understands the financial risks involved. Looking at Japanese companies' spending, this criterion seems to apply to larger suppliers, while medium-size companies have spent over 20 percent of their revenue, and companies with specific product orientation in discrete and optical areas have spent characteristically less than 15 percent of their revenue. Noteworthy is the ratio for NEC, the largest semiconductor supplier and capital spender among Japanese companies, which is less than 15 percent. Taking into consideration that NEC tends to construct its own proprietary fabs with the exception of recent two cases in China, NEC's investment efficiency is strikingly high among Japanese companies. With the exception of NEC, however, major Japanese companies have started to seek alliances in outsourcing manufacturing at a pace never seen before. This is causing a restructuring of the Japanese semiconductor industry, and Dataquest believes that this is an unavoidable step for Japanese companies to regain strength in the semiconductor business.

Taking into consideration the current trends toward SLI, as well as prolonged DRAM oversupply, it is not likely that Japanese companies will resume a high pace of spending in manufacturing capacity. Even 300mm wafer production has dropped from the list of top priorities, while some companies have not given up technology development and pilot production. Some Japanese companies are facing the ultimate question of whether to make or buy in some product areas where investment efficiency cannot easily be achieved, given their own product portfolio and large amount of expenditure. Dataquest believes that semiconductor vendors that make the bold but required decision to refocus their business, with ample consideration of and emphasis on SLI, will come out shining beyond the current turmoil in the semiconductor industry.

Chapter 1
Japanese Fab Database

Background and Methodology

This report contains the Japanese portion of Dataquest's wafer fab database. The records in these tables are fabs located in the Japan region. The Semiconductor Equipment, Materials, and Manufacturing Worldwide (SEMM) program conducts extensive annual surveys, complemented with quarterly secondary research to maintain this database. Published once a year, this document represents Dataquest's best insights and estimates into the end-market of semiconductor equipment.

The tables in this report cover planned and existing merchant, captive, and foundry fab lines. A fab line is a series of equipment to do front-end (from initial oxide through wafer probe) semiconductor manufacturing. Occasionally, two or more separate product-specific fab lines or wafer sizes operate in a single clean room or physical plant. In this situation, Dataquest divides the clean room as separate fab lines if the company dedicates equipment to each wafer size or product line. If a company installs substantially different equipment during an expansion (for example, equipment to increase its maximum wafer diameter), again Dataquest divides the clean room and creates two entries into the database. Therefore, a company may operate many fab lines at one location.

Worldwide Geographic Region Definitions and Regional Roll-Ups

Americas

Includes Central America (all nations), Canada, Mexico, United States, Puerto Rico, and South America (all nations).

Japan

Japan is the only single-country region.

Europe, Africa, and Middle East

Includes Africa (all nations), Albania, Andorra, Armenia, Azerbaijan, Belarus, Belgium, Bulgaria, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Georgia, Germany, Gibraltar, Hungary, Iceland, Israel, Italy, Kazakhstan, Kyrgyzstan, Latvia, Liechtenstein, Lithuania, Luxembourg, Malta, Middle East (all nations), Moldova, Monaco, Netherlands, Norway, Poland, Romania, Russia, San Marino, Scandinavia, Slovakia, Spain, Sweden, Sweden, Switzerland, Tajikistan, Turkey, Turkmenistan, Ukraine, United Kingdom, Uzbekistan, Vatican City, and all nations within the former Yugoslavia.

Asia/Pacific

Includes Australia, Bangladesh, Cambodia, China, Hong Kong, India, Indonesia, Laos, Malaysia, Maldives, Myanmar, Nepal, New Zealand, Pakistan, Philippines, Singapore, South Korea, Sri Lanka, Taiwan, Thailand, and Vietnam.

©1999 Dataquest

Field Definitions

The Company field indicates the operator of the fab line. For contract manufacturers that trade capacity for capital investment in the fab, Dataquest lists the contract manufacturer. For incorporated joint ventures, Dataquest lists either the incorporated entity or the major investors, separated with slashes.

The City field displays the most detailed location information. This reference is usually a city or town, but could be an often-used district name (for example, Science Park in the city of Hsinchu, Taiwan). If this field lists a district, Dataquest will list the city in the State or Province field. In some cases, a reference to a state or province will be included in the City or District field to create a unique identifier for this location.

The Prefecture field denotes the second most detailed location. This reference is usually a state (for the United States), province (for Canada and many European and Asian countries), or a prefecture (for Japan). For countries within the United Kingdom, Dataquest lists the country name (for example, "Scotland") in this field so Dataquest can list the descriptor "U.K." in the Country field.

The Country field indicates the broadest location identifier in this report. This reference is usually a country, except in the case of the United Kingdom (see "State or Province" above). Because Japan is a single-country region, there is no regional qualifier for fabs in Japan.

The Fab Name field provides a reference to a particular fab or fab line to distinguish it from other fabs or lines owned by that company. Although Dataquest makes every attempt to match the nomenclature used by the company, occasionally some additional qualifiers (for example, "Phase 1") will appear to provide insight to the facility's history or organization.

The Products field lists the products manufactured at this site. The listings generally fall into five product groups, with the following nomenclature and definitions (when warranted):

- MOS memory
  - DRAM: Dynamic RAM
  - EEPROM: Electrically erasable PROM
  - EPROM: Ultraviolet erasable PROM
  - FERRAM: Ferroelectric RAM
  - FIFO: First-in/first-out memory
  - Flash: Flash memory
  - Mem: Memory
  - NV Mem: Nonvolatile memory (ROM, PROM, EPROM, EEPROM, and FERRAM)
  - PROM: Programmable ROM
  - RAM: Random-access memory

 ©1999 Dataquest

- ROM: Read-only memory
- SGRAM: Synchronous graphics RAM
- Sp Mem: Other specialty memory (such as dual-port, shift-register, or color lookup)
- SRAM: Static RAM
- VRAM: Video RAM

- MOS microcomponent/digital logic
  - Array: Gate array
  - ASIC: Application-specific IC
  - ASSP: Application-specific standard product
  - Bit: Bit slice (subset of MPU functions)
  - CBIC: Cell-based IC
  - Custom: Full-custom IC (single user)
  - DSP: Digital signal processor
  - FPGA: Field-programmable gate array
  - LISP: 32-bit list instruction set processor for AI
  - Logic: Standard logic
  - LSI: Large-scale integration
  - MCU: Microcontroller unit
  - MixSig ASIC: Mixed-signal ASIC
  - MPR: Microperipheral
  - MPRCom: MPR digital communication (ISDN, LAN, UART, or modem)
  - MPU: Microprocessor unit
  - PLD: Programmable logic device
  - RISC: Reduced-instruction-set computation 32-bit MPU
  - Telecom: Telecommunications chip
- Power/discrete/analog (including bipolar power)
  - A/D D/A: Analog-to-digital, digital-to-analog converter
  - Automotive: Dedicated to automobile applications
  - CODEC: Coder/decoder
  - Diode
  - Discrete
  - FET: Field-effect transistor
  - GTO: Gate turn-off thyristor
  - HEMT: High-electron-mobility transistor
  - IGBT: Insulated-gate bipolar transistor

- Interface: Interface IC
- Linear: Linear/analog device
- MDiode: Microwave diode
- MESFET: Metal semiconductor field-effect transistor
- MFET: Microwave field-effect transistor
- Modem: Modulator/demodulator
- MMIC: Monolithic Microwave IC
- MOSFET: MOS-based field-effect transistor
- Op Amp: Operational amplifier
- Pwr IC: Power IC
- Pwr Tran: Power transistor
- Rectifier
- Reg: Voltage regulator
- RF: Radio frequency
- SCR: Schottky rectifier
- Sensor
- Smart Pwr: Smart power
- SST: Small-signal transistor
- Switches: Switching device
- Thyristor
- Tran: Transistor
- Zener Diode

- Optoelectronic
  - CCD: Charge-coupled device (imaging)
  - Coupler: Photocoupler
  - IED: Infrared-emitting diode
  - Image Sensor
  - Laser: Semiconductor laser or laser IC
  - LED: Light-emitting diode
  - Opto: Optoelectronic
  - PDiode: Photo diode
  - PTran: Photo transistor
  - SAW: Surface acoustic wave device
  - SIT Image Sensor: Static induction transistor image sensor

©1999 Dataquest

- Bipolar Digital and Other Devices (includes all digital ICs using a bipolar process)
  - Darlington
  - Micromachining sensors
  - MilStd: Military Standard Logic
  - RadHard: Radiation hardened

The Process Technology field indicates each fab's use of five major types of processes. The process grouping is as follows:

- P/CMOS: P-channel metal-oxide semiconductor (PMOS) or complementary metal-oxide semiconductor (CMOS)
- NMOS: N-channel metal-oxide semiconductor (NMOS)
- BiCMOS: Bipolar and CMOS combined on a chip
- Bipolar
- III-V: Gallium arsenide and other compound semiconductor processes

The Estimated Minimum Geometry is the smallest linewidth feature size, measured in microns, attainable in production volume.

The Wafer Diameter represents the maximum wafer size that the fab or fab line can process. Wafer diameters, although expressed colloquially in inches, conform to metric specifications. For wafers greater than 3 inches in diameter, expression in inches becomes inaccurate. When calculating square inches, Dataquest uses the following approximations:

- Stated diameter of 4 inches (100mm) = Approximate diameter of 3.938 inches
- Stated diameter of 5 inches (125mm) = Approximate diameter of 4.922 inches
- Stated diameter of 6 inches (150mm) = Approximate diameter of 5.906 inches
- Stated diameter of 8 inches (200mm) = Approximate diameter of 7.87 inches
- Stated diameter of 12 inches (300 mm) = Approximate diameter of 11.84 inches.

The Year and Quarter of Initial Production displays the year (and quarter, if available) in which this line, having completed all qualifications, began manufacturing in production volumes. The format for this reference is "year.quarter" (for example, 1994.3 translates to the third calendar quarter of 1994).

The Initial Monthly Wafer Starts field indicates the initial monthly volume of production wafer throughput.

The Estimated Maximum Monthly Wafer Starts field contains the equipment-limited wafer start capacity per four-week period. Only the throughput of the installed equipment and the process complexity limits the maximum starts. Dataquest does not consider current staffing or the number of shifts operating in determining this metric.

 ©1999 Dataquest

The Fab Type field shows the types of semiconductor manufacturing performed at this location. The fab types include the following:

- "F" indicates that this is a production-based fab.
- "R" indicates a semiconductor R&D and/or trial production facility.
- "P" means that this location produces a pilot line.
- "T" means that this location performs assembly or testing.
- "N" indicates that this location performs foundry production, or contract manufacturing.
- "VD" means that this location performs VHDL design.
- "PD" means that this location performs IC place and route design.

Preface

Dataquest's *Japanese Semiconductor Consumption Forecast by Electronics Application, Fall 1998* is a revised and reformatted version of our long-standing semiannual semiconductor consumption by electronics application market forecast. We have made several changes to this publication in an effort to make it more relevant and meaningful; we have also included a new category of information that shows unit production trends for selected systems. Major changes include:

- Categorization changes to secure consistency with electronic equipment production forecasts
- Addition of high-volume electronic equipment unit production forecast data for 40 major systems

Dataquest has directed its semiconductor applications research toward better understanding the dynamics of production and semiconductor use across individual electronic systems. We have developed forecast models capable of tracking production and estimating total semiconductor consumption for some 40 different individual electronic systems, shown in full scale for the first time in this report.

Project Analyst: Motoya Ohgami

Chapter 1
Introduction and Discussion

Introduction

This document contains Dataquest's forecast of Japanese semiconductor consumption by electronics application, 1997 to 2002, based both on U.S. dollars and Japanese yen. It also contains our forecast of worldwide semiconductor consumption by broad categories over the same period. This is the second of two semiannual forecasts. This forecast reflects changes since this spring in Dataquest's view of semiconductor consumption by electronic equipment worldwide and in Japan. It incorporates changes suggested by Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments.

The tables in this document present data intended to answer the following questions:

- What is the estimated semiconductor consumption of various categories of electronic equipment?
- What is the estimated semiconductor consumption of the key individual electronic systems that make up these broad categories?

The estimates offered in this document are intended to provide very general answers to these questions. They are meant as a broad guide to semiconductor consumption by electronic equipment production in Japan. The most detailed information about estimated semiconductor consumption by individual electronic systems is available in the last chapter of this document.

The semiconductor consumption forecasts presented here complement Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments. Updated Japanese electronic equipment forecasts can be found in the Market Statistics report *Japanese Electronic Equipment Production Forecast, Fall 1998* (November 1998). Our updated semiconductor forecast is found in the Market Trends report *Worldwide Semiconductor Forecast and Trends, Fall 1998* (November 1998). Additional regional and semiconductor device details for this forecast can also be requested through Dataquest's inquiry service.

The tables in this document are organized as follows:

- Tables 2-1 and 2-2 summarize the worldwide semiconductor consumption forecast and compare it to the worldwide semiconductor shipments forecast.
- Tables 2-3 and 2-4 summarize the Japanese semiconductor consumption forecast on a dollar basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-5 to 2-12 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a dollar basis.

- Tables 2-13 and 2-14 summarize the Japanese semiconductor consumption forecast on a yen basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-15 to 2-22 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a yen basis.
- Tables 3-1 to 3-40 present unit production and semiconductor consumption forecasts in Japan for 40 major electronic systems.
- Figures 3-1 to 3-40 show Japan's share of the worldwide unit production for 40 major electronic systems for 1997 and 2002.

Segmentation of Semiconductor Applications

Dataquest forecasts semiconductor consumption by end-use electronic application. We divide electronic applications into six broad groups in accordance with our segmentation of electronic equipment production. These groups are, in turn, disaggregated into more narrow electronic systems categories, as follows:

- Data processing
    - Computers
    - Data storage
    - Input/output devices
    - Dedicated systems
    - Other data processing
- Communications
    - Premise telecommunications
    - Public telecommunications
    - Mobile communications
    - Broadcast and studio equipment
    - Other communications
- Industrial
    - Security and energy management systems
    - Manufacturing systems and instruments
    - Medical equipment
    - Other industrial equipment
- Consumer
    - Audio
    - Video
    - Personal electronics
    - Appliances
    - Other consumer equipment

- Military/civil aerospace
- Transportation

As part of the forecast process, Dataquest develops forecasts for about 40 individual electronic systems within these various categories and subcategories. These include the following:

- Data processing
  - Mainframes/supercomputers (computers)
  - Midrange computers (computers)
  - Workstations (computers)
  - PCs (computers)
  - Motherboards (computers)
  - Rigid disk drives (data storage)
  - Optical disk drives (data storage)
  - Removable magnetic storage (data storage)
  - Page printers (input/output)
  - Serial printers (input/output)
  - Monitors (input/output)
- Communications
  - LAN cards (premise telecommunications)
  - Premise line cards (premise telecommunications)
  - Answering machines (premise telecommunications)
  - Fax machines (premise telecommunications)
  - Modems (premise telecommunications)
  - Corded telephones (premise telecommunications)
  - Analog cordless phones (premise telecommunications)
  - Digital cordless phones (premise telecommunications)
  - Central office line cards (public telecommunications)
  - Analog cellular phones (mobile telecommunications)
  - Digital cellular phones (mobile telecommunications)
  - Pagers (mobile telecommunications)
  - Mobile telecommunications infrastructure (mobile telecommunications)
  - Other mobile telecommunications products (mobile telecommunications)

©1998 Dataquest

- Consumer
  - Personal/portable stereos (audio)
  - Color TVs (video)
  - VCRs (video)
  - Analog camcorders (video)
  - Digital camcorders (video)
  - DVDs (video)
  - Analog set-top boxes (video)
  - Digital set-top boxes (video)
  - Digital still cameras (personal electronics)
  - Video game controllers (personal electronics)
- Transportation
  - Automotive stereos
  - Automotive engine control units (ECUs)
  - Antilock braking systems
  - Air bags
  - Automotive navigation systems

Geographic Segmentation

Dataquest's worldwide electronic equipment production forecast is aggregated from individual forecasts for four principal geographic regions:

- Americas
- Japan
- Europe, Middle East, and Africa
- Asia/Pacific

Exchange Rates

Dataquest's worldwide electronic equipment forecast aggregates data from many countries, each of which uses a currency that has a different and fluctuating exchange rate relative to the U.S. dollar. Because we compile our worldwide forecast from individual regional forecasts, we use the U.S. dollar as a common currency for comparisons and aggregation. As a rule, Dataquest calculates forecasts in local currencies and then converts them to U.S. dollars using projected average annual exchange rates. Dataquest does not forecast exchange rates per se. Instead, we calculate projected average annual exchange rates from current exchange rates. Our projections are based on estimates of the latest available monthly exchange rate at the time the forecast is developed. These rates are based on monthly exchange rates observed through July 1998. Additional information about historical exchange rates and Dataquest's method of calculating future average exchange rates may be requested through Dataquest's client inquiry service.

©1998 Dataquest

Forecast Methodology

When discussing semiconductor consumption, it is critical to remember that semiconductors are not end products consumed for their own sake. They are intermediate products used as inputs for electronic end products that are eventually consumed by individuals and businesses for the utility they provide. Implicit in the concept of semiconductor consumption is the notion that the electronic end products in which semiconductors will be incorporated or consumed can be specified. A semiconductor forecast that does not or cannot specify this is not a forecast of semiconductor consumption. At best, it is merely a forecast of semiconductor shipments.

Dataquest's semiconductor consumption by electronic application forecast grew out of the recognition that a truly complete semiconductor forecast must specify the electronic end uses of semiconductors. However, specifying semiconductor end uses has proved far more difficult than recognizing that it must be done. Although it appears possible to specify semiconductor consumption by the variety of electronics produced, there are simply too many different types of semiconductor devices consumed in too large a variety of electronic products. As a result, semiconductor consumption must invariably be estimated. This can be done in any number of ways. Before this forecast, Dataquest used a mathematical model to estimate semiconductor consumption by various electronic end uses. Taking Dataquest's electronic equipment production and semiconductor shipments forecasts as inputs, this model allocated estimated semiconductor shipments across forecast electronics production subject to various assumptions about the semiconductor content of electronic products. The model also imposed several balancing conditions intended to guarantee that estimated semiconductor shipments were completely allocated across all forecast electronics production.

The model applied a top-down approach to estimating semiconductor consumption. In effect, it calculated estimates of semiconductor consumption by compelling agreement between the details of the electronics production forecast and the semiconductor shipments forecast. As a result, the estimates of semiconductor consumption were more an artifact of a mathematical process than truly independent estimates of semiconductor consumption. Although the model offered considerable flexibility, it was nonetheless limited by the validity of its semiconductor content assumptions and the balancing requirement that semiconductor consumption equal semiconductor shipments. Despite its potential drawbacks, the model provided the best estimates we could offer, given a paucity of knowledge about semiconductor applications in specific electronic systems.

Over the last several years, Dataquest's semiconductor applications research has been concentrated on the study of semiconductor use in specific individual electronic systems. We have successfully developed models to track and forecast the production and semiconductor consumption of some 40 different individual electronic systems. These include PCs and PC motherboards, rigid disk drives, LAN cards and modems, digital cellular phones, digital set-top boxes, and automotive navigation systems, among others. The electronic systems encompassed by our models account for about one-half of all electronics production and nearly two-thirds of estimated semiconductor consumption.

©1998 Dataquest

These models have allowed us not only to codify our knowledge about individual electronic systems but also to approach the task of estimating semiconductor consumption using a bottom-up forecast method. This method was used for the forecast and will be used for future forecasts. The method essentially involves building a forecast of semiconductor consumption for all electronics production by leveraging estimates of semiconductor consumption for individual electronic systems. Dataquest uses individual systems estimates as a forecast base and augments this with estimates of semiconductor consumption for other electronic equipment categories not tracked individually. Precisely because the method uses well-researched knowledge about individual electronics systems that dominate semiconductor consumption, Dataquest believes it is capable of providing far better forecasts of semiconductor consumption than our former top-down method, especially for electronic equipment categories such as computers, where individual systems forecasts account for virtually the entire category. The results of this analysis are shown in Chapter 3.

Forecast Highlights

Dataquest estimates that worldwide semiconductor consumption will decrease by 0.2 percent in 1998 to about $148.0 billion. Dataquest expects approximately two-thirds of this growth will come about because of growth in worldwide electronics production, which is now forecast to grow 2.2 percent in 1998 to about $935.8 billion. The remainder will be the result of expected growth in the average semiconductor content of electronics, which we forecast will increase to about 15.8 percent of electronics factory value. Longer-term, we estimate worldwide semiconductor consumption will average 10.3 percent annual growth through 2002. This should raise worldwide semiconductor consumption to about $241.6 billion by 2002. Dataquest expects slightly over half of the longer-term growth in worldwide semiconductor consumption to come about because of growth in worldwide electronics production, which we are now forecasting to average 6.1 percent annual growth through 2002. Once again, remaining growth in semiconductor consumption will be the result of increases in the average semiconductor content of electronics. We now expect average semiconductor content will rise to about 19.7 percent of electronics factory value by 2002.

We are now forecasting Japanese semiconductor consumption will decrease by 10.4 percent in 1998. This compares to anticipated growth rates of 3.8 percent for Asia/Pacific and 5.0 percent for Europe, the Middle East, and Africa. In the long term, Japanese consumption is expected to average just 4.6 percent annual growth between 1997 and 2002, as opposed to 13.9 percent for Asia/Pacific and 10.2 percent for Europe, the Middle East, and Africa. (Note: All of our forecasts are valued in U.S. dollars and thus reflect projected exchange rate movements in addition to expected changes in semiconductor consumption expressed in local currencies.) Underlying these marked differences in long-term growth are equally marked differences in expected sources of growth.

There is a strong desire among suppliers to believe that semiconductor shipments, and with them semiconductor revenue, can continue to post high rates of long-term growth. However, this desire needs to be tempered with the recognition that long-term shipments growth is only possible so long as electronics makers are able to profitably increase semiconductor consumption, either by expanding electronics production or increasing semiconductor content. A number of fundamental changes are taking place in several key electronics markets that will limit the future ability of electronics makers to profitably increase semiconductor consumption. Semiconductor suppliers would be well advised to acknowledge these emerging limits because failure to do so will only intensify competition and further imperil both future shipment and revenue growth in Japan.

Chapter 3

High-Volume Electronic Equipment Unit Production and Semiconductor Consumption Forecast in Japan

Tables 3-1 through 3-40 present Dataquest's forecast of electronic equipment unit production and semiconductor consumption for 40 major electronic systems. Figures 3-1 through 3-40 show the trends of Japan's share in production volume for 40 major electronic systems, 1997 versus 2002, in comparison with other regions.

Table 3-1
Production and Semiconductor Consumption Forecast for Mainframe/Supercomputers in Japan, 1997-2002

	1997	1998	1999	2000	2001	2002	CAGR (%) 1997-2002

Chapter 1
Japanese Electronic Equipment Production Forecast

Introduction

Electronic equipment production is an important determinant of semiconductor market activity. This is true because semiconductor demand is derived, in part, from the underlying demand for the systems that use semiconductors. That is, the demand for semiconductors is a positive (or increasing) function of the demand for electronic systems. Therefore, forecasting electronic systems production is an essential component of assessing expected semiconductor market activity.

This document contains tables detailing the fall 1998 electronic equipment production forecast. Japanese production is estimated for the years 1992 to 2002. Production tables contain both historical data and forecasts. In most tables, historical data begins with 1992 and ends with 1997, while forecast data provides estimates for 1998 through 2002. The tables detail the type of production data by application market.

Definitions and Conventions

The objective of analyzing electronic systems production activity is to estimate the important implications for semiconductor consumption. In this document, the value of production is estimated as factory revenue. Dataquest defines factory revenue as the exchange value of the commodity transaction between the original equipment manufacturer and the point of entry into distribution. In the case of a direct sale that involves no distribution, as is the case with military systems, factory revenue is equal to the final user cost, net of sales taxes.

Production is the value-adding process by which the factors of production (labor and capital) and material input are transformed into the goods and services that are desired for consumption and investment. As such, production can span both time and geography. For example, a Japanese color television company may minimize its cost of production by manufacturing its products (that is, consuming chips) in Asian countries. Dataquest would estimate this as Asia/Pacific production, because we are interested in that portion of the production process that relates specifically to semiconductor consumption.

Electronic equipment is divided into the following six semiconductor application markets and is further divided into the designated segments:

- Data processing
  - Computers
  - Data storage
  - Input/output
  - Dedicated systems
  - Other data processing

- Communications
  - Premise telecom
  - Public telecom
  - Mobile and radio equipment
  - Broadcast and studio
  - Other communications
- Industrial
  - Security/energy management
  - Manufacturing systems/instrumentation
  - Medical equipment
  - Other industrial
- Consumer
  - Audio
  - Video
  - Personal electronics
  - Appliances
  - Other consumer
- Military/civil aerospace
- Transportation

Data Sources

The historical information presented in the production data has been consolidated from a variety of sources, each of which focuses on a specific part of the market. These sources include the following:

- Japanese production statistics compiled and published by the Ministry of International Trade and Industry (MITI)
- Estimates presented by knowledgeable and reliable industry spokespersons
- Published information on products and prices

Valuation of Production

Japanese production is expressed in Japanese yen and translated into U.S. dollars. To make the tables in this document useful in comparing different regions, it is necessary to express all values in a common currency, and Dataquest chose the U.S. dollar for convenience. However, the choice of the U.S. dollar or any other currency brings with it some problems that require the readers' careful consideration in interpreting the data.

 ©1998 Dataquest

Exchange rates are an example of this. When forecasting electronic equipment production, it is important to ensure consistency and continuity. The preliminary 1998 exchange rate estimate is based on actual monthly exchange rates through July 1998, and we assume that the July rate applies for all the future months in 1998. For the years 1999 through 2002, we maintain exchange rates at constant 1999 calendar-year values. This prevents any inconsistencies in the conversion of growth projections and currency fluctuations. The estimates in this Market Statistics report are generated primarily on a yen basis and then are converted to U.S. dollars.

Japanese Electronic Equipment Production Definitions

Data Processing Equipment

Defined as computers, data storage, input/output devices, dedicated systems, and other data processing, as follows:

- Computers include supercomputers, mainframe computers, midrange computers, entry-level servers, workstations, PCs, motherboards, and handheld computers.
- Data storage includes rigid disk drives, removable disk drives, optical disk drives, tape drives, and other data storage.
- Input/output includes all equipment that transfers data between the CPU and a peripheral device, such as printers, monitors, and other input/output devices.
- Dedicated systems include dedicated data processing systems such as copiers, personal organizers, chip cards, and other systems.
- Other data processing includes sound/audio, digital, and graphics accelerator boards. This category also includes the value of aftermarket sales of single in-line memory modules (SIMMs) and dual in-line memory modules (DIMMs).

Communications Equipment

Defined as premise telecom, public telecom, mobile and radio communications, broadcast and studio, and other communications, as follows:

- Premise telecom includes telecommunications equipment on private premises such as image and test communications equipment, data communications equipment (WAN/LAN and remote access), premise voice systems, and desktop terminals (telephones excluding mobile handsets).
- Public telecom includes key equipment involved in the public switching and transmission markets.
- Mobile and radio communications includes cellular/broadband personal communications services (PCS)/enhanced special mobile radio (ESMR) handsets, pagers, and mobile communications infrastructure, among others.
- Broadcast and studio includes audio, video, and other broadcast and studio equipment.
- Other communications includes other communications equipment not counted elsewhere, such as intercommunications systems.

©1998 Dataquest

Industrial Equipment

Defined as security/energy management, manufacturing systems/instruments, medical equipment, and other industrial systems, as follows:

- Security and energy management includes alarm systems and energy management.
- Manufacturing systems/instrumentation includes semiconductor production equipment, control and process control equipment, control and processing display equipment, and robots. This category also includes automatic test equipment (ATE) semiconductor equipment, nuclear electronics, and other test and measurement equipment.
- Medical equipment includes diagnostic, therapeutic, patient monitoring and measuring systems, surgical support equipment, and irradiation equipment.
- Other industrial includes vending machines, automatic service equipment, commercial clothes-washing equipment, teaching machines and aids, particle accelerator electronic equipment, electron microscopes, and scientific equipment not counted elsewhere.

Consumer Equipment

Defined as audio, video, personal electronics, appliances, and other consumer equipment, as follows:

- Audio includes consumer audio equipment.
- Video includes consumer video equipment.
- Personal electronics includes video games, cameras, electronic watches, clocks, and toys.
- Appliances include consumer appliances.
- Other consumer includes automatic garage door openers, electronic tape measures, electronic tire gauges, and other consumer equipment not counted elsewhere.

Military/Civil Aerospace Equipment

Defined as radar/sonar/reconnaissance, missile/space, navigation, electronic warfare, aircraft flight systems, and command/control systems.

Transportation Equipment

Defined as entertainment, vehicle/body control, driver information, power train, and safety and convenience electronics.

Project Analyst: Motoya Ohgami

Chapter 2
Market Statistics Tables

Tables 2-1 through 2-24 contain statistics for Japanese electronic equipment production. Tables 2-1 through 2-6 contain historical data and forecasts for six semiconductor application markets divided into major segments. Tables 2-7 through 2-24 show more detailed forecasts for each application market.

Table 2-1
Japanese Electronic Equipment Production History (Factory Revenue in Billions of Yen)

Segment	1992	1993	1994	1995	1996	1997	CAGR (%) 1992-1997

Preface

Dataquest's *Japanese Semiconductor Consumption Forecast by Electronics Application, Spring 1998* is a revised and reformatted version of our long-standing semiannual semiconductor consumption by electronics application market forecast. We have made several changes to this publication in an effort to make it more relevant and meaningful, as well as more consistent with Dataquest's other research of semiconductor applications in electronic systems. Three major changes include:

- We are publishing only forecast data.
- We have increased the electronic systems detail reported in our forecast of total semiconductor consumption while eliminating the forecasts of specific semiconductor device consumption offered in previous reports.
- Dataquest's estimate of semiconductor consumption no longer equals the value of forecast semiconductor shipments.

The decision to publish only forecast data is significant. This decision stemmed from several considerations. On one hand, we have found that clients are generally far more interested in a forecast of semiconductor consumption than in estimates of past consumption. Given this and given that our estimates of historical consumption are always available to those who desire them through Dataquest's client inquiry services, Dataquest believes readers lose little from our decision to publish only forecast data. More important, we are in the midst of instituting an important and fundamental change in our forecast methodology. Data limitations severely restrict our ability to extend this method back into history. Rather than undertake the effort required to publish historical data consistent with the dictates and conventions of our new forecast method, we have decided to publish only forecast data.

The third change is admittedly quite significant and is related to the methodology change mentioned. Put succinctly, this forecast marks Dataquest's move away from a decidedly top-down method of estimating semiconductor consumption toward a bottom-up forecast approach, motivated by several factors. First, our forecast should more explicitly reflect the knowledge that Dataquest has rapidly been acquiring about semiconductor applications among individual electronic systems. For several years, Dataquest has directed its semiconductor applications research toward better understanding the dynamics of production and semiconductor use across individual electronic systems. We have developed forecast models capable of tracking production and estimating total semiconductor consumption for some 40 different individual electronic systems.

