NSW Steering Committee Letter

1 3-JUL-75 18:47:37-EDT,8601;000000000000
Mail from USC-ISI rcvd at 3-JUL-75 1847-EDT
Date: 3 JUL 1975 1439-PDT
From: CARLSON at USC-ISI
Subject: Steering Committee Guidance
To: warshall at BBNB
cc: [BBNB]<POSTEL>NSW-DISTRIBUTION.LIST: 1

2 Dear Steve: 2

   2a The Steering Committee would like to thank you for taking on
   the task of technical coordination for NSW System Software.
   Attached is a statement of the Steering Committee's objectives
   during the next eighteen months. NSW contractors will look to
   COMPASS for
   resolution of technical issues and priorities for their work. The
   Steering Committee will support you in every way, including
   allocation of additional funds and changes to Statements of Work,
   so that these objectives can be attained on schedule.   2a

      2a1 ARPA   = Bill Carlson
      AFDAA   = L/C Tony Baggiano
      AFDSDC   = 1Lt Larry Crain

   3a ARPA and the Air Force are jointly developing the National
   Software Works (NSW) to demonstrate a new approach to reducing
   both the cost and the time for DOD agencies to design, develop,
   test, document, and maintain computer software. A great deal of
   software to aid in program design, implementation, etc. has been
   developed, but numerous problems have been encounted in the
   distribution of these aids. A mechanism is needed to make these
   existing software tools available in a uniform manner to DOD.
   Thus, the concern of NSW is the development of this delivery
   mechanism (rather than the development of the tools themselves).
   This focus on the delivery mechanism is also required for the
   implementation of automated access control and management
   strategies, a necessary complement to the software tools. The
   consequences of this approach can be characterized as follows: 3a

      3a1 = Software development and maintenance will take place in
      the software world's equivalent of a factory. The factory is
      to contain "tools" which aid programmers and managers. Despite

NSW Steering Committee Letter

the term "factory", no buildings are to be constructed, and for
the most part existing computer facilities can be used.   3a1

3a2 - A large fraction of the software development and
maintenance tools will be machine independent. That does not
mean that tools (which are themselves computer programs) can
run on arbitrarily chosen computers. Machine independence is
meant to imply that computer specialists building software for
many different kinds of computers can share a single version of
a tool. Examples of capabilities which can be shared include
text editors, the filing system, bookkeeping operations,
project management tools, program test data generators, and
documentation aids.   3a2

3a3 - Compilers and other execution dependent development and
maintenance tools will be provided separately for each target
machine (machine on which the software which is being written
will run).   3a3

3a4 - The tools will be embedded in a resource-sharing
framework which minimizes the user's awareness of the fact that
resources are scattered over many hosts. Thus, the programmer
requests resources in a uniform way, without having to learn
the idiosyncrasies of different host operating systems or
log-in procedures. The manager can contract for services with
the NSW, without having to negotiate accounts on each host.   3a4

3a5 - A central design criterion for the framework is that it
minimize the difficulties of appending new tools and new
resource-bearing hosts to the set of facilities in the NSW.   3a5

3a6 - The framework will provide the project manager with much
tighter controls over his project than are currently in use.
There will be unified and consistent mechanisms for access and
accounting control of resources, where the resources include
tools and files on several dissimilar hosts. The control
mechanisms will support sophisticated tools for the
specification and implementation of management policies of
project control. These policies typically will specify who may
access and/ or change which modules, what crosschecks must be
carried out whenever a module is changed, and what consequent
actions are required for each change.   3a6

3b Planning for the NSW began in the Summer of 1973, with
development starting a year later in July 1974. The initial
version of the National Software Works is being implemented on the
ARPANET. As capabilities become available, they will be tested by
the Air Force Data Systems Design Center at Gunter AFB, Alabama
and by the Air Force Data Services Center in the Pentagon.

Software for the Burroughs B3500, which is the standard Air Force
Base level computer, is developed at Gunter and distributed to
over 130 Air Force installations throughout the World. An
important goal is to demonstrate the NSW's effectiveness in
supporting the development of software to run on the B3500.   3b

3c The heart of the NSW system is a program called the Works
Manager, which is a family of procedures designed to provide a
unified and consistent mechanism for access control and
accounting. The Works Manager has as its central data base a
catalogue of resources. The information this catalogue contains
about tools, users, and files is believed to be sufficiently
general to represent extremely sophisticated strategies of
management control and accounting, involving quite complex rules
of access control and sophisticated strategies of fund commitment
and expenditure restriction.   3c

3d Users will access the NSW through a hardware/software system
called the Front-End, which provides a consistent interface to
software development and maintenance tools running on a variety of
dissimilar computers. The Front-End will standardize the control
characters the user must type to interrupt an activity, initiate a
command, erase a character or word, etc. The Front-End will also
allow a wide variety of different kinds of terminals to be used
with the NSW. Device dependent code will be isolated in the
Front-End, so the remainder of the NSW can assume that terminals
obey the conventions of a small number of device classes. It has
been hypothesized that the Front-End can control almost all user
interactions with NSW tools, using tables which define tool
command languages. The NSW can operate with a less intelligent
Front-End, but tighter standards for interactive tool user
interfaces can be enforced if they share a common command
interpreter. A prototype FrontEnd which offers generalized
command interpretation is being constructed, and the production
version of the Front-End will offer this service if the prototype
is found to be sufficiently robust to support most if not all
manners of dialogue between users and tools, and if the operating
costs are not excessive.   3d

3e In order for the Works Manager to control resources in the
collection of dissimilar computers where software tools will run,
a set of standard software functions must be implemented in each
of those computers. The functions will be invoked by the Works
Manager using standard communications protocols. Functional
requirements for this software to be implemented in each
Tool-Bearing Host have been defined, and a first attempt at
specifying the software and communications protocols in detail has
been made. Initial Tool-Bearing Hosts will be TENEX, MULTICS, an
IBM 360/91, and a Burroughs B4700 connected through a Network

Connection Subsystem, As these implementations proceed, the
specifications will be reviewed and revised in ways which simplify
implementation but still satisfy the functional requirements for
the Works Manager to control resources throughout the NSW.   3e

3f During the eighteen months, July 1975 to December 1976, the
initial NSW system will be completed and evaluated, and the
feasibility of expanding the system and operating it
costeffectively for production applications will be determined.
The experiments will provide the NSW Steering Committee with the
information it needs to project usage requirements, An analysis
of the cost/performance tradeoffs in building a scale, hardened,
optimized version of the NSW will be conducted, A detailed design
will be prepared for a system which represents a reasonable
compromise between performance and cost in satisfying projected
usage requirements,   3f

More Dialogue on The Help Data Base for the Worksmanager.

1 Here are the comments I promised on (sattley, Wm-help,) I hope you
find them useful. When you are ready to have it become the help
file, we are.   1

2 Somewhere in Helpd Kirk says we try to write for an intellegent
secretary. Or an sargent at Gunter AFB might be more appropriate
here. I find paragraphs like (sattley,wm-help,NSW-filenames) too
complicated for an uninitiated sargent. I have been guilty of the
same thing in my draft. Below is a try at rewriting that guy. In
particular I have found that learners are not interested in planned
changes. It is hard enough for them to understand what is happening
now, (i.e.,."initially..").   2

   2a NSW-filenames. Complete NSW-filenames have a slash (/) in the
   middle. The items on the left of the slash are called attributes.
   They give technical information about the file. The system
   attaches attiributes. On the right are name componenets. They are
   what you use to call files.   Sometimes the system attaches a
   name component, but the user always speicifes atleast one of them.
   The name components are separated by periods, and the attributes
   by semicolons. There can be up to ten name components.   The
   first name component is always NSW, the second will generally be
   the name of a project. The order of name components matters!
   NSW.IVTRAN.PARSE.BOLDUC is not the same as
   NSW.IVTRAN.BOLDUC.PARSE. The order of attributes does not matter.
   You will seldom, if ever, have to type a full NSW filename. When
   you are working, you will have several active scopes which
   automatically supply the first few name components, so in using
   NSW filenames in commands you need to type in only enough parts of
   the name to specify it uniquely within your scope.
   > See: Name-components, Attributes, Scope, File-spec,
   Entry-name.   2a

3 Re Projects (2a2),..I fear "a tree of nodes" will blow the mind of
our Airforce sargent.   3

4 Re 2b3b for appearances in a menu and future links, you might put
something like "Creation identification<CR>" in front of this
statement. Also we need "warrant" in the concepts.   4

5 Re 2b3a. For MenuePurposes and future links you might put
"Duplication of names <CR>" infront of this node or something like
that.   5

6 Re File-spec (2b2). I think it is well to assign responsibility
clearly for such things. How about "The worksmanager will extend the
file-spec by appropriate scope.." "   6

1

More Dialogue on The Help Data Base for the Worksmanager.

7 Re: Userid (2d). In that case I think we don't need to talk about
it in the Help data base.   7

8 Maybe everything that used the word "gripe" could use"protest"   8

2 Jon: 2

3 In no particlar order, the following questions arise: 3

4 Front End
1) new tool - old tool. Is the distinction here due to user TELNET?
If so, then we have a serious problem since there are no tools now
other than encapsulated ones.   4

5 2) What does "runs" mean - "fully" debugged or just available for
use?   5

6 3) You don't have milestones for FE-10 (display, old tool), FE-11
(half duplex tty, new and old tool), FE-11 (display, old tool).
Aren't these part of FE task 3?   6

7 4) How much resource will be diverted to produce the three reports?   7

8 Tools
1) You don't say when you're taking the cake out of the oven. I.e.,
what are milestones for installing NLS in NSW (per your SOW Tools
task 1)? Could you split these milestones into two heaps - one
relating to NLS installation and the other to NLS enhancements (per
Tools tasks 3 and 4)?   8

9 Regards,   9

10 Bob   10

  1k (REMARKS)   1k

    1k1 Bamford called me on the draft proposal we are sending him
for a utility slot.   1k1

    1k2 In the course of the conversation he mentioned the program
solicitation (NSF 75-23) that was just sent out that we might
be interested in. I believe DCE has a copy but Hal said he
would send me it to be sure.   1k2

    1k3 Additionally, he spoke of a RFP (NSF 75-136) that will be
coming out very soon on analysis of scientific and technical
communication. This might be interesting to us if we wish to
get into analysis of our sort of system. (DCE: This was the
RFP we spotted in the Commerce Business Daily).   1k3

CONTACT: NSF, Hal Bamford on 25 Jul 75

1k4 Mrs. Rose of Bamford shop will be here in August to see
what we have. I told Bamford of our seminar the week of 25
August. He said it seemed interesting but $1000 might preclude
any staff member from going. He will let me know.   1k4

1k5 He expressed a very strong desire to have our unsolicited
proposal for the utility slot locked up by October 1975. This
means we must make some decisions on next year's proposal very
soon.   1k5

XL10 VALUE construct

1 I have modified (and brought up) a new x110 runtime package, the
modification involves a modification to the procedure
<nls,x110runtime,srval> which is used by the language construct
VALUE. (special note to jle and dia: i didnt modify 11011 because i
forgot where it is, but one of you should make corresponding mod.)
The modification allows for conversion of strings for bases greater
than 10, the mods will not effect the conversion of purely numeric
strings, but for strings that contain alphabetics, they will now have
a different value. herein follow the old and new algorithms: 1

   1a new: 1a

      1a1 (srval) PROCEDURE(astrng, base);   1a1

         1a1a %convert string to value%   1a1a

         1a1b LOCAL value, cnt, char;   1a1b

A Marginal Existence

1 I currently have my print margin set to 72, my display right margin
set to 72, and my output quickprint margin set to 72 in Useroptions.
As of Saturday the TNLS terminal output was 70, output quickprint was
71, output printer is actually 72, my display is 72, output
sequential is 71, and a sendprint file made from a print file is 72.
A conservative estimate is that this nagging but trivial problem has
cost us a month's time and money in work being
redone. Again I request that default right margins on all devices be
standardized to 72 with useroptions available for deviations from the
standard.   1

Documentation Weekly Report

ARC tool interface file (Help) name changed to Core; sample sessions
in final form; Quarterly Management Report first draft; Air Force
Format revisions.

Documentation Weekly Report

1 Week ending 7/25/75   1

  1a Bev   1a

    1a1 This Week   1a1

      1a1a Completed revisions of Sample Sessions, except for
      Sendmail I and II. All of Applications suggestions
      included, Gave Format SS to Dirk for some clean-up.   1a1a

      1a1b Wrote first draft of Quarterly Management Report.   1a1b

      1a1c Reviewed with App. group the viewgraphs to be used with
      courses.   1a1c

      1a1d Went over doc. milestones with Jon.   1a1d

      1a1e Toured NASA.   1a1e

    1a2 Next Week   1a2

      1a2a Revamp Sendmail SS I and II.   1a2a

      1a2b Complete final version of QMR.   1a2b

      1a2c Work on Help with Kirk.   1a2c

  1b Kirk   1b

    1b1 Done last week to July 25   1b1

      1b1a Changed name of ARC tool interface file to "Core" (for
      "Core AKW") and began re-organization from this point of
      view. Set up all existing tool description files to work in
      the new multi-file environment.   1b1a

      1b1b Discussed general documentation transfer and
      maintenance procedures with Jeanne B, to be carried out with
      the new Substitute command in Modify tool/subsystem.   1b1b

      1b1c Made further modifications to AFM format program.
      Found a bug in OP to COM.   1b1c

    1b2 Do   1b2

      1b2a Continue re-organization of Core, prioritize and
      responsibilitize the parts of Help with Bev.   1b2a

      1b2b Begin on Letter Program.   1b2b

Clarifications on Cassette Restriction Document (26163,)

Prompted by Kirk's questios ouestions (33043,)

Clarifications on Cassette Restriction Document (26163,)

1 Kirk's questions (33043,) about our Cassette restriction document
(26163,) were quite good. Control-W is indeed used by Termicettes as
the rewind control character. Thus the suggestion in our earlier
document about the appropriate escape character setting for operating
the cassette system through TELNET should have been generalized to
suggest that the escape character should not be one of the control
characters which activate the cassette terminal being used. (I think
control-P is OK, but we shouldn't generalize about all terminal
types: they may each require a different TELNET escape character.)   1

2 The second question is more difficult to answer: there is NO
command to change TIP input buffers! The TIP, as stressed by Joel
Malman of NCC, was not designed to handle cassette terminals. TIP
buffer sizes are assigned by NCC and must be changed by them. I can
assure you that they would not want to change them frequently. All
we can do is find out from the user which port is being used if data
is being lost and suggest they get on a port with bigger buffers.
This is not possible on some TIPs which have phone lines assigned to
non-specific ports. If some customers are assigned dedicated lines
(and ports) it may be possible to set one or two of them to a size
large enough to be used by a cassette terminal. The ultimate
solution awaits the development of buffering flow control hardware in
the LSI-11 lineprocessor.   2

3 Martin Hardy has suggested that our phrasing of required functions
to be present on the Cassette terminal device was confusing: none of
our current devices has a stop read control. We meant to imply that
the read record command should stop reading at the end of a
reasonably sized record, generally a line of text.   3

cml selection routines

the file (isic, nsw-debugger, p2func.nls,) contains modified
versions of rdlit (modified version called r2dlit) and gettext
(modified version called g2exttext) and a number of selection
routines (listed below). you are welcome to take what you want from
there. let me know which ones you build into the language. we
should probably talk about what i did in person, but herein follows a
summary of what i did: (if you care to try any of these you can use
<isic,nsw-debugger,c2ml.nls,> as a test cml to drive these selection
routines or just run <isic,nsw-debugger,c2ml.sav,>)   1

   r2dlit: 1a

      takes an additional parameter, ccnt. if ccnt is 0 then it
      operates as the old rdlit. if ccnt is greater than 0, then it
      is a count of the exact number of characters to be collected.
      for example if ccnt is 2 and a user inputs 1 char followed by a
      CA, the CA will look like a disallowed character and the user
      must input exactly ccnt characters. after inputting ccnt
      characters, no final confirmation character is required. if
      ccnt is less than 0 (e.g. -N), then N is an uper bound on the
      number of allowed characters to collect. if the user inputs N
      allowed characters then no final confirmation is required. if
      the user inputs less than N allowed characters followed by a
      terminator or a disallowed character, then this last character
      will act as a confirmation character and if it is a disallowed
      character it will be unput.   1a1

   g2ettext   1b

      takes 5 additional parameters: an allowed char string, a
      disallowed char string, a terminators char string, a ccnt, and
      an intbase. the first 4 of these parameters are the same as in
      rdlit; the last parameter if non-zero means select an integer
      in base intbase.   1b1

Pun of the year award goes to...

Answer to Millstein on Milestones

Bob: 1

Here are answers to your questions on the milestones we sent last
week, these are a preliminary response and we will be send a updated
set in the next week.   2

Front End   3

  1) new tool - old tool, Is the distinction here due to user
TELNET? If so, then we have a serious problem since there are no
tools now other than encapsulated ones.   3a

    *** The old vs. new tool distinction is accurately
characterized by the use or not of Telnet for communication
between the Front End and the tool. ***   3a1

    *** NLS is a new tool and is not encapsulated. *** 3a2

  2) What does "runs" mean - "fully" debugged or just available for
use?   3b

    *** "runs" means available for use. ***   3b1

  3) You don't have milestones for FE-10 (display, old tool), FE-11
(half duplex tty, new and old tool), FE-11 (display, old tool).
Aren't these part of FE task 3?   3c

    *** We are not sure that it makes sense to talk about accessing
old tools in display mode. This should not be a difficult task
to do if it does prove to be desirable. ***   3c1

    *** We are NOT planning to implement half duplex access via the
PDP-11 version of the Front End. ***   3c2

  4) How much resource will be diverted to produce the three
reports?   3d

    The reports on: 3d1

      a) Front End Measurements and Efficiency 3d1a

      b) CML evaluation   3d1b

      c) New Front End Features   3d1c

    are a scheduled part of our work and do not represent a
diversion of effort.   3d2

Tools   4

Answer to Millstein on Milestones

1) You don't say when you're taking the cake out of the oven.
I.e., what are milestones for installing NLS in NSW (per your SOW
Tools task 1)? Could you split these milestones into two heaps -
one relating to NLS installation and the other to NLS enhancements
(per Tools tasks 3 and 4)?   4a

    *** Our milestone "Base in NSW accessed in char tty mode" is
    the first step in "taking the cake out of the oven". We now
    realize that by the date given we will only be able to access
    this core set of nls via the front end, not have nls use the
    works manager file system. i would not claim nls (or any tool)
    was installed in nsw until it both (1) was controlled by the
    works manager and interacted with the user via the front end,
    and (2) utilized the works manager file system. We now believe
    that we can only achieve part 1 by mid august. The second and i
    think very important part depends on you. we need very definate
    and specific specifications of the interface to the nsw file
    system, either the works manager primitives or the "tenex
    forman", and we need to know when these procedures will be
    available for use. we cant take the cake out of the oven till
    we know what kind of oven it is and when it will be turnned on.
    ***   4a1

As i said this is a preliminary response, we will try to get our note
reorganized as you suggest and take another look at the items you ask
about. We will be sending along a revised list in the next week.   5