Dataquest believes these models are now sufficiently developed to use them as the backbone of our forecast of semiconductor consumption. Indeed, Dataquest believes that by leveraging the bottom-level knowledge provided by these models, we can provide far more accurate forecasts than ever before. Using these models as the basis for our forecast also allows us to report total semiconductor consumption for individual electronic systems, something that many clients have been requesting.

©1998 Dataquest

Unfortunately, we are still in the process of developing semiconductor device detail for many of our individual systems models. Rather than perpetuate old ways, we have opted to forgo publishing consumption forecasts of specific semiconductor devices, at least until our individual systems models are complete enough to let us generate forecasts consistent with our new methodology.

Second, Dataquest is seeking to eliminate our dependence on an assumption-sensitive mathematical model for our estimates of semiconductor consumption. Past forecasts of semiconductor consumption were created using a top-down mathematical model. Using Dataquest's forecasts of electronic equipment production and semiconductor shipments as inputs, this model generated estimates of semiconductor consumption by mathematically matching estimated semiconductor shipments to our forecast of electronics production based on a variety of assumptions about the semiconductor content of the various electronics product categories. Thus, our semiconductor consumption estimates were more by-products of a mathematical process than true estimates of consumption. In its defense, the model was extraordinarily flexible and allowed us to create very reasonable estimates of semiconductor consumption for broad categories of electronic products. Nonetheless, its results were highly sensitive to the semiconductor content assumptions needed to drive the model. Moreover, it offered little opportunity to incorporate our growing insights into the semiconductor consumption of individual electronics systems.

Above all, we are hoping to establish a truly separate and independent forecast of semiconductor consumption that can be compared and contrasted to Dataquest's long-standing semiconductor shipments forecast. One important feature of our now-discarded mathematical forecast model was its insistence that estimated semiconductor consumption always equal forecast semiconductor shipments. Putting aside its validity, this insistence essentially robbed our semiconductor consumption forecast of any independent insight into the dynamics of the semiconductor market in the future. By forsaking this insistence, Dataquest is not only able to provide an independent view of future semiconductor developments but also a view that can and should be compared to Dataquest's well-established semiconductor shipments forecast. Our hope is that readers will find contrasting views of the semiconductor market helpful in their efforts to divine its future.

As always, Dataquest welcomes readers' comments and would greatly appreciate any suggestions about improving our research.

Chapter 1
Introduction and Discussion

Introduction

This document contains Dataquest's forecast of Japanese semiconductor consumption by electronics application, 1997 to 2002, based both on U.S. dollars and Japanese yen. It also contains our forecast of worldwide semiconductor consumption by broad categories over the same period. This is the first of two semiannual forecasts; the second will be published this coming fall. This first forecast reflects changes since last fall in Dataquest's view of semiconductor consumption by electronic equipment worldwide and in Japan. It incorporates changes suggested by Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments.

Long-time readers will note significant changes in the focus and format of this forecast, compared to previous forecasts. This document reports only a forecast for 1997 to 2002. More significantly, we have greatly expanded the electronic systems detail supporting our forecast of total semiconductor consumption, and we have eliminated our forecasts of semiconductor device consumption by electronic application. These changes are related to a fundamental change in our forecast methodology. Dataquest's previous semiconductor consumption forecasts were a top-down mathematical reconciliation of updated electronic equipment production and semiconductor shipment forecasts. The forecast in this document represents an effort to independently estimate from the bottom up the semiconductor consumption generated by Dataquest's forecast of electronics production. Dataquest no longer attempts to specify how forecast semiconductor shipments will distribute themselves across electronics applications. Instead, the forecast separately estimates semiconductor consumption by electronic systems, unconstrained by the requirement that semiconductor consumption equal semiconductor shipments. It leaves open the possibility that estimated semiconductor consumption may differ from estimated semiconductor shipments. Unfortunately, this document is not the appropriate forum for discussing the consequences of the semiconductor demand/supply imbalance implied by persistent differences between estimated semiconductor consumption and estimated semiconductor shipments. That task will be left for other Dataquest publications.

The tables in this document present data intended to answer the following questions:

- What is the estimated semiconductor consumption of various broad categories of electronic equipment?
- What is the estimated semiconductor consumption of the key individual electronic systems that make up these broad categories?

The estimates offered in this document are intended to provide very general answers to these questions. They are meant as a broad guide to semiconductor consumption by electronic equipment production in Japan. More detailed information about estimated semiconductor consumption by individual electronic systems is available in other Dataquest documents.

©1998 Dataquest

The semiconductor consumption forecasts presented here complement Dataquest's recently updated forecasts of electronic equipment production and semiconductor shipments. Updated Japanese electronic equipment forecasts can be found in *Japanese Electronic Equipment Production Forecast, Spring 1998* (SEMI-JA-MS-9802, June 1998). Our updated semiconductor shipments forecast is found in *Worldwide Semiconductor Five-Year Forecast Trends: Spring 1998* (SCND-WW-MT-9801, June 1998). Additional regional and semiconductor device detail for this forecast can also be requested through Dataquest's inquiry service.

The tables in this document are organized as follows:

- Tables 2-1 and 2-2 summarize the worldwide semiconductor consumption forecast and compare it to the worldwide semiconductor shipments forecast.
- Tables 2-3 and 2-4 summarize the Japanese semiconductor consumption forecast on a dollar basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-5 to 2-12 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a dollar basis.
- Tables 2-13 and 2-14 summarize the Japanese semiconductor consumption forecast on a yen basis and compare it to the Japanese semiconductor shipments forecast.
- Tables 2-15 to 2-22 detail Japanese semiconductor consumption by individual electronic system, grouped by equipment type, on a yen basis.

Segmentation of Semiconductor Applications

Dataquest forecasts semiconductor consumption by end-use electronic application. We divide electronic applications into six broad groups in accordance with our segmentation of electronic equipment production. These groups are, in turn, disaggregated into narrower electronic systems categories, as follows:

- Data processing
  - Computers
  - Data storage
  - Input/output devices
  - Other data processing
- Communications
  - Premise telecommunications
  - Public telecommunications
  - Mobile communications
  - Broadcast and studio equipment
  - Other communications

- Industrial
  - Security and energy management systems
  - Manufacturing systems and instruments
  - Medical equipment
  - Other industrial equipment
- Consumer
  - Audio
  - Video
  - Personal electronics
  - Appliances
  - Other consumer equipment
- Military/civil aerospace
- Transportation

As part of the forecast process, Dataquest develops forecasts for about 40 individual electronic systems within these various categories and subcategories. These include:

- Data processing
  - Mainframes/supercomputers (computers)
  - Midrange computers (computers)
  - Workstations (computers)
  - PCs (computers)
  - PC motherboards (computers)
  - Rigid disk drives (data storage)
  - Optical disk drives (data storage)
  - Removable magnetic storage (data storage)
  - Page printers (input/output)
  - Serial printers (input/output)
  - Monitors (input/output)
- Communications
  - LAN cards (premise telecommunications)
  - Premise line cards (premise telecommunications)
  - Answering machines (premise telecommunications)
  - Fax machines (premise telecommunications)
  - Modems (premise telecommunications)
  - Corded telephones (premise telecommunications)
  - Analog cordless phones (premise telecommunications)
  - Digital cordless phones (premise telecommunications)

  - Central office line cards (public telecommunications)
  - Analog cellular phones (mobile telecommunications)
  - Digital cellular phones (mobile telecommunications)
  - Pagers (mobile telecommunications)
  - Mobile telecommunications infrastructure (mobile telecommunications)
  - Other mobile telecommunications products (mobile telecommunications)
- Consumer
  - Personal/portable stereos (audio)
  - Color TVs (video)
  - VCRs (video)
  - Analog camcorders (video)
  - Digital camcorders (video)
  - DVD (video)
  - Analog set-top boxes (video)
  - Digital set-top boxes (video)
  - Digital still cameras (personal electronics)
  - Video game controllers (personal electronics)
  - Video game cartridges (personal electronics)
- Transportation
  - Automotive stereos
  - Automotive engine control units (ECUs)
  - Antilock braking systems
  - Air bags
  - Automotive navigation systems

Geographic Segmentation

Dataquest's worldwide electronic equipment production forecast is aggregated from individual forecasts for four principal geographic regions:

- Americas
- Japan
- Europe, Middle East, and Africa
- Asia/Pacific

 ©1998 Dataquest

Exchange Rates

Dataquest's worldwide electronic equipment forecast aggregates data from many countries, each of which uses a currency that has a different and fluctuating exchange rate relative to the U.S. dollar. Because we compile our worldwide forecast from individual regional forecasts, we use the U.S. dollar as a common currency for comparisons and aggregation. As a rule, Dataquest calculates forecasts in local currencies and then converts them to U.S. dollars using projected average annual exchange rates. Dataquest does not forecast exchange rates per se. Instead, we calculate projected average annual exchange rates from current exchange rates. Our projections are based on estimates of the latest available monthly exchange rate at the time the forecast is developed. These rates are based on monthly exchange rates observed through February 1998. Additional information about historical exchange rates and Dataquest's method of calculating future average exchange rates may be requested through Dataquest's client inquiry service.

Forecast Methodology

When discussing semiconductor consumption, it is critical to remember that semiconductors are not end products consumed for their own sake. They are intermediate products used as inputs for electronic end products that are eventually consumed by individuals and businesses for the utility they provide. Implicit in the concept of semiconductor consumption is the notion that the electronic end products in which semiconductors will be incorporated or consumed can be specified. A semiconductor forecast that does not or cannot specify this is not a forecast of semiconductor consumption. At best, it is merely a forecast of semiconductor shipments.

Dataquest's semiconductor consumption by electronic application forecast grew out of the recognition that a truly complete semiconductor forecast must specify the electronic end uses of semiconductors. However, specifying semiconductor end uses has proved far more difficult than recognizing that it must be done. Although it appears possible to specify semiconductor consumption by the variety of electronics produced, there are simply too many different types of semiconductor devices consumed in too large a variety of electronic products. As a result, semiconductor consumption must invariably be estimated. This can be done in any number of ways. Before this forecast, Dataquest used a mathematical model to estimate semiconductor consumption by various electronic end uses. Taking Dataquest's electronic equipment production and semiconductor shipments forecasts as inputs, this model allocated estimated semiconductor shipments across forecast electronics production subject to various assumptions about the semiconductor content of electronic products. The model also imposed several balancing conditions intended to guarantee that estimated semiconductor shipments were completely allocated across all forecast electronics production.

 ©1998 Dataquest

The model applied a top-down approach to estimating semiconductor consumption. In effect, it calculated estimates of semiconductor consumption by compelling agreement between the details of the electronics production forecast and the semiconductor shipments forecast. As a result, the estimates of semiconductor consumption were more an artifact of a mathematical process than truly independent estimates of semiconductor consumption. Although the model offered considerable flexibility, it was nonetheless limited by the validity of its semiconductor content assumptions and the balancing requirement that semiconductor consumption equal semiconductor shipments. Despite its potential drawbacks, the model provided the best estimates we could offer, given a paucity of knowledge about semiconductor applications in specific electronic systems.

Over last several years, Dataquest's semiconductor applications research has been concentrated on the study of semiconductor use in specific individual electronic systems. We have successfully developed models to track and forecast the production and semiconductor consumption of some 40 different individual electronic systems. These include PCs and PC motherboards, rigid disk drives, LAN cards and modems, digital cellular phones, digital set-top boxes, and automotive navigation systems, among others. The electronic systems encompassed by our models account for about one-half of all electronics production and nearly two-thirds of estimated semiconductor consumption.

These models have not only allowed us to codify our knowledge about individual electronic systems but also to approach the task of estimating semiconductor consumption using a bottom-up forecast method. This method was used for the forecast and will be used for future forecasts. The method essentially involves building a forecast of semiconductor consumption for all electronics production by leveraging estimates of semiconductor consumption for individual electronic systems. Dataquest uses individual systems estimates as a forecast base and augments this with estimates of semiconductor consumption for other electronic equipment categories not tracked individually. Precisely because the method uses well-researched knowledge about individual electronics systems that dominate semiconductor consumption, Dataquest believes it is capable of providing far better forecasts of semiconductor consumption than our former top-down method, especially for electronic equipment categories such as computers, where individual systems forecasts account for virtually the entire category.

This change to a new method has a number of consequences. Dataquest has, at least temporarily, eliminated forecasts of specific semiconductor device consumption by electronic application. Although informative, these forecasts were largely an artifact of our old top-down method. Recent research indicates that these forecasts were especially sensitive to the assumptions and balancing conditions of our top-down method. We are still in the process of developing semiconductor device detail for many of the individual systems forecasts that now serve as the basis for our new bottom-up method.

 ©1998 Dataquest

Consequently, our systems forecasts have yet to reach the point at which they can be leveraged to provide reasonable consumption forecasts for specific semiconductor devices. We hope to reinstate device consumption forecasts as soon as possible according to this bottom-up method. In the meantime, we trust that readers will find the added electronics system detail we can now offer in our forecast adequate compensation.

More important, Dataquest no longer insists that estimated semiconductor consumption equal the forecast of semiconductor shipments. In truth, our long-standing insistence that consumption estimates equal shipment estimates was more a matter of mathematical necessity than a reflection of market realities. There are several reasons why semiconductor consumption as we estimate it may differ from a forecast of semiconductor shipments. First, there can be significant slippage between semiconductor shipments and semiconductor consumption by electronics producers over short periods because of changes in the semiconductor inventories held by electronic producers. Electronics producers naturally adjust their semiconductor inventories in response to expected changes in their level of production. Although just-in-time practices are reducing producers' inventories, the continued existence of inventories means semiconductor shipments and consumption may differ.

Second, not all semiconductor shipments are consumed by electronics producers manufacturing new electronics. Some find their way into so-called "aftermarkets" where they are eventually "consumed" by existing electronics. Dataquest excludes aftermarket activity from the estimates of semiconductor consumption. Aftermarket consumption is virtually impossible to track and, in any event, appears to be small relative to the consumption generated by electronics producers. Finally, Dataquest's estimates of both electronics production and semiconductor consumption no doubt suffer from errors of omission. We know our estimates probably exclude at least some current semiconductor applications and certainly exclude more than a few applications that cannot be anticipated now. We have good reason to believe these omissions are minor. Still, they represent yet another reason why estimated semiconductor consumption may differ from forecast semiconductor shipments.

It nonetheless seems reasonable to expect that estimated semiconductor consumption and forecast semiconductor shipments will closely parallel one another, especially over the long term. As already noted, semiconductors are first and foremost intermediate inputs to the production of electronics. Growth in semiconductor shipments is ultimately fueled by growth in the semiconductor consumption generated by electronics production. Growth in the semiconductor consumption of electronics producers is, in turn, fueled by growth in both the volume and semiconductor content of electronics production. In the end, all growth in semiconductor shipments can be attributed to growth in one or the other of these key consumption drivers. Estimation errors aside, persistent differences between estimated semiconductor consumption growth and forecast semiconductor shipment growth prefigure a demand/supply imbalance in the semiconductor market.

 ©1998 Dataquest

In the past, Dataquest's top-down method obscured potential semiconductor market imbalances by assuming that estimated semiconductor consumption must equal forecast semiconductor shipments. The beauty of the bottom-up method is that we can offer important insights into the future of the semiconductor market. We realize that separate forecasts of semiconductor consumption and semiconductor shipments have the potential to create confusion. However, Dataquest believes that separate forecasts may actually help clarify semiconductor market movements by revealing potential market imbalances.

Forecast Highlights

Dataquest estimates that worldwide semiconductor consumption will increase by 10.7 percent in 1998 to about $160.6 billion. Dataquest expects approximately two-thirds of this growth will come about because of growth in worldwide electronics production, which is now forecast to grow 6.9 percent in 1998 to about $968.9 billion. The remainder will be the result of expected growth in the average semiconductor content of electronics, which we forecast will increase to about 16.6 percent of electronics factory value. Longer-term, we estimate worldwide semiconductor consumption will average 12.2 percent annual growth through 2002. This should raise worldwide semiconductor consumption to about $257.6 billion by 2002. Dataquest expects slightly over half of the longer-term growth in worldwide semiconductor consumption to come about because of growth in worldwide electronics production, which we are now forecasting to average 6.6 percent annual growth through 2002. Once again, remaining growth in semiconductor consumption will be the result of increases in the average semiconductor content of electronics. We now expect average semiconductor content will rise to about 20.6 percent of electronics factory value by 2002.

Japan currently ranks as the world's second-leading regional consumer of semiconductors. Asia/Pacific, in turn, ranks third just ahead of our Europe, Middle East, and Africa region. Dataquest expects at least one if not two significant changes in this ranking as time progresses. It now looks very probable that Asia/Pacific will overtake Japan as the world's No. 2 regional consumer of semiconductors by 2002. An additional possibility is that Europe, Middle East, and Africa will also overtake Japan before the end of the forecast period, placing Japan last among the regions as a semiconductor consumer. These changes appear inherent in the markedly different consumption growth rates anticipated for each region. We are now forecasting Japanese semiconductor consumption will grow just 1.9 percent in 1998. This compares to anticipated growth rates of 17.6 percent for Asia/Pacific and 10.6 percent for Europe, Middle East, and Africa. Longer-term, Japanese consumption is expected to average just 8.8 percent annual growth between 1997 and 2002 as opposed to 16.3 percent for Asia/Pacific and 12.8 percent for Europe, Middle East, and Africa. (Note: All our forecasts are valued in U.S. dollars and thus reflect projected exchange rate movements in addition to expected changes in semiconductor consumption expressed in local currencies.) Underlying these marked differences in long-term growth are equally marked differences in expected sources of growth.

 ©1998 Dataquest

About 80 percent of Japan's longer-term consumption growth is forecast to come from increases in semiconductor content. In contrast, just over 70 percent of Asia/Pacific's longer-term consumption growth is expected to come from growing electronics production. For Europe, Middle East, and Africa, consumption growth will come from a more equally balanced combination of production growth and increased semiconductor content.

We need to note that our regional forecasts, especially for Japan and Asia/Pacific, are considerably more tentative than usual. Ongoing economic and political events in Japan and Asia/Pacific, some quite dramatic, have introduced significant uncertainty into our forecasts. In particular, Dataquest believes there is much greater potential for downward deviations from our forecasts than in the past. Readers should keep this in mind when using and interpreting our results.

As discussed earlier, this forecast represents an effort to independently forecast semiconductor consumption, free of the assumption that semiconductor consumption must always and everywhere equal semiconductor shipments. At least for the near-term, our semiconductor consumption forecasts generally agrees with our recently published forecast of semiconductor shipments. According to the latter, semiconductor supplier shipments are expected to increase 8.2 percent in 1998 to about $159.2 billion. This compares quite well to our forecast of a 10.7 percent increase in semiconductor consumption to about $160.6 billion for 1998. Given that the downside risks of ongoing turmoil in Japan and Asia/Pacific threaten our forecast, we would not be surprised to see semiconductor consumption growth move into even closer agreement with the growth currently expected for semiconductor shipments as 1998 progresses. In fact, there is a significant chance that both semiconductor consumption and semiconductor shipments growth will fall well below 8 percent before the year is out because of continuing troubles in Japan and Asia/Pacific.

Longer-term, there is significant disagreement between our two forecasts. According to Dataquest's semiconductor shipments forecast, semiconductor shipments are expected to average 14.4 percent annual growth through 2002. If realized, that would raise the value of semiconductor shipments to $287.9 billion by 2002. Recall that semiconductor consumption is forecast to average 12.2 percent annual growth through the forecast period so that it reaches $257.6 billion by 2002. As noted earlier, semiconductor consumption may reasonably differ from semiconductor shipments on several accounts. But even after due consideration of these factors, the $30.3 billion difference between our forecasts for semiconductor consumption and semiconductor shipments appears excessive. The difference suggests there is likely to be a sizable oversupply of semiconductors around 2002. We would especially urge semiconductor suppliers to consider this a distinct possibility and to ponder its consequences.

 ©1998 Dataquest

There is a strong desire among suppliers to believe that semiconductor shipments, and with them semiconductor revenue, can continue to post high rates of long-term growth. But this desire needs to be tempered with the recognition that long-term shipments growth is only possible so long as electronics makers are able to profitably increase semiconductor consumption, either by expanding electronics production or increasing semiconductor content. A number of fundamental changes are taking place in several key electronics markets that will limit the future ability of electronics makers to profitably increase semiconductor consumption. Semiconductor suppliers would be well advised to acknowledge these emerging limits since failure to do so will only intensify competition and further imperil both future shipment and revenue growth in Japan.

Chapter 1
Japanese Electronic Equipment Production Forecast

Introduction

Electronic equipment production is an important determinant of semiconductor market activity. This is true because semiconductor demand is derived, in part, from the underlying demand for the systems that use semiconductors. That is, the demand for semiconductors is a positive (or increasing) function of the demand for electronic systems. Therefore, forecasting electronic systems production is an essential component of assessing expected semiconductor market activity.

This document contains tables detailing the spring 1998 electronic equipment production forecast. Japanese production is estimated for the years 1992 to 2002. Production tables contain both historical data and forecasts. In most tables, historical data begins with 1992 and ends with 1997, while forecast data provides estimates for 1998 through 2002. The tables detail the type of production data by application market.

Definitions and Conventions

The objective of analyzing electronic systems production activity is to estimate the important implications for semiconductor consumption. Therefore, generalized economic concepts such as production and consumption are tailored to isolate these implications.

The value of production is estimated as factory revenue. Dataquest defines factory revenue as the exchange value of the commodity transaction between the original equipment manufacturer and the point of entry into distribution. In the case of a direct sale that involves no distribution, as is the case with military systems, factory revenue is equal to the final user cost, net of sales taxes.

Production is the value-adding process by which the factors of production (labor and capital) and material input are transformed into the goods and services that are desired for consumption and investment. As such, production can span both time and geography. For example, a Japanese color television company may minimize its cost of production by manufacturing its products (that is, consuming chips) in Asian countries. Dataquest would estimate this as Asia/Pacific production, because we are interested in that portion of the production process that relates specifically to semiconductor consumption. Production would be valued as the exchange value of the transaction between the Japanese company's Asian operations (which is factory revenue) and the European distributor or final user.

©1998 Dataquest

Electronic equipment is divided into the following six semiconductor application markets and is further divided into the designated segments. Japanese production is further divided into specific types of equipment systems.

- Data processing
  - Computers
  - Data storage
  - Input/output
  - Dedicated systems
  - Other data processing
- Communications
  - Premise telecom
  - Public telecom
  - Mobile and radio communications
  - Broadcast and studio
  - Other telecom
- Industrial
  - Security and energy management
  - Manufacturing systems/instrumentation
  - Medical equipment
  - Other industrial
- Consumer
  - Audio
  - Video
  - Personal electronics
  - Appliances
  - Other consumer
- Military and civil aerospace
- Transportation
  - Entertainment
  - Control unit
  - Safety and convenience

Data Sources

The historical information presented in the production data has been consolidated from a variety of sources, each of which focuses on a specific part of the market. These sources include the following:

- Japanese production statistics compiled and published by the Ministry of International Trade and Industry (MITI)

- Estimates presented by knowledgeable and reliable industry spokespersons
- Published product literature and prices

Dataquest believes that the estimates presented here are the most accurate and meaningful generally available today.

Valuation of Production

Japanese production is expressed in Japanese yen and translated into U.S. dollars. To make the worldwide tables in this document useful in comparing different regions, it is necessary to express all values in a common currency, and Dataquest chose the U.S. dollar for convenience. However, the choice of the U.S. dollar or any other currency brings with it some problems that require the readers' careful consideration in interpreting the data, as follows:

- Inflation and deflation—No adjustment has been made in the historical or forecast data to account for the effects of past inflation or deflation or for possible future inflation or deflation. Production is expressed in current dollars (that is, dollars that include the effects of inflation and changes in exchange rates).
- Exchange rates—When forecasting electronic equipment production, it is important to ensure consistency and continuity so that we maintain exchange rates at constant 1998 calendar year values. This prevents any inconsistencies in the conversion of growth projections and currency fluctuations. The estimates in this Market Statistics report are generated primarily on a yen basis and then converted to U.S. dollars. The preliminary 1998 exchange rate estimate is based on actual exchange rates through December 1997, and we assume that the December rate applies for all the future months.

Japanese Electronic Equipment Production Definitions

Data Processing Equipment

Defined as computers, data storage, terminals, input/output, dedicated systems, and other data processing, as follows:

- Computers include general-use computers, office-use computers, personal-use computers, and control-use computers.
- Data storage includes rigid disk drives, flexible disk drives, other drives, and other data storage.
- Input/output includes printers, display units, other input/output units, general-use terminals, terminals for special use, and terminals for supporting systems.
- Dedicated systems include calculators, cash registers, copying machines, typewriters, word processors, and other dedicated equipment.
- Other data processing includes PC cards, single in-line memory modules (SIMMs), and other data processing equipment.

 ©1998 Dataquest

Communications Equipment

Defined as premise telecom, public telecom, mobile and radio communications, broadcast and studio, and other communications, as follows:

- Premise telecom includes telephones (standard, multifunction, cordless, PHS, and others), applied telephone, facsimile, PBX telephone systems, key telephone systems, and modems.
- Public telecom includes carrier transmission equipment and central office switching.
- Mobile and radio communications includes radio communications (radio base station equipment, mobile radio equipment, and mobile communications equipment) and applied radio equipment.
- Broadcast and studio includes all electronic equipment used to make information public by means of radio and television.
- Other communications includes communications control units and other communications equipment.

Industrial Equipment

Defined as security and energy management, instrumentation, manufacturing systems, medical equipment, and other industrial equipment, as follows:

- Security and energy management includes alarm systems (intrusion detection and fire detection) and energy management (air conditioners for industrial use).
- Manufacturing systems/instrumentation includes NC machines, robotics, ultrasonic applied equipment, metering units, measuring instruments, industrial meters, and other instrumentation equipment such as analyzers.
- Medical equipment includes X-ray systems, measuring systems, and other medical equipment such as radioisotope equipment.
- Other industrial includes vending machines, automatic service equipment, commercial-type washers, electron microscopes, ultrasonic equipment, and all other industrial equipment not accounted for in the preceding segments.

Consumer Equipment

Defined as audio equipment, video equipment, personal electronics, appliances, and other consumer equipment, as follows:

- Audio includes audio amplifiers, digital audio disc (DAD) players, radios, stereo sets, tape recorders, headphone stereos, musical instruments, and other audio equipment (tuners and turntables).
- Video includes video cassette recorders (VCRs), video cameras, DVD players, color televisions, and LCD televisions.
- Personal electronics includes cameras, clocks, electronic toys, watches, and game systems and software.
- Appliances include air conditioners for home use, microwave ovens, refrigerators, and washers and dryers.

©1998 Dataquest

- Other consumer includes gas heaters, gas fan heaters, oil fan heaters, electric heaters, fans, electric water heaters, gas water heaters, oil water heaters, electric pots, rice cooker and rice jar combinations, gas rice cookers, sewing machines, electric irons, vacuum cleaners, and other consumer equipment.

Military/Civil Aerospace Equipment

Defined as electronic systems for defense agencies, such as communications equipment and instrumentation.

Transportation Equipment

Defined as in-car entertainment systems, control units and safety and convenience electronics.

- In-car entertainment includes FM/AM radios, radio-cassette combination systems, and car stereo cassette units.
- Control units include electronics control equipment for engine, body, and powertrain.
- Safety and convenience includes in-car equipment for safety and convenience, such as car air conditioners.

Chapter 1
Final 1997 Japanese Semiconductor Market Share

Introduction

This document contains detailed information on Dataquest's view of the semiconductor market. Included in this document are the following:

- 1995-1997 market share estimates
- 1996-1997 market share rankings

Worldwide market share estimates combine data from many countries, each of which has a different and fluctuating exchange rate. Estimates of non-U.S. market consumption or revenue are based on the average exchange rate for the given year. Refer to the section titled "Exchange Rates" for more information regarding these average rates. As a rule, Dataquest's estimates are calculated in local currencies and then converted to U.S. dollars.

More detailed data on this market may be requested through Dataquest's client inquiry service. Qualitative analysis of this data is provided in the Dataquest Perspectives.

Segmentation and Definitions

A detailed explanation of device segmentation and related definitions is contained in the Semiconductor Market Definitions Guide (SCND-WW-GU-9801).

Market Share Methodology

Dataquest uses both primary and secondary sources to produce market statistics data. In the fourth quarter of each year, Dataquest surveys all major participants within each industry. Selected companies are resurveyed during the first quarter of the following year to verify final annual results. This primary research is supplemented with additional primary research and secondary research to verify market size, shipment totals, and pricing information. Sources of data used by Dataquest include the following:

- Information published by major industry participants
- Estimates made by knowledgeable and reliable industry spokespersons
- Government data or trade association data (such as WSTS, MITI, and U.S. DOC)
- Published product literature and price lists
- Interviews with knowledgeable manufacturers, distributors, and users
- Relevant economic data
- Information and data from online and CD-ROM data banks
- Articles in both the general and trade press

©1998 Dataquest

- Reports from financial analysts
- End-user surveys

Dataquest believes that the estimates presented in this document are the most accurate and meaningful statistics available.

Despite the care taken in gathering, analyzing, and categorizing the data in a meaningful way, careful attention must be paid to the definitions and assumptions used herein when interpreting the estimates presented in this document. Various companies, government agencies, and trade associations may use slightly different definitions of product categories and regional groupings, or they may include different companies in their summaries. These differences should be kept in mind when making comparisons between data and numbers provided by Dataquest and those provided by other sources.

Notes on Market Share

In the process of conducting data collection and preparing market statistics information, Dataquest will sometimes consolidate or revise a particular company, model, series, or industry's numbers. In this section, we explain any such changes contained within this document for your reference.

Notes to Market Share Tables

1. Cyrix was acquired by National Semiconductor in 1997.

2. National Semiconductor divested itself of Fairchild in 1997.

3. National Semiconductor's 1997 revenue includes all of Cyrix's 1997 revenue and part of Fairchild's calendar first quarter revenue.

4. Power Innovations was formed through the acquisition of the Power Semiconductor interests of Texas Instruments.

5. Melexis was formerly known as Elex.

6. Micronas acquired ITT in 1997.

7. The following companies were added to the market share database in 1997:

- Fairchild
- Vitesse
- TriQuint
- Power Innovations
- Robert Bosch
- Stanley

8. Toko is now tracked in other Japanese companies.

9. IBM's 1996 revenue was restated in 1997.

Exchange Rates

Dataquest uses an average annual exchange rate in converting revenue to U.S. dollar amounts. Table 1-1 outlines these rates for 1995 through 1997.

Table 1-1
Exchange Rates

	1995	1996	1997
Japan (Yen/U.S.$)	93.90	108.81	121.10
France (Franc/U.S.$)	4.97	5.12	5.84
Germany (Deutsche Mark/U.S.$)	1.43	1.50	1.73
United Kingdom (U.S.$/Pound Sterling)	1.59	1.56	1.64

Chapter 1

Executive Summary

Scope of This Report

This report analyzes the following Japanese semiconductor user trends in 1997:

- Overall electronic equipment production and semiconductor consumption trends in Japan
- Electronics production trends of 22 major Japanese semiconductor users
- Semiconductor purchasing trends of each of the 22 companies

Chapter 2 discusses electronic equipment production trends, focusing on four major categories: data processing, communications, industrial, and consumer. Chapter 3 analyzes semiconductor purchasing trends in 1997 for the 22 top-ranking semiconductor users as a group. Chapter 4 discusses the company profile of each semiconductor user, noting major electronic products by category as well as semiconductor purchasing trends, and ends with a "Dataquest Perspective" section.