Notes About Case Shift at ISIC: Solution to Content Searching
Problems in TNLS

A warning to those of us using TNLS at ISIC: 1

Have you iscovered substitutes not working? Have you discovered
content searches not working? Do not be deceived as I once was.
Just because you don't need to say NO RAI at ISIC doesn't mean you
can get away without telling it you are a TERMINAL TYPE TI733!
Without doing this, all your characters (even with shifts) are taken
to be lower case for the sake of content searches, etc. in TNLS.
After much frustration, I discovered this quite by accident and
discovered that others were similarly ignorant. Note that this
secret holds even though you are able to get Upper and Lower case
text in upon entry. Ah, sweet mystery of NLS. Note also that you
cannot just quit or control-C to the EXEC, change your terminal type,
and continue. You must change your terminal type and start over with
a fresh NLS.   2

Note to Applications: Could this be a bug?   3

Notes About Case Shift at ISIC: Solution to Content Searching
Problems in TNLS

Inconsitencies in Margins

Rejournalized to put it in the DPCS subcollection

A Marginal Existence

I currently have my print margin set to 72, my display right
margin set to 72, and my output quickprint margin set to 72 in
Useroptions. As of Saturday the TNLS terminal output was 70,
output quickprint was 71, output printer is actually 72, my
display is 72, output sequential is 71, and a sendprint file made
from a print file is 72. A conservative estimate is that this
nagging but trivial problem has cost us a month's time and money
in work being
redone. Again I request that default right margins on all devices
be standardized to 72 with useroptions available for deviations
from the standard.   1a

Inconsitencies in Margins

(J26202) 26-JUL-75 20:01;;;; Title: Author(s): Elizabeth J. Feinler/JAKE; Distribution: /SRI-ARC([ACTION]) FEEDBACK([ACTION]) ; Sub-Collections: SRI-ARC FEEDBACK; Clerk: JAKE;

message journalized for the record

18-JUL-75 1138-EDT VANNOUHUYS: Parts of DPCS, distribution of
planning documents
     Distribution: WATSON, vannouhuys, michael
     Received at: 18-JUL-75 11:38:34-EDT   1

     By chance I was looking at Elizabeth's screen when a message from
     you about staged growth od DEXlike things came across. If we are
     talkiing abcut the"the DPCS thing" there are two parts you don't
     mention but are relevant in my mind: aids to editing (things like
     devices that will work like blue pencil and further developments
     of the kind of editing aids recetnly added to Modify) and Control
     mechanisms for published docuements, rpresumably related to the
     journal.
     I see it as part of nucleation that I know about these things and
     relay ARC thinking to appropriate people, e.g, Tom Humphry. I
     hope if this planning goes on it gets into some like a journal
     item that helps recording and relay.
     That sounds a little snippy. HmmmI didn't mean it that way, as Jim
     Norton would   1a

Weekly Report of the NLS Development Group

Substantial progress on detailed coding and debugging of
formatting part of COBOLAID. Reread LAC's original COBOL memo
and journalized a response (kjournal, 26186, 1:w) setting forth
the formatting algorithm for COBOLAID.   2a1

To do next week   2b

Finish COBOLAID, await LAC's response to my comments. Begin
study of routines I am to inherit from Kelley, these include
Help and user subsystems.   2b1

Changed name of ARC tool interface file to "Core" (for "Core
AKW") and began re-organization from this point of view. Set
up all existing tool description files to work in the new
multi-file environment.   3a1

Discussed general documentation transfer and maintenance
procedures with Jeanne B. to be carried out with the new
Substitute command in Modify tool/subsystem.   3a2

Made further modifications to AFM format program. Found a bug
in OP to COM.   3a3

Do   3b

Continue re-organization of Core, prioritize and
responsibilitize the parts of Help with Bev.   3b1

Begin on Letter Program.   3b2

1

Weekly Report of the NLS Development Group

Trip to D>C> (Pentagon) to determine status and future of AFM
66-1 and other NSW problems   6a10

Write critique of the Analysis of 5 Text Editors including NLS
done at the Pentagon   6a11

Fix problems in the AF Format program   6a12

Revise two sections of the 'Final Report'   6a13

Write NLS accomplishments for the quartly management report   6a14

Review File package document written by HGL   6a15

Create (with HGL) a new OP directive to facilitate formatting
Air Force documents for COM, the printer, and microfiche   6a16

To do next week (July 28 - Aug 1)   6b

Catch up on what's going on, find out where we stand in
relation to schedules, and make a plan.   6b1

Assign Karolyns work to DSM, HGL, EKM   6b2

Assign Kirk's work to Cornish   6b3

Review File Package Document and make sure it gets off   6b4

Work on Ident system Document and very rough Journal design   6b5

Get proofs of Vol 3 Ch 1 to Pentagon and Gunter   6b6

Review time cards to see what's getting charged to the NLS NSW
subprojects   6b7

Assorted meetings - no doubt   6b8

Front End Meeting Notes

This note summarizes a series of meetings about the NSW Front End
(FE) implementation.   1

The attendees were : rww dlr jle chi jew llg jbp andy dia   2

Our current estimates of the sizes of the various code and data
modules are given in the file <ehardt, fe-memory-consumption,>.   3

The following issues and tasks have evolved over the series of
meetings, under each issue or task is the current status or
resolution.   4

   (1) CHI - reduce to size of the CLI context: goal 8K   4a

      8K is ok   4a1

   (2) CHI JEW LLG - combine DPS and CLI into a single process   4b

      case 1 - B4700 code also works with DPS   4b1

      case 2 - only CLI uses DPS   4b2

         This appears not to be promising, rather a design utilizing
         a shared page between DPS and CLI containing both code and
         data, and using signals or EMTs to communicate events to
         each other looks more interesting. (see--number 11)   4b2a

   (3) DIA - fix L1011 compliler to parse large segments of code to
   generate more optimal code (this version of the compiler will not
   run under nls but from the exec)   4c

      This looks to be more work that previously discussed, but is
      still being explored. (See--number 18)   4c1

   (4) JEW - reduce the size of the DPS context: goal 2K   4d

      2K appears to be fine.   4d1

   (5) JLE DLR - investigate the buffer and memory magement in ELF,
   investigate buffer and code optimization in exec and telnet.   4e

      Suggested that demand paging system would be a win, but this
      appears to be far more work than we want to take on.   4e1

      For system with no normal TELNET, only special TELNET for CLI
      old tool access the TELNET code could be reduced from 1000 to
      600 words for a savings of 400 words. In such a system if the
      CLI were to play the role of the EXEC the 3000 word EXEC would
      be eliminated.   4e2

JLE now says that this cant be right but dosent know what
the true statement is.   4e2a

(6) JLE - talk to DEC about prices for disks, memory etc, for
11/40, 11/45, and 11/70.   4f

Price List Obtained   4f1

(7) CHI - figure out the size of the code for CLI mannaged context
switching and for display featurets   4g

Display Code on 10 takes 4K, so estimate 6-8K on 11.   4g1

Context switch code should be small a few hundred words at the
most.   4g2

(8) LLG - investigate the ELF facilities that can be used to
reduce the size of the DPS code   4h

There is not very much to be saved here, but the ELF primitives
will be used where appropriate, An estimate of 20-24K for the
DPS code is reasonable.   4h1

This goes with (2) above.   4h2

(9) DLR JEW CHI - investigate eliminating ELF.   4i

There is not much to be saved, but it would be useful to list
the primitives along with the amount of space that would be
saved if the primitive were deleted and the programs that would
be impacted if the primitive were deleted.   4i1

*** Still Not Done ***   4i2

(10) JLE DLR - Evaluate the relative merits of ELF, UNIX and RSX11
for our needs.   4j

prepare a note for our internal use that compares these systems
and our requirements especially noting their facilities
relating to: 4j1

real and virtual address space management   4j1a

disk management   4j1b

process structure   4j1c

interprocess communication   4j1d

    *** Still Not Done ***   4j2

(11) LLG - DPS-CLI communication   4k

    prepare a note on the design for the DPS - CLI communication
    considering both the shared page and message mapping
    techniques, incorporating comments by CHI and JEW.   4k1

    *** Still Not Done ***   4k2

(12) JLE - Prepare order for disk   4l

    Order for 512 K fixed head disk to be prepared ASAP. (Also an
    order for an additional 32 K of memory).   4l1

    *** Still Not Done ***   4l2

(13) RWW - Send note stating our general problem to nsw steering
committee.   4m

    A note was sent (see -- 26099,).   4m1

(14)CHI JEW LLG - Review of the proposed DPS/CLI interface design
with attention to the single vs. multi- process alternatives.   4n

    Done (see-- number 11)   4n1

(15) DLR JLE - Investigate alternative memory management schemes 4o

    Rough estimate is that 4 man months would be required to revise
    ELF to use variable size real pages, and that this would be
    desirable for other reasons (eg input output management). To
    revise ELF to allow variable size virtual pages might be
    accomplished with 1 man month of effort.   4o1

        [to be scheduled] note on implications and effort involved
        if this task is undertaken.   4o1a

        *** Still Not Done ***   4o1b

(16) JLE - Develop the position paper for the steering committee,
deliver a draft version to COMPASS.   4p

    Position Paper sent, (See -- 26181,).   4p1

(17) CHI - Breakdown of CLI code.   4q

    Done (see--26144)   4q1

Front End Meeting Notes

   (18) DIA - L1011 status report: what remains to be done, current
expectations of savings.   4r

    Done <see--26176.>   4r1

   (19) ??? - Study the relative efficiency of L1011 vs assembly
code.   4s

    [to be scheduled]   4s1

    *** Still Not Done ***   4s2

   (20) LLG DLR - Storage Management   4t

    prepare a note on storage management techniques, there must be
a choice between the following: 4t1

      current ELF primitives   4t1a

      L10 runtime   4t1b

      new (or modified) routines   4t1c

    if the l10 routines were chosen and compiled by l1011 the
savings to be made by hand coding are estimated to be 20% by
CHI and 50% by JLE   4t2

    Done. (See--Garlick,stgmngt,)   4t3

   (21) JLE - B4700 code   4u

    Estimate received from Triolo that the "null-IP" will take
7000-8000 words.   4u1

   (22) ??? - coordinate KEV's debugger with PP-11 testing.   4v

    *** Still Not Done ***   4v1

   (23) LLG ANDY CHI DLR JLE - Design the FE-11   4w

    Prepare a draft design document on the FE-11 that is based on
the following assumptions: 4w1

      Mimimal ELF changes   4w1a

      A clean interface between CLI and DPS so that DPS could be
run in another machine if necessary   4w1b

      CLI and DPS do self overlays and control disk i/o themselves   4w1c

The design should enable us to answer questions such as the
following: 4w2

How many processes are there in the FE   4w2a

How many address spaces are there in the FE   4w2b

What are the modification we want to make to ELF   4w2c

For storage management   4w2c1

For Disk i/o management   4w2c2

*** Still Not Done ***   4w3

(24) ANDY LLG JLE DLR - FE-11 Implementation   4x

It was also resolved that we should proceed to construct a test
version of the system even tho it may only support one or two
users.   4x1

This requires several pieces to be operational: 4x2

VM ELF - DLR   4x2a

Loader - ANDY   4x2b

Flea DDT - DLR   4x2c

CLI-11 - JLE & ANDY   4x2d

DPS-11 - LLG   4x2e

*** Still Not Done ***   4x3

(24) RWW JBP - FE functionality vs. minimial implementation   4y

We will be called on to defend the need for specific functional
capabilities in the FE vs. the expense and difficulty of
implementation.   4y1

*** Still Not Done ***   4y2

(25) JLE JBP - Design FE-11 using alternate architectures   4z

- Using PDP11/70   4z1

- Using PDP11/03 (=LSI11) distributed CLIs   4z2

Front End Meeting Notes

    *** Still Not Done ***   4z3

The next meeting is scheduled for 10 am Tuesday 5 August.   5

Sent to Millstein@BBN, Schantz@BBN, and Carlson@ISI via SNDMSG.

Overview-- Works Manager / NLS-Backend File System Interface   1

For the NLS Backend (NLS-BE) to be fully integrated into the NSW
environment, it must make use of the Works Manager (WM) file
system for file management. Discussions held earlier in July
between ARC staff, Bob Millstein of MCA and Rick Schantz of BBN
concerned the mode of interfacing the NLS Backend operation to the
Works Manager file system.   1a

Before these discussions we had intended to directly access WM
functions such as those outlined in Millstein's memo of 22 May
1975, WM-PROCEDURES. Schantz' development of the Encapsulator for
existing tools with its implicit calls on these functions and the
related development of the Foreman would permit us to avoid such
direct access. Our earlier understanding of the intention of the
Foreman (outlined in an earlier draft of this note dated 3 July
1975) has been supplemented by further discussions with Millstein.   1b

Thus two different but related approaches have been considered:
in the first NLS-BE would interract with the WM through direct DPS
calls on WM procedures; NLS-BE would be responsible for
maintenance of the Local Name Dictionary (LND). In the second
approach, NLS would access the necessary WM file system functions
through a component known as the Foreman. As we currently
understand the Foreman, calls would be in the form of
pseudo-JSYSs. It would appear to the NLS-BE as an extension of
the TENEX operating system. The Foreman would manage the LND; all
necessary interaction with the WM would be through this channel.   1c

The only documentation we have of WM procedures is Millstein's
memo of 22 May 1975. To a large extent the functions listed would
be sufficient to allow us to develop the NLS code changes
necessary to interface to the WM file system. There are some
minor exceptions: we feel some functions need clarification and
possibly minor redefinitions in order to handle some NLS-BE
capabilities described below (e.g., SETSEMAPHORE and
UNSETSEMAPHORE); at least one new function would be desirable
(READSEMAPHORE). These additions are described in a later
section. Parameter specifications in Millstein's memo need
elaboration and confirmation before code can be written from the
procedure descriptions.   1d

Our conversations with Millstein in early July opened the
possibility of the use of the Foreman, but did not expand upon the
document we had. No design currently exists for the Foreman,
though our assumption has been that at least all the WM file
system functions would be accessible. Again, no interface code in
NLS-BE can be written until a detailed design document is
produced.   1e

1

To create the NLS-BE interface to the WM file system via either of
these approaches will require almost the same amount of work.
Given the fact that NLS-BE is embedded in DPS, the code
differences between direct calls on the WM and pseudo-JSYS Foreman
calls is largely syntactic with minor exceptions.   1f

NLS-BE can operate in the NSW environment as a tool talking
through DPS to the FE even without using the WM file system; we
can continue to use the local TENEX file system. We feel,
however, that this hole needs to be filled as soon as possible
since other tasks must await its completion. For example, our
design for the installation into NSW of a Journal system
necessarily requires knowledge and experience with the WM file
system. We must select between the Foreman and direct calls to
the WM: the latter may be useable sooner, but the former is
esthetically more attractive. We feel it will take about one
calendar month after final specification of the WM functions (or
the Foreman functions/syntax) for us to complete the necessary
code modifications to NLS-BE with the exact time dependent on
vacation schedules and other commitments. In order to firmly set
our milestone date for NLS-BE operating in NSW completely
interfaced to the WM file system, we must have a date for the
publication of these specifications and an estimated date of
implementation.   1g

   For our purposes the publication of the design is more
   critical: we can code without the Foreman or WM file system
   being completed as long as the procedures and their parameters
   are well specified.   1g1

The rest of this note outlines some of these considerations in
greater detail and describes some of the file operations currently
performed in NLS.   1h

Our Current Understanding of the Foreman   2

The running version of NLS accesses the TENEX file system through
the use of various JSYSs such as GTJFN, OPENF, and CLOSF with
certain flag settings. The Foreman would make available a set of
additional pseudo-JSYSs (the set to be determined) which would
gain control through the TENEX JSYS trap mechanism. The Foreman
would do appropriate WM calls and maintain the Local Name
Dictionary (LND).   2a

   Note that such functions are implicit in the Encapsulator for
   exsisting tools developed by Schantz at BBN. The Encapsulator,
   however, additionally does TELNET interaction for the tool and
   handles DPS interaction. Tools such as the NLS-BE live in a
   DPS environment and already have terminal interaction handled

by the FE. Thus while there is some overlap between the
Encapsulator and the Foreman, and while some of the code
modules may be identical, the Foreman may be more properly
thought of as being an extension to the operating system (TENEX
in this case, but potentially others as well) which serves as
the WM interface to NSW tools.   2a1

Jon Postel and Jim White have considered in a preliminary
manner possible modifications to the TENEX implementation of
DPS necessary for the Foreman to coexist with the NLS BE.
Minor changes are probably needed to handle interrupts and fork
structure communication. They should be made aware of any
decisions concerning the Foreman design.   2a2

Aside from minor code to manage the LND in the
direct-call-on-the-WM approach, the NLS code involving these
direct calls would be structurally identical to code calling
Foreman pseudo-JSYSs: in one case we would make Foreman
pseudo-JSYS calls; in the other case, we would make PCP calls on
the WM. While the former would be esthetically preferable since
the WM functions would appear as extensions to the operating
system, the amount of design and coding effort at ARC would be
about the same in both cases.   2b

Current NLS Use of File JSYSs   3

In the parts of the NLS Backend which will be used in NSW, GTJFN,
OPENF and CLOSF are used in fairly unexotic and straightforward
manners. For instance, we do not have the JSYSs complete the
names of files or ask the user for confirmation. All terminal
interaction is isolated in higher level procedures in the current
NLS and will probably be handled by the FE under NSW.   3a

In only one case do we currently attempt to get a JFN on an
unusual device: this is in the "Connect terminal" command to
accomplish shared screens. This command, if implemented at all
in the NSW environment, will probably be handled through the
Front End anyway.   3a1

There will be no problem putting a file name into the appropriate
form for the pseudo-JSYSs of the Foreman: either Works Manager or
TENEX format are acceptable to us since we currently are doing an
internal translation most of the time in NLS anyway. We could map
one form into the other as necessary. Extensive use is made of
the JFNS (JFN to string) JSYS, but in fairly non-critical areas
(i.e., to display error messages when files are not opened, to
obtain strings for internal tables). Again, the format required
by the Foreman does not appear to be critical.   3b

This is not to say that we will not have to put many changes
into the current code to get into the correct NSW file name
format, but such additions to the code were anticipated under
any implementation.   3b1

Rick Schantz was concerned with session termination and special
uses of terminals. We feel such questions are irrelevant in our
case: all terminal interaction and termination is handled by the
FE. We are not interested in the parts of the Encapsulator which
do TELNET interaction: this part is not needed by us as, again,
we will be communicating via DPS with the FE.   3c

Creation of New Files   4

Another unusual file operation done by NLS occurs in the creation
of a new file: because of some problems in TENEX, a file does not
really exist until it has been closed. We therefore open, close
and open the file at creation. In the NSW environment, we assume
that on creation a copy of the file exists in the NSW environment,
even if there is a subsequent crash. This is in keeping with our
goal of minimizing the amount of work which can be lost in the
event of a crash.   4a

Non-NSW Files   5

NLS will make minimal use of non-NSW files. Instances in which
non-NSW files would occur include temporary work files and general
system files (save files of processors or system data bases).
Since we will issue Foreman pseudo-JSYSs or calls on the WM when
necessary in addition to the usual TENEX file JSYSs, we can
selectively avoid dealing with the Foreman and the WM in the case
of non-NSW system or work files. Thus, an escape mechanism for
non-NSW files in the Foreman is not essential for NLS (though it
may be necessary for other tools.)   5a