Research Methodology and Definitions

This Focus Report analyzes the results of Dataquest's recent survey of Japanese semiconductor users. To arrive at the estimates in this report, Dataquest conducted extensive research into semiconductor purchasing practices in the Japanese market. Also incorporated into the estimation is public information on each semiconductor-user company, regarding both electronic equipment production trends as well as semiconductor usage. Based on primary information, Dataquest has estimated the semiconductor purchasing trends of major Japanese companies for 1996 and 1997. All numbers are shown in Japanese yen unless otherwise stated.

The definitions used in this report are as follows:

- Semiconductor consumption—This refers to the number of semiconductors actually used in electronic systems manufactured by user companies.
- Semiconductor purchasing—This refers to the number of semiconductors purchased by user companies. Regional semiconductor consumption discussed in this report refers to the number of semiconductors booked and billed in each region, based on user location.
- Data processing—This is defined as computer systems, data storage, input/output devices, dedicated systems, and other data processing equipment.
- Industrial—This is defined as security/energy management systems, manufacturing systems/instruments, medical equipment, and other industrial equipment.

©1998 Dataquest

- Communications—This is defined as premise telecom equipment, public telecom equipment, mobile communications equipment, broadcast and studio equipment, and other telecom equipment.
- Consumer—This is defined as audio equipment, video equipment, personal electronics, appliances, and other consumer equipment.
- Military and civil aerospace—This is defined as military and civil aerospace electronic equipment.
- Transportation—This is defined as in-car entertainment, body control electronics, power train systems, and safety and convenience systems.

Highlights of the Report

The major points discussed in this document include the following:

- In 1997, while electronics equipment production in Japan grew 7.8 percent, semiconductor consumption in Japan recorded modest growth of 5.7 percent.
- The 22 top-ranking Japanese electronics companies together increased semiconductor purchasing by 2.4 percent in 1997. Individually, however, some leading companies, such as Hitachi and Mitsubishi Electric, decreased their semiconductor purchasing.
- Comparatively strong growth (more than 8 percent) in semiconductor purchasing was seen in the communications category; this was mainly due to a rise in the unit production of that type of equipment, including digital cellular phones and other wireless communications systems.
- Modest growth (approximately 4 percent) in semiconductor purchasing was seen in the data processing category; this was mainly due to an increase in the unit production of computer peripherals and dedicated systems.
- Several products in the consumer category, such as the digital video camera (DV-C) and digital still camera (DSC), recorded strong growth in production, but semiconductor purchasing of consumer equipment was down by 2.4 percent in 1997.
- While production of automotive navigation systems was growing rapidly, semiconductor purchasing trends in the transportation category declined by 1.6 percent in 1997; this was mainly due to sluggish sales and decreases in price.

Chapter 2
Japanese Electronic Equipment Production and Semiconductor Consumption

In 1997, after a temporary surge in domestic demand prior to the consumption tax hike in April, the Japanese economy was beleaguered by turmoil in the financial system, a decline in consumer expenditure, and a slowdown in capital spending. The economic hardship was amplified by the Asian financial crisis (AFC) toward the year-end.

In 1997, against all of the economic backlash in Japan as well as in Asia/Pacific, electronic equipment production showed stronger growth than expected: 7.8 percent over 1996, reaching ¥23,715 billion (see Figure 2-1 and Table 2-1). Cellular phones contributed greatly, fueled by a series of price cuts and the shift in demand from personal handyphone systems (PHSs). Data processing equipment also outgrew the forecast, despite a slowdown in domestic PC shipments, and consumer equipment added some momentum, which came from video game systems and digital equipment.

The following section provides detailed analysis of electronic equipment production in Japan for the four major categories: data processing, communications, industrial, and consumer.

Note: Columns may not add to totals shown because of rounding.
Source: Dataquest (October 1998)

Data Processing Equipment

In 1997, data processing equipment production revenue in Japan soared 8.3 percent to ¥7,380 billion (see Figure 2-2). While PC shipments to the domestic market slowed down to less than 5 percent on a unit basis, the price decline spurred the purchase of peripherals such as printers and display units. Also, storage devices led by high-speed optical disc drives—24x-to-32x CD-ROM and CD-R drives and newly introduced DVD-ROM drives, for example—enjoyed strong growth. This segment is expected to drive the market during the forecast period.

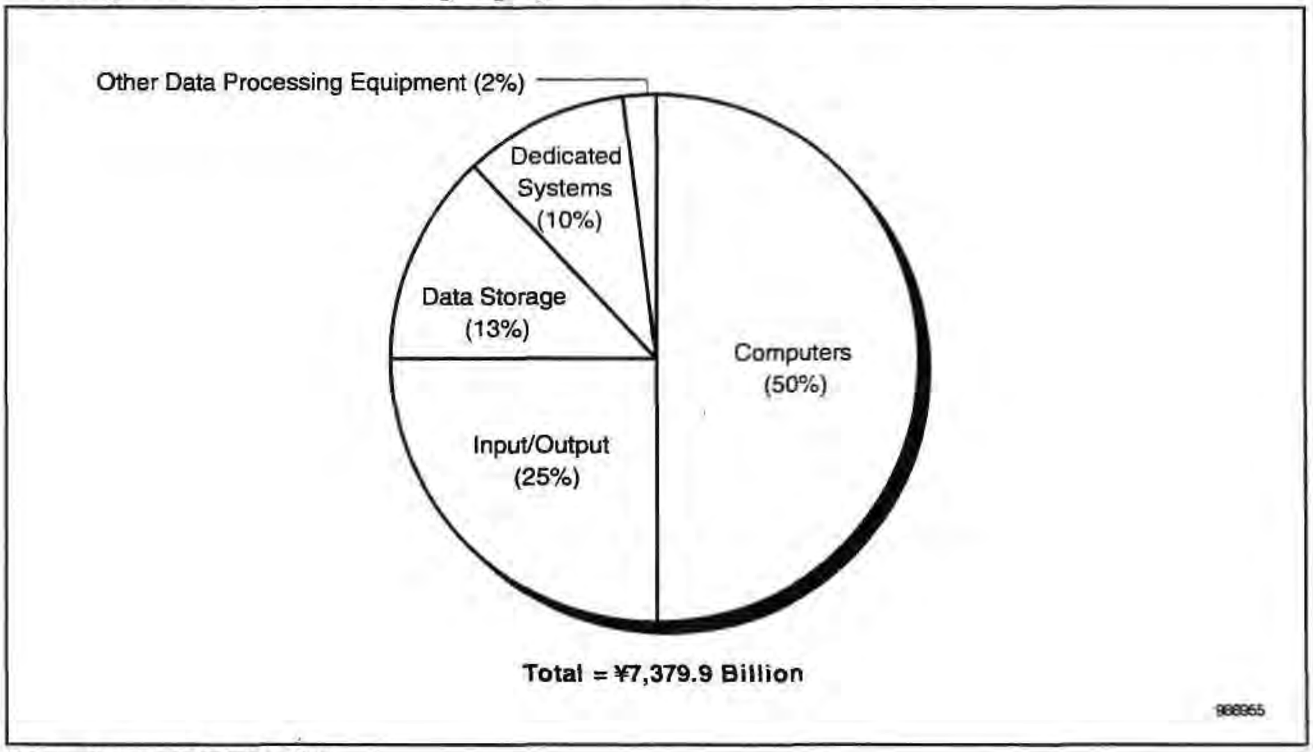
These trends affected various system vendors in this category, such as Canon and Seiko Epson, which are very well known for computer peripheral products such as printers. NEC, Toshiba, and SANYO decreased their semiconductor purchasing mostly because of price cuts and sluggish production. Fujitsu and Matsushita Kotobuki increased their semiconductor purchasing, owing much to the production increase of hard disk drives (HDDs) and CD-ROMs.

Communications Equipment

In 1997, communications equipment production revenue jumped 19.8 percent to ¥4,844 billion (see Figure 2-3). A prime driver was mobile communications equipment; subscribers grew much faster than expected, recording a net increase of 10 million in 1997. While PHS production decelerated by 7 million units in 1997, the market is expected to expand and shift its focus from personal to office use. Nevertheless, the penetration of mobile phones combining PHS and personal digital cellular (PDC) phones has surpassed 30 percent in Japan, and continuation of the previous high growth in domestic demand has become inevitably difficult. Meanwhile, the digitization of infrastructure facilities by Nippon Telegraph and Telephone (NTT) was completed at the end of 1997. This can be translated into the end of robust growth in infrastructure equipment production.

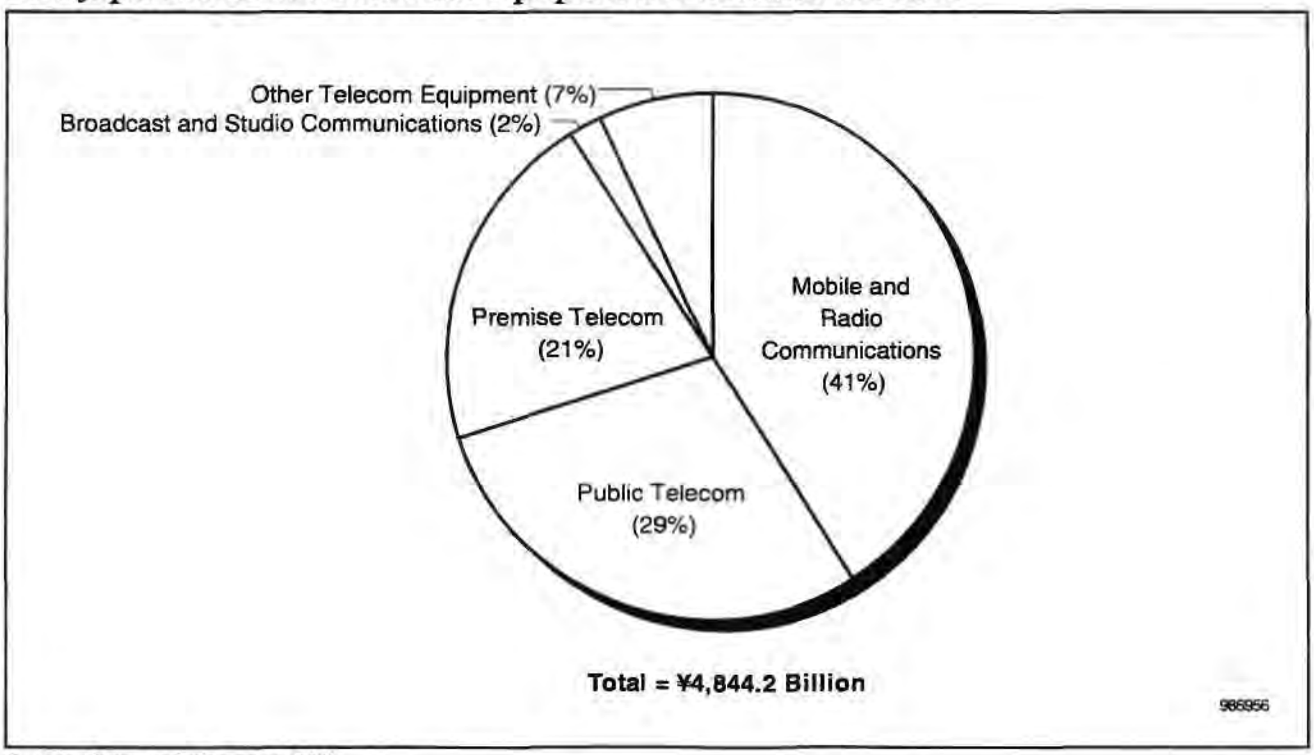
These trends affected system vendors in this category, such as Matsushita Communication, NEC, and Mitsubishi Electric—the top three vendors in the domestic market for digital cellular phones.

Figure 2-2
1997 Japanese Data Processing Equipment Production Revenue



Source: Dataquest (October 1998)

Figure 2-3
1997 Japanese Communications Equipment Production Revenue



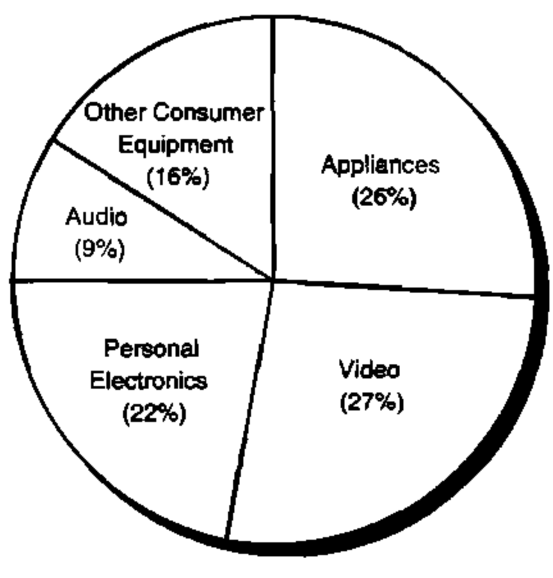
Source: Dataquest (October 1998)

Consumer Equipment

Consumer equipment production revenue recorded a 1.3 percent increase in 1997, reaching ¥6,098 billion (see Figure 2-4). In the video equipment segment, where TVs and VCRs sold in the domestic market are made mostly overseas, replacement demand for wide-screen TVs produced at domestic sites contributed greatly. In the digital consumer equipment market, DV-Cs recorded notable growth, and unit shipments at the end of 1997 were estimated at slightly below 1 million. The DV-C quickly will become pervasive, driven by price declines and the improved availability of key components. Similarly, DSCs will ramp up rapidly because they can be easily connected to PCs or TVs via a flash memory card or standard serial interface. In the audio equipment segment, a sudden rise in demand for minidiscs (MDs) has spurred the introduction of various systems equipped with MD drives. TV games continued to expand the market, helped by price cuts.

These trends affected system vendors in this category, such as Victor Company of Japan, Sony, and Nintendo.

Figure 2-4
1997 Japanese Consumer Equipment Production Revenue



Source: Dataquest (October 1998)

©1998 Dataquest

Industrial Equipment

Industrial equipment production revenue in 1997 was up 7.2 percent, totaling ¥3,908 billion (see Figure 2-5). Among the segments in this category, manufacturing systems and instruments recorded the highest growth rate, with 14.9 percent. As the wave of production site relocation to Asia/Pacific countries subsides, the focal point of the market will shift to computerization and sophistication for adding value and further automation for new products.

These trends affected system vendors in this category, such as Hitachi, Toshiba, and Mitsubishi Electric; these big companies did not contribute much to the growth of semiconductor purchasing in this category in 1997.

Semiconductor Market

Thus, even in the year when the overall gross domestic product (GDP) in Japan recorded negative growth, electronics production increased fairly well. This gain in electronics production, however, did not mean as robust of an increase in semiconductor purchasing in Japan.

In 1997, the Japanese semiconductor market recorded a growth rate of 5.7 percent over the previous year—the only negative growth rate on a dollar basis among the four regional markets in the world: the Americas, Europe, Asia/Pacific, and Japan. The difference in trends between electronics production and semiconductor consumption was caused by two factors: An increase in electronics production took place in categories with lower semiconductor contents, such as industrial equipment, and the price erosion of semiconductor devices betrayed the increase on a unit basis. Also, PC shipments lost momentum in Japan, exerting a negative impact on the consumption of a variety of semiconductor products, including memories, microprocessors (MPUs), and logic.

As a result, the Japanese semiconductor market has become less than one-fourth of the worldwide market for the first time since 1980. It is still the second-largest regional market following the Americas, but both European and Asia/Pacific markets are close behind. In fact, there were months within 1997 when the Japanese semiconductor market fell behind those two markets.

Affecting this is the sluggishness in the domestic market as well as the fast growth in other regions, especially in the Americas and Europe. Semiconductor procurement to support Japanese electronics companies' Asian production sites has moved to each site or to international purchasing offices (IPOs) outside Japan, and the yen depreciation observed in 1997 did not reverse the trend.

Japanese semiconductor consumption by application category in 1997 is given in Figure 2-6.

Chapter 3
Japanese Semiconductor User Trends by Application

This chapter analyzes Japanese semiconductor consumption by application categories, focusing on the 22 top-ranking companies.

It should be noted that the semiconductor purchasing estimated in this report was measured as the amount of semiconductors booked and billed within Japan, regardless of where the bought semiconductors were actually mounted to circuit boards and systems. This implies that if the Japanese electronics companies analyzed here chose to buy semiconductors in Japan and then send them to their overseas production sites, that amount is still included in the semiconductor purchasing in Japan. Therefore, the semiconductor purchasing in this report may not equal semiconductor consumption in the true sense of the word. In Dataquest's methodology, however, even that portion of semiconductor purchasing is regarded as part of the "consumption," measured as the semiconductor companies' aggregated shipments into the Japanese market.

Table 3-1 and Figure 3-1 show the ranking of 22 major semiconductor-user companies based on their semiconductor purchasing trends in 1997. The top three users were NEC, Sony, and Fujitsu. The development of systems targeted at the domestic market tends to be conducted within Japan. The tendency is clearer in areas such as communications, where the differences in each country's format are so conspicuous—to the level of being incompatible with each other—that system development needs to be done within the country or region of its use. On the other hand, consumer electronics have been developed in Japan to be shipped to export markets, resulting in a large number of developed and produced systems.

Data Processing

In this category, there are several products that contribute to the growth of semiconductor purchasing; they are mainly PC peripherals such as printers, monitors, digital copy systems, multifunctional dedicated machines, and optical disc storage, such as CD-ROM/R/RW and DVD players. Table 3-2 and Figure 3-2 show semiconductor purchase ranking in the data processing equipment area. Fujitsu, NEC, and Toshiba have sizable amounts of computer business, resulting in large purchase numbers. Canon follows the top three companies with its expertise in copiers and computer peripherals.

Table 3-1

Communications

In the communications area, wireless communications and LAN/WAN equipment, including hubs, switches, and routers, are increasing in production volume, consuming an increasing portion of the semiconductors shipped worldwide. In Japan, the rapid growth in digital cellular phones helped vendors of both handsets and base stations. This contributed to increases in semiconductor consumption at companies such as Matsushita Electric, Sony, Toshiba, and Denso, some of which may not have been giants in the communications area but are growing fairly well in production. Table 3-3 and Figure 3-3 show the Japanese semiconductor purchase ranking of communications equipment.

Table 3-3
Japanese Semiconductor Purchase Ranking of Communications Equipment, 1996-1997 (Billions of Yen)

1997 Rank	Company	1996	1997	Change (%)
1	NEC	113.1	122.8	8.6
2	Fujitsu	61.2	64.4	5.2
3	Sony	43.6	44.1	1.1
4	Matsushita Communication	37.3	41.3	10.7
5	Hitachi	42.5	41.0	-3.5
6	Toshiba	26.3	29.9	13.7
7	Matsushita Electric	16.9	27.4	62.1

Consumer

In the consumer equipment area, Sony, Nintendo, and Matsushita Electric lead other companies by far. In the sluggish domestic market, MD has been showing an accelerating growth, pulling demand for other audio systems as well. Other digital consumer equipment, such as digital camcorders and DSCs, grew, too, and contributed to the semiconductor purchasing of those vendors. Table 3-4 and Figure 3-4 show the Japanese semiconductor purchase ranking of consumer equipment.

Table 3-4
Japanese Semiconductor Purchase Ranking of Consumer Equipment, 1996-1997 (Billions of Yen)

1997 Rank	Company	1996	1997	Change (%)
1	Sony	140.7	165.1	17.3

Industrial

Overall capital expenditure in the Japanese industry declined in 1997, and manufacturing systems and instruments showed growth that was positive but smaller than that of the previous year. A drop in housing and building construction also hurt security and energy management equipment. The onset of the AFC brought down the demand for infrastructure-related equipment for Asian countries. Leading semiconductor users in this area are Toshiba, Matsushita Electric, SANYO, Mitsubishi Electric, and Hitachi. Table 3-5 and Figure 3-5 show the Japanese semiconductor purchase ranking of industrial equipment.

Table 3-5
Japanese Semiconductor Purchase Ranking of Industrial Equipment, 1996-1997 (Billions of Yen)

1997 Rank	Company	1996	1997	Change (%)
1	Toshiba	17.4	17.5	0.6
2	Hitachi	14.0	13.0	-7.1
3	Mitsubishi Electric	12.5	12.4	-0.8
4	Matsushita Electric	10.0	11.7	17.0

Transportation

Domestic car sales in 1997 declined by around 5 percent. However, automotive equipment production saw a slight increase in all areas except car audio/video systems. Navigation system production, especially, continued to grow very rapidly. This trend benefited the semiconductor purchasing of companies such as Sony, Pioneer Electronic, and Matsushita Electric. The production of automobiles was becoming sluggish, which affected semiconductor demand in equipment in power train and body control, such as electronic control units (ECUs) and antilock brake systems (ABSs). Table 3-6 and Figure 3-6 show the Japanese semiconductor purchase ranking of transportation equipment.

Table 3-6
Japanese Semiconductor Purchase Ranking of Transportation Equipment, 1996-1997 (Billions of Yen)

1997 Rank	Company	1996	1997	Change (%)
1	Denso	65.4	64.2	-1.8
2	Sony	19.2	17.9	-6.8
3	Pioneer Electronic	15.7	17.0	8.3
4	Matsushita Communication	10.1	10.4	3.0
5	Matsushita Electric	9.9	9.9	0

Chapter 4
Japanese Semiconductor User Profiles

This section analyzes each of the major Japanese electronics companies as semiconductor users.

Canon Inc.

Canon is the world's leading manufacturer of cameras, and in the area of dedicated business systems, Canon's copier has a sizable share in the worldwide market. Also, Canon's coverage includes a lot of optical equipment; semiconductor manufacturing equipment, such as steppers; and computer peripherals, such as printers. About 40 percent of Canon's products are shipped to various export markets. Its domestic sales grew in segments such as computer peripherals; multifunctional products such as copiers, fax machines, and printers; and handy terminals.

Canon's production sites are concentrated in Japan and so is its semiconductor usage. In digital camcorders and cameras, Canon has made every effort to differentiate its products by incorporating ASICs with proprietary system function designs.

Table 4-1 shows Canon's major electronic products. Figures 4-1 through 4-3 show Canon's equipment production and semiconductor purchase trends. Computer peripherals, such as printers and scanners, and dedicated business equipment have large shares in Canon's semiconductor purchasing.

Table 4-1
Canon's Major Electronic Products

Application	Products
Data Processing	PCs, midrange computers, flexible disk drives, terminals, laser beam printers, other printers, word processors, calculators, copiers
Communications	Multifunction phones, fax machines
Consumer	Camcorders, cameras, digital still cameras
Industrial	Manufacturing systems, test and measuring equipment

Casio Computer Company Ltd.

Casio was founded to develop and market purely electric calculators applying relays used in telephone exchange systems. Later, Casio diversified its product line to include desktop and portable calculators, electric watches and clocks, LCD TVs, DSCs, and electronic musical instruments. Consumer equipment production was responsible for 52 percent of Casio's revenue, of which a large portion came from the sales of watches/clocks. Another 41 percent came from the sales of data processing equipment, including calculators, handheld computers, and peripherals. Sales of data processing equipment grew in the private-use markets, but business-use products saw a decline in sales because of a drop in unit shipments as well as in selling prices. Exports grew to represent 40 percent of the total sales. Semiconductor purchasing experienced a mild decrease, which was partly influenced by the price cuts of semiconductor devices used in data processing equipment.

Table 4-2 shows Casio's major electronic products. Figures 4-4 through 4-6 show Casio's equipment production and semiconductor purchase trends.

Denso Corporation

Car air conditioners represent one-third of Denso's revenue, having the largest share among all product lines. Another one-third is accounted for by all other automotive electronics. Although Denso is expanding its product lines to areas such as communications and appliances, sales in those areas are still comparatively small. Although car production still holds the key for Denso's overall production, the company has sought a wider customer base among worldwide car manufacturers, which has helped Denso's revenue growth to show steady trends. Semiconductor purchasing has amounted to about ¥73 billion, and 88 percent of this is for transportation equipment.

Table 4-3 shows Denso's major electronic products. Figures 4-7 through 4-9 show Denso's equipment production and semiconductor purchase trends.

Fujitsu Ltd.

Fujitsu has traditionally been dependent on the domestic market. In 1997, however, while its domestic sales grew—helped by sound market share gains in PCs—its sales of data processing and communications equipment in the Americas and Europe grew rapidly, too, contributing to a decline in dependence on the Japanese market. About 70 percent of its semiconductor purchases are in the data processing area, while the communications segment is increasing its share because of increases in infrastructure business in mobile communications handsets and base stations.

Table 4-4 shows Fujitsu's major electronic products. Figures 4-10 through 4-12 show Fujitsu's equipment production and semiconductor purchase trends.

Hitachi Ltd.

Hitachi is a typical Japanese "general electric" company, having its basis on heavy-industry electric equipment and having a wide range of product offerings. Computers and communications are contributing to corporate profits. Data processing and communications products have large shares of semiconductor purchasing.

Table 4-5 shows Hitachi's major electronic products. Figures 4-13 through 4-15 show Hitachi's equipment production and semiconductor purchase trends.

Kyushu Matsushita Electric Co. Ltd.

Kyushu Matsushita has focused on the data processing, communications, and industrial areas, including factory automation (FA) equipment. One-half of its products are exported, while cordless phones are increasing in production targeted at both the domestic and overseas markets. In the FA area, the company has a wide coverage, including chip mounters. The majority of its semiconductor purchasing is in communications and peripheral equipment for export markets.

Table 4-6 shows Kyushu Matsushita's major electronic products. Figures 4-16 through 4-18 show Kyushu Matsushita's equipment production and semiconductor purchase trends.

Matsushita Electric Industrial Company Ltd.

Matsushita Electric had a difficult year in 1997. In the consumer area, audio/video equipment experienced steady sales, helped by MD and digital video equipment, while the sales of appliances such as air conditioners and refrigerators decreased. On the other hand, communications equipment experienced an increase in revenue. Contributing to that growth were fax machines, cordless phones, PDCs, and broadcasting equipment that grew with increasing sales of the new digital video format (DVCPRO) products. The majority of Matsushita's semiconductor purchasing is in consumer applications, while the highest growth rate in its semiconductor purchasing was recorded in communications.

Table 4-7 shows Matsushita Electric's major electronic products. Figures 4-19 through 4-21 show Matsushita Electric's equipment production and semiconductor purchase trends.

Matsushita Communication Industrial Co. Ltd.

Nearly one-half of Matsushita Communication's sales comes from communications equipment, including digital cellular phones for NTT DoCoMo. While the overall Japanese economy is in recession, Matsushita Communication's business has a clear focus on the growing sector of communications, showing a large increase in semiconductor purchasing, too.

Table 4-8 shows Matsushita Communication's major electronic products. Figures 4-22 through 4-24 show Matsushita Communication's equipment production and semiconductor purchase trends.

Matsushita Kotobuki Electronics Industries Ltd.

Matsushita Kotobuki has strength in storage devices such as CD-ROM, CD-R, and the emerging DVD-RAM, as well as in consumer appliances and industrial equipment. The majority of its semiconductor purchasing is in consumer equipment.

Table 4-9 shows Matsushita Kotobuki's major electronic products. Figures 4-25 through 4-27 show Matsushita Kotobuki's equipment production and semiconductor purchase trends.

Mitsubishi Electric Corporation

Mitsubishi Electric is the third-largest "general electric" company in Japan; its products range from data processing, communications, and consumer, to heavy electric and industrial products. It experienced growth in wired communications and data processing, helped by the systems integration business. However, the decline in sales in appliances, heavy electric products, and industrial products brought the overall sales down. Data processing has the largest share of semiconductor purchasing, while the largest gain was seen in communications and the largest loss was felt in the consumer segment.

Table 4-10 shows Mitsubishi Electric's major electronic products. Figures 4-28 through 4-30 show Mitsubishi Electric's equipment production and semiconductor purchase trends.

Table 4-10

NEC Corporation

NEC's core business has been in the communications area, while it leads the Japanese computer industry as well. The infrastructure equipment market in various Asian countries brought increases in communications equipment production and sales as well as in domestic NTT infrastructure equipment production. NEC was positioned as the second-largest company in terms of Japanese digital cellular phone market share in 1997.

Table 4-11 shows NEC's major electronic products. Figures 4-31 through 4-33 show NEC's equipment production and semiconductor purchase trends.

Nintendo Corporation

Nintendo boasts a wide range of product offerings in game machines, including the 8-bit Game Boy, 16-bit Super Famicon, and 64-bit Nintendo64. In particular, 8-bit machines have experienced constant expansion in market, with their portability and inexpensive pricing. Nintendo's TV games have fared better in export markets such as the United States than in the domestic market, but Nintendo's overall exports are still small in volume. Semiconductor purchasing rose because of production increases of Nintendo64s and 8-bit Game Boys with popular games such as "Pocket Monster."

Table 4-12 shows Nintendo's major electronic products. Figures 4-34 through 4-36 show Nintendo's equipment production and semiconductor purchase trends.

Oki Electric Industries Company Ltd.

Oki has its focus on the domestic communications market, leveraging on its strong tie with NTT. Oki also sought to expand its business in midrange computers and peripherals such as printers, but the lack of integration in product offerings brought growth only to limited segments, and Oki's overall data processing business has yet to become comparable to other leading companies in Japan.

Table 4-13 shows Oki's major electronic products. Figures 4-37 through 4-39 show Oki's equipment production and semiconductor purchase trends.

Pioneer Electronic Corporation

Sales declines in laser discs and karaoke systems hurt Pioneer Electronic's overall revenue, but growth was seen in DV-Cs, MDs, DVDs, and in-car navigation systems. The company's expertise in the optical disc business has encouraged it to penetrate into business-use systems and FA equipment. It is also placing new emphasis on the video business. Pioneer Electronic also has unique product lines in cellular phones and cordless phones, but the business sizes of those areas have yet to grow.

Table 4-14 shows Pioneer Electronic's major electronic products. Figures 4-40 through 4-42 show Pioneer Electronic's equipment production and semiconductor purchase trends.

Ricoh Company Ltd.

Ricoh is a manufacturer of dedicated data processing systems. In 1997, copy machines represented nearly 70 percent of its sales. Ricoh has leveraged on image processing technologies and has become the top vendor of facsimile machines in Japan. Optical products, including cameras and DSCs, recorded two-digit growth in sales in 1997. In the area of data processing peripherals, Ricoh has developed CD-RW media drives, offering new media that enable "Write" and "Delete" in CDs. As the penetration of office-use dedicated systems becomes high, Ricoh's continuous growth in production is not so easy. Ricoh has established global production sites in countries such as the United States, Europe, and Asia, including China, resulting in a comparatively low export ratio of about one-fourth of total sales.

Table 4-15 shows Ricoh's major electronic products. Figures 4-43 through 4-45 show Ricoh's equipment production and semiconductor purchase trends.

Table 4-15

SANYO Electric Company Ltd.

SANYO has successfully leveraged on its expertise in digital audio systems by penetrating into storage devices such as CD-ROM. Its audio technology has also helped it to develop communications products such as cordless phones and fax machines, which are growing steadily. SANYO is known to be very aggressive in seeking export markets as well as overseas equipment production. Because of this, its semiconductor purchasing in Japan has demonstrated only a constant trend, betraying its worldwide equipment revenue growth.

Table 4-16 shows SANYO's major electronic products. Figures 4-46 through 4-48 show SANYO's equipment production and semiconductor purchase trends.

SEGA Corporation

SEGA has a diversified business, including game machines and software for home use, amusement machines for business use, karaoke systems, and entertainment centers (similar to a video arcade but also including restaurants, movie theaters, and so forth) with its own machines. Home-use and business-use machines each represent 35 percent of SEGA's total revenue, and 18 percent of those machines are exported. While SEGA fares well in business-use machines, including pachinko, it is losing ground in the hardware of TV games to two other large competitors. As a result, SEGA's semiconductor purchasing declined in 1997.

Table 4-17 shows SEGA's major electronic products. Figures 4-49 through 4-51 show SEGA's equipment production and semiconductor purchase trends.

Seiko Epson Corporation

Data processing equipment, including PCs and peripherals, represents about one-half of Seiko Epson's revenue, with printers as the leading product. Seiko Epson also has entered the DSC market, along with its traditional product line of scanners. Other product offerings include LCD panels and application equipment, such as TV and video equipment, electric watches/clocks, and FA equipment, but the combined sales of these represent only 10 percent of total sales. Seiko Epson has been aggressive in setting up overseas production in various parts of the world, including the United States, Europe, and Asian countries, resulting in a low export ratio from Japan. Eighty percent of its semiconductor purchasing is in data processing.

Table 4-18 shows Seiko Epson's major electronic products. Figures 4-52 through 4-54 show Seiko Epson's equipment production and semiconductor purchase trends.

Sharp Electronics Corporation

Sharp's technology and products have a clear focus: LCD products. This core competence has led the company to effectively market application products such as note PCs, digital video products, and personal digital assistants (PDAs), represented by the well-known "Zaurus" product line. While Sharp's traditional consumer product lines declined, its communications equipment lines expanded. As a result, Sharp's semiconductor purchasing has increased.

Sony Corporation

The trends toward digital consumer equipment are bringing audio/video equipment another stage of business opportunity. Growth in mobile communications has exceeded expectations. Broadcast equipment has brought sound profits, but Sony is increasingly exposed to harsh competition. Sony has leveraged on its optical disc technology to grow in computer peripherals, such as CD-ROM, but it is not free from intense competition. Sony has experienced outstanding success in the game machine area. Thus, growth in various product areas increased Sony's semiconductor purchasing in 1997, while most other consumer-oriented manufacturers decreased their semiconductor spending.

Table 4-20 shows Sony's major electronic products. Figures 4-58 through 4-60 show Sony's equipment production and semiconductor purchase trends.

Toshiba Corporation

Toshiba has been known as the second-largest "general electric" company in Japan, covering all of the heavy electric, IT, and consumer equipment segments. Its recent focus, however, clearly has been in communications and data processing, where cellular phones and note PCs lead overall revenue growth.

Toshiba's semiconductor purchasing has decreased slightly because of sluggish production in the home appliance area, even though communications experienced an increase in semiconductor usage. In the consumer segment, Toshiba has been spreading production sites, resulting in large semiconductor spending outside Japan.

Table 4-21 shows Toshiba's major electronic products. Figures 4-61 through 4-63 show Toshiba's equipment production and semiconductor purchase trends.

Victor Company of Japan Limited

Victor Company of Japan (JVC) belongs to the Matsushita Group, but it has sought its own proprietary technology and markets; for example, it developed its own original digital camcorders. Victor's core competence lies in audio/video equipment, for both broadcasting and business use; however, it is expanding its product line to include cordless phones and PHSs. The production of computer peripherals—mainly optical discs—is expanding, but fierce competition is hurting its profits. Digital consumer equipment holds the key to Victor's future success. It may also need to explore the possibility of overseas operation.

Table 4-22 shows Victor's major electronic products. Figures 4-64 through 4-66 show Victor's equipment production and semiconductor purchase trends.

Dataquest Perspective

This survey and analysis is based on the results in 1996 and 1997, which were not years when the Japanese market showed a clear direction of future growth. Instead, those were the years when the Japanese market lost ground to foreign markets. Nevertheless, the results of this analysis seem to point out the following key concepts:

- Large companies are not necessarily going to be growth engines in Japanese electronics production, nor will they be stable and strong, if they do not have competitive products in key, growing categories.
- In the consumer category, companies of various sizes are increasing production, leveraging on new, niche product offerings.
- The growth rate of semiconductor purchasing was stronger among smaller users not included in the top 22 companies analyzed in this report.
- The category that is driving growth has shifted from data processing to communications, and in the future, users in this category will be the target customers for semiconductor vendors selling into Japan.
- Companies using semiconductors are changing their business focus, affecting semiconductor purchasing by application. Semiconductor vendors will need to focus more on tracking each user's trends rather than on measuring application markets en masse.

It should be noted that digital consumer equipment is rising steadily even though the market size is still small. Also, the production sites of Japanese electronics companies are becoming more and more regionally diversified. Moreover, sluggishness in Japanese production does not correlate with some companies' worldwide activity.

The previous statements, however, suggest the need for vendors to review customer-support strategies, especially at a time when system-oriented marketing and system-level integration (SLI) are becoming the keys to success, but these are also beginning to represent a larger load for vendors.

A more detailed analysis by application will identify the exact drivers of semiconductor consumption growth for each company using semiconductors. Also, it is essential to look into the technology potential of these companies to decide strategies for each company, both in terms of system technology to be incorporated into system-oriented chips and in terms of supporting the development of such chips, including SLI ASICs. This report does not describe whether internal user divisions are contributing to semiconductor divisions' sales, system marketing capability, and product development.

Dataquest believes that, in the era of SLI, semiconductor vendors face the challenge of strengthening their customer support and system-oriented marketing capability.

List of Figures

List of Tables

Chapter 1
Executive Summary

Despite continued economic troubles in Japan and elsewhere in Asia, Japanese vendors still engaged in a relatively high number of semiconductor-related alliances in 1997. For the second year in a row, the number of Japanese semiconductor-related alliances rose. Figure 1-1 illustrates the Japanese semiconductor alliance rate from 1980 through 1997.

There are growing indications from alliance activity in 1997 that Japanese vendors are banking on the market success of merged logic-DRAM technology as the future mainstay of their semiconductor businesses. The timing of a transition from a DRAM-centric to an embedded DRAM-centric strategy is significant, because a miscalculation by Japanese vendors could cause them to lose ground in the development of next-generation commodity DRAMs while they divert resources toward the development of embedded DRAM products. The possible gains, however, are significant because the technology has the potential to increase market share in the application-specific IC (ASIC) and logic businesses, a goal that most Japanese vendors have targeted for several years. Alliances not only will allow Japanese vendors to redistribute their resources from a DRAM to an embedded DRAM production orientation, which would effectively merge their now separate memory and logic businesses into a single unit, but they might also provide a fast-response safety net in case the companies' projected time line is off and they need to retreat to a more conservative strategy. If the embedded DRAM technology, for whatever reason, fails to mature before commodity DRAMs return to a supply-limited market, alliances will almost certainly be used as a mechanism for Japanese companies to get back into the commodity DRAM business.

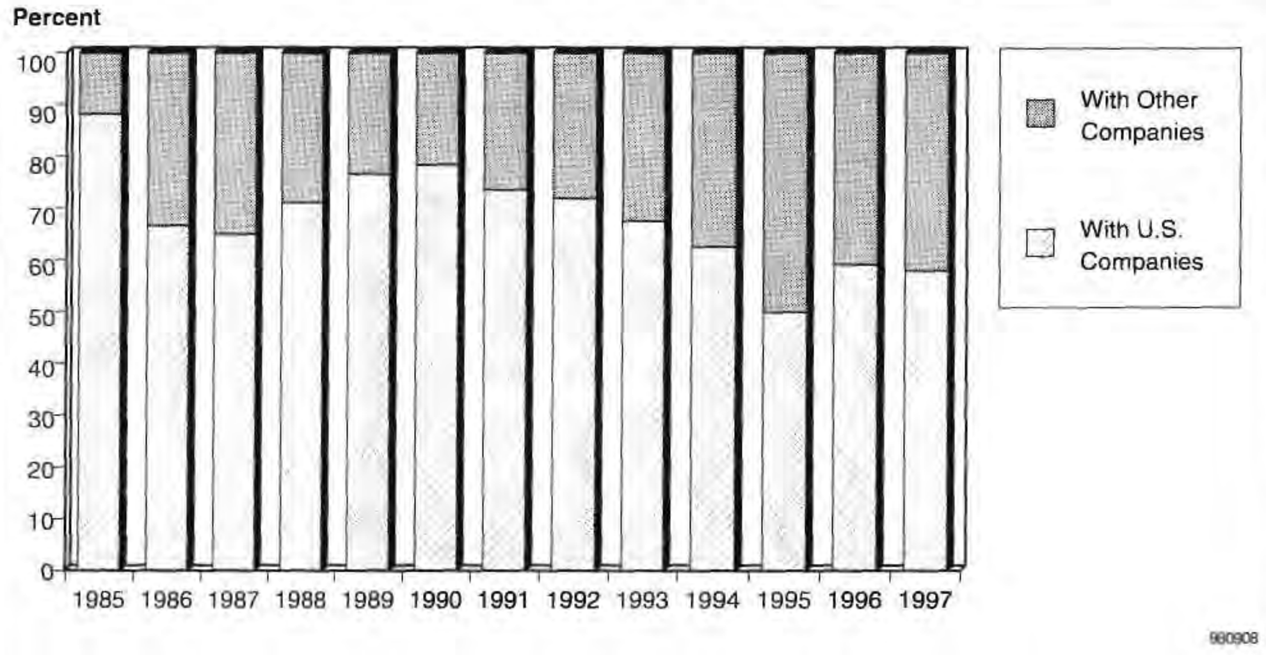
Chapter 2
Diversification and Resource Allocation with Alliances

Many parts of the electronics industry were showing signs of weakness as 1997 came to a close. DRAM production lines were either being shut down or had their expansion plans delayed. Semiconductor fabrication equipment manufacturers experienced order cancellations that eventually led to layoffs of substantial portions of their workforces. Even application vendors, such as disk drive producers, were experiencing market pressures that have resulted in corporate restructuring. While the economic crisis in many parts of Asia, particularly Korea, has forced a change in the semiconductor business practices at companies in these countries and will undoubtedly have a ripple effect on electronics companies worldwide, Japan's economy has, for several years, remained in a state bordering on recession. Despite the weak economic condition of Japan, its domestic PC markets were expected to continue the growth trend that had been established during the previous year. During 1996, PC prices had fallen to world market levels, which caused a growth spurt in PC sales. However, by mid-1997, sales had flattened even though DRAM prices continued to fall, lower-priced machines had been introduced into the Japanese market, and PCs had far less penetration in the Japanese home market than in the United States.

The economic crisis that was beginning to affect many Asian countries in the last quarter of 1997 does not seem to have had much impact on the overall number of alliances that Japanese companies signed in specific countries or regions in the past two years. Nearly 60 percent of the Japan's semiconductor alliances formed in 1997 were with U.S.-based partners. This level is more or less unchanged from 1996 and reflects the continued importance that Japanese vendors place on partnerships with American companies. Figure 2-1 shows the percentage of the alliances that pair a Japanese company with a U.S.-based company over the last 13 years.

©1998 Dataquest

Figure 2-1
Japanese Semiconductor Alliances (U.S. Partners versus Non-U.S. Partners)



Source: Dataquest (March 1998)

DRAMs and 300mm Equipment

In 1997, Japanese vendors continued their quest to diversify away from their traditional overdependence on DRAM revenue. However, in implementing diversification plans, there are often conflicting goals that require a delicate balance of priorities in business strategy, particularly with regard to alliances. A transition to 300mm wafer production is clearly a long-term technology change that all major Japanese vendors will seek to make to remain cost competitive, but it will be difficult to justify the necessary investment in the face of a money-losing DRAM business. Furthermore, most vendors will need to secure permanent sources of commodity DRAMs for both internal consumption and to maintain their semiconductor sales organizations. The difficulty of achieving these goals increased during the year as DRAM prices continued to fall in an oversupplied market. The mass transition to 300mm production technology will occur eventually, but the weak DRAM market will likely delay or slow the adoption rate, because the large-scale equipment consumption of the commodity DRAM manufacturers will be a prerequisite to reducing the cost of 300mm equipment and make it affordable to the majority of logic and ASIC producers. For this reason, commodity DRAM alliances will likely continue with specific emphasis on 300mm equipment development. On the other hand, if DRAMs do not return to profitability before deployment of embedded DRAM products that can generate self-sustaining revenue, then a company could justify minimizing its DRAM-specific investments, farm out commodity DRAM production, and focus resources on building and accelerating its embedded DRAM capabilities. Alliances seem to provide a lot of flexibility for companies to distribute their resources to match their particular array of priorities.

 ©1998 Dataquest

Alliances Send DRAM Production to Partners

Four alliances explicitly involving commodity DRAM occurred in 1997, but almost all can be interpreted within the context of a strategy that diversifies away from an emphasis on the commodity DRAM business (see Table 2-1). This has generally meant developing 300mm technology in joint ventures or licensing DRAM production technology to foreign-based companies, of which the Japanese company may hold a minority stake, in order to secure production output. As an example of transferring DRAM production to foreign companies, Toshiba Corporation agreed in February 1997 to purchase 20 percent of the Austin, Texas-based 64Mb DRAM facility of Samsung Electronics Company Ltd., allowing OEM procurement for Toshiba of 20 percent of the production output. In September 1997, Toshiba also provided Taiwan-based Winbond Electronics Corporation with DRAM production technology, which will secure a supply of both 64Mb and 256Mb from the Taiwan-based facility. Finally, in October 1997, Mitsubishi Electric Corporation agreed to provide Seiko Epson Corporation with 64Mb production technology. Mitsubishi will initially purchase all the production output of Seiko Epson's Sakata plant. Earlier, in May 1997, Mitsubishi had licensed Seiko Epson to produce video memory, also to be built at the Sakata plant, that would integrate 10Mb of DRAM with 2Kb of SRAM and graphics interface logic. All these alliances are consistent with a strategy of diversifying resources away from commodity DRAMs.

The only major joint venture of 1997 involving DRAMs was signed in February by Hitachi Ltd., Mitsubishi, and Texas Instruments Inc. and specified that the partners would jointly develop 1Gb DRAMs. However, this project was put on hold in February 1998. Although the partners have specified that they will resume joint development of 1Gb DRAM in one year, the future of this project will probably depend on the market outlook in 1999.

Table 2-1
DRAM and Next-Generation Wafer/Production Alliances

File Number	Company 1	Company 2	Product	Date
9	Fujitsu	Advantest	Advanced electron beam exposure system	February

70	Seiko Epson	Mitsubishi	64Mb DRAM design, technology	October

Source: Dataquest (March 1998)

When Will 300mm Standardization Arrive?

Several other alliances made in 1997 address 300mm technology development.

Toshiba and IBM will cooperate in commercializing 300mm production, and will possibly set up a 300mm line at their joint production plant. Similarly, NEC Corporation and Samsung have agreed to share development of 300mm wafer fabrication equipment and technology across their memory plants. Both alliances are expected to have operational 300mm wafer production lines up and running by 1999. The oversupply of DRAMs, along with weak Asian currencies and economies, are contributing to very tentative ramp-ups of Japanese, Korean, and Taiwanese next-generation DRAM and 300mm wafer facilities. However, although no company has voiced concern, it seems that, if Japanese companies intend to focus their semiconductor businesses on embedded DRAM products, then they would not want any delay in the arrival of next-generation DRAM capabilities that would impede the transition to the next level of embedded DRAM products. This, of course, assumes there exists a next-level single-chip device or application that can use the higher amounts of DRAM, and presumably faster logic, provided by the next-generation merged processes. The applications that will drive the adoption of next-generation embedded DRAM products are not clear, but there are a few candidates, as described in the following sections. This uncertainty is a looming factor in the decision process that will dictate how Japanese vendors structure their alliance activities.

From DRAMs to Embedded DRAMs: How Fast Can We Get There?

There are skeptics, including individuals representing companies such as Intel Corporation, who have voiced their conviction that embedded DRAM technology will never become a mainstream technology. The basis of their argument is that the logic and memory processes of the future are incompatible. Nevertheless, if the critics are proven wrong, this would be somewhat ironic because Intel itself has essentially used its own processing expertise, including the use of BiCMOS, to counter the assault of RISC, with its inherent performance advantages, over the last few years. There have been many processing transitions over the years, such as NMOS to CMOS and bipolar to BiCMOS, and with each transition, there were always a few who either did not believe the new technology would ever become competitive or who miscalculated the timing of the transition. Today, there are enough companies that seem convinced that combining DRAM with fast logic is both feasible and an inevitable mainstream technology that one must consider the implications if these companies are correct. History has frequently proven that processing and circuit innovation has consistently surmounted the barriers they have encountered. The accuracy of Moore's law is a testament to the steady progress being made in integration capabilities. Table 2-2 lists the alliances occurring in 1997 that explicitly covered embedded DRAM technology. However, many of the other alliances of 1997, particularly those relating to RISC MPUs—described in a subsequent section—have also been extended to cover embedded DRAM technology. This is a logical extension of these alliances, since many RISC alliances involve the use of cores in ASIC libraries, which have recently been expanded to include embedded DRAM in addition to the usual RISC cores.

Table 2-2
Embedded-Related Alliances

File Number	Company 1	Company 2	Product	Date
87	Toshiba	Sun Microsystems	Embedded Java processors	April

Notebook Graphics Accelerators Still the Only Application for Embedded DRAM in 1997

In contrast to the splash that embedded DRAM alliances made in 1996, the alliance activity involving embedded DRAM technology in 1997 was very subdued. Part of the reason for this is that the graphic accelerator market, the initial market to capitalize on the benefits of embedded DRAM technology, had become overcrowded in 1997. Too many players meant steep drops in accelerator prices and shrinking market windows that resulted in some once high-flying start-ups dropping off the radar screen. With these conditions, it wasn't surprising that the shifts in the market diverted attention away from the progress being made on the merged logic-DRAM processing front. Moreover, falling graphics controller and accompanying memory prices may have also confined the embedded DRAM graphics controllers to the notebook segment only, where power efficiency is the primary selling point, and prevented migration to the desktop world, where the ratio of processing power to cost is usually the only criterion that determines market success.

Although only three or four alliances explicitly involving embedded DRAM technology were signed by Japanese companies in 1997, two of the 1997 alliances were inked by Toshiba. In June, Toshiba licensed its 0.35-micron DRAM-mixed logic technology, later to be migrated to 0.25-micron, to Chartered Semiconductor Mfg. Pte. Ltd. of Singapore. Chartered is expected to launch production with this technology in 1998. As an update to a Toshiba-Chromatic Research Inc. alliance formed in 1995, Toshiba has disclosed plans to use the second generation of Chromatic's Mpact 2 core in an embedded DRAM chip targeting notebook computers. The Mpact DSP uses a very long instruction word architecture, and the Toshiba part will be built sometime in 1998 with 4MB of DRAM and a 128-bit internal bus using Toshiba's 0.25-micron merged logic-DRAM process. The Mpact 1 and 2 were originally designed to use the Rambus DRAM and interface, and the move to an embedded DRAM part is expected to reduce power consumption by several watts, an important savings for notebook applications.

©1998 Dataquest

Interestingly, Toshiba also signed an alliance agreement in May 1997 to act as foundry for NeoMagic Corporation notebook graphics controllers. Strong demand for NeoMagic controllers has evidently required the company to supplement its supply of controllers being produced by Mitsubishi. Mitsubishi, an original investor in NeoMagic, will continue to make embedded DRAM controllers for NeoMagic; however, both Mitsubishi and Toshiba are, or shortly will become, competitors to NeoMagic because both have plans to build graphic controllers for notebook applications using their own designs and embedded DRAM technology. As seen below, the Mpact digital signal processor (DSP) is not the only device intended to make a transition from an external Rambus memory interface to an embedded DRAM solution.

Teams Research Multiple-MPU Parallel Processing with Embedded DRAM

Although no Japanese vendor has yet announced a formal alliance with the start-up PixelFusion Limited, based in Bristol, England, its work is particularly interesting in that it is specifically addressing the needs of the very high end of 3-D graphics accelerators by using massively parallel designs, developed at the University of North Carolina at Chapel Hill, in conjunction with an implementation in a merged logic-DRAM process. Silicon prototypes have been built by Chartered Semiconductor Manufacturing of Singapore, but the demands of building numerous processing units with large amounts of memory on a single chip may call for cutting-edge processes. It would therefore not be surprising if PixelFusion sought Japanese vendors as alliance partners to build its production designs. Indeed, the work at PixelFusion parallels the three-year research project being conducted at a Japanese consortium formed at the end of 1996. Based on the work of Professor Murakami from Kyushu University, the consortium initially anticipated that media processors using parallel processing architecture would reach the market by 1998. Similarly, a European research consortium, based at a university in Belgium, announced in December 1997 its intention to develop MPEG-4 chips that will be implemented with mixed logic-DRAM technology. Japanese partners have been included in the consortium, and project is also scheduled to run for three years, beginning in January 1998.

Because Japanese vendors arguably have been working on the development of embedded DRAM technology the longest, they have entered into several noteworthy alliances covering embedded DRAMs. This alliance activity is expected to continue; however, it should also be noted that there are conflicts within the industry that seem to be having a distinctly antialliance effect. Japanese vendors are currently suing several of their major Korean DRAM competitors for royalty payments, and, in some cases, seeking injunctions designed to prevent Korean vendors from selling their parts in the United States. With the Koreans expected to follow the Japanese vendors into the merged DRAM-logic markets, it may be that recent legal actions against the Korean companies are designed to force these competitors to pay for some of the cost of developing an embedded DRAM technology that is likely to benefit all manufacturers eventually, including Korean vendors.

©1998 Dataquest

As strange as it might sound, the legal action may actually have the effect of promoting alliances involving embedded DRAM development between Japanese and Korean vendors. Considering the lack of profit from the sales of commodity DRAMs, the cost of developing embedded DRAM technology will be difficult to sustain—predicting when a profitable return-on-investment will occur is not trivial, because it is dependent on finding the right uses for the technology at the right time. Furthermore, once an effective embedded DRAM process is achieved, the learning curve for nondevelopers will be simplified by information passing by way of both direct and indirect alliances. The Korean memory vendors will benefit from the pioneering work and probably cannot afford to pioneer the technology independently. The recent legal action by Japanese vendors is expected to force some Korean vendors to at least discuss either royalty payments, which would help defray the cost of developing technology, or more alliances in which vendors share the development cost of next-generation technologies.

ASICs Combine RISC Cores with Embedded DRAM to Open New Application Areas

Embedded DRAM may need to become the primary driver of the transition to 300mm technology if DRAMs continue to provide inadequate return on investment. Intel is sufficiently afraid of a mass vendor exit from the commodity DRAM business and the potential for a subsequent DRAM shortage that might affect its own microprocessor sales that the company is considering boosting its investments in major DRAM vendors by $1 billion. Meanwhile, most Japanese vendors are pushing ahead with research and development of merged logic and DRAM processes that seeks to minimize performance compromises. Besides graphics controllers for portable computing platforms, embedded DRAM products were expected to make their next appearance in hard disk drives. Because the disk drive industry seems to be in turmoil, there is less discussion of this happening soon. However, many other applications are being discussed as possible system-on-a-chip implementations that would include on-chip DRAM. A number of alliances that originally covered collaboration or licensing of RISC technology have been expanded to include RISC microcontroller (MCU) cores combined with embedded DRAM.

Alliances in Video Games, Windows CE Machines, ...

NEC is working with Nintendo Company Ltd. to eventually migrate its MIPS RISC-based video game controllers away from use of a Rambus memory interface architecture to a more efficient embedded DRAM solution. As with most custom ASICs, this can result in a lower cost-to-performance ratio in very high-volume applications only, such as video game consoles. This application is interesting because it represents a mass market product that, unlike the notebook graphics controller, is probably not using the superior power consumption efficiency of the embedded DRAM technology as its primary selling point. NEC expects to have available to ASIC customers by spring 1998 the capability of merging 200-MHz logic with 32Mb of 100-MHz DRAM connected over a 128-bit bus.

©1998 Dataquest

The electrical and market performance of both the Nintendo embedded DRAM video controller and Toshiba's embedded DRAM Mpact 2 chip, both having potentially abandoned the Rambus interface and memory combination, may provide an interesting comparison benchmark for ASIC customers thus far unconvinced of the advantages of using embedded DRAM technology.

In early February 1998, Sega Inc. confirmed a long-rumored alliance with Microsoft Corporation to cooperate on the construction of a game machine. The confirmation by Sega included the revelation that the new platform will use the Windows CE operating system. Just as with the Nintendo-NEC alliance, the Sega-Microsoft game console is an application that can benefit from the use of an integrated game controller that merges embedded DRAM with logic. Dataquest would therefore expect to see in the not too distant future an alliance with a semiconductor producer, such as a manufacturer already building RISC cores for Windows CE platforms and probably at least planning on an embedded DRAM version of the Windows CE device. A large and growing number of vendors would qualify for such a project.

In the first quarter of 1997, Mitsubishi began working with ACCESS Corporation to customize a Mitsubishi chipset for use in portable Internet terminals, which include the M32R/D, a 32-bit RISC processor currently embedded with 2MB of DRAM. This processor family is scheduled to reach a clock speed of 400 MHz with 16MB of embedded DRAM, built with a 0.2-micron geometry, by the year 2000. Mitsubishi will also codevelop, as well as cross license, microcomponent cores embedded with DRAM with Motorola Incorporated, as a continuation of an alliance formed in October 1996. This alliance involves an embedded DRAM version of Mitsubishi's M32R and Motorola's 68EC000 and Coldfire processors.

In the second quarter of 1997, Toshiba partnered with Sun Microsystems Inc. to develop a Java processor for use in network computers. The microJava chip will incorporate a picoJava core, a memory controller, and embedded DRAM. Toshiba also announced in July 1997 the development of its MIPS based, Virtual Socket Interface (VSI)-compliant, TX19. This is a low-power, low-cost, embedded RISC processor that Toshiba intends to combine with embedded DRAM in the company's 0.25-micron DRAM-ASIC process.

In the third quarter of 1997, Hitachi announced that its SH-3 and SH-4 RISC MPU cores would be available in an embedded DRAM-enabled 0.35-micron process that ASIC clients can use to add DRAM in 256Kb increments, called "micromodules" by Hitachi. By 1999, Hitachi expects to field an SH-4 core with flash and micromodules based on 256Mb 0.25-micron DRAM technology. The number of RISC core license agreements, combined with embedded DRAM agreements, would suggest that mobile computing devices, particularly Windows CE machines, are expected to become a significant product segment making heavy use of system-on-a-chip designs that include embedded DRAM.

In the fourth quarter of 1997, NEC and Lucent Technologies formalized an alliance that has Lucent licensing NEC's V800 series of RISC MCUs. As part of this alliance and possibly two previous alliances formed between the partners in June and October 1996, the two companies are said to be working together on an embedded DRAM process that Lucent expects to incorporate into its own 0.25-micron ASIC process by mid-1999.

Table 2-3 shows the alliances that covered RISC technology in 1997.

Table 2-3
RISC-Related Alliances

File Number	Company 1	Company 2	Product	Date
38	Mitsubishi	Access	M32R-base embedded DRAM chipset	February
49	NEC	Wind River Systems	Embedded RISC operating system	January
19	Hitachi	Mentor Graphics	CAD tools for SH RISC processor	April
88	Toshiba	MIPS Technologies	MIPS RISC technology	April
44	Mitsubishi	Mentor Graphics	M32R-base system-on-a-chip development	June

Chapter 3

Displays, Micromachines, and Sensors Also Head toward Merged Processes

The synergy between traditional semiconductor circuits and integrated displays, sensors, and micromachines continues to grow and, in some cases, is already showing signs of merging with mainstream IC manufacturing. Moreover, VSI will facilitate the connection of not only standard IC cores, but also a growing array of new, CMOS-compatible devices that include sensors, micromachines, and even displays. Although start-up companies have always been expected to gamble on some of these esoteric technologies, many traditional IC companies, never having strayed too far from standard analog or digital IC fabrication technologies (at least in production), are also aggressively building exotic production-worthy process portfolios. For example, National Semiconductor Corporation is attempting to build active-matrix LCDs on standard wafers, Toshiba and Atmel Corporation are building CMOS image sensors, and Texas Instruments has made a heavy, highly publicized investment in its micromachined mirrors, also on standard wafers. The integration of such technologies with a memory-logic process should allow for the creation of such things as a true system-on-a-chip digital camera.

Although traditional IC manufacturing processes are incorporating more nonstandard components, from the opposite end of the processing spectrum, flat panel display manufacturers are starting to build circuits on their thin semiconductor films on glass or quartz substrates. There has been a recent surge in active-matrix LCDs research as this segment of the flat panel display industry continues to give upstart flat panel technologies a moving target. Nine new alliances involving LCDs occurred in 1997, which outpaced the LCD alliance activity of 1996. These alliances are listed in Table 3-1. The breadth of the technologies that are being combined with liquid polarizing crystals is beginning to overwhelm the work in other nascent technologies, such as field emission devices (FEDs), to the degree that some may already have missed their window of opportunity for commercialization because of the rapidly falling cost and improving performance of active-matrix LCDs. Active-matrix LCD reflective displays are being touted for their extreme power efficiency in mobile computing and communications applications, as well as for use in head-mounted displays or viewfinders in digital cameras and camcorders. Windows CE machines and personal digital assistants (PDAs) are expected to be among the first application markets to benefit from efficient reflective devices, some equipped with part-time backlighting capabilities. Sharp Electronics Corporation announced in September 1997 a reflective display for Windows CE machines that features a 30 percent reflection and 10:1 contrast ratio.

Table 3-1
Display-Related Alliances

File Number	Company 1	Company 2	Product	Date
37	Mitsubishi	Compaq	TFT LCDs	January

76	Sony	Sharp/Philips	Next-generation large LCDs	July
8	Fuji Film	Kopin	Display technology	November

Source: Dataquest (March 1998)

On the materials research front, the films used to make active-matrix LCD panels are continuing to reach higher quality levels—meaning fewer defects. Although low-temperature polysilicon films are just beginning to reach commercialization, the films still in development are even closer in characteristics to bulk crystalline silicon. The fundamental materials and thin-film transistor research is yielding advances that suggest that active-matrix LCD and system ICs may well merge into another hybrid class of devices based on yet another merged process. Along these lines, Sharp's continuous grain silicon has continued the trend of improving thin films from amorphous films toward the ultimate goal of crystalline silicon-like electrical characteristics. Achieving this goal would improve the performance of active-matrix LCDs, as well allow the construction of all peripheral circuits right on the same substrate, with improved yield. If this trend continues, the 300mm technology of the silicon wafer industry may begin to have even more in common with the flat panel TFT processing technology than it already has.