Simultaneous Multi-user Access to Files-- Locking Mechanism and File
Data Validity   6

NLS has implemented code which deals with the problem of files
which have (possibly) multiple readers with one writer. The
solution additionally provides a file system which is very secure
across system crashes. While it is anticipated that the exact
current implementation (which makes use of a locking mechanism
based in the TENEX user settable word and something known as a
"Partial Copy File" described below) will not be used in NSW, we
feel Foreman / WM file system functions which permit similar
capabilities are necessary. In this section we discuss the user
view of the mechanism as well as the current implementation and

some system commands it makes possible. We abstract what we feel
are essential features to be carried over to the NSW.   6a

NLS currently permits files to be opened for read access; if a
user tries to write on the file, an attempt is made to "lock" the
file. When a file is locked, it may be modified only by the user
who has it locked. Other users may examine the file with read
access, but do not see the current editor's changes while the lock
is still on the file. When a locked file is loaded by a user
other than the one who has the file locked, the file is seen in
the state it was in at the time the lock was set; only read access
may be obtained, and a message is displayed stating that the file
is locked along with the name of the user who has it locked. This
information often proves useful in personal negotiations between
members of a group who may wish to work on the same material. The
fact that only one person may have the file locked at a time
implies that only one person may make edits at a time. This
minimizes the problems involved in collating simultaneous changes
to the same file by more than one user.   6b

  In the current NLS a file is locked by changing a bit in the
  user settable word using the CHNFDB JSYS followed by creating a
  partial copy file opened for write access; changes in the
  contents of the original file are reflected only in the partial
  copy until an explicit update causes the data to be merged.   6b1

  Note that unlike the TECO edit buffer, the partial copy is a
  real file: output is made to the disk and the data is as safe
  as data in the original file. The partial copy is NOT a
  buffer. In most instances in the event of a crash, barring
  only massive hardware failure, users would lose only material
  currently being entered, i.e., one line or statement. We aim
  for this level of security on NSW as well.   6b2

The mechanism is invisible to the user and is reasonably secure.
It permits many people safe access to a body of data; if a user
loads a file which someone else has locked, he will not be able to
edit it, but will be able to see its state before the edits began.
Works in progress are not visible to anyone other than their
creator until an update which also unlocks the file. This concept
has proven to be very useful in the case of users making major
edits: files may be locked indefinitely and personal negotiation
may be carried out by other users with the user who has the file
locked. In a programming environment such as the one at ARC, the
locking mechanism has saved costly integration of code changes
made on a file simultaneously by more than one user. This
feature would be valuable in the NSW as well.   6c

In the NSW environment, we will not be using the partial copy

mechanism directly. Because the WM maintains a secure version of
the original file, a user may make his edits in his copy of the
file and incorporate them upon delivery in the WM sense. The
locking mechanism is however still useful and could be implemented
through the use of the SETSEMAPHORE and UNSETSEMAPHORE WM
commands. Semaphores should be settable after a file has been
transmitted to the NLS tool. Users may just want to read a file
and not deprive other users of the possibility of obtaining the
file for write access and locking if desired. (It goes without
saying that one should only be able to set the semaphore if one
has write access in the TENEX sense, delete access in the WM
sense.) Delivery back to NSW should not imply the resetting of
the semaphore. A user may want to keep a file locked for several
sessions; for security, however, it is desirable for the file to
be delivered back to the WM at the end of sessions, perhaps with a
different name which may be calculated by NLS from the original
name. The semaphore on the original would remain set.   6d

   The description of the OPEN function in Millstein's memo
   suggests that most of this is possible. OPEN checks if the
   user has COPY access to the file (read access in the TENEX
   sense.) If the user also has DELETE access and a parameter is
   true or the i/a tool descriptor (which we don't fully
   understand) has a particular value, the semaphore is set if it
   is not set already and the file copied to the current tool. An
   earlier version of the file may be obtained if the user so
   indicates. In NLS we do not want the semaphore to be set upon
   OPEN. We definitely want to be able to get an earlier version
   of the file if the semaphore is already set by another user; it
   may be useful for us to have the file in which edits are made
   have another file name to prevent "trims" of directories
   (deletions of all but the highest versions). This would
   suggest a slightly different use of the semaphore mechanism; of
   course, implementation details can be worked out and must be
   done in conjunction with MCA. While we are not committed to a
   particular implementation, we are committed to the user view of
   the system described above.   6d1

   It would be useful for us to have a user id associated with the
   setting of the semaphore. It would also be useful to be able
   to read the semaphore before doing the OPEN; this reading
   function would return a false if the semaphore of the file is
   not set and, if it is, would return the user id of the user who
   has the semaphore set. The exact implications of a set
   semaphore are not clear from the 22 May memo. A clear
   understanding of the function is essential both by ARC and by
   MCA.   6d2

   For the system to work efficiently there may have to be

provision in the Foreman and the WM for reading the semaphore
to find out if a file is locked and by whom; this information
could be used by NLS to translate the name of the original file
into the file in which edits are being made. If a file is
locked by the current user, the request may be "changed" by NLS
to a request for the related file with modifications in it;
all other users would access the original file and would not be
permitted write access. We want to minimize and if possible
eliminate the necessity of the Foreman knowing about NLS, but
efficient facilities to handle the locking mechanism are
desirable.   6d3

This area appears to be the one which poses the most potential
difficulty in our use of the Foreman and the WM File system as
it is currently designed.   6d4

The NLS command "Delete Modifications" may be used by a user who
has a file locked and has been making edits. Upon execution of
this command, all changes made since the last update disappear and
the file is unlocked. The "Delete Modifications" command may be
implemented in NSW by deleting the copy of the file with the
modifications, unsetting the semaphore in the original and getting
a new copy of the original from the WM.   6e

Functions Needed in the WM File System or Foreman by the NLS-BE   7

The following is a list of functions described in Millstein's 22
May memo which are essential to the implementation of the NLS-BE
file system interface; the more detailed specifications in that
document are assumed to be in effect. The parameters need a bit
more elaboration before we can program from them. Cases which
require minor redefinition and suggested new functions follow.   7a

DELETE   7a1

RENAME   7a2

SETSEMAPHORE (see below)   7a3

UNSETSEMAPHORE (see below)   7a4

CLOSE   7a5

COPY   7a6

OPEN (possibly acceptable, but read the discussion on the
locking mechanism above)   7a7

DELIVER   7a8

The semaphore mechanism needs clarification; as noted above we
would like to have a user id associated with a set semaphore.
Moreover, we would like to be able to read this value without
copying the file. A careful (perhaps too careful) reading of the
22 May memo suggests that ids can be supplied as parameters to WM
functions only by the FE! (See the paragraph in section 1 of that
document which discusses ids as parameters.) Assuming this was a
mistake, we make the following suggestions for the semaphore
commands.   7b

    SETSEMAPHORE(id, filespec, maxlist, qhelp)
       -> NSW-filename   7b1

    The WM verifies that the tool can use SETSEMAPHORE, that
    filespec designates a unique file to which the user has
    delete access, and that the semaphore is not already set.
    Assistance is obtained via PCP HELP return or direct FE call
    as in the file system memo. If all is well, the semaphore
    is set on behalf of the user whose id is passed and the
    NSW-filename is returned.   7b1a

    UNSETSEMAPHORE(id, filespec, maxlist, qhelp)
       -> NSW-filename   7b2

    The WM verifies that filespec designates a unique file to
    which the user has delete access, and that the semaphore is
    set on behalf of the user. Assistance is obtained as usual.
    If all is well, the semaphore is unset on behalf of the user
    whose id is passed and the NSW-filename is returned.   7b2a

    READSEMAPHORE(filespec, maxlist, qhelp)
       -> file-semaphore-value   7b3

    The WM verifies that filespec designates a unique file to
    which the user has COPY access. Assistance is obtained as
    usual. If all is well, the semaphore value of the file is
    returned. It is either FALSE if the semaphore is not set or
    the id of the user who has the semaphore set.   7b3a

The OPEN function may need slight modification to avoid implicit
semaphore setting if it is not desired. Other parameters need
clarification.   7c

We stress again that we are not committed to a particular
implementation; we just want the functional characteristics of
the NLS-BE to be as described in the other sections of this
document. Other suggestions will be welcomed.   7d

NLS-BE / NSW File System Interface Time Requirements   8

It will take approximately one calendar month after the receipt of
detailed Foreman or WM file system specifications to implement the
NLS-BE interface to the NSW file system whether the Foreman or
direct WM call approach is selected. Note that this estimate does
not take into account considerations such as vacations which are
scheduled in the near future by key members of the NLS-BE team.
In order to get exact dates for our milestone estimates, we should
receive a date for the expected publication of these detailed
specifications of either or both the Foreman or NSW File System
functions from MCA as soon as possible. The expected date of
complete implementation of these functions would also be useful
for estimating when debugging could take place. Only upon receipt
of these estimates can we decide which approach to follow.   8a

NLS Backend / Works Manager File System Interface Requirements

Sent to Millstein@BBN, Schantz@BBN, and Carlson@ISI via SNDMSG.