Chapter 4
Dataquest Perspective

There is a prevailing notion that for some Japanese vendors, DRAMs and embedded DRAMs have become one and the same industry. During the current DRAM oversupply, it appears that many Japanese chip vendors will continue to use alliances either to shift their commodity DRAM production to offshore joint ventures or to completely transfer their commodity production to licensed Asian partners. At the same time, the major Japanese vendors will attempt to accelerate the transition to embedded DRAM technology for a widening array of multichip products that currently use separate memory parts, particularly those that either require better power-consumption performance, such as notebook computer components, or that rely on high-speed logic-to-memory buses, such as the Rambus interface. There is certainly risk in this strategy, because the Japanese vendors may be forcing themselves to exit the commodity DRAM prematurely, at a time when embedded DRAM revenue may be insufficient to support the upgrades to 300mm equipment. However, the DRAM business for many Japanese vendors is a losing proposition with a cloudy outlook, and the successful deployment of a competitive embedded DRAM technology has the potential to boost the competitiveness of Japanese ASIC and logic businesses substantially. Moreover, alliances may also provide a fast recovery mechanism if the transition to systems-on-a-chip, using embedded DRAM technology, is delayed or the commodity DRAM business again becomes too lucrative to ignore. Regardless of how individual Japanese companies will implement their particular memory and ASIC strategies, the common denominator is certain to be their use of alliances to adapt quickly to market conditions and technology shifts. There are just too many advantages to alliances that outweigh the potential drawbacks.

The last U.S.-Japan Semiconductor Trade Agreement was allowed to expire over a year ago. The robust rate at which Japanese and U.S. companies have entered into new alliances since the expiration, as well as the continuing high market share of foreign companies in Japan, often exceeding 30 percent in the past year, provides some support for those that argue that the decision not to renew the trade agreement at the end of July 1996 was correct.

Appendix A

1997 Japanese Semiconductor Strategic Alliances

Table A-1 lists the companies involved in publicly announced strategic alliances occurring in 1997. The individual alliance agreements are summarized in Appendix.

Dataquest classifies strategic alliances into the following 12 major categories.

- LA—Licensing agreement: A Japanese company receives or issues a license to a partner for an up-front fee or royalties.
- SS—Second-source agreement: Both companies agree to develop consistent specifications to ensure a second source.
- SA—Sales agency agreement: A Japanese company sells its partner's products, either as a sales representative or value-added reseller (VAR).
- FA—Fab agreement: A Japanese company offers fab capacity for a partner's product technology.
- AT—Assembly and testing agreement: A Japanese company sends or receives devices for assembly or testing.
- TE—Technology exchange: Both companies exchange technology, which may or may not include a transfer of money.
- JV—Joint venture: The two companies form a new joint-venture company to develop, manufacture, and market new products.
- JD—Joint development: Both companies agree to develop new products jointly, which may or may not be marketed separately.
- IV—Investment: A Japanese company invests in a partner company to secure new technology or access to new markets.
- CO—Coordination of standards: A Japanese company and a partner agree to device standards to ensure compatibility.
- PC—Procurement agreement: A Japanese company agrees to buy more foreign semiconductors as part of market access program.
- OT—Other: Joint symposia and programs

Appendix B
1997 Alliance Agreements

Access

1. National Semiconductor (United States), September 1997

National Semiconductor Japan has teamed up with Tokyo-based software developer Access in the systems development for Internet-capable home electronics. The Japanese subsidiary of National Semiconductor intends to supply home electronics makers in Japan with a system-on-a-chip LSI that supports Access' Internet connection and search program, Netfront. The system-on-a-chip LSI centers around National's NS486 processor core, complying with Intel's x86 architecture, and integrates PCMCIA controller, IrDA, and other peripherals, providing all the functionality necessary to give a TV or satellite receiver Internet connectivity.

Asahi Glass

2. ASPEC Technology (United States), January 1997

Asahi Glass will market ASIC libraries developed by ASPEC Technology of the United States in Japan. ASPEC already handles ASIC libraries supporting the production processes of 15 chipmakers. The price is ¥300 million per kit. Asahi Glass has also started taking orders from customers in Japan for the ASIC Division of Hyundai Electronics, which uses ASPEC's libraries.

3. Advanced Micro Devices (United States), March 1997

Asahi Glass will step up sales of Advanced Micro Devices microprocessors this fiscal year. The company deals with AMD's Windows PC MPUs and in-built processors. For Windows PC MPUs, Asahi Glass hopes to tap demand for the K6 chip from domestic PC makers. In a move to market built-in processors for numerical control and point-of-sale systems, Asahi Glass has signed a distribution agreement with Microsoft to obtain an MS-DOS license. Plans also call for commercializing AMD MPU boards that incorporate Asahi Glass hybrid ICs.

Canon

4. Scientech (Taiwan), January 1997

Canon set up a stepper sales and support joint venture in Taiwan in early February. The company's third service center in Asia, Canon Semiconductor Equipment Taiwan will be headquartered in Taipei and will be capitalized at about ¥300 million, 80 percent by Canon and 20 percent by a local distributor, Scientech. The new company will initially be staffed by 22 employees. Canon, which has already won an order for more than 20 steppers from ProMos Technologies, a joint venture between Siemens and Mosel Vitelic of Taiwan, is aiming to nearly double its share to about 50 percent of the Taiwanese stepper market by 1999.

Dainippon Screen

5. Kyoto Technica (Japan), March 1997

Dainippon Screen Manufacturing and Kyoto Technica will jointly set up a semiconductor/LCD equipment maintenance service company. Based in Kyoto, DS Tec Kansai is capitalized at ¥50 million, with Dainippon Screen investing 82 percent and Kyoto Technica 15 percent; it will start operations with more than 100 employees. Dainippon Screen, which has entrusted maintenance service to a subsidiary and Kyoto Technica, will commission delivery and maintenance of equipment for its customers in the Kinki, Chugoku, and Shikoku regions to the new company. DS Tec Kansai is expected to achieve annual revenue of ¥1.1 billion in its first year.

DSI

6. Korean company (Korea), October 1997

DSI, a Japan-based semiconductor equipment production venture, will establish a joint venture in Korea in October to manufacture vertical electric furnaces for use in next-generation semiconductor production. To be capitalized at ¥40 million, DSI Korea will be owned 70 percent by a local company and 30 percent by DSI. With an initial staff of three salespeople and two engineers, the joint venture will have a clean room at its main office. DSI, which has been assembling vertical high-vacuum annealing systems at its Shizuoka plant, intends to scale down its domestic operations and shift manufacturing technologies and equipment to the Korean company.

Emplas

7. Hicad (China), June 1997

Emplas will set up an IC test socket sales joint venture in Shanghai with its Singapore distributor, Hicad. To be capitalized at $600,000, Emplas Hicad National Trading will import IC test sockets from Japan and launch sales in late July. The joint venture will target chipmakers, including NEC and Motorola, with IC manufacturing operations in China and will aim for annual sales of ¥2 billion in three years.

Fuji Film Microdevices

8. Kopin (United States), November 1997

Kopin and Fuji Film Microdevices, Japan, announced a strategic business agreement under which the companies will incorporate Kopin's CyberDisplay active-matrix LCD into Fuji's digital camera chipsets. Fuji and Kopin will work together to integrate Fuji charge-coupled device analog and logic circuits with Kopin's CyberDisplay. The goal of the strategic alliance is to make the chipsets available to Fuji internal and external customers by the second quarter of 1998. Based on Kopin's patented Smart Slide technology, the CyberDisplay is a 0.24-inch diagonal transmissive active-matrix LCD imaging device that displays information at 320 x 240 full-color-pixel resolution. It enables portable communications devices and personal information products to display photographic images and other data or video sources.

Fujitsu

9. Advantest (Japan), February 1997

Fujitsu and Advantest will concentrate their joint electron beam (EB) exposure system business at Advantest. The two companies jointly developed the F5120 EB exposure system for use in 256Mb or larger DRAM production, and Advantest has started marketing it. From April 1997, about 50 Fujitsu employees engaged in EB systems development will be on loan at Advantest's R&D center now under construction. Advantest expects to sell five of the ¥1 billion systems the first year.

10. LG Semicon (Korea), March 1997

Fujitsu and LG Semicon in Korea will unify the design guides of their proprietary chip-scale packages under the name "USON," for ultrathin small-outline nonleaded package. The companies plan to ask the Joint Electronic Device Engineering Council (JEDEC) to designate USON as a new standard package for memory devices. Fujitsu developed a chip-scale SON package, which has been used for its flash memory since September 1996. Compared with the conventional thin small-outline package (TSOP), the company claims, the SON package takes up about half the space in mounting, is two-thirds of the thickness, and is half the weight for 16Mb flash memory. LG Semicon developed the bottom-leaded plastic (BLP) package and has been using it for DRAM packaging. BLP is almost the same size as SON.

11. Sand Microelectronics (United States), March 1997

Fujitsu will license Virtual Socket Interface (VSI)-compliant Universal Serial Bus (USB) microcomponents from Sand Microelectronics and will commercialize a microcontroller with integrated USB microcomponents for use in monitors. The USB interface allows peripheral equipment to be connected with the PC with ease. By supporting the USB macro, Fujitsu will be able to offer LSIs that support various standard interfaces, including IEEE 1394, SCSI, and IrDA.

12. Nantong Huada Microelectronics (China), May 1997

Fujitsu has reached agreement with leading Chinese chipmaker Nantong Huada Microelectronics to establish a semiconductor assembly joint venture in China in late June. To be capitalized at $10 million, Nantong Fujitsu Microelectronics will be owned 40 percent and 60 percent by the Japanese and the Chinese companies, respectively. The joint venture will initially employ 400 people to assemble 10 million microcontrollers and linear ICs per month and will construct a new facility starting in fiscal 1998 to raise output to 40 million units.

13. Rambus (United States), July 1997

Fujitsu will team up with Rambus of California in 64Mb high-speed DRAM technology. Fujitsu will receive high-bandwidth Direct Rambus DRAM technology to develop memory systems with gigabyte-per-second-class data transfer speeds. A major reason for the alliance seems to be Intel's plan to use DRAMs with the Rambus interface as the main memory for PCs that will ship starting from 1999. Rambus' high-speed DRAM technology has been transferred to most of DRAM makers including NEC, Toshiba, Hitachi, Samsung, LG Semicon, and Hyundai.

14. Orckit (Israel), August 1997

Fujitsu Microelectronics and Orckit Communications are teaming up to produce a single-chip, discrete multitone-standard-based Asymmetric Digital Subscriber Line (ADSL) modem. The companies will recast Orckit's two-chip digital solution and its analog front-end, currently based on discrete components, into a 0.35-micron mixed-signal CMOS chip. They will also add Asynchronous Transfer Mode (ATM) and rate-adaptation features in line with a new definition of ADSL known as Issue II. Fujitsu will market the device commercially and to Orckit. The chip is expected to be available in mid-1998.

15. Advanced Micro Devices (United States), October 1997

Advanced Micro Devices and Fujitsu will codevelop a serial NAND-type flash memory architecture, and they expect to begin production with a 64Mb device by October 1999. The two companies currently manufacture NOR-type flash at a joint-venture fab in Aizuwakamatsu, Japan, and have not sold serial flash, which offers a smaller cell size at the expense of random access speeds. A team with staff from both companies is being formed to develop the NAND-type architecture.

16. Sun Microsystems (United States), November 1997

Fujitsu has reached agreement with Sun Microsystems to license Sun's picoJava I, a Java microprocessor core. The company will develop 32-bit RISC microcontroller core specialized in Java software using 0.35-micron technology in 1998 and begin marketing the core for use in PDAs and cellular phones in 1999. The Java processor based on picoJava I is reported to outperform conventional RISC processors such as the SPARClite by a factor of five, and Fujitsu plans to use 0.25-micron technology to expand the core's applications to Network Computers. The company is aiming for Java MPU core sales of ¥10 billion in 2001, and ¥50 billion, or 30 percent of the dedicated Java MPU market, in 2003.

Furukawa Electric

17. Lucent Technologies (United States), February 1997

Furukawa Electric and Lucent Technologies have established an optical semiconductor assembly joint venture in the United States. Finet Technologies will assemble laser diodes, photo detectors, and other optical semiconductors starting in April and will market the products through the partners' sales channels in Japan and the United States. Furukawa and Lucent, already joined in an optical fiber cable manufacturing venture, Fitel Lucent Technologies, plan to invest a total of about $10 million in the new joint venture by fiscal year 2000.

 ©1998 Dataquest

Gunze Sangyo

18. Plasmaquest (United States), February 1997

Gunze Sangyo has acquired a capital stake in Texas-based semiconductor equipment maker Plasmaquest. Gunze, which has been distributing plasma etching and plasma chemical vapor deposition systems made by Plasmaquest in Japan since 1993, has bought with its U.S. subsidiary, Gunsan America, 14.81 percent of the U.S. company for $1 million. Plasmaquest needed financial support to expand production capacity to keep up with brisk demand for etching equipment in the North American market. Gunze wants to expand Japanese sales of Plasmaquest products to ¥1 billion in two years.

Hitachi

19. Mentor Graphics (United States), April 1997

Hitachi will work with Mentor Graphics to strengthen its 32-bit RISC processor development environment. Plans call for jointly developing SeamlessCVE, a hardware/software coverification tool for the Hitachi SH series microcontrollers. The tool, which will support MCUs in the SH-1, SH-2, and SH-3 series, will allow system designers to verify hardware and software and debug the software in the early stage of SH MCU-based equipment development, slashing development time by over one month. The tool is priced at ¥12 million.

20. Seiko Epson (Japan), November 1997

Hitachi and Seiko Epson announced an agreement concerning the licensing of Hitachi's 32-bit RISC microprocessor core technology to Seiko Epson. Seiko Epson intends to combine its low-power semiconductor technology with Hitachi's SH-3 core to build new ASICs and application-specific standard products (ASSPs) that better meet system requirements. Hitachi has been actively forming partnerships as part of establishing its 32-bit SH RISC engine family as an industry standard. The present agreement makes Seiko Epson the first Japanese partner and, for customers, will mean that more PC peripheral devices and portable information products built around SH MPUs will be available. Seiko Epson has developed 4-, 8-, and 32-bit CPUs. With the SH-3, Seiko Epson will address the need for products with a standard embedded CPU capable of running a standard operating system with its associated development environment.

21. NTT Electronics (Japan), November 1997

Hitachi and NTT Electronics will work together to develop a low-power SH-3 RISC microprocessor using a 0.25-micron process technology. Hitachi will provide its SH-3, designed for a 0.35-micron process, while NTT Electronics, which develops and manufactures ICs for its parent company, Nippon Telegraph & Telephone, will provide its 0.25-micron technology. Hitachi expects the collaboration will help it lower the power consumption of the SH-3 nearly 3 percent and shorten the 0.25-micron SH-3's time to market. The CPU is expected by spring of 1999.

22. SGS-Thomson (France), December 1997

Hitachi and SGS-Thomson Microelectronics formally unveiled plans to undertake joint development of 64-bit microprocessor cores for the Super-H family. The processor architecture will be backward compatible with Hitachi's SH-4 and is being targeted as a general-purpose engine for a wide range of products. The architecture of the first core that the companies will work on together, called SH-5 by Hitachi and ST50 by SGS-Thomson, is due to be disclosed in 1998, with first implementations sampled in the second half of 2000 and volume production in 2001.

Hitachi/Mitsubishi

23. Texas Instruments (United States), February 1997

Hitachi, Mitsubishi Electric, and Texas Instruments have signed an agreement to jointly develop 1Gb DRAM. The agreement, part of a trend toward huge investments to develop complex and expensive technologies, will allow the three chipmakers to share resources and leading-edge technologies. The three companies are aiming for sample shipments of the next-generation chips by early 2000, sharing the estimated development cost of more than ¥100 billion. Since 1988, TI and Hitachi have been teaming up to research and develop 16Mb, 64Mb, and 256Mb DRAMs, while Hitachi and Mitsubishi have jointly developed 8Mb, 16Mb, and 64Mb flash memory chips. In 1995, Hitachi and TI formed a joint venture, Twinstar, a $0.5 billion wafer fab located in Richardson, Texas.

Hitachi Chemical

24. DuPont (United States), September 1997

Hitachi Chemical and DuPont of the United States will jointly set up ventures in both countries to produce and market liquid polyimide materials for semiconductors and other electronic devices. The two companies have established Hitachi Chemical DuPont Microsystems LLC in the United States, slated to open in April 1999. An initial capital contribution of $14 million for the venture will be shouldered equally by DuPont and Hitachi Chemical's sales subsidiary, Hitachi Chemical America. The new joint venture will then establish Hitachi Kasei DuPont Microsystems K.K., as a wholly owned subsidiary in Japan, with capital of ¥400 million and a targeted operation date in 2002.

Hitachi Construction Machinery

25. Hitachi Medico (Japan), December 1997

Hitachi Construction Machinery has formed a partnership with Hitachi Medico in the semiconductor inspection equipment business. The company will procure as an OEM two types of x-ray-based semiconductor inspection systems from Hitachi Medico. Its goal is to nearly double its factory automation system sales to ¥3.6 billion by 2001 by broadening its x-ray inspection system product line. The MF130M and the MF80M feature focuses of 10 micron, and 8 micron, respectively.

Hitachi Maxell

26. Singlechip Systems (United States), December 1997

Hitachi Maxell has teamed up with Singlechip Systems of California to enter the IC tag business. The partners will combine Hitachi Maxell's non-contact IC card production technology with SCS' single-chip technology to manufacture and market an IC tag that will measure 10 x 60 x 0.25mm and have a memory capacity of 1,024 bits. A reader/writer will use 2.45-GHz signals to simultaneously read data on more than 30 write-once tags that can be 35cm apart. A set of the reader/writer and 100 tags will be priced at ¥600,000 to ¥1,000,000.

Innotech

27. Credence Systems (United States), November 1997

Innotech has established in Yokohama a semiconductor tester production joint venture with Credence Systems of California. Capitalized at ¥100 million, Innotech Credence is 49.9 percent owned by the Japanese semiconductor equipment distributor and 50.1 percent by the U.S. tester maker. The joint venture will manufacture logic and memory testers and put them on the market by spring 1998, aiming to ship a total of 50 units the first year. The first-year sales target is set at ¥4 billion.

Itochu

28. Grand Pacific Petrochemical (Taiwan), April 1997

Itochu, in cooperation with Fukushima-based technical consulting company Sumcon and Taiwanese chemical company Grand Pacific Petrochemical, will set up a joint LCD production company in Taiwan. The new company, Grand Pacific Optoelectronics, will be capitalized at about (4 billion, in which Itochu, Sumcon, and Grand Pacific Petrochemical invest 25 percent, 5 percent, and 70 percent, respectively. The joint venture expected to start constructing a plant in the Hsinchu industrial park in April 1997 and to produce sub-10-inch STN color LCDs for portable information devices and notebook computers from June 1998, aiming for first-year sales of about ¥10 billion.

29. Comdisco Inc. (United States), September 1997

Itochu and U.S. semiconductor equipment leasing company Comdisco have established a joint semiconductor equipment leasing company, Commit Equipment Management Service. Capitalized at ¥490 million, the joint venture is owned 60 percent by the U.S. company and 40 percent by the Japanese trading house. The joint venture is aiming for 20 billion in leasing contracts by 2000. Predicting that demand for used equipment may expand in Asia, the partners plan to sell used equipment to Taiwanese and Korean chipmakers. The used semiconductor equipment market in Japan is estimated at ¥5 billion, about 1/10th of the size of the U.S. used equipment market.

©1998 Dataquest

Kaijo

30. Robotic Vision Systems Inc. (United States), November 1997

Kaijo has teamed up with Robotic Vision Systems Inc. of New York to expand its inspection system business. Kaijo will start marketing and providing support for RVSI's ball grid array (BGA) inspection and bump attachment systems in December. Through an alliance with Kaijo, RVSI wants to boost its Japanese market share, currently about 20 percent of the market.

31. Quad Systems (United States), December 1997

Kaijo has begun marketing a flip-chip bonder made by Quad Systems of Pennsylvania, signing an exclusive domestic sales contract with the U.S. company. The Advanced Packaging System APS-1 supports various types of packaging, including chip-scale package (CSP) and chip on board (COB) and uses an optical noncontact alignment system to achieve a high level of alignment. The price is ¥40 million.

Kanematsu Semiconductor

32. Intergraphics Systems (United States), September 1997

Intergraphics Systems of California will team up with semiconductor distributor Kanematsu Semiconductor and software house Access to market in Japan the CyberPro2010, a system-on-a-chip LSI enabling users to browse Internet home pages on TV. The chip integrates monitor output circuit and image control functions and a flicker-prevention function and features a built-in interface called Flexibus that makes the chip usable with all existing CPUs, including x86 and PowerPC microprocessors and Hitachi SH series microcontrollers. Intergraphics Systems claims that the chip helps Internet TV makers slash development time and design costs by nearly 60 percent, enabling them to lower retail prices from the current ¥300,000 to ¥100,000.

Kyocera Electronics Inc.

33. Johnson Matthey (United Kingdom), October 1997

Kyocera has signed a cross-license agreement with Johnson Matthey of London in the semiconductor plastic package business. The company will introduce plastic package technology from Johnson Matthey and start mass production of plastic land grid arrays (PLGAs) for microprocessors at its Sendai plant in Kagoshima Prefecture in January 1998. In return, Kyocera will provide the U.K. company with build-up substrate technology. Plans call for launching production at 500,000 units per month (45 x 45mm, 540 pins) and boosting output to 1.5 million units by July 1998, when the company will complete a new 10 billion production facility at the plant. Kyocera is aiming for PLGA sales of ¥5 billion to ¥6 billion in fiscal 1998.

Lapmaster SFT

34. Super Silicon Crystal Research Institute (Japan), August 1997

Lapmaster SFT of Tokyo will collaborate with Super Silicon Crystal Research Institute of Gunma Prefecture to develop a fully automated chemical mechanical polishing machine for processing 400mm wafers. Super Silicon will provide wafer samples, while Lapmaster will be in charge of hardware design and software development. Development costs are estimated at (100 million. Scheduled to be developed by May 1998, the machine will achieve a wafer-processing flatness of less than 0.13 micron, a surface particle diameter size of 0.04 micron, and a surface metal impurity level of 10 x 8 stoms/cm^2. The 400mm wafer-processing machine is likely to be priced at about ¥200 million.

Matsushita

35. Texas Instruments (United States), January 1997

Texas Instruments Japan and Matsushita Electric have jointly developed a digital video camera DV terminal IC that conforms to IEEE 1394, a high-speed serial bus standard for next-generation PCs and consumer electronics. The TSB13LV01 integrates on a single chip the functions of conventional LINK and PHY chips and is available in a 144-pin CSP. TI Japan will initially mass-produce the new IC exclusively for use in the latest NV-DE digital video camera from Matsushita Electric.

36. CBL (United States), July 1997

Matsushita Electronics signed an agreement with a California-based venture CBL under which the companies will jointly develop a blue-light laser. Matsushita is aiming by 1999 to commercialize a blue-light laser, necessary for next-generation DVD drives with a storage capacity of 15GB, three times the current level. Set up by Stanford University researchers, CBL has developed large-diameter gallium nitride substrates. Use of this type of substrates increases the life of a blue-light laser from the conventional 30 hours to 5,000.

Mitsubishi

37. Compaq (United States), January 1997

Compaq Computer Corporation has teamed up with Mitsubishi Electric and with Advanced Display, Mitsubishi's LCD production subsidiary, in PC LCD monitor development. The alliance brings together Compaq's understanding of customer needs, Mitsubishi's flat panel technology, and Advanced Display's motherboard and glass processing technologies. The companies developed an LCD monitor and put it on the market in the second half of 1997. Compaq will be in charge of sales and will initially target the financial and health care sectors.

©1998 Dataquest

38. Access (Japan), February 1997

Mitsubishi Electric has teamed up with Access, an Internet appliance operating system developer, in the development of a portable Internet terminal chipset. The two companies will jointly develop a three-chip set including Mitsubishi's M32R/D DRAM-embedded microcontroller and a mask ROM and market the chipset at $30 to $40. Mitsubishi plans to develop a two-chip set in 1998 by integrating an ASIC and the M32R/D on a single chip. Mitsubishi, which started shipping samples of the DRAM-embedded MCU in October 1996, will launch production in April and produce 1 million units a month in late 1997. Access' Internet OS has been adopted by Sharp in its Internet TVs and word processor.

39. Wind River Systems (United States), March 1997

Wind River Systems, Japan, will develop the Tornado embedded system development environment for Mitsubishi Electric's 32-bit M32R/D RISC processor, based on an agreement the two companies have signed. The agreement will allow domestic M32R/D users to collectively purchase from Mitsubishi the license to use the VxWorks real-time operating system that is integrated into the Tornado development environment, helping them reduce system development time. Mitsubishi, which teamed up with Integrated Systems Inc. of the United States regarding its pSOS real-time OS in 1996, will support the real-time operating systems that account for some 70 percent of the world market.

40. Rambus (United States), April 1997

Mitsubishi Electric has licensed the Rambus interface technology needed to make 1.6GB/sec Direct Rambus DRAMs. The company has previously been a vocal proponent of other next-generation DRAM technologies. Nine DRAM makers have taken Rambus licenses, and some of the holdouts are believed to be negotiating with Rambus. IBM has a license for the Rambus logic interface but has yet to take a license for the memory-interface technology.

41. Seiko Epson (Japan), May 1997

Mitsubishi Electric will license 3-D video memory technology to Seiko Epson. Mitsubishi's 3D-RAM integrates 10Mb DRAM, 2Kb SRAM, and logic functions on a chip. Seiko Epson is expected to ship samples of the SDM 10092, a 3D-RAM-compatible chip, this fall and launch volume production at 20,000 units per month at its Sakata plant next spring. The sample price is likely to be set at about ¥5,000.

42. Chunghwa Picture Tube (China), May 1997

Mitsubishi Electric and Advanced Display have agreed to license their advanced thin-film transistor (TFT) LCD technologies to Chunghwa Picture Tube, a cathode-ray tube (CRT) manufacturer in Taiwan. Under the agreement, Chunghwa Picture will receive key technologies for the manufacture of TFT LCDs from Advanced Display. The displays to be manufactured by Chunghwa include 12.1-inch SVGA and XGA and 15.1-inch XGA and SXGA models. Volume production is expected to begin in January 1999. Chunghwa, an affiliate of Tatung, develops CRTs for the television and display market as well as super-twisted nematic (STN) LCD flat-panel displays.

 ©1998 Dataquest

43. Stone Group (China), June 1997

Mitsubishi Electric has teamed up with Chinese electric equipment maker Stone Group in semiconductor sales. Mitsubishi, Stone, and Mitsui & Co. established a joint venture in Beijing in 1996, and the joint venture is building a semiconductor plant expected to be ready for operations in April 1998. Mitsubishi plans to market semiconductors to be made by the plant for use in electric appliances. First-year China semiconductor sales are expected to be ¥10 billion, including sales to be generated through distribution via Hong Kong.

44. Mentor Graphics (United States), June 1997

Mitsubishi Electric will develop system-on-a-chip LSI development software with Mentor Graphics. Hardware-Software Cosimulation Environment, the software the two companies will develop, will combine Mentor's Seamless CVE and Mitsubishi's 32-bit M32R RISC microcontroller core instruction set simulator. The new software will allow system-chip LSI design engineers to test software as hardware is being designed, helping reduce design and development time from the current eight months to five months. Sample shipment is slated for late this year.

45. Powerchip Semiconductor (Taiwan), November 1997

Mitsubishi Electric expects to provide Powerchip Semiconductor of Taiwan with DRAM-embedded microcontroller production technology in early 1998. A joint venture established by Mitsubishi, a trading company, Kanematsu, and a Taiwanese electronics maker, the UMAX Group, Powerchip will begin to produce eRAM, a system-on-a-chip LSI that integrates Mitsubishi's proprietary 32-bit RISC MCU and DRAM on a single chip. Slated to begin in mid-1998, production will reach 4,000 eight-inch wafers per month by September 1998.

Mitsubishi Materials

46. Symmetrix (United States), December 1997

Mitsubishi Materials has licensed technology to produce and market ferroelectric materials from Symmetrix of Colorado. Plans call for producing Y-1, a ferroelectric material developed by the U.S. company for forming thin-film capacitors through enhanced metallorganic deposition (EMOD) at a mass production facility under construction in the company's Mita plant. Construction will be completed by year's end, and operations have been slated to start in March 1998. The company is aiming for sales of ¥200 million in 2000.

Mitsui & Co.

47. Micron Communications/ID Micro Systems (United States), April 1997

Mitsui & Co. will work with Micron Communications and ID Micro Systems, both of the United States, to develop a low-cost noncontact tag. The new tag will have a storage capacity of 256 bits and use the spread spectrum format to read and write data. The companies aim to price the product at about (100, enabling it to be used as a disposable tag in production and distribution management and IC card applications. Mitsui and Micron Communications will share the development cost, while ID Micro will provide noncontact tag technology. Mitsui will sell the tag in Japan and overseas, except for the United States. The tag was expected to reach the market in late 1997, with a first-year sales goal set at 10 million units.

Mitsui High-Tec

48. Ball Semiconductor (United States), August 1997

Mitsui High-Tec has invested in Ball Semiconductor of Texas, acquiring nearly 50 percent of the U.S. company for $26 million. Ball Semiconductor was established by former Texas Instruments vice president Akira Ishikawa in October 1996. Ball has developed technology to create semiconductor circuits on the surface of a silicon ball in order to increase the level of integration. The U.S. company claims that the silicon balls are easier to manufacture than silicon wafers and that a silicon ball semiconductor plant can be constructed at lower cost than conventional chip plants. Semiconductor equipment maker Disco is also reported to have chipped in more than ¥100 million to the U.S. venture.

NEC

49. Wind River Systems (United States), January 1997

NEC will procure an embedded RISC microprocessor operating system from Wind River Systems. NEC and the Japanese arm of Wind River have signed an agreement, under which the U.S. software company will develop a version of the Tornado operating systems supporting NEC's V830 series of 32-bit RISC MPUs. The B830 family is popular among office business machines and car navigation system applications, and the combination of the RISC MPU and Tornado will allow designers to develop such application systems easily. Japanese customers have been able to purchase the Tornado runtime version license together with the MPU from April 1997.

50. Datapath Systems (United States), February 1997

NEC has teamed up with U.S. venture Datapath Systems to develop an extended partial response maximum likelihood (EPRML) LSI for use in large-capacity hard disk drives (HDDs). NEC will continue its process technology with the U.S. company's circuit design technology to develop as early as this year the LSI that will enable 30 percent HDD capacity expansion over the conventional PREL system. NEC, which has to date manufactured HDD write and read LSIs, intends to expand its semiconductor business by moving into the HDD LSI market, a promising segment with huge growth potential.

 ©1998 Dataquest

51. Synopsys (United States), April 1997

NEC and Synopsys of California have reached an agreement to jointly develop microcontroller-embedded ASIC design verification technology. The move is aimed at providing a tool to enable single-chip embedded system designers to simultaneously verify both hardware and software functions and at reducing development lead time. For the development of embedded systems, hardware functions are typically verified using EDA capability and software functions using an in-circuit emulator. NEC expects the new tool will help expand sales of its V850 family of ASICs.