Overview-- Works Manager / NLS-Backend File System Interface   1

   For the NLS Backend (NLS-BE) to be fully integrated into the NSW
   environment, it must make use of the Works Manager (WM) file
   system for file management. Discussions held earlier in July
   between ARC staff, Bob Millstein of MCA and Rick Schantz of BBN
   concerned the mode of interfacing the NLS Backend operation to the
   Works Manager file system.   1a

   Before these discussions we had intended to directly access WM
   functions such as those outlined in Millstein's memo of 22 May
   1975, WM-PROCEDURES. Schantz' development of the Encapsulator for
   existing tools with its implicit calls on these functions and the
   related development of the Foreman would permit us to avoid such
   direct access. Our earlier understanding of the intention of the
   Foreman (outlined in an earlier draft of this note dated 3 July
   1975) has been supplemented by further discussions with Millstein.   1b

   Thus two different but related approaches have been considered:
   in the first NLS-BE would interract with the WM through direct DPS
   calls on WM procedures; NLS-BE would be responsible for
   maintenance of the Local Name Dictionary (LND). In the second
   approach, NLS would access the necessary WM file system functions
   through a component known as the Foreman. As we currently
   understand the Foreman, calls would be in the form of
   pseudo-JSYSs. It would appear to the NLS-BE as an extension of
   the TENEX operating system. The Foreman would manage the LND; all
   necessary interaction with the WM would be through this channel.   1c

   The only documentation we have of WM procedures is Millstein's
   memo of 22 May 1975. To a large extent the functions listed would
   be sufficient to allow us to develop the NLS code changes
   necessary to interface to the WM file system. There are some
   minor exceptions: we feel some functions need clarification and
   possibly minor redefinitions in order to handle some NLS-BE
   capabilities described below (e.g., SETSEMAPHORE and
   UNSETSEMAPHORE); at least one new function would be desirable
   (READSEMAPHORE). These additions are described in a later
   section. Parameter specifications in Millstein's memo need
   elaboration and confirmation before code can be written from the
   procedure descriptions.   1d

   Our conversations with Millstein in early July opened the
   possibility of the use of the Foreman, but did not expand upon the
   document we had. No design currently exists for the Foreman,
   though our assumption has been that at least all the WM file
   system functions would be accessible. Again, no interface code in
   NLS-BE can be written until a detailed design document is
   produced.   1e

To create the NLS-BE interface to the WM file system via either of
these approaches will require almost the same amount of work.
Given the fact that NLS-BE is embedded in DPS, the code
differences between direct calls on the WM and pseudo-JSYS Foreman
calls is largely syntactic with minor exceptions.   1f

NLS-BE can operate in the NSW environment as a tool talking
through DPS to the FE even without using the WM file system; we
can continue to use the local TENEX file system. We feel,
however, that this hole needs to be filled as soon as possible
since other tasks must await its completion. For example, our
design for the installation into NSW of a Journal system
necessarily requires knowledge and experience with the WM file
system. We must select between the Foreman and direct calls to
the WM: the latter may be useable sooner, but the former is
esthetically more attractive. We feel it will take about one
calendar month after final specification of the WM functions (or
the Foreman functions/syntax) for us to complete the necessary
code modifications to NLS-BE with the exact time dependent on
vacation schedules and other commitments. In order to firmly set
our milestone date for NLS-BE operating in NSW completely
interfaced to the WM file system, we must have a date for the
publication of these specifications and an estimated date of
implementation.   1g

    For our purposes the publication of the design is more
    critical: we can code without the Foreman or WM file system
    being completed as long as the procedures and their parameters
    are well specified.   1g1

The rest of this note outlines some of these considerations in
greater detail and describes some of the file operations currently
performed in NLS.   1h

Our Current Understanding of the Foreman   2

    The running version of NLS accesses the TENEX file system through
    the use of various JSYSs such as GTJFN, OPENF, and CLOSF with
    certain flag settings. The Foreman would make available a set of
    additional pseudo-JSYSs (the set to be determined) which would
    gain control through the TENEX JSYS trap mechanism. The Foreman
    would do appropriate WM calls and maintain the Local Name
    Dictionary (LND).   2a

        Note that such functions are implicit in the Encapsulator for
        exsisting tools developed by Schantz at BBN. The Encapsulator,
        however, additionally does TELNET interaction for the tool and
        handles DPS interaction. Tools such as the NLS-BE live in a
        DPS environment and already have terminal interaction handled

by the FE. Thus while there is some overlap between the
Encapsulator and the Foreman, and while some of the code
modules may be identical, the Foreman may be more properly
thought of as being an extension to the operating system (TENEX
in this case, but potentially others as well) which serves as
the WM interface to NSW tools.   2a1

Jon Postel and Jim White have considered in a preliminary
manner possible modifications to the TENEX implementation of
DPS necessary for the Foreman to coexist with the NLS BE.
Minor changes are probably needed to handle interrupts and fork
structure communication. They should be made aware of any
decisions concerning the Foreman design.   2a2

Aside from minor code to manage the LND in the
direct-call-on-the-WM approach, the NLS code involving these
direct calls would be structurally identical to code calling
Foreman pseudo-JSYSs: in one case we would make Foreman
pseudo-JSYS calls; in the other case, we would make PCP calls on
the WM. While the former would be esthetically preferable since
the WM functions would appear as extensions to the operating
system, the amount of design and coding effort at ARC would be
about the same in both cases.   2b

Current NLS Use of File JSYSs   3

In the parts of the NLS Backend which will be used in NSW, GTJFN,
OPENF and CLOSF are used in fairly unexotic and straightforward
manners. For instance, we do not have the JSYSs complete the
names of files or ask the user for confirmation. All terminal
interaction is isolated in higher level procedures in the current
NLS and will probably be handled by the FE under NSW.   3a

In only one case do we currently attempt to get a JFN on an
unusual device: this is in the "Connect terminal" command to
accomplish shared screens. This command, if implemented at all
in the NSW environment, will probably be handled through the
Front End anyway.   3a1

There will be no problem putting a file name into the appropriate
form for the pseudo-JSYSs of the Foreman: either Works Manager or
TENEX format are acceptable to us since we currently are doing an
internal translation most of the time in NLS anyway. We could map
one form into the other as necessary. Extensive use is made of
the JFNS (JFN to string) JSYS, but in fairly non-critical areas
(i.e., to display error messages when files are not opened, to
obtain strings for internal tables). Again, the format required
by the Foreman does not appear to be critical.   3b

This is not to say that we will not have to put many changes
into the current code to get into the correct NSW file name
format, but such additions to the code were anticipated under
any implementation.   3b1

Rick Schantz was concerned with session termination and special
uses of terminals. We feel such questions are irrelevant in our
case: all terminal interaction and termination is handled by the
FE. We are not interested in the parts of the Encapsulator which
do TELNET interaction: this part is not needed by us as, again,
we will be communicating via DPS with the FE.   3c

Creation of New Files   4

Another unusual file operation done by NLS occurs in the creation
of a new file: because of some problems in TENEX, a file does not
really exist until it has been closed. We therefore open, close
and open the file at creation. In the NSW environment, we assume
that on creation a copy of the file exists in the NSW environment,
even if there is a subsequent crash. This is in keeping with our
goal of minimizing the amount of work which can be lost in the
event of a crash.   4a

Non-NSW Files   5

NLS will make minimal use of non-NSW files. Instances in which
non-NSW files would occur include temporary work files and general
system files (save files of processors or system data bases).
Since we will issue Foreman pseudo-JSYSs or calls on the WM when
necessary in addition to the usual TENEX file JSYSs, we can
selectively avoid dealing with the Foreman and the WM in the case
of non-NSW system or work files. Thus, an escape mechanism for
non-NSW files in the Foreman is not essential for NLS (though it
may be necessary for other tools.)   5a

Simultaneous Multi-user Access to Files-- Locking Mechanism and File
Data Validity   6

NLS has implemented code which deals with the problem of files
which have (possibly) multiple readers with one writer. The
solution additionally provides a file system which is very secure
across system crashes. While it is anticipated that the exact
current implementation (which makes use of a locking mechanism
based in the TENEX user settable word and something known as a
"Partial Copy File" described below) will not be used in NSW, we
feel Foreman / WM file system functions which permit similar
capabilities are necessary. In this section we discuss the user
view of the mechanism as well as the current implementation and

some system commands it makes possible. We abstract what we feel
are essential features to be carried over to the NSW.   6a

NLS currently permits files to be opened for read access; if a
user tries to write on the file, an attempt is made to "lock" the
file. When a file is locked, it may be modified only by the user
who has it locked. Other users may examine the file with read
access, but do not see the current editor's changes while the lock
is still on the file. When a locked file is loaded by a user
other than the one who has the file locked, the file is seen in
the state it was in at the time the lock was set; only read access
may be obtained, and a message is displayed stating that the file
is locked along with the name of the user who has it locked. This
information often proves useful in personal negotiations between
members of a group who may wish to work on the same material. The
fact that only one person may have the file locked at a time
implies that only one person may make edits at a time. This
minimizes the problems involved in collating simultaneous changes
to the same file by more than one user.   6b

   In the current NLS a file is locked by changing a bit in the
   user settable word using the CHNFDB JSYS followed by creating a
   partial copy file opened for write access; changes in the
   contents of the original file are reflected only in the partial
   copy until an explicit update causes the data to be merged.   6b1

   Note that unlike the TECO edit buffer, the partial copy is a
   real file: output is made to the disk and the data is as safe
   as data in the original file. The partial copy is NOT a
   buffer. In most instances in the event of a crash, barring
   only massive hardware failure, users would lose only material
   currently being entered, i.e., one line or statement. We aim
   for this level of security on NSW as well.   6b2

The mechanism is invisible to the user and is reasonably secure.
It permits many people safe access to a body of data; if a user
loads a file which someone else has locked, he will not be able to
edit it, but will be able to see its state before the edits began.
Works in progress are not visible to anyone other than their
creator until an update which also unlocks the file. This concept
has proven to be very useful in the case of users making major
edits: files may be locked indefinitely and personal negotiation
may be carried out by other users with the user who has the file
locked. In a programming environment such as the one at ARC, the
locking mechanism has saved costly integration of code changes
made on a file simultaneously by more than one user. This
feature would be valuable in the NSW as well.   6c