52. Shanghai Hua Hong Microelectronics (China), May 1997

NEC announced that it will set up a joint venture with Chinese chipmaker Shanghai Hua Hong Microelectronics to supply technology to a Chinese national project to boost domestic semiconductor output. Shanghai Hua Hong is affiliated with the Chinese government. The Chinese government will own about a 70 percent stake in the venture, to be capitalized at $700 million, and NEC will own the rest. The project, which is part of China's five-year economic plan, is called Project 909. Running through 2000, the venture will produce 20,000 chips a month. NEC will provide technology for processing memory chips.

53. Cadence Design Systems (United States), July 1997

Cadence Design Systems has signed an IC design tool contract with NEC. The three-year, $18 million contract will allow NEC to use Silicon Ensemble-DSM, an IC design tool, for deep-submicron design at its design centers worldwide. The tool boosts circuit design speed more than 20 times that of conventional tools.

54. Samsung (Korea), July 1997

NEC and Samsung have decided to cooperatively design a plant for 300mm wafers and help each other in equipment development. The alliance is aiming to get its 300mm wafer line up and running around 1999.

55. Tseng Labs (United States), September 1997

NEC Electronics announced the availability of an OEM reference design that combines the PowerVR PCX2 3-D graphics accelerator with Tseng Labs' 128-bit ET6100 2-D graphics and multimedia engine. NEC has formed a strategic alliance with Tseng Labs to develop PCI-compliant single-card reference designs based on the PowerVR architecture. This design offers PC OEM and graphics board manufacturers an all-in-one graphics solution that delivers arcade-quality 3-D rendering and high-performance 2-D acceleration for Windows applications. The single-slot PCI card supports game and entertainment titles written for Direct3D, PowerSGL, and DirectDraw, including more than 100 game titles that have been developed for or ported to the PowerVR architecture. VideoLogic's Apocalypse 5-D graphics board is the first product using the technology from NEC and Tseng Labs.

 ©1998 Dataquest

56. Philips Semiconductor (Netherlands), November 1997

NEC and Philips Semiconductor have reached agreement to jointly develop system-on-a-chip LSIs for use in digital consumer electronic products. They will use the 64-bit VR4300 RISC microprocessor based on MIPS Technologies architecture as a core for the system-chip LSIs and share peripheral circuit libraries. Consumer sales account for 15 percent of NEC's semiconductor sales and 45 percent of Philips', respectively. The two companies plan to begin to commercialize system-chip LSIs in the second half of 1998, cooperating in production as well as marketing.

57. Lucent Technologies (United States), December 1997

Lucent Technologies' Microelectronics Group and NEC announced that Lucent has licensed NEC's 32-bit V850 MCU family core. Lucent will integrate the core into its 0.25- and 0.35-micron Silicon Suite system-level IC offering, enabling customers to design system-level integrated circuits based on NEC's 32-bit RISC MCU architecture. The agreement means the V850 core will now be available from the two companies. The core will be available to Lucent customers for integration in April 1998.

Nichimen Electronic Components

58. Luxsonor (United States), May 1997

Nichimen Electronic Components has teamed up with Luxsonor of California in DVD chip sales. The U.S. fabless company focuses on MPEG-2 decoder part development, and Nichimen planned to release as early as June the LS220, a DVD decoder chip built into a PC motherboard. To be made in Taiwan, the chip will be sold for less than 4,000. The Japanese distributor is aiming for first-year sales of ¥500 million. Luxsonor is working on the LS240, a power-saving chip, and Nichimen intends to market it, targeting notebook computer makers, within the year.

NKK Corporation

59. Toshiba (Japan), September 1997

NKK will reorganize its semiconductor business by introducing state-of-the-art semiconductor technology from Toshiba. Plans call for starting 32-bit RISC microcontroller production within the year. The steel company will pay Toshiba a one-time fee of an estimated ¥1 billion as well as license fees and will manufacture RISC chips at its Ayase Research Laboratory. NKK, which entered the semiconductor business in 1992, hopes to put its semiconductor operations into the black by fiscal year 2000, reducing its dependence on the memory business significantly.

Nomura Microsciences

60. Ionics (United States), July 1997

Nomura Microsciences has teamed up with Ionics Inc. of Massachusetts to market pure water-processing electrical deionization (EDI) equipment targeting semiconductor, pharmaceutical, and food processing companies in Japan, Korea, and Taiwan. The EDI system uses no chemicals and requires no waste water processing and therefore can remove 99 percent of silica, a task considered difficult. The U.S. company has supplied its EDI equipment to more than 50 plants worldwide, and Nomura is aiming to sell ¥20 billion to ¥30 billion worth of ultrapure water-processing systems over the next five years.

Nozaki Industry

61. High Yield Technology (United States), May 1997

Nozaki Industry will import a particle monitor system from High Yield Technology of California. The In Situ Particle Monitor (ISPM) is attached to vacuum process semiconductor equipment and eliminates use of a dummy safer. The standard system is priced at about ¥4 million. Nozaki is aiming first-year shipment of 100 ISPM systems.

Oki

62. Synopsys (United States), January 1997

Silicon Architects of Synopsys has announced that Oki Electric of Japan has licensed Synopsys' cell-based array (CBA) architecture for its 0.35-micron ASIC products. Oki will use the CBA architecture to develop 0.35-micron ASICs for both internal and commercial use. Other products will include microcontrollers, MPU and peripheral ICs, speech ICs, and telecom ICs. Oki will develop designs using CBA design tools, which integrate CBA libraries, CBA compilers, the CBA Design Systems, and commercial EDA tools. Over the past year, Synopsys has also announced CBA licensing agreements with Fujitsu, Matsushita, Mitsubishi, NEC, Toshiba, and TriTech.

63. Artisan (United States), April 1997

Artisan Components, formerly VLSI Libraries, a supplier of embedded memories and other physical component intellectual property (IP), has received a multimillion dollar worldwide purchase agreement from Oki Electric. Oki has selected Artisan as its sole external supplier of memory generators and has agreed to incorporate Artisan's family of physical IP components into all of its new 0.35- and 0.45-micron internal standard products and ASSPs. Under the agreement, Oki will purchase a complete family of Artisan's memory generator, including standard single-port and dual-port SRAMs. Also, Oki's R&D centers in both Japan and the U.S. are adopting Artisan's technology.

 ©1998 Dataquest

Rohm

64. DSP Group (United States), March 1997

Rohm will license DSP core technology from DSP Group of California. Rohm will use DSP Group-developed 16-bit fixed-point PineDSPCore and OakDSPCore to develop system-on-a-chip LSIs for mobile communications and multimedia equipment. Specifically, Rohm expected to commercialize controllers for cellular phones, high-speed modems, and CD-ROM/DVD drives by the end of 1997. DSP Group licenses its audio-compression technology to a dozen companies, including AT&T, Intel, and Microsoft, and its DSP core technology to more than 20 companies, including Asahi Chemical, Kenwood, and NEC.

Ryosho Electronics

65. NeoParadigm Labs (United States), April 1997

Ryosho Electronics signed an exclusive agreement to sell in Japan LCD signal processing ICs developed by NeoParadigm Lab (NPL) of California, a start-up developer of multimedia LSIs. Designed for large STN LCD panels, the new LCD signal-processing IC directly processes analog RGB signals from the PC, reducing the signal-processing circuit cost to less than ¥10,000. Sample shipment was expected to begin in September, and Ryosho aims to sell 50,000 units the first year. Ryosho was established to sell DRAMs produced by Powerchip Semiconductor, a Taiwan-based joint venture, and by Mitsubishi Electric, Kanematsu and the UMAX Group of Taiwan, and aimed for fiscal 1997 sales of ¥6 billion.

Sankyo Engineering

66. Sugai (Japan), April 1997

Japan-based Sankyo Engineering and Sugai revealed that the companies will form a partnership for developing new auto wet stations, which can be used for 256Mb DRAM cleaning processes and new processes for 12-inch wafers. The companies will also begin developing common part specifications for their equipment in order to reduce parts inventory, and hence cost, while maintaining availability. According to the announcement, Sankyo Engineering and Sugai will consider exchanging stock or further investment in future partnerships if they find enough benefits.

Santoku Chemical

67. Mitsui & Co./Merck (Germany), October 1997

Santoku Chemical, Mitsui & Co., and Merck of Germany have established a joint venture in Singapore to produce ultrapure hydrogen peroxide water for cleaning semiconductor chips. Capitalized at about ¥700 million, Santoku Merck is owned 49 percent by Merck, 31 percent by Santoku, and 20 percent by Mitsui. The partners will invest ¥2 billion to construct a plant with an annual processing capacity of 10,000 tons, which will start operations in November 1998. Plans call for producing hydrogen peroxide water with particle per trillion-level purity. Santoku Merck is aiming for sales of ¥2.5 billion in 2005.

Seiko Epson

68. Lattice Semiconductor (United States), March 1997

Lattice Semiconductor has signed an agreement to advance Seiko Epson up to $150 million to assist in the funding of a new 8-inch wafer fab, currently under construction in Sakata, Japan. The agreement calls for Lattice to make a $90 million advance payment to Seiko Epson to set up the new fab over the next two years, with an option for an additional $60 million advance. In return, Lattice will receive guaranteed 8-inch, submicron wafer capacity. The advance payments will be repaid by Seiko Epson with wafers over a multiyear period. Lattice planned to manufacture next-generation, high-density, in-system programmable logic devices (PLDs) at the new facility beginning in 1998, initially using 0.35-micron CMOS process technology and later migrating to 0.25-micron process technology.

69. Exemplar (United States), June 1997

California-based logic synthesis tool supplier Exemplar Logic announced an agreement to jointly develop libraries for Seiko Epson/SMOS ASIC libraries for Exemplar's Leonardo design environment. As a result of this agreement, Seiko Epson/SMOS ASIC libraries are being distributed by both Seiko Epson and Exemplar Logic, and Exemplar's Leonardo becomes part of Seiko Epson/SMOS ASIC design flow worldwide. The high-precision delay models jointly developed by both companies interface to the Seiko Epson ASIC development system, Auklet. They are available to Seiko Epson/SMOS customers.

70. Mitsubishi (Japan), October 1997

Seiko Epson has tied up with Mitsubishi Electric in the DRAM business. The companies have agreed that Mitsubishi will provide Seiko Epson with 64Mb DRAM design and production technology and that the latter will launch production at 1 million units per month at its Sakata plant from the second quarter of 1998. Mitsubishi will initially purchase all units to be produced at the plant, but Seiko Epson is considering marketing the memory chips under its own brand name. Seiko Epson, which recently completed a ¥100 billion semiconductor production facility at the plant, had been looking for memory products, which will help with stability of operation.

Seiko Seiki

71. Jenoptik Infab (Germany), December 1997

Seiko Seiki, a Seiko Instruments Group company, will team up with German automated semiconductor production system maker Jenoptik Infab. The companies are signing an agreement concerning the standard mechanical interface SMIF() system, a localized clean environment system for wafer transport. Under the agreement, Seiko will provide installation, maintenance, and servicing in Japan for Jenoptik's SMIF systems, which are widely used in Europe, the United States, and Taiwan.

 ©1998 Dataquest

Sharp

72. SanDisk (United States), January 1997

SanDisk and Sharp signed a cross-licensing agreement that gives the companies worldwide rights to each other's patents for flash memory products. Terms of the agreement were not disclosed.

Shin-Etsu Handotai

73. Soitec (France), May 1997

Shin-Etsu Handotai will form a partnership with France-based Silicon on Insulator Technologies to mass-produce next-generation SOI wafers. Soitec has a cutting-edge SOI wafer technology known as Smart Cut, which combines a hydrogen ion implantation process with a conventional wafer-bonding method. This process seems to have an advantage in fabricating so-called ultrathin-film SOI wafers. Soitec has shipped the wafers under the Unibond name since the middle of 1996, and the company plans to expand its production facility in Grenoble, France. SEH and Soitec will develop mass-production technology for this process, and SEH also will construct a factory for SOI wafer production in Japan. Both companies plan to provide 1 million 8-inch wafers per year by 2000.

Sony

74. Toyoda Automatic Loom (Japan), June 1997

Sony and Toyoda Automatic Loom, the funding company of the Toyota Motor Group, are negotiating joint manufacturing of low-temperature, polysilicon active-matrix LCDs. The arrangement would give Sony the production capability to take advantage of emerging high-volume display opportunities, including the enormous automotive market, and it would provide Toyota with captive access to leading-edge display components.

75. Advanced RISC Machines (United Kingdom), July 1997

Sony has forged an alliance with Advanced RISC Machines of the United Kingdom in the 32-bit RISC processor business. Sony will develop and supply system-on-a-chip LSIs based on the ARM7TDMI RISC processor core targeting digital AV equipment, cellular phone, and PDA applications. Sony positions the ARM7 core as an MPU core for its 0.4-micron ASCS ASIC products. ARM's MPU core has been licensed to about 20 chipmakers and used for a range of applications.

76. Sharp/Philips (Netherlands), July 1997

Sony, Sharp, and Philips are jointly developing a next-generation large LCD for such applications as a wall TV. Not to be outdone by its competitors, including Fujitsu, that are leading in the large-screen display competition by concentrating on plasma display panels, the three partners will develop a plasma address LCD that they believe can be as large as 40 inches. Plans call for installing a pilot line at Sony Mizunami, where the partners will send their engineers to develop mass production technology. The companies are aiming for commercialization in 1998.

77. Oki (Japan), August 1997

Sony and Oki Electric will team up in the system-on-a-chip LSI business. They are discussing mutually commissioning production of a chip that integrates a microprocessor and DRAM on a single chip using a 0.25-micron process technology. The two companies, which reached agreement to jointly develop 0.25-micron system-chip LSIs in May 1995, are independently marketing system-chip LSI made using a 0.35-micron process. Sony and Oki, which are about to see the result of their joint development effort, seek to effectively use their management resources by commissioning production to each other.

Sumitomo Chemical

78. Olin (United States), September 1997

Sumitomo Chemical announced that it will cooperate with Olin, a U.S. chemical company, in the area of i-line photoresists used in production of 16Mb to 64Mb memories. Olin will have exclusive manufacturing rights to Sumitomo Chemical's advanced i-line photoresists in the United States and Europe. Olin, a supplier of i-line photoresists in the U.S. and European markets, will also have nonexclusive rights to sell such materials in those regions. Use of Olin's production facilities will enable Sumitomo Chemical to secure a foothold in these markets. Sumitomo Chemical is planning to increase annual sales of i-line photoresists from the current ¥12 billion to ¥30 billion in five years.

Sumitomo Corporation

79. Tokyo Kaseihin and others (Japan), January 1997

Tokyo Kaseihin will establish a lead frame production venture in Singapore with two Japanese manufacturers through its local subsidiary. To be capitalized at $50,000, the new venture will be owned by Tokyo Kaseihin subsidiary TOK Singapore, Osaka-based parts maker Iijima Metal Seisakujo, and Osaka-based packaging materials maker Shinko at a ratio of 1:2:2.

80. R. Howard Strasbaugh (United States), June 1997

Sumitomo Corporation set up in July a joint venture with R. Howard Strasbaugh of California to sell next-generation wafer-polishing machines developed by Strasbaugh. SC Semicon Technology is capitalized at 300 million, in which Sumitomo and Strasbaugh invested 85 percent and 10 percent, respectively. The CMP machine developed by Strasbaugh features a wafer surface roughness of 250 angstroms, 10 times the precision of conventional machines, and can process about 60 wafers per hour, three times the usual throughput. It is priced at ¥200 million. SC Semicon is aiming for first-year sales of ¥3.5 billion, targeting manufacturers of 64Mb DRAM chips.

©1998 Dataquest

81. Pixtec (United States), November 1997

Sumitomo Corporation has bought exclusive domestic sales rights to field-emission display (FED) panels from California-based Pixtec. The company, which is also authorized to market the products in Asia, will invest $10 million in the U.S. company in return. Pixtec plans to commission 5.2-to 8.0-inch FED panel production to leading Taiwanese LCD maker Unipac and ship 10,000 units per month starting in April 1998. Sumitomo, which handles ¥50 billion worth of CRT and LCD materials and products annually, is aiming to expand FED sales to ¥3 billion and ¥10 billion in the first and third years, respectively.

Tokyo Seimitsu

82. Super Silicon Institutes (Japan), March 1997

Tokyo Seimitsu will develop a 400mm-wafer wire saw jointly with the Super Silicon Institutes (SSI). The company will deliver a wire saw to the SSI by November, and the parties will jointly make enhancements with the goal of completing a practical unit by 2001. The SSI is a Gunma-based institute specialized in 400mm wafer technologies, established in March 1996.

83. Seiko Seiki (Japan), December 1997

Tokyo Seimitsu will form an alliance with Seiko Seiki in the semiconductor equipment business. The partners will combine Tokyo's alignment-measuring technology with Seiko's high-precision processing technology to develop wafer dicing and other technologies. In the meantime, Seiko Seiki, which has been marketing dicing saws since 1995, will stop production and procure products from Tokyo Seimitsu.

Toshiba

84. Unigen (United States), February 1997

Unigen announced that it will work with Toshiba America Electronic Components as a manufacturer of Toshiba-certified memory modules for sale under the Toshiba brand name. Toshiba expected to audit and qualify Unigen's production facility in the first quarter of 1997, and the Unigen/Toshiba team could begin shipping Toshiba product in the second quarter. Unigen is a Fremont, California-based third-party memory module manufacturer that focuses on the OEM channel.

85. Samsung (Korea), February 1997

Toshiba will acquire 20 percent of Samsung Austin Semiconductor of Texas, a Samsung Electronics subsidiary, and procure the 20 percent of 64Mb DRAMs the Texas company will manufacture for sales under its own brand name. Slated for completion in June 1997, the first facility of the Korean subsidiary, in which Intel also has a capital stake, expected to launch 64Mb DRAM production by year's end and have a monthly output capacity of 2.3 million units by the end of 1998, when it expects to be fully operational. Samsung Austin Semiconductor plans to invest $1.3 billion to construct three facilities by 2003.

 ©1998 Dataquest

86. Motorola/Fairchild (United States), March 1997

Toshiba, Motorola, and Fairchild Semiconductor will jointly develop next-generation high-speed CMOS standard logic ICs. The three companies will work together to develop 2.5- and 3.3V CMOS standard logic ICs with a propagation delay time of 2ns. The new devices will be suited for ATM and ISDN network and engineering workstation memory address control use. They will introduce compatible products simultaneously to develop an untapped market. Plans called for commercializing the fast standard logic ICs by the end of 1997. The high-speed standard logic IC market is forecast to grow to ¥35 billion in 2000.

87. Sun Microsystems (United States), April 1997

Toshiba and Sun Microsystems have agreed to develop a Java processor chip for use in network computer terminals. The chip will consist of picoJava, microJava, and ultraJava. PicoJava will be the microprocessor's core, and microJava will integrate DRAM and a controller into picoJava. UltraJava will be an advanced model. Toshiba will be involved in developing a low-power microJava chip, with commercialization by Sun in 1998.

88. MIPS Technologies (United States), April 1997

Toshiba has licensed RISC microcontroller technology from the MIPS Group. The MIPS 16ASE is a 32-bit MCU core that helps to reduce the size and power consumption of printers and portable information devices. It allows for significant reduction of overall code size by compressing some instruction sets to 16-bit. The company plans to commercialize TX19 series MCUs based on the licensed core. The RISC type accounts for less than 10 percent of the company's total MCU sales in volume terms.

89. Technology Modeling Associates (United States), April 1997

Toshiba and Technology Modeling Associates have entered into a multi-year agreement in which the two companies will work jointly on development of software for 3-D simulation of semiconductor processes. The software tool will perform advanced modeling for diffusion, oxidation, ion implantation, rapid thermal annealing, silicidation, and point defects modeling. Toshiba is expected to use the simulator for the development of future generations of memory, microprocessor, and ASIC devices. Under the term of the agreement, Toshiba will provide funding, deep-submicron process technology development requirements, and test data. The TMA product, part of TMA's suite of semiconductor simulation tools, is expected to be released in late 1998.

90. NeoMagic (United States), May 1997

Toshiba announced in May that the company was about two months away from first silicon on a notebook graphics controller, with embedded DRAM, that will be manufactured for NeoMagic. To date, NeoMagic has worked with Mitsubishi Electric as the foundry for its graphics controllers. Toshiba will employ a 0.25-micron process optimized for embedded memory and a 128-bit on-chip memory bus.

©1998 Dataquest

91. Chartered Semiconductor (Singapore), June 1997

Toshiba will license DRAM-mixed logic IC technology to Chartered Semiconductor of Singapore, to which it licensed CMOS logic technology in November 1994. The Singapore company will use Toshiba's 0.25- to 0.35-micron process technology to launch production in 1998. The DRAM-mixed system-chip LSI market is expected to reach about ¥400 billion in 2000.

92. iReady (United States), June 1997

Toshiba will license Internet access LSI technology from iReady of California. The company has signed a five-year contract to use the U.S. company's Internet tuner technology for providing Internet access using an LSI, which eliminates control by a CPU and cuts power to 1/700th the level of software-driven Internet access. Toshiba planned to develop by the fall a functional block that will be embedded on a system-on-a-chip LSI to be built into cellular phones and TVs.

93. ViewLogic (United States), July 1997

Toshiba has teamed up with ViewLogic of the United States in the ASIC business. The companies will support Motive, a static timing tool that helps significantly reduce the time needed to design system ASICs with 1 million gates, and Testgen, a tool to automatically generate test patterns to test path delay trouble. Toshiba explained that, with the tools, logic testing time can be slashed to 1/40th the time it takes now. They were expected to become available starting in October.

94. IBM (United States), July 1997

Toshiba and IBM will form an alliance in new memory plant construction. The two companies will cooperate in commercializing a 300mm wafer by exchanging equipment technology information and are considering installing a joint production line at their joint production plant.

95. Winbond (Taiwan), September 1997

Toshiba has expanded its relationship with Winbond Electronics of Taiwan to include 256Mb DRAM production. Toshiba will provide Winbond with 256Mb DRAM production technologies and procure chips as an OEM starting around 2000, when demand is expected to pick up. As part of its move to establish a global DRAM production system, Toshiba expected to begin procuring 64Mb DRAMs from the Taiwanese chipmaker in January 1998.

96. Worldwide Semiconductor Manufacturing Co. (Taiwan), October 1997

Toshiba has teamed up with WSMC of Taiwan in semiconductor production. Toshiba will provide 0.25-micron logic PC process technology to the Taiwanese chipmaker and commission some of its logic IC production. A dedicated foundry set up in May 1996, WSMC is expected to start foundry production in July 1998 and launch a new line in 1999.

Tosoku

97. Samsung (Korea), October 1997

Automotive part and precision machinery maker Tosoku has teamed up with Samsung Aerospace of Korea in the semiconductor wire bonder business. The partners planned to begin in December marketing a IC wire bonder they developed cooperatively by combining the Japanese company's semiconductor equipment and the Korean maker's linear motor technologies. The wire bonder achieves a leadframe transfer speed of 0.5 seconds/26.42mm and can process 400 42SOJ packages per hour. The companies are inclined to set the price below ¥9 million and intend to sell 100 units the first year.

Ulvac

98. Ramtron International (United States), March 1997

Semiconductor equipment maker Ulvac teamed up with Ramtron International of Colorado in ferroelectric RAM (FRAM) technology development. The companies will jointly develop ferroelectric materials such as lead zirconium titanate, ferroelectric thin-film process technology, and sputtering, etching, and ashing equipment over the next four years. Ulvac will start in 1999 to supply the new equipment it is developing in the joint project to chipmakers such as Hitachi, Rohm, Samsung, and SGS-Thomson, which uses Ramtron's FRAM technology.

99. Idemitsu Kosan (Japan), June 1997

Ulvac and Idemitsu Kosan will jointly develop a TFT panel transparent conductive film for larger substrates. They will combine Idemitsu-developed indium lead-based IDIXO film and Ulvac's sputtering equipment and process techniques to develop a transparent conductive film for use with LCD substrates of 13 and 14 inches to 17 and 20 inches. At present, polycrystal indium thin oxide film is typically used for TFT transparent conductive film. Ulvac and Idemitsu expect that LCD panel makers will start using the new film on production lines as early as 1998.

Yamaha

100. Xicor (United States), February 1997

Yamaha has teamed up with Xicor of California in the EEPROM business. Initially, the U.S. company will commission the Japanese company to manufacture EEPROMs, and both companies will cooperate in process technology development. Yamaha Kagoshima Semiconductor will start production in May 1998 at 2,000 six-inch wafers per month and will supply EEPROMs to cellular phone makers under Xicor's brand name. The world's No. 3 EEPROM maker, Xicor is reported to control the largest share, 30 percent, of the Japanese market for EEPROM used in cellular phones. Yamaha projects that Xicor-brand sales will reach ¥2 billion in the first year.

Chapter 1

Executive Summary

Japanese companies once enjoyed the largest share of the worldwide semiconductor market, but they are now exposed to aggressive competition, not only from new players in Asia/Pacific, but also from the American companies that the Japanese companies once thought they had beaten. However, the worldwide market continues to see oversupply in various MOS digital products, and prices do not show any sign of tightening up. This market condition is forcing Japanese companies to review their strategies in search of clues to the next growth stage.

This Competitive Trends focuses on the top 20 Japanese semiconductor companies and analyzes their competitiveness from the viewpoint of sales power, manufacturing power, and overall strategy. Sales, regional orientation, and penetration are examined for each company. In analyzing manufacturing trends, manufacturing power, defined as brand shipments plus foundry/OEM shipments, is analyzed for the first time. All metrics except for fabs, capital spending, and R&D spending, are taken from Dataquest's 1996 database because Dataquest is still in the process of finalizing 1997 revenue survey and analysis.

The appendix provides metrics such as product revenue, regional revenue, and market share by region and product for each of the top 20 Japanese companies.

©1998 Dataquest

Chapter 2
Brand Sales Power

In 1996, Japanese companies recorded a combined share of 36 percent of the worldwide semiconductor market. The year was marked by rapid price declines for DRAMs and various MOS digital products, such as flash memories, microcontrollers (MCUs), and application-specific ICs (ASICs). Japanese semiconductor vendors that were largely dependent on those product categories were no exception to the sluggish revenue growth that accompanied continued robust unit shipments. This was also the year in which the yen depreciated against the U.S. dollar, and Japanese companies' revenue in dollar terms was scaled down compared with that of global competitors. As a result, Japanese companies' market share fell four points from 1995, widening the gap with Americas companies to nine points.

In the 1980s, Japanese companies rapidly increased their revenue, pumped by DRAM sales and the consumer applications on which they focused. Their combined revenue showed a record high market share of 51 percent in 1988 to 1989, which has not been achieved by any companies since.

Or take a look at rankings. In 1986 through 1992, six Japanese companies were listed in the top 10 worldwide ranking. For 1985 through 1991, the largest semiconductor company in the world was Japanese—NEC Corporation. For 1986 through 1989, the top three companies in the worldwide market were Japanese. In 1996, however, only one company was among the top three, there were only four companies in the top 10, and the leading company was Intel Corporation. Americas companies enjoyed a combined share of 45 percent in 1996, a seven-point increase over 1988.

Korean companies are quickly catching up. In 1993, when Samsung Electronics entered the global top 10 ranking, Korean companies recorded combined revenue of $5.1 billion, which was about one-seventh that of Japanese companies. In 1996, Korean companies' combined revenue had grown to equal 22 percent of Japanese companies' revenue.

What has caused this decline in Japanese companies' share of the worldwide market? Is the trend going to persist in the near future?

Japanese Companies' 1996 Market Share

In the worldwide market, the Japanese companies' decline in market share was seen in all regions, caused mainly by the DRAM revenue contraction. Non-DRAM revenue showed growth of 10 percent on a yen basis for Japanese companies but a contraction of 5 percent on a dollar basis (see Table 2-1). In DRAM, Americas companies showed the largest contraction of the four regional bases, but they also recorded the largest growth in non-DRAM revenue. This is a result of Americas companies' penetration of the MOS logic area, as well as Intel's increase in MPUs. European companies fared well, too, and surpassed Asia/Pacific companies.

Table 2-1
Japanese Companies' Revenue Growth: A Comparison between DRAM and Non-DRAM (Percent)

	Total Semiconductor	DRAM	Non-DRAM
Total Companies	-6.3	-38.6	6.2
Japanese Companies (Dollar-Based)	-16.0	-40.3	-5.1
Japanese Companies (Yen-Based)	-2.7	-30.8	10.0
Americas Companies	6.0	-47.6	15.0
Europe, Africa, and Middle East Companies	6.6	-35.0	11.3
Asia/Pacific Companies	-24.1	-30.9	-2.9

Source: Dataquest (March 1998)

In the worldwide market, eight Japanese companies ranked in the top 20: NEC Corporation, Hitachi Ltd., Toshiba Corporation, Fujitsu Ltd., Mitsubishi Corporation, Matsushita Electric Industrial Co. Ltd., SANYO Electric Company Ltd., and Sharp Electronics Corporation. Only the first four of these made it into the top 10, with Mitsubishi slipping to the 11th position, replaced by SGS-Thomson Microelectronics B.V. This is the first time since 1985 that only four Japanese companies were included in the top 10 worldwide.

Figure 2-1 shows Japanese companies' market share the in major product categories. Bipolar digital is the category in which Japanese companies still rank second to Americas. The devotion of Japanese companies to this product area stems from their internal user in their computer and communications equipment divisions. In this shrinking portion of the market, Japanese companies' combined share amounted to 41 percent in 1996.

MOS memory, especially DRAM, has been the technology driver for Japanese semiconductor industry. In this market, however, Japanese companies are being exposed to a very competitive situation. The 1996 DRAM market declined 39 percent, and it was Americas companies whose combined revenue recorded the biggest decline—negative 48 percent against 1995. Asia/Pacific companies showed the smallest decrease of all—31 percent. Japanese companies recorded a 40 percent decline and had still the largest market share, 43 percent. But a trend among Japanese companies is evident: Larger Japanese companies maintained their respective positions, but smaller Japanese DRAM suppliers showed faster declines in revenue and lower rankings. Because the DRAM market is expanding more rapidly in foreign markets, it is the larger players that can access large-volume users, including PC vendors and module manufacturers, with favorable terms of trade. Dataquest's market share survey in memory revenue and unit shipments indicated a general trend in which smaller companies' average selling prices (ASPs) are significantly lower than those of larger companies.

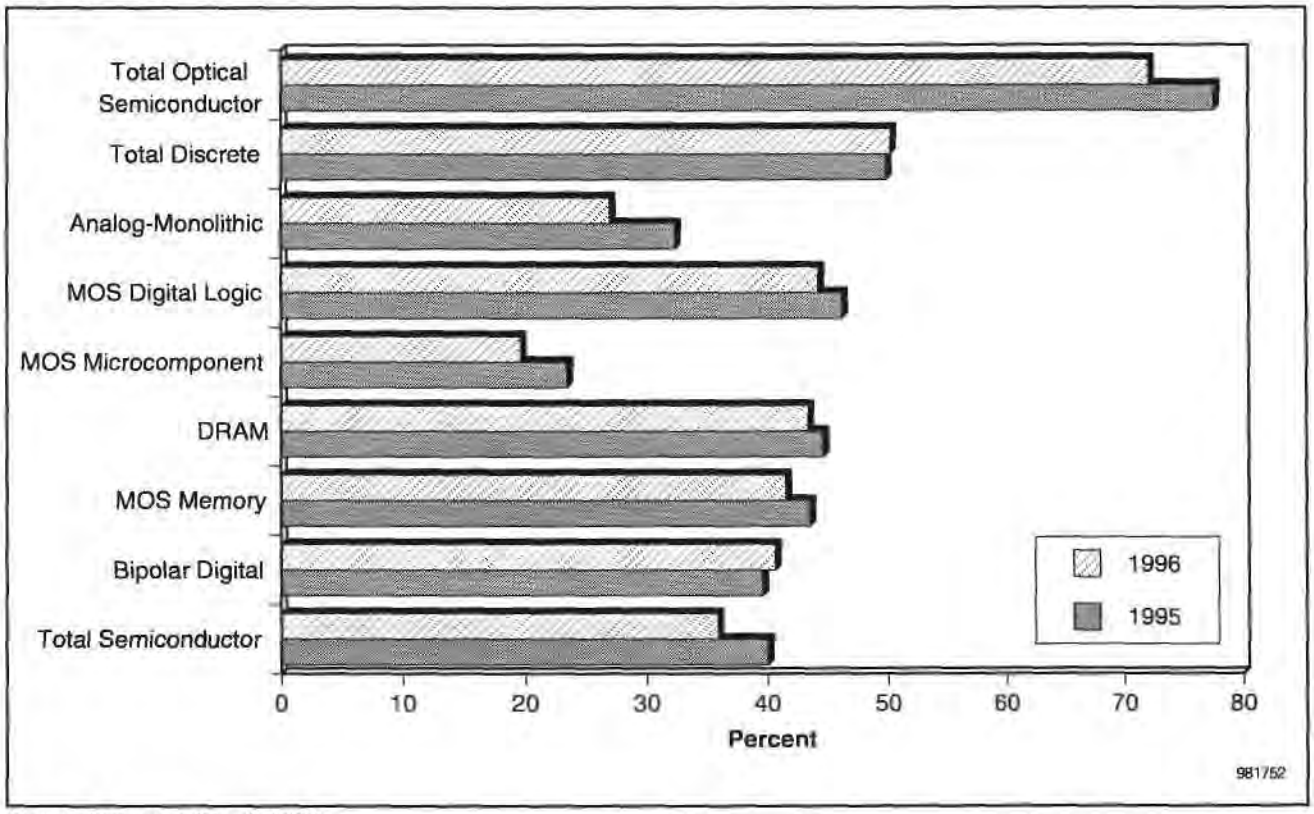
Figure 2-1
Japanese Companies' Worldwide Market Share in Major Product Categories, 1995 to 1996



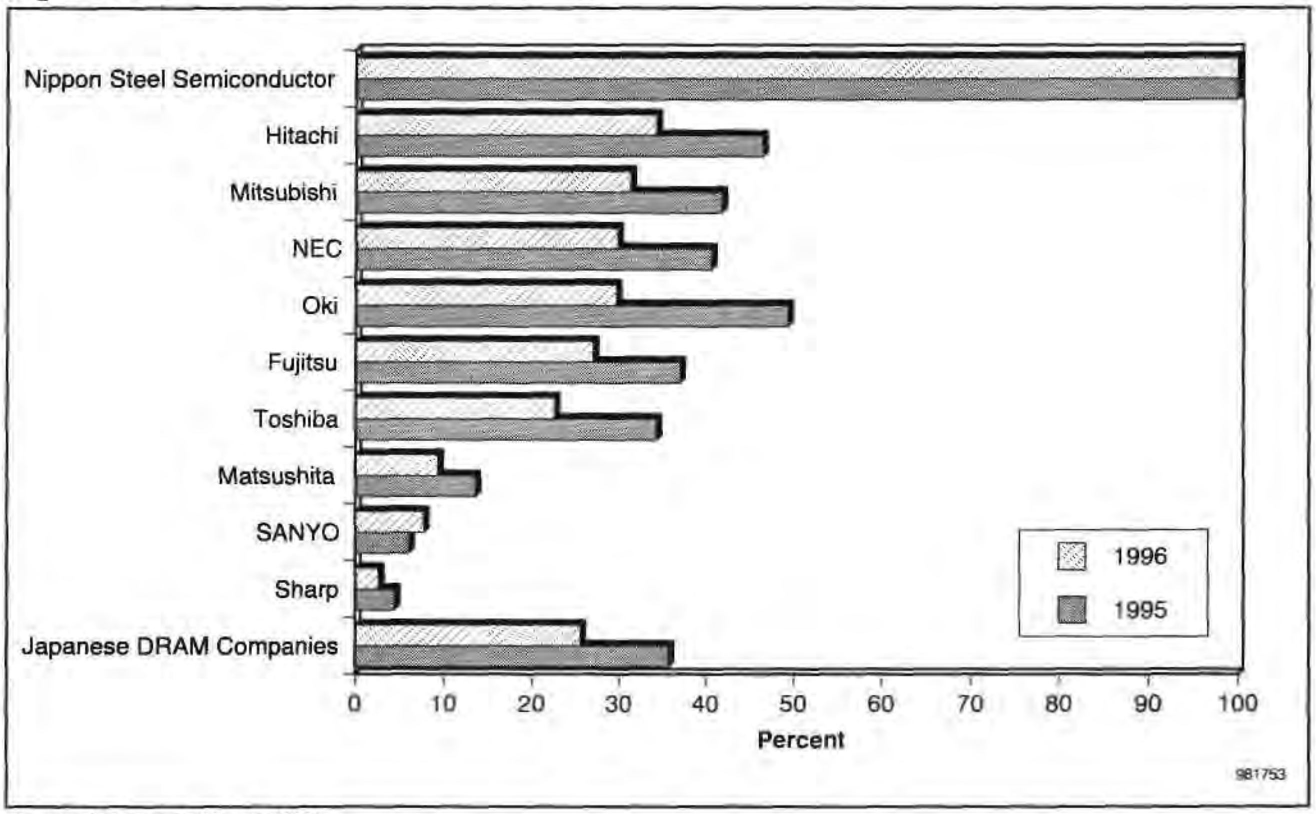
Source: Dataquest (March 1998)

DRAMs account for 22 percent of the total revenue of combined Japanese companies in 1996, a decline from 31 percent in 1995. Figure 2-2 shows DRAM ratio, focusing on Japanese DRAM vendors. After Nippon Steel Semiconductor came Hitachi, with 34 percent, followed by Mitsubishi. Japanese companies are not necessarily going out of DRAM business just because of the severe competition with Korean and Americas companies, but the diversification of products that Japanese companies planned to pursue has not yet brought significant revenue increases, forcing some Japanese companies to be even more selective in their DRAM business.

In the 1996 MOS microcomponents market, Japanese companies have nurtured expertise and consequently have enjoyed a large share of the market in MCUs. This resulted from their users' focus on consumer equipment, which brings a large number of MCU orders. As Japanese electronic equipment production shifted focus from consumer equipment to data processing and communications and as MCUs were upgraded to higher bits, Japanese semiconductor users started to explore a wider selection, including MPUs and digital signal processors (DSPs). As system-level integration (SLI) becomes the key technology for emerging applications such as digital consumer equipment, Japanese companies face decisions about reorganizing their microcomponent and logic operations to offer the best SLI solutions to users.

 ©1998 Dataquest

Figure 2-2
Japanese DRAM Vendors' DRAM Ratios



Source: Dataquest (March 1998)

In the MOS logic market, Japanese companies also leveraged consumer product large-volume orders. Among ASIC products, gate arrays have been the major product offering from Japanese vendors. This dependence caused Japanese companies to lag behind worldwide trends, which show large-scale systems preferring cell-based ICs (CBICs) and smaller systems preferring programmable logic devices (PLDs). Gate arrays fall between those two fast-growing categories, and here again, Japanese ASIC vendors must go through structural changes to refocus their operations. Also a part of the "other MOS logic" category are application-specific standard products (ASSPs); this category includes various consumer-use logic ICs, especially those used for audio and video applications equipment and LCD drivers.

Analog devices also benefited from the traditional consumer orientation of the Japanese electronics and semiconductor industry. As electronic equipment production shifts focus to data processing, communications, and automotive applications, Japanese companies have started to emphasize what they called industry-use linear ICs and then mixed-signal ICs. (The traditional consumer orientation has caused Japanese companies to call all other applications "industrial" in their own categorization.) In the standard product area, general-purpose products have found their way into a wide selection of applications, helping Japanese analog vendors run their fabs, albeit with low profits.

 ©1998 Dataquest

Some dedicated vendors have sought to expand markets and applications for discrete devices, first in consumer equipment and then in peripherals such as flexible disk drives (FDDs), rigid disk drives (RDDs), and, recently, CD-ROMs. Small-signal products, both transistors and diodes, have always found new markets in emerging applications. Because new system designs required new circuit blocks and glue logic, small-signal transistors were the best choice to start with, to be replaced by ICs afterwards. In the fastest-growing area of power devices, there are mainly two lines of products being offered by Japanese companies, power supply devices and radio frequency (RF) power devices. RF products have also become an area in which Japanese manufacturers nurtured expertise, first with radio equipment, then TV equipment, and now mobile communications.

In optical semiconductors, there are dedicated suppliers such as Stanley Electric Co. Ltd. and Hamamatsu Photonics K.K. Although larger semiconductor suppliers also cover optical semiconductors, smaller, dedicated vendors have expanded the market by responding to precise requirements from customers, a practice that big companies found inefficient. As a result, LED suppliers may know of a wider range of users than IC suppliers do. Coupler and sensor markets have expanded because they are used along with microcontrollers and logic ICs and for systems with different voltage blocks. In the traditional model, volume orders for charge-coupled devices (CCDs) came from only a few consumer applications, such as camcorders, and small-volume, high-ASP orders came from broadcasting and various industrial applications. As imaging became a feature of PCs and PC peripherals, CCDs for scanners have come to hold a larger share of the increment of the CCD market. Laser diodes were high value-added products but were a small-volume market until CD players came into production. With the expansion of CD technology applications, demand for laser diodes rose rapidly, which brought costs lower and further expanded the market. Here again, Japanese vendors have leveraged domestic users' orientation in this area.

The Product Mix

Figures 2-3 and 2-4 show Japanese companies' and all companies' share of worldwide product revenue for 1992 and 1996, respectively. Figure 2-5 shows MOS digital product revenue share for Japanese companies and the worldwide market. In 1992, for both, MOS digital ICs represented a little more than half of total revenue, and the difference was negligible—one point—between the two. But in 1996, MOS digital products accounted for more than 70 percent of the worldwide market, while for Japanese companies, revenue from these products accounted for only a little more than 60 percent. Subtracting Intel's microprocessors, a unique situation, reveals basically the same picture—Japanese companies are lagging behind the worldwide market in digitization.

Although it is true that Japanese companies are losing market share to Korean and American companies even in DRAM, which has driven market share for Japanese companies, the lag is more evident in the microcomponent and logic areas, posing a threat to Japanese companies in light of trends toward system-level integration.

Regional Trends of Japanese Companies' Semiconductor Revenue

Historically, Japanese companies benefited from the fast-growing domestic market, where the Japanese consumer equipment manufacturers that dominated the worldwide market increased production of consumer electronics. Thus, the Japanese market was dominated by Japanese vendors (see Figure 2-6), and a large portion of Japanese companies' revenue came from the domestic market (see Figure 2-7).

The first drastic change occurred in the mid-1980s, when the Japanese yen started to appreciate and electronic equipment manufacturers started to move their production sites overseas, mostly into various Asia/Pacific countries. This meant that Japanese semiconductor companies had to have sales offices, technology support centers, and eventually, production facilities in Asia/Pacific.

The second wave came in 1993, when the yen soared again, but this was also a year when the Japanese semiconductor market continued to be sluggish while all the other regional markets began to expand rapidly, driven by the PC boom. This trend prompted Japanese companies to expand foreign operations.

Source: Dataquest (March 1998)

Figure 2-8 compares regional companies' trends in regional sales. Among all regional companies, a sales focus on the company's own region is commonly seen. The extent of focus varies, however, according to market size and growth potentials. A notable difference between Japanese and non-Japanese companies is that non-Japanese companies tend to focus on at least one more regional market, while the domestic market seemed to be the only focus for Japanese companies. With the shift of application equipment production overseas, a focus on the Japanese semiconductor market alone could not bear much fruit. In fact, the sum of the market in Japan and in Asia/Pacific still represents about half the worldwide market, and this has encouraged Japanese companies to do close follow-up of their domestic users at foreign sites.

Tables 2-2 and 2-3 compare Japanese companies' trends in regional sales. Companies that focus on non-Japanese markets are Nippon Steel Semiconductor, Toshiba, Oki Electric Industries Company Ltd., and SANYO. They either followed their domestic users at foreign sites very closely or sought foreign markets for general-purpose products, including DRAM.

Companies such as Nippon Steel Semiconductor, Oki, NEC, Hitachi, Seiko Epson Corporation, Toshiba, and Mitsubishi generate more than 20 percent of their worldwide revenue in the Americas market. Those are the companies that are focusing heavily on either memories or logic in the region. It should be noted that, of these, NEC, Hitachi, and Mitsubishi have wafer fabs in the United States, and Toshiba has set up a joint venture with IBM.

The European market shows a somewhat different trend. Fujitsu leads Japanese companies, with 14 percent of its worldwide revenue coming from the Europe, Africa, and Middle East region. This is a benefit of having an internal user there. Hitachi, Mitsubishi, NEC, and Toshiba have a comparatively high dependence on the European market, and here again, the first three companies have wafer fab operations within the region, while Toshiba has back-end operation.

Source: Dataquest (March 1998)

Many Japanese companies sell hard into the Asia/Pacific market, but are not enjoying a high market share. In fact, when compared with the average orientation of Japanese companies, only Toshiba shows a determined regional orientation across the regions, while most other companies focus either on Americas and Europe or Asia/Pacific. Notably, it is the smaller companies that show high dependence on Asia/Pacific, which seems to represent their efforts to maintain business relationship with the Japanese users.

Matsushita and Sony do not seem to focus on overseas sales, but their internal sales need to be noted: These are the companies with large internal demand from user divisions and companies, and their sales of components tend to take place within Japan rather than at user divisions' actual production sites in Asia/Pacific.

A Quick Look at the 1997 Rankings

Dataquest has completed its annual 1997 market share survey. Details of the survey have been discussed in Perspectives, and trends in the Japanese market will be discussed extensively in an upcoming Market Trends report. Tables 2-4 and 2-5 show worldwide and Japanese market share rankings, respectively.

Table 2-4
Revenue of Japanese Companies in the Top 20 Worldwide Ranking from Shipments of Semiconductors to the Worldwide Market, 1997 (Millions of Dollars)

1996 Rank	1997 Rank	Company	1996 Revenue	1997 Revenue	Growth (%) 1996-1997
2	2	NEC	10,428	10,222	-2.0
5	5	Toshiba	8,065	7,253	-10.1
4	6	Hitachi	8,071	6,298	-22.0

©1998 Dataquest

NEC maintained the top position among Japanese companies, but the gap between it and the worldwide top company, Intel, has widened, with Intel recording nearly double NEC's revenue. The second- and third-ranked Japanese companies, Toshiba and Hitachi, changed places, mainly because of the hardship Hitachi faced in 1997 from DRAM price declines and slow expansion of its proprietary microcomponent product line. Other companies maintained their positions, including Toshiba and Fujitsu, but Mitsubishi could not find its way back into the top 10 ranking.

In the Japanese market, there were only a couple of changes in the ranking. Toshiba and Hitachi switched positions, as did Mitsubishi and Intel; all the others maintained their 1996 rankings. NEC not only remained at the top but widened the gap with the followers, showing only a modest decline in revenue.

Chapter 3

Manufacturing Power

This chapter measures and analyzes Japanese companies' manufacturing power, as opposed to their brand sales power in the previous chapter.

Dataquest defines manufacturing power as:

- Manufacturing power = brand sales + foundry sales - foundry purchase

Some Japanese companies choose to announce production numbers on a fiscal year basis. Production numbers usually include both foundry shipments and foundry purchases, but some details remain unexplained. In this analysis, Dataquest applies its own measurement of all three factors in the equation above, based on its proprietary definitions.

1996 Foundry Trends

Japanese companies' foundry activity can be classified as either OEM business or foundry. OEM designates the kind of partnership business in which the provider company designs and manufactures a product sold under the partner's brand. Thus, the basic difference between OEM manufacturing and foundry lies in designing—in foundry, the user of foundry capacity designs the products, the provider manufactures them, and the products are marketed by the foundry user under its brand.

Starting in mid-1980s, Japanese semiconductor companies' foundry activity included a unique business type in which Japanese companies formed a cooperative framework to market their foreign counterparts' products, primarily to enhance foreign vendors' presence in the Japanese market. This took various forms of collaboration, including codevelopment of new products, fine-tuning of foreign-origin products to meet Japanese users' needs, sharing of production capacity and sales channels, and so on. This practice has decreased as foreign vendors built their own business systems in the Japanese market, and the recent rise in foreign companies' combined market share clearly shows that non-Japanese companies can be competitive in this market without the help of domestic competitors. In 1996, the Japanese market share of all non-Japanese semiconductor companies rose to 26 percent, and it is expected to increase further in 1997.

Historically, there was another type of foundry/OEM practice, especially among Japanese companies: fab transition, when old-generation DRAM fabs are refurbished with additional equipment to be used for other products, characteristically for microcomponents, logic, and then analog, or in the final stage, even for discrete. Those non-DRAM products could be produced at fabs that were largely, if not completely, depreciated, and thus the profitability of the overall semiconductor business was secured. Dataquest has identified this trend as the "Japan model," because this transition was possible with wide range of product offerings, which major Japanese companies have managed to grow.

 ©1998 Dataquest

One form taken by this Japan model was OEM, with the provider offering manufacturing capacity for other companies' non-DRAM products. There were various strategic reasons for this kind of arrangement. Company A might be lagging behind in microcomponents. Rather than develop and manufacture microcomponents starting from ground zero, it might opt to turn to leading company B's product area, and then company A might provide B with A's own products in which B might not have invested as strongly. This kind of collaboration was actually based on very strategic decisions and was usually done among Japanese companies. Dataquest believes the scope and the amount of this kind of practice has largely been reduced in the 1990s.

Pure foundry has been regarded by Japanese semiconductor companies as a zero-profit operation, mostly because Japanese companies, with a few exceptions, used foundry as a way to fill their fabs. This kind of opportunistic foundry sales was encouraged when the market was in oversupply and the utilization of fabs dropped below the sound level. Rather than running the fab at low utilization, Japanese companies opted to find low-margin foundry business. Of course, there were several cases of Japanese companies' seriously seeking foundry opportunities to strengthen ties with foreign companies, especially some American and European companies. This took the form of production capacity sharing as part of an alliance on new product development or on new technology.

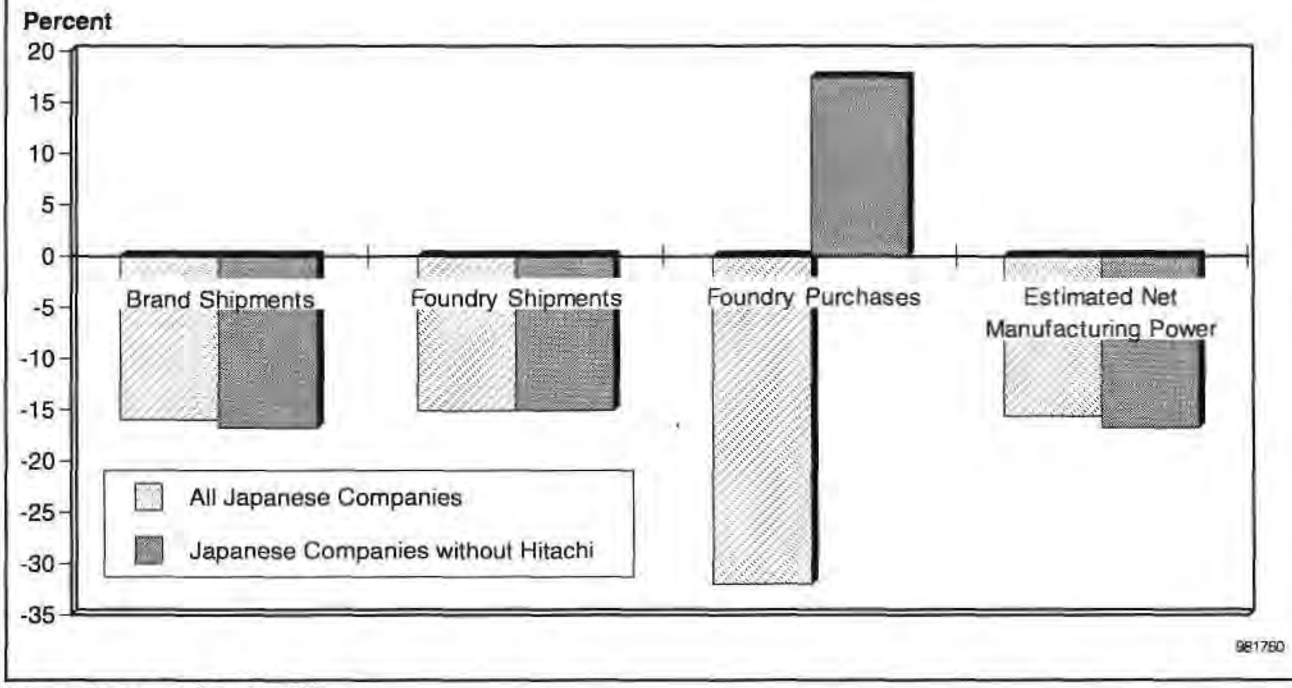
The emergence of dedicated foundry providers, however, has changed the framework. New foundry providers applied leading-edge technology and focused on manufacturing efficiency. (Detailed analysis of dedicated foundry providers is provided in various publications in the Dataquest's Semiconductor Contract Manufacturing Services Worldwide program.) The decline in foundry shipments stems from various factors, such as severance of a company's collaborative framework with its foreign counterparts or discontinuation of old-type Japanese OEM, but the most characteristic reason is weakening competitiveness against dedicated foundries. In view of the continued oversupply in the DRAM market, Japanese companies have sought foundry opportunities. The success of dedicated foundries in both revenue and profit has also encouraged some Japanese companies to include foundry among their business planning options.

1996 Manufacturing Revenue Estimates

Using the formula given earlier, Figure 3-1 shows Japanese companies' total foundry and manufacturing power trends, while Figures 3-2 and 3-3 show estimated manufacturing revenue for each Japanese company for 1995 and 1996, respectively.

 ©1998 Dataquest

Figure 3-1
Japanese Companies' Foundry and Manufacturing Power, 1995 and 1996 (Percentage Change)



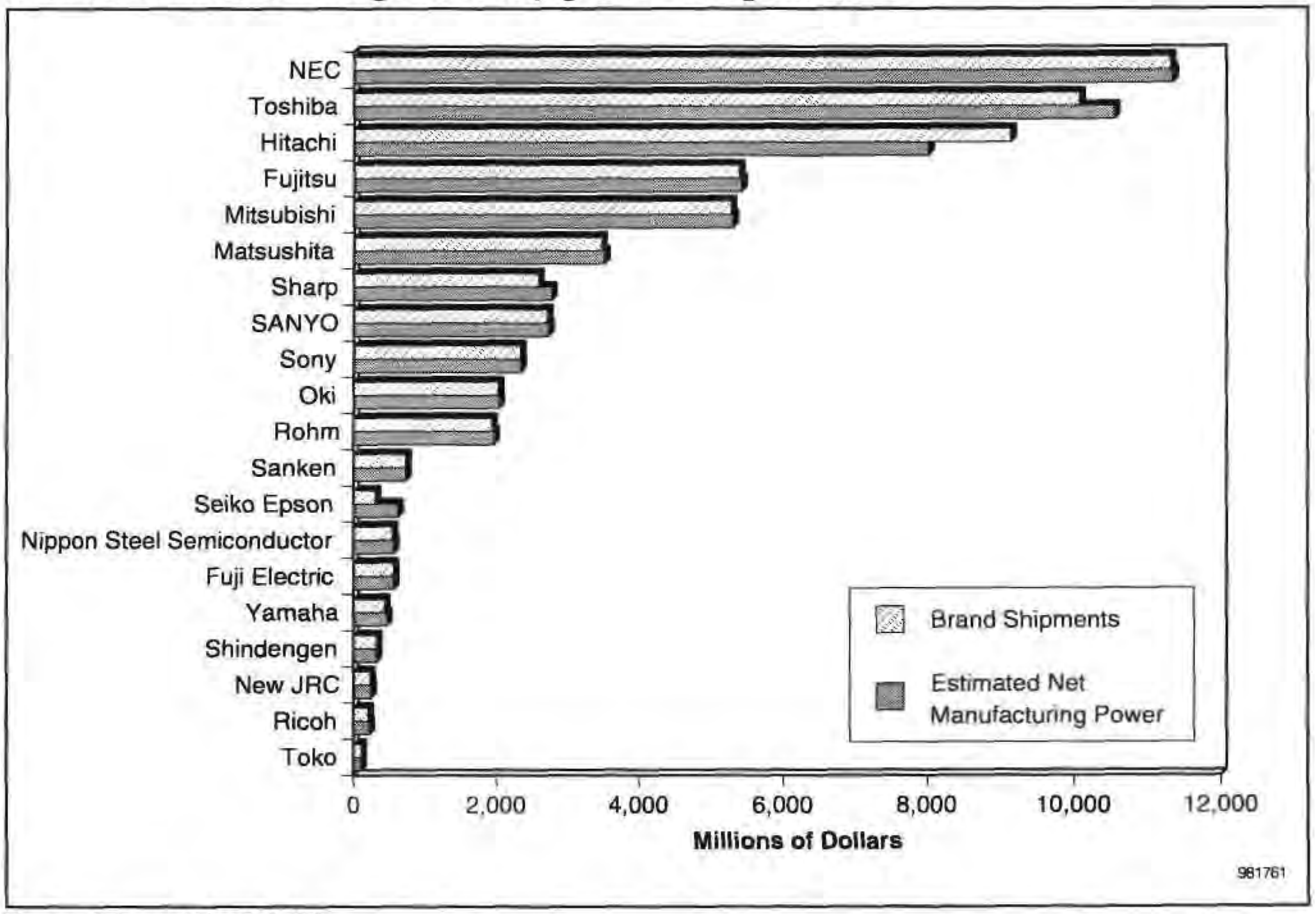
Source: Dataquest (March 1998)

The analysis of manufacturing power reveals some trends. In 1996, Japanese companies' brand shipment revenue was heavily impacted by weak pricing and declined. This was caused by the oversupply in MOS digital products caused by fast expansion of production capacity in the preceding few years. In these situations, Japanese companies have typically made efforts to increase foundry shipments to "fill the fab." Dataquest believes that this opportunism is one of the characteristics of Japanese companies' foundry business, which can still be observed in their business decisions.

But in 1996, foundry shipments declined faster than brand shipments. Revenue information for 1997 is yet to be finalized, but a preliminary look at the survey results indicates another year of declining foundry shipments. This clearly represents the hardship Japanese companies are facing in competition with dedicated foundry providers, such as some Taiwanese companies, as discussed earlier. This also seems to represent another trend—there is very little foundry business left among Japanese companies, except for some examples, such as the Mitsubishi-Seiko Epson agreement on foundry of proprietary embedded DRAM products.

 ©1998 Dataquest

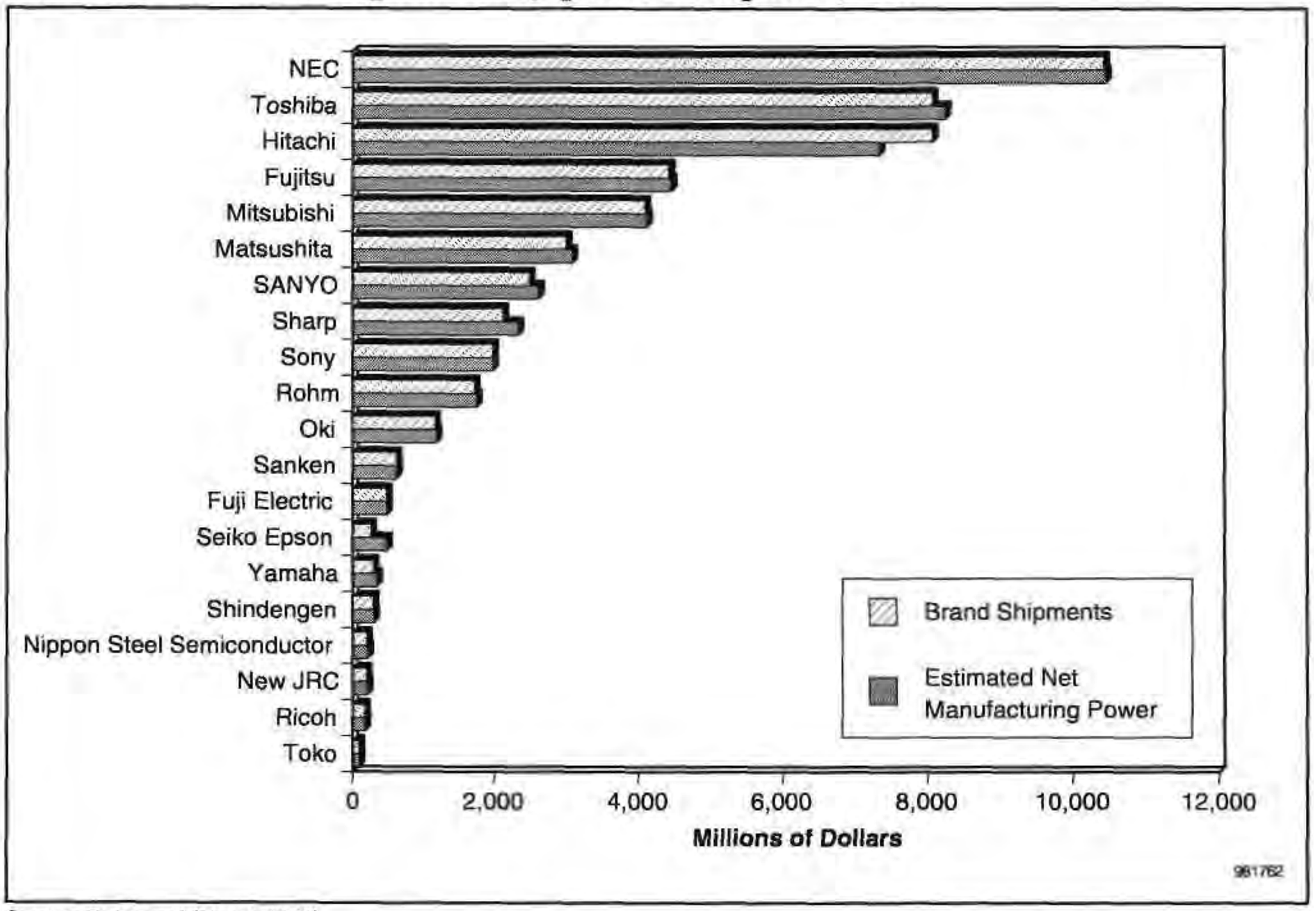
Figure 3-2
Estimated Manufacturing Power of Japanese Companies, 1995



Source: Dataquest (March 1998)

Another trend is becoming clearer: Japanese companies are increasing foundry purchases. It should be noted that DRAM OEM purchasing, such as Hitachi-LG Semicon, has been impacted by the fast price decreases, while, on a unit basis, it is growing. Again, because inter-Japanese foundry is decreasing, this increase in foundry purchases can only be attributed to alliances with non-Japanese companies. Contributing to this trend are examples such as Toshiba-Winbond and Fujitsu-Taiwan Semiconductor Mfg. Co. (Dataquest does not regard Powerchip Semiconductor Corporation as a foundry to Mitsubishi at this time). Although still small, the trend toward increasing foundry purchases is evident, and there will be more of this, both in size and in product categories, as Japanese companies try to focus on a limited number of products for efficient management of their semiconductor business.