In the NSW environment, we will not be using the partial copy

mechanism directly. Because the WM maintains a secure version of
the original file, a user may make his edits in his copy of the
file and incorporate them upon delivery in the WM sense. The
locking mechanism is however still useful and could be implemented
through the use of the SETSEMAPHORE and UNSETSEMAPHORE WM
commands. Semaphores should be settable after a file has been
transmitted to the NLS tool. Users may just want to read a file
and not deprive other users of the possibility of obtaining the
file for write access and locking if desired. (It goes without
saying that one should only be able to set the semaphore if one
has write access in the TENEX sense, delete access in the WM
sense.) Delivery back to NSW should not imply the resetting of
the semaphore. A user may want to keep a file locked for several
sessions; for security, however, it is desirable for the file to
be delivered back to the WM at the end of sessions, perhaps with a
different name which may be calculated by NLS from the original
name. The semaphore on the original would remain set.   6d

The description of the OPEN function in Millstein's memo
suggests that most of this is possible. OPEN checks if the
user has COPY access to the file (read access in the TENEX
sense.) If the user also has DELETE access and a parameter is
true or the i/a tool descriptor (which we don't fully
understand) has a particular value, the semaphore is set if it
is not set already and the file copied to the current tool. An
earlier version of the file may be obtained if the user so
indicates. In NLS we do not want the semaphore to be set upon
OPEN. We definitely want to be able to get an earlier version
of the file if the semaphore is already set by another user; it
may be useful for us to have the file in which edits are made
have another file name to prevent "trims" of directories
(deletions of all but the highest versions). This would
suggest a slightly different use of the semaphore mechanism; of
course, implementation details can be worked out and must be
done in conjunction with MCA. While we are not committed to a
particular implementation, we are committed to the user view of
the system described above.   6d1

It would be useful for us to have a user id associated with the
setting of the semaphore. It would also be useful to be able
to read the semaphore before doing the OPEN; this reading
function would return a false if the semaphore of the file is
not set and, if it is, would return the user id of the user who
has the semaphore set. The exact implications of a set
semaphore are not clear from the 22 May memo. A clear
understanding of the function is essential both by ARC and by
MCA.   6d2

For the system to work efficiently there may have to be

provision in the Foreman and the WM for reading the semaphore
to find out if a file is locked and by whom; this information
could be used by NLS to translate the name of the original file
into the file in which edits are being made. If a file is
locked by the current user, the request may be "changed" by NLS
to a request for the related file with modifications in it;
all other users would access the original file and would not be
permitted write access. We want to minimize and if possible
eliminate the necessity of the Foreman knowing about NLS, but
efficient facilities to handle the locking mechanism are
desirable.   6d3

This area appears to be the one which poses the most potential
difficulty in our use of the Foreman and the WM File system as
it is currently designed.   6d4

The NLS command "Delete Modifications" may be used by a user who
has a file locked and has been making edits. Upon execution of
this command, all changes made since the last update disappear and
the file is unlocked. The "Delete Modifications" command may be
implemented in NSW by deleting the copy of the file with the
modifications, unsetting the semaphore in the original and getting
a new copy of the original from the WM.   6e

Functions Needed in the WM File System or Foreman by the NLS-BE   7

The following is a list of functions described in Millstein's 22
May memo which are essential to the implementation of the NLS-BE
file system interface; the more detailed specifications in that
document are assumed to be in effect. The parameters need a bit
more elaboration before we can program from them. Cases which
require minor redefinition and suggested new functions follow.   7a

    DELETE   7a1

    RENAME   7a2

    SETSEMAPHORE (see below)   7a3

    UNSETSEMAPHORE (see below)   7a4

    CLOSE   7a5

    COPY   7a6

    OPEN (possibly acceptable, but read the discussion on the
    locking mechanism above)   7a7

    DELIVER   7a8

The semaphore mechanism needs clarification; as noted above we
would like to have a user id associated with a set semaphore.
Moreover, we would like to be able to read this value without
copying the file. A careful (perhaps too careful) reading of the
22 May memo suggests that ids can be supplied as parameters to WM
functions only by the FE! (See the paragraph in section 1 of that
document which discusses ids as parameters.) Assuming this was a
mistake, we make the following suggestions for the semaphore
commands.   7b

    SETSEMAPHORE(id, filespec, maxlist, qhelp)
        -> NSW-filename   7b1

    The WM verifies that the tool can use SETSEMAPHORE, that
    filespec designates a unique file to which the user has
    delete access, and that the semaphore is not already set.
    Assistance is obtained via PCP HELP return or direct FE call
    as in the file system memo. If all is well, the semaphore
    is set on behalf of the user whose id is passed and the
    NSW-filename is returned.   7b1a

    UNSETSEMAPHORE(id, filespec, maxlist, qhelp)
        -> NSW-filename   7b2

    The WM verifies that filespec designates a unique file to
    which the user has delete access, and that the semaphore is
    set on behalf of the user. Assistance is obtained as usual.
    If all is well, the semaphore is unset on behalf of the user
    whose id is passed and the NSW-filename is returned.   7b2a

    READSEMAPHORE(filespec, maxlist, qhelp)
        -> file-semaphore-value   7b3

    The WM verifies that filespec designates a unique file to
    which the user has COPY access. Assistance is obtained as
    usual. If all is well, the semaphore value of the file is
    returned. It is either FALSE if the semaphore is not set or
    the id of the user who has the semaphore set.   7b3a

The OPEN function may need slight modification to avoid implicit
semaphore setting if it is not desired. Other parameters need
clarification.   7c

We stress again that we are not committed to a particular
implementation; we just want the functional characteristics of
the NLS-BE to be as described in the other sections of this
document. Other suggestions will be welcomed.   7d

NLS-BE / NSW File System Interface Time Requirements   8

It will take approximately one calendar month after the receipt of
detailed Foreman or WM file system specifications to implement the
NLS-BE interface to the NSW file system whether the Foreman or
direct WM call approach is selected. Note that this estimate does
not take into account considerations such as vacations which are
scheduled in the near future by key members of the NLS-BE team.
In order to get exact dates for our milestone estimates, we should
receive a date for the expected publication of these detailed
specifications of either or both the Foreman or NSW File System
functions from MCA as soon as possible. The expected date of
complete implementation of these functions would also be useful
for estimating when debugging could take place. Only upon receipt
of these estimates can we decide which approach to follow.   8a

Annotated DPS-10 Storage Breakdown

An annotated version of (32949,) for SNDMSG to Bill Carlson and Steve
Warshall.

This memo presents the current sizes in decimal words of the various
components of DPS-10. This breakdown does not include the L10
runtime environment or writable storage.   1

Symbols to the right of the various size figures are defined as
follows: 2

    #   code which is present in another form in DPS-11   2a

    <   code of which only part is present in DPS-11   2b

    -   code absent in DPS-11   2c

15530   Total   3

    184   Global catchphrases (for error handling)   3a

    220   Main program   3b

    230 < Record definitions (defining internal data structures) 3c

    395   Main programs for various DPS contexts   3d

    509 # Processor operation processing routines [IVDPS, RRDPS,
    etc.]   3e

    778   Incoming message processing routines   (CALPE, RTNPE,
    etc.]   3f

    790   Read-only tables   3g

          5 # Processor operation dispatch table [IVDPS, RRDPS, etc.] 3g1

        18 < IPC dispatch table   [inter-fork/inter-host] 3g2

        24   Message definitions   (CALPE, RTNPE, etc.]   3g3

        28   Data structure definitions   (USER INFO, PSEL, DSEL,
        etc.]   3g4

        100 < System procedure definitions [HLPPE, ABRPE, etc.]   3g5

        100 < User call definitions   [PECAL, LRDDT, etc.]   3g6

        105 < Table definitions   (describing internal
        tables]   3g7

        210 < System call definitions   [CRTPS, CALPE, etc.]   3g8

Recently Published Cassette Information Collected and Sent to Larry
Crain at Gunter

These are being reentered into the Journal in order to have a record
of their collective transmission to Larry.

Recently Published Cassette Information Collected and Sent to Larry
Crain at Gunter

The following are copies of recent Journal items which reflect our
current policies with respect to the CASSETTE system. Please note
that some of the limitations are due to TIP buffer sizes and the lack
of any flow control on the network. We can only guarantee the
validity of cassette material read in under the circumstances
described below until further notice. There will be some minor
changes made to some of the support programs upon Jan Kremers return
from his vacation.   1

JHK HGL 21-JUL-75 19:24 26163-- Current (15-JUL-75) Cassette
Restrictions   2

  The following restrictions currently apply to the use of the
  CASSETTE utility and DEX. Software modifications to be made
  within the next weeks will offer greater security of data capture
  through the network and will permit a wider variety of cassette
  hardware to be used, but problems with the nature of the TIP
  device (which was not designed with the cassette process in mind)
  preclude major improvements without further developments which
  will be outlined in later notes.   2a

    The Cassette recorder used must have the folowing remotely
    addressable controls:
                                                                       2a1

        1) rewind   2a1a

        2) record   2a1b

        3) stop record   2a1c

        4) read   2a1d

        5) stop read
                                                                       2a1e

    Additional cassette hardware specifications may be found in the
    WORKSTATION EQUIPMENT REFERENCE MANUAL, NIC # 23809.   2a2

    At present (7/15/75) the only (!) specific cassette drives
    supported are the following:
                                                                       2a3

        ICP-TERMICETTE 3100   2a3a

        TECHTRAN 4100
                                                                       2a3b

Recently Published Cassette Information Collected and Sent to Larry
Crain at Gunter

Operation of the CASSETTE UTILITY and hence DEX itself cannot
be guaranteed when any other type of drive is used. This list
will be expanded in the future.   2a4

At the present time cassette input through line processor
terminals is not supported. This facility will be available in
the new version of the CASSETTE UTILITY.   2a5