Figure 3-3
Estimated Manufacturing Power of Japanese Companies, 1996



Source: Dataquest (March 1998)

1997 Fab Trends

Manufacturing power has been the biggest factor in the rise of Japanese semiconductor companies in the worldwide market. In a fast-growing market, supply capacity played a key role in increasing revenue, and Japanese companies' strategies centered around the decision to increase capital spending on manufacturing capacity.

Trends over Time

Japanese companies' fab construction has been driven basically by two factors—DRAMs for major companies and cyclical business trends.

DRAM companies accelerate fab construction during DRAM boom years, including new shells and even new sites. To simplify the pattern, some of this effort results in oversupply after the boom years, and new shells remain empty for some time, to be filled only in the next cycle. This pattern has caused radical ups and downs in DRAM companies' capital spending.

©1998 Dataquest

Non-DRAM companies have built fabs at a comparatively constant pace, but again on a cyclic pattern. To these companies, business cycles were triggered by demand cycles observed up to the 1980s. When such cycles became less visible in the 1990s, the companies started to increase fab capacities at a constant but gradual pace. Some companies have chosen to make certain product areas the driver of technology and fab expansion, such as microcontrollers, analog, or power discretes, depending on product coverage.

Regional Fab Trends

In the rise of the Japanese semiconductor companies, the fast-expanding domestic market was more than enough to consume output from Japanese companies' fabs. As regional market trends changed, however, and Japan became the slowest-growing market and as the Japanese yen appreciated, Japanese semiconductor companies had to expand overseas production operations while they had a way of concentrating production facilities in the domestic region. Only a handful of companies have continuously invested in foreign countries for manufacturing. The few foreign production sites secured by Japanese companies were mostly acquired or built during or right after the semiconductor market boom. Table 3-1 lists major foreign fabs of Japanese companies.

Type of Operation

Japanese companies' foreign wafer fab operations started through acquisition of existing fabs of local companies. Then those fabs were expanded and upgraded to produce DRAMs or logic products to be marketed locally. There were exceptions, such as NEC's Roseville fab, part of the output of which has been sent to other regions to be packaged and marketed globally.

During the PC-driven boom years of 1993 to 1995, Japanese companies announced plans to enhance their overseas wafer fab operations, including new fabs such as NEC Scotland's Phase 2 and Hitachi's HISUS U3, to develop new wafer fabs at back-end sites, such as Mitsubishi's Aachen fab, or to enter joint ventures with non-Japanese companies, such as Powerchip Semiconductor (Mitsubishi-UMAX), TwinStar (Hitachi-Texas Instruments Inc.), Dominion Semiconductor (Toshiba-IBM), or joint ventures between Japanese companies, such as Hitachi-Nippon Steel Semiconductor in Singapore. The strategy varied according to each company's global strategy and the technology alliances the company had formed.

For back-end operation, an increasing portion of foreign operations seems to have been shifted from Japanese companies to local assembly and test houses, but details are yet to be surveyed. Also noteworthy is the increase in module production overseas, where local sales offices and production sites have chosen local subcontractors to assemble memory modules to meet fast-changing local demand as well as stringent price requirements.

Source: Dataquest (March 1998)

Detailing trends in design is beyond the scope of this analysis, but significant numbers of design centers have been set up around the world in the past few years to meet local system requirement. In a limited number of cases, however, locally designed products can be marketed autonomously—a central control from the headquarters is still the norm for most Japanese companies, which foreign local users may find inefficient and time-consuming.

The Advantages in Constructing an Overseas Fab

There are various reasons for Japanese companies to set up foreign production facilities, which can be classified as demand-side (or environmental) and supply-side (or corporate-oriented) reasons. Demand or environment are also characterized as "pull" factors, because companies are pulled to overseas sites for those reasons, while supply or corporate reasons are "push" factors, for these push the companies to foreign production. The following are the factors pulling and pushing Japanese fab construction overseas:

- Demand/environment
  - Timely response to local demands
  - Enhanced dependability for local customers
  - Fast growth in local demand
  - Avoidance of trade barriers such as tariffs
  - Avoidance of trade friction by substituting export into the region with local production
  - Integration of the production process from design to assembly and test
  - Strengthening of partnerships with allied local companies
  - Alliances with local user companies
- Supply/corporate
  - Sharing fruits of codevelopment with local companies
  - Technology transfer
  - Risk diversification by having multiple suppliers
  - Slow growth in domestic demand
  - Reduction in manufacturing cost
  - Reduction in logistics cost
  - Incorporation of or deployment of local human resources
  - Deployment of various local resources from local allied companies
  - Recycling profits from local sales
  - Ample funding

Characteristics of Japanese Fab Expansion Overseas

Historically, Japanese companies' fab construction has been aggressive during semiconductor boom years. This can be attributed to two reasons. One was the increase in profits generated by the stable prices companies enjoy in up cycles. The other was semiconductor trade friction: Foreign investments were accelerated when a sudden increase of semiconductor exports from Japan caused a trade imbalance. Foreign fabs that have been built or acquired with this kind of background were not exactly based on Japanese companies' own long-term strategies, and, with a couple of exceptions, those fabs remained comparatively small in terms of wafer processing capacity. In back-end operations, reimport of output at Asia/Pacific sites to Japan was seriously considered, and in some cases, actually done to leverage on yen appreciation.

The rush in Japanese companies' overseas fab construction in 1993 through 1995 was characterized by one factor significantly different from the past—foreign markets were expanding much faster than the domestic market and "manufacturing near the market" had become the norm. NEC upgraded its Roseville, California, fab and started constructing a 200mm wafer fab in Scotland for 64Mb DRAM production. Toshiba, for the first time in its history, decided to build a DRAM wafer fab outside Japan, in alliance with IBM. Hitachi made two plans—TwinStar to produce DRAMs and HISUS U3 for production of proprietary microcomponent products. Fujitsu announced expansion at its Oregon site for production of 64Mb. Mitsubishi finally started a DRAM wafer fab at Aachen, Germany, after several years' hesitation. Matsushita decided to strengthen its fab operation in the United States by adding a 0.25-micron fab for 64Mb DRAM production. And Hitachi and Nippon Steel Semiconductor began construction of a joint wafer fab to produce 64Mb DRAM in Singapore. All those plans were aimed at seriously expanding sales of targeted products both locally and internationally.

This sudden flourish of overseas fab construction is, actually, nothing new for boom years. As discussed earlier, there are various reasons for Japanese companies to build foreign fabs, but one reason for all companies and all occasions is the ample financial resources available in boom years. This, in turn, implies that in bust years, Japanese companies' fab expansions dwindle, and in actuality, the record confirms that trend. So will negative attitudes among Japanese companies toward overseas fabs prevail in this adverse environment? There are signs to support that view, but details are yet to be announced.

Regional Spending Trends

Capital spending in Japan has been mostly done by Japanese companies. Table 3-2 shows 1997 capital spending in Japan. In that year, almost the whole amount was estimated to have been spent by Japanese companies. During the 1980s through the early 1990s, when access to the Japanese market was a hot topic on the international scene, Japan was the largest single semiconductor market in the world. In an effort to increase sales here, non-Japanese companies started chip production in Japan. Texas Instruments could be described as one of the most aggressive, in the sense that it moved the headquarters of its DRAM operation into Japan. Some companies chose to set up joint ventures, such as Tohoku Semiconductor (Motorola Incorporated and Toshiba), Nippon Precision Circuits (LSI Logic Corporation and Kawasaki Steel Corporation), and KTI Semiconductor (Texas Instruments and Kobe Steel Ltd.). Fujitsu-AMD Semiconductor became the last to take this approach. Currently the interest of non-Japanese companies seems to have shifted to other regions, especially Asia/Pacific, for both a market and a supply base.

However, Japanese companies' spending still goes mostly into their domestic sites. In the 1980s, Japanese companies are estimated to have spent about 85 to 90 percent of their total capital spending within Japan, while in the early 1990s the ratio has dropped to 80 to 85 percent, leading to an increase in foreign production. This trend was caused by two factors: yen appreciation, which made it more lucrative for companies to produce and sell in the dollar economies, and market expansion. Foreign markets were expanding faster than Japanese markets, and if the name of the game is to "manufacture near the market," it was not advantageous to continue producing within Japan and then export the output. There were other reasons, including political decisions, but overall, the Japanese companies' spending overseas continued to increase up to the year 1996. Because total spending continued to increase in 1996, the ratio of overseas spending against the total peaked in 1995 (see Figure 3-4).

Then the tide changed. The yen started to depreciate, and the semiconductor market showed contraction. Reduced profits constrained capital spending, but Japanese companies also had to maintain capital spending for next-generation technologies and products. This has led them to spend more in advanced fabs within Japan and to review foreign operations. This was a difficult choice, because non-Japanese markets were still growing faster than the domestic market.

Table 3-2
Manufacturing Capital Spending in Japan, 1992 to 1997

	1992	1993	1994	1995	1996	1997
Japanese Spending ($M)	3,958	4,413	6,667	9,912	9,654	8,342
Growth (%)	-30.6	11.5	51.1	48.7	-2.6	-13.6

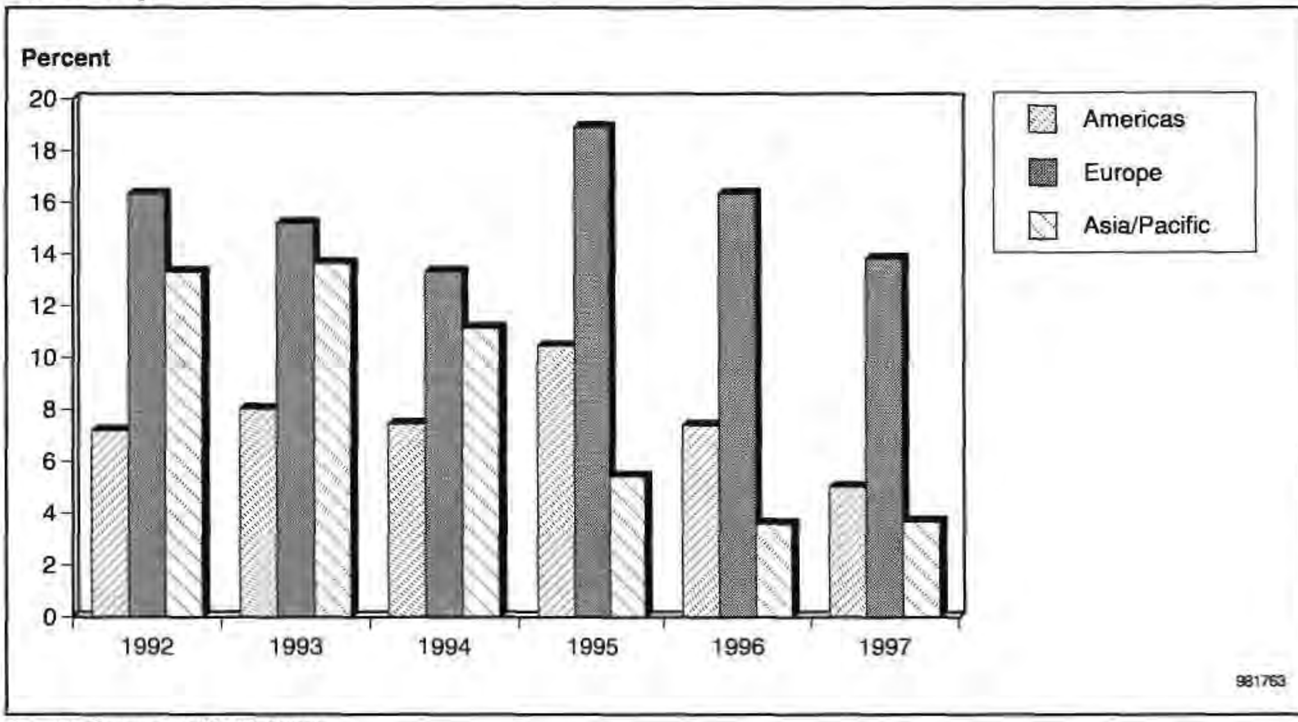
©1998 Dataquest

Figure 3-4
Japanese Companies' Overseas Capital Spending, 1992 to 1997 (Percentage of Total Spending)



Source: Dataquest (March 1998)

Product Trends

Japanese companies' capital spending trends by product area are shown in Figure 3-5. DRAM alone represented about half the capital spending in Japan in the 1980s and more than 40 percent in the first half of 1990s. As excess capacity prevailed in the MOS digital product area, additional capacity plans for DRAMs were the first to be reviewed and eventually abandoned. Those fabs were then either redesigned for other memory products, such as flash memory, and microcomponents and logic products or postponed. In 1997, the whole memories category still represented more than half the total spending of Japanese companies. This decline in DRAM ratio does not necessarily mean that Japanese companies are abandoning the DRAM business—in fact, an increasing amount of DRAM foundry purchasing indicates that Japanese companies are determined to stay in the market while reducing the burden of capital spending into this volatile product category.

Spending for microcomponents and logic products is on the rise. Japanese companies have repeatedly attempted to focus on non-DRAM MOS digital products when the DRAM market has crashed. This time, however, the situation is quite different, because the market is moving fast toward system-level integration. The emphasis on non-DRAM products meant adding equipment to fabs originally constructed for the most advanced DRAM products, but the current focus on microcomponents and logic, especially cell-based ICs, requires the most advanced manufacturing equipment. Thus, the Japan model does not work anymore, and Japanese companies face the decision of whether to build a fab initially for logic products or memories. This implies that they will either need to prepare products that can fill those fabs afterwards to lighten the depreciation cost or they will have to turn to outsourcing—in other words, foundries.

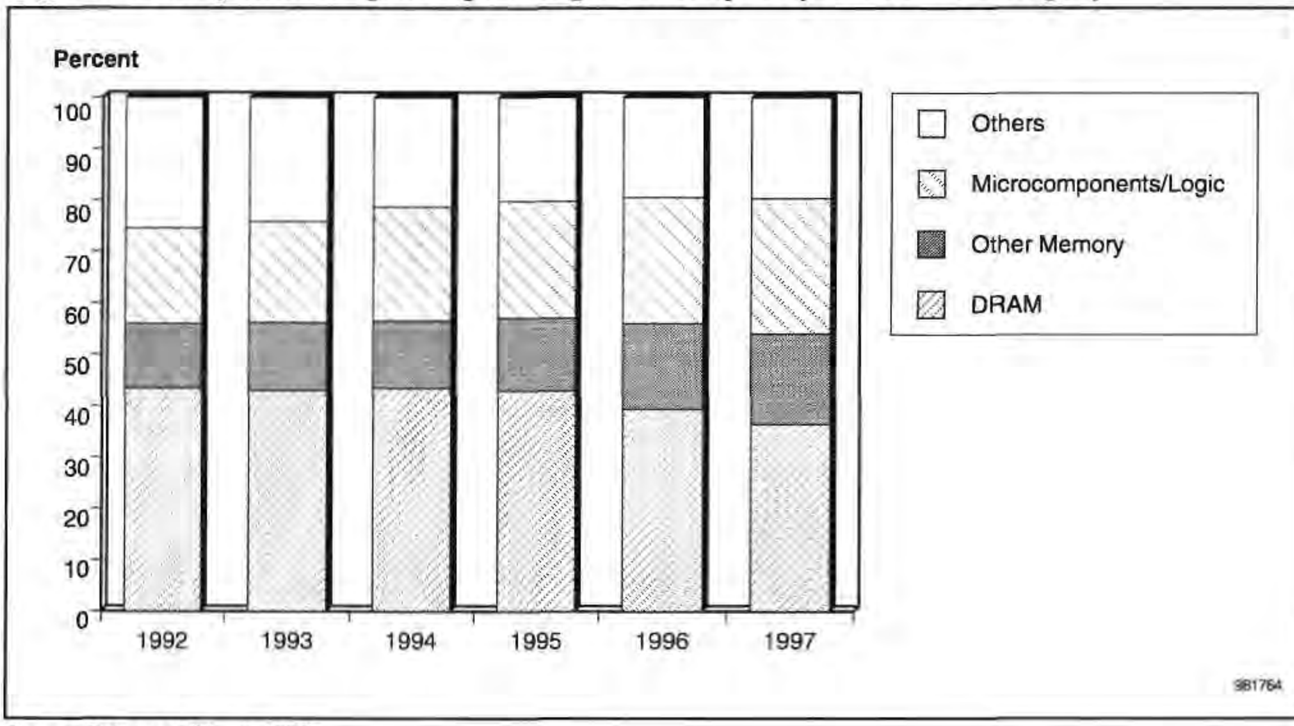
Figure 3-5
Japanese Companies' Capital Spending Trends by Major Product Category



Source: Dataquest (March 1998)

As discussed in the section on foundry and manufacturing power, Japanese companies are adopting a new business model to make more use of contract manufacturing.

Research and Development Expenditure

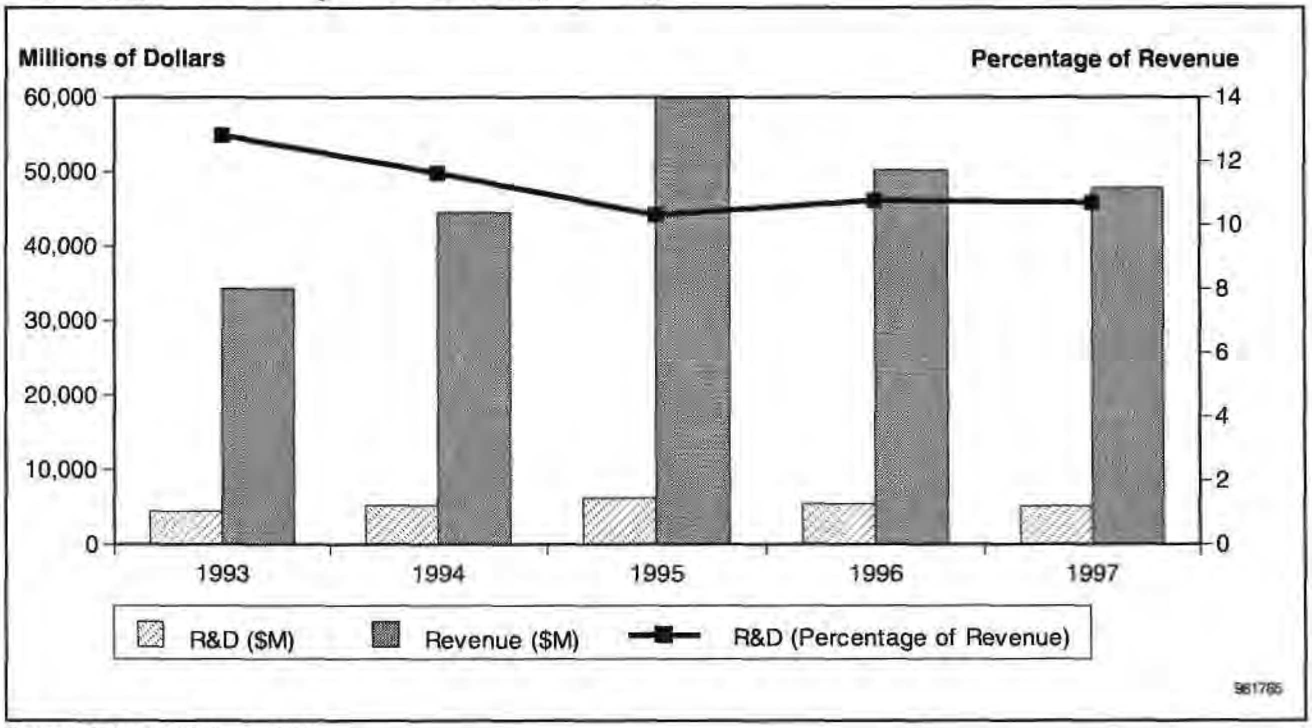
Technology and product development, another aspect of manufacturing operations, will be covered in more detail in future documents. In this section, Dataquest looks only briefly at R&D expenditure; detailed information on alliances will be covered in a future Dataquest document.

The R&D spending of Japanese semiconductor companies was revisited in Dataquest's recent survey to clarify the distinction between manufacturing capital spending and R&D spending. Figure 3-6 shows estimated R&D spending for major Japanese companies. The companies can be divided into three groups according to level of spending.

Top companies spend about 10 to 15 percent of their semiconductor revenue on R&D activities, and they tend to maintain this level of spending over time (see Figure 3-7). These are the companies that lead technology development, competing hard with each other to develop and market new products ahead of everyone else. Not all of their spending brings additional revenue directly, because some part is spent on fundamental technologies and because some R&D is not fruitful. In view of the need to clarify their business focus, companies are changing this attitude and have started to explore the possibility of reducing their spending in areas on which they may not focus.

 ©1998 Dataquest

Figure 3-6
Top 20 Japanese Companies' R&D Spending

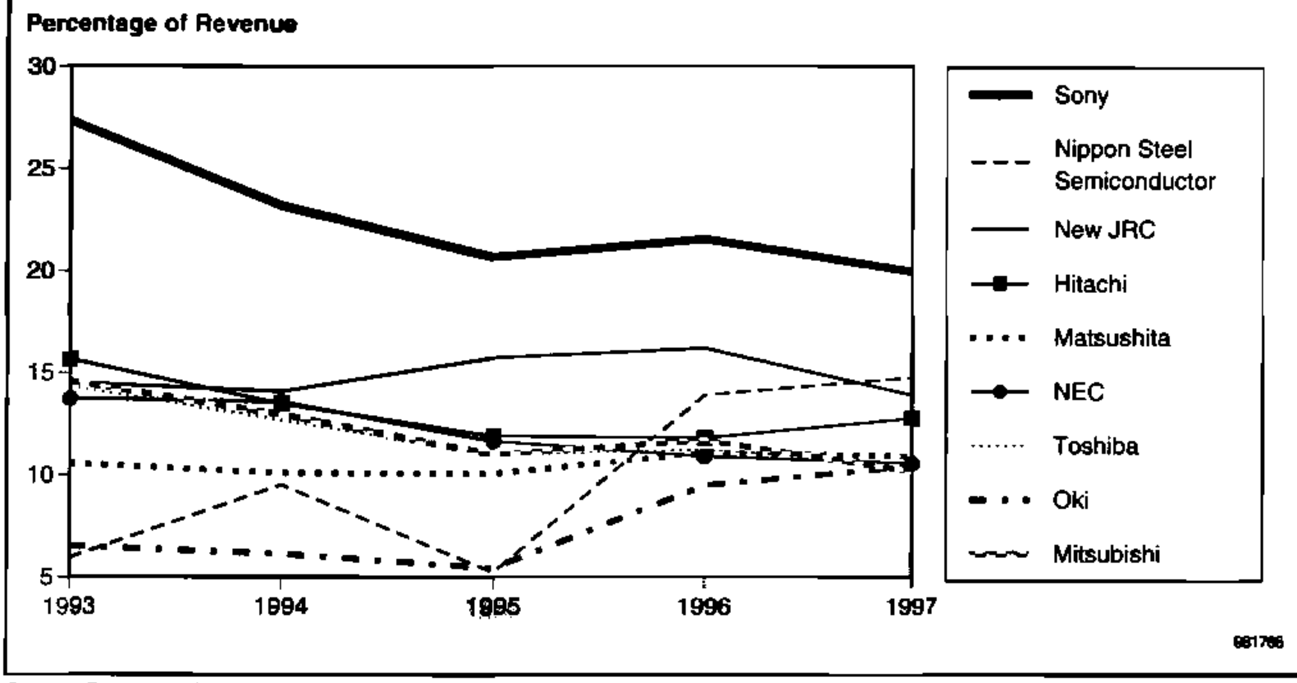


Source: Dataquest (March 1998)

This does not necessarily mean they will reduce their total spending or the ratio against revenue. But the increasing need for a strict business focus will drive those top companies to turn more to outside resources. Hitachi is an example. It is characterized by the large amount of DRAM needed from LG Semicon, as well as from joint ventures with other companies such as TI (TwinStar) and Nippon Steel Semiconductor (Hitachi/Nippon Steel Semiconductor Singapore). DRAMs produced at LG Semicon fabs to be supplied to Hitachi are generally made with Hitachi masks, and TwinStar uses a different mask set, based on codeveloped technologies. Hitachi uses yet another set of masks at its own proprietary fabs. This arrangement has enabled Hitachi to diversify risks, as well as making it easier for partners to participate in Hitachi's production scheme. This arrangement, of course, is not a complete solution and has its drawbacks in technology management, but the eventual result of this attempt will be of interest in the industry.

NEC, however, is going solo in manufacturing while participating in various technology and product alliances. Toshiba has sought alliance and foundry opportunities rather boldly among top Japanese companies. Its collaboration with Motorola on overall semiconductor operation and its codevelopment of DRAMs with Siemens and IBM have both brought about joint ventures—Tohoku Semiconductor and Dominion Semiconductor. Fujitsu followed, with Fujitsu-AMD Semiconductor Ltd. (FASL), as did Mitsubishi with Powerchip Semiconductor. Powerchip is actually a new form of joint venture in that it involves a semiconductor user company as well as financial circles, while other joint ventures have characteristically been between or among semiconductor companies.

Figure 3-7
Japanese Top-Tier Companies' R&D Spending



Source: Dataquest (March 1998)

Middle-tier companies spend around 10 percent of revenue (see Figure 3-8), and the amount varies over time, depending mainly on revenue fluctuations. Those are the companies still dependent on internal demands, and similar trends can be seen in technology. These companies tend to have smaller application engineering groups, indicating that their system technology advisers lie in their user divisions, in-house.

Companies at the lower end of the list spend between 5 and 10 percent of their revenue (see Figure 3-9). They do not burden themselves with R&D expenditure and instead turn to outside resources, such as alliances. Their alliances tend to focus on specific technology and product areas that they have identified as their "battlefield," and they do not attempt to widen their coverage overnight. The spirit of kaizen, the Japanese term for gradual improvement, persists here. The companies in this group also leverage foundry opportunities, by either starting technology partnerships that include "production cooperation," a euphemism for foundry, or starting foundry businesses with additional (but usually not disclosed) contracts on technology transfer.

Chapter 4
The Future of Japanese Semiconductor Companies

The analysis in Chapters 2 and 3 has illustrated the difficult environment as well as the difficulty in positioning faced by Japanese semiconductor companies. In the coming five years, there will be opportunities and threats for Japanese semiconductor companies. The threats can be summarized as follows:

- Demand side
  - Lack of proprietary system technology
  - Faster advances of system technology at non-Japanese systems companies
  - Diversification of regional demand
  - Sluggish outlook for domestic application equipment production
- Supply side
  - Growth of foreign competitors in the DRAM market
  - Growth of dedicated foundry providers
  - Growth of non-Japanese equipment manufacturers
  - Rising prices for manufacturing equipment
  - 300mm wafer production lead by non-Japanese companies
  - Non-Japanese ASIC companies
  - Expansion in cell-based ICs, an area in which Japanese companies have lagged behind

The opportunities that Japanese companies could enjoy can be summarized as follows:

- Demand side
  - Japanese systems companies flourishing in digital consumer equipment production
  - Expansion in communications applications, including networking
- Supply side
  - 300mm wafer production
  - Having strong manufacturing equipment and wafer companies within Japan
  - Facing, and in some cases actually making, fundamental changes as the profitability of the semiconductor business remains low for major product areas

©1998 Dataquest

On the demand side, the realization that the domestic market cannot drive Japanese semiconductor companies' growth is leading to a careful but determined approach toward foreign markets. Globalization has long been a cliché in the Japanese semiconductor industry. There have been efforts made in various aspects of the semiconductor business ranging from sales offices, technical support and design centers, back-end production, and wafer fab operation targeted at capturing local demand efficiently, but these were made mostly after demand prevailed. The globalization that is now required calls for a more aggressive approach toward non-Japanese systems companies, for those are the users that bring faster growth to vendors.

On the supply side, the time has come to give up the conventional Japan model of capital spending and fab utilization. In view of the rapid rise of both manufacturing capital spending and R&D spending requirements, Japanese companies have to seek ways to incorporate outsourcing in their long-term strategies, as opposed to seeking short-term helping hands in partnership. A potential shortage of engineers is also looming globally, especially in Japan, with the size of its younger population decreasing. This also increases the need for strategic alliances and global business operations to make better use of resources outside Japan. And the advent of system-level integration will require a wide range of intellectual property resources that no Japanese company is ready to provide alone. Only through alliances among semiconductor companies and through close ties with semiconductor users in various applications systems can this resource be realized.

These key factors, both on the demand and supply sides, call for organizational changes. Up to this point, Japanese companies have basically run the semiconductor business with product-oriented organizations. A few companies, such as NEC and Toshiba, are developing either virtual or actual organizations that are system- or application-oriented but most companies still follow a manufacturing-oriented organizational model with some application flavor, such as application engineering groups.

A company may have a strong, product-oriented "vertical" organization while struggling to nurture application marketing functions for "horizontal" operation. Those that have been dependent on internal user divisions may not have been burdened with big application engineering groups, but they have faced the challenge of outside system technology. As foreign markets grow faster and emerging system technologies are developed by non-Japanese users, Japanese companies have no choice but to expand overseas operations in all aspects, supported by application-oriented organizations at their headquarters.

Sales integration is also in progress. Japanese companies have had huge sales organizations, either in the form of direct sales or distributors. On one hand, the size of the salesforce not only helped in finding business opportunities, but also allowed the "mother ship" company to gather market information through the sales channel. But the slow growth of the domestic market has made a huge salesforce too burdensome in some cases, and some level of rationalization has been inevitable. One such attempt was to move direct accounts to a big sales agency and relocate the salesforce along with the accounts. Another form was to integrate distributors in the corporate groups to form a bigger entity, in expectation of improved efficiency.

 ©1998 Dataquest

Whether these "rationalization" processes will improve efficiency has yet to be seen, but they have been viewed as inevitable. And whether Japan can revive both as a regional market and as a supplier depends primarily on the overall development of electronics technology in Japan.

Appendix A
Japanese Semiconductor Company Profiles

Basic information such as revenue and capital spending has been covered by a Competitive Trends document in the Semiconductors Worldwide program for the top 20 companies in the 1996 worldwide ranking (Competitive Markets in Semiconductors, 1996, SEMI-WW-CT-9701. December 1997). In this appendix, the basic information for all 20 Japanese companies is illustrated (see Tables A-1 through A-21 and Figures A-1 through A-105).