When the CASSETTE UTILITY is used on a TIP line one must be
absolutely sure that the size of the TIP buffer for the line
being used is greater than the size of the longest tape record
to be processed. This restriction is necessary because the
cassette drive cannot be stopped while it is reading a record.
If this rule is not followed, the program will hang, drop
characters and in general behave in an unpredictable and
unreliable manner. In some cases, modifications to the sizes
of buffers used for cassette input will have to be arranged
with the Network Control Center to follow specifications of
ARC. If there is difficulty getting all data through the
network, ARC should be consulted with information about the TIP
used, the TIP port, and the tape record size.   2a6

When the CASSETTE UTILITY is used via a TELNET connection the
TELNET escape character must be changed to something other that
the default ^Z. (^W is recommended). TELNET must also be told
to operate in "transparent mode" to avoid interception of
control and special characters from the tape.   2a7

We are in the process of investigating the CASSETTE problem and
hope to have a somewhat more reliable software package
available within the next few weeks. The above restricions,
however, will remain in force. Problems and questions
concerning the DEX and CASSETTE UTILITY systems should be
forwarded to LEHTMAN@BBNB, or KREMERS@BBNB.   2a8

HGL 21-JUL-75 20:44   26164-- Some TIP buffer sizes   3

The following list of TIP buffer assignments was provided by Joel
Malman of the Network Control Center on 16 and 18 July. They
should be useful in the analysis of Cassette problems. The list
of TIPs was obtained from Applications; there are a few others
which should also be included (such as RADC?) Numbers are octal.
Input buffers are measured in words at two characters per word.
Output buffers are double buffered; therefore the output buffer
listed may be taken as the octal buffer size in characters.
Except for AMES and Tymshare, the list was compiled over the phone
and may be incorrect in places due to my stenographic ineptitude. 3a

Recently Published Cassette Information Collected and Sent to Larry
Crain at Gunter

Note also the fact that Joel expressed shock that we would even
consider putting the TIP which was designed "for people typing at
keyboards" to use in the middle of a cassette based system. There
is no flow control in the TIP and buffers will indeed overflow.   3b

HGL 28-JUL-75 15:09 26204-- Clarifications on Cassette Restriction
Document (26163,)   4

Kirk's questions (33043,) about our Cassette restriction document
(26163,) were quite good. Control-W is indeed used by Termicettes
as the rewind control character. Thus the suggestion in our
earlier document about the appropriate escape character setting
for operating the cassette system through TELNET should have been
generalized to suggest that the escape character should not be one
of the control characters which activate the cassette terminal
being used. (I think control-P is OK, but we shouldn't generalize
about all terminal types: they may each require a different TELNET
escape character.)   4a

The second question is more difficult to answer: there is NO
command to change TIP input buffers! The TIP, as stressed by Joel
Malman of NCC, was not designed to handle cassette terminals. TIP
buffer sizes are assigned by NCC and must be changed by them. I
can assure you that they would not want to change them frequently.
All we can do is find out from the user which port is being used
if data is being lost and suggest they get on a port with bigger
buffers. This is not possible on some TIPs which have phone lines
assigned to non-specific ports. If some customers are assigned
dedicated lines (and ports) it may be possible to set one or two
of them to a size large enough to be used by a cassette terminal.
The ultimate solution awaits the development of buffering flow
control hardware in the LSI-11 lineprocessor.   4b

Martin Hardy has suggested that our phrasing of required functions
to be present on the Cassette terminal device was confusing: none
of our current devices has a stop read control. We meant to imply
that the read record command should stop reading at the end of a
reasonably sized record, generally a line of text.   4c

    Bill, we will get together a detailed breakdown of the cost
    comparison of 11/40 and 11/70 along with cost of 11/05 and send
    you. The 11/05 used on a per terminal basis will need to
    interface to some sort of host or TIP and we will want to discuss
    the various considerations and likely total system and per
    terminal costs for various likely cases ie a situation like at
    Gunter where there wll be many terminals, a case where a site
    might only want a couple etc. That will be the subject of a think
    piece we will get together. The cost of PDP 11 type hardware is
    coming down at a fair rate. will get difference in cost of PDP 11
    memory today versus what it was a year ago as example. As
    mentioned yesterday I think cost of 16K from DEC is around $3K
    today and can be obtained from independent suppliers for as little
    as $2.3K for 16K, will look up what it was a year ago. Back with
    more details soon. Dick -------

messages from watson

From: WATSON
Subject: perspective on FE costs
To: carlson at ISI
cc: watson, warshall   1d

in thinking about FE costs there are many angles that one can go
at it. Some useful in comparing different design approaches but
the couple that are really dominant economically are raw
hardware costs for fe as part of the total computing picture for
the user, his time, training time, communications across the
network, , cost of TBH time etc. For example taking one incomplete
example using BBN prices of 600K per year to run a machine. The
cost of the 11/40 fe is about 100K amortized over 4 years yields
$25K / year. On the assumption that each one supports 20 users the
cost for a one user slice is 1,250 for fe and $30K for TBH use or
fe is about 4% of total cost, if network packet costs are thrown
in it is less. Now if fe supported 40 users cost per year per user
would be $625 and percent would be around 2. The second point is
the decrease in hardware cost at about 20% per year. Such that a
$100K system today will be around $30K in the 1979-80 time frame
reduces above percents for fe even more. One can go on to show
significant savings for communications and in TBH if fe begins to
do tasks thus allowing more users to be supported in TBH. For NLS
as an example we expect fe to free TBH of from 10-30% of its
cycles. If one then adds to above cost savings to tool builders of
being able to write user interface program rather than building
terminal control parser etc the total picture for NSW fe can be
painted very economically attractive even when cost of memory
requirements are as described. On top of that one gets into the
hard to define cost savings of various user services, more
responsive service of having fe close to user etc. The above crude
outline is type that would need to be used to look at economics
and cost benefit of fe or various approaches. I think the present
approach when compared on such a basis with simpler ones will come
out very favorably. Just thought I would throw above at you for
mind fodder. Best Dick -------

                                                                           1e

From: WATSON
Subject: some after thoughts on fe economics
To: carlson at ISI
cc: watson   1f

Bill,   1g

    As pointed out in previous note we are talking about a very
    small amount of money per year per terminal for the fe no

matter what approach is used and it does concern me to see you
worrying so hard at this stage of a new development about
trying to find ways to optimize that small percentage.
The point I did not make in the previous note which to me may
be the most important one is that there is so much to learn
about what facilities we want in the NSW that is really going
to be scaled for delivery in the 78-80 time frame, that we want
to offer as advanced services as we can with in reason now so
we can get experience with them ourselves, users can get
experience, tool vendors can get experience etc so we can spec
the final product from real knowledge.   1g1

The fe 10 is going to be essentially done in next week or so
before WM demo. With out modifying their tools old tool vendors
could write the CML interface spec for their tool and we
provide the full range of fe services to their users with very
little work assumming of course they can turn off the normal
messages from their tool when it parses the command string that
finally gets sent. We think it would only take Charles for
example 2-4 hours max to write the CML discription of the SOS
editor. Its even easier to insert old tools with less service
for user. A simpler fe approach may save a few dollars
initially but will deprive us of a chance to test services and
ideas that could prove directly or in their next pass or two
to be worth far far more even if they only prove we do not want
them in the final product. It is this important developmental
exploratory flavor even with real users doing real work that
seems to me to be getting lost.   1g2

I remember back 7-8 years ago when I was getting some graphics
and interactive R&D going in Shell that when management saw the
price tag for general graphics terminals which back then cost
around $100K they got stuck with that number stuck with that
number. But even with that number, which is an order of
magnitude almost bigger than the per terminal numbers we are
talking about for fe, when you pointed out the amortization and
computed the hourly cost of running one and placed it in
perspective with communications costs and the costs of the
timesharing system behind it they could relax think in whole
system terms including the users overheaded salary and support
what was going on.
Now we are talking in order of magnitude per user smaller
numbers but same big picture needs to be kept in mind.   1g3

   Bill if you are being pressured from some body on steering
   committee who does not see this type of picture I would be
   glad to try and put it in perspective for them as on a
   sensitivity basis the whole NSW system economics are just

3

not very sensitive to fe costs or whether it supports 20 or
60 users.   1g3a

The economics are very sensitive some quick arithmetic shows to
savings fe can give to TBH cycles and communication costs.
Quick assumptions show me that for NLS the fe could save
possibly as much as $5,000 per year in communications costs per
terminal and from10-30% per year in TBH costs depending on
assumptions on TBH CPU cycle savings assumed. For other tools
it could be more or less. I used Telenet rates in thinking
about packets above.   1g4

This quick analysis shows me we want to push more functions out
of the large TBHs like the Tenexes into the local machine and
favors the larger 11/70 running tools locally like NLS editing
etc that are frequently used even if fewer users are supported
and we want to encourage tool suppliers to do their parsing in
the fe and other functions that would reduce TBH loads.   1g5

We need the NSW evaluation contractor who has the time to work
with people like us to get all these full picture ways to look
at things out on the table. I sure would appreciate some
feedback on these two notes as to whether or not they were
useful. Must get home now. Dick   1g6

Date: 30 JUL 1975 2204-EDT
From: WATSON
Subject: Now for some good news
To: [BBNB]<POSTEL>NSW-STEERING-COMMITTEE.LIST:
cc: postel, ehardt, watson   1i

TO NSW STEERING COMMITTEE   1j

Our document sent out last week listing address requirements
for FE software (we need to be careful to distinguish term
"address requirement" from "memory requirement" as the two are
independent assuming a secondary storage device; however, then
transfer bandwidth and memory access interference between CPU
and secondary device need to be considered) indicated that the
11/40 with limitations on both main memory size and bandwidth
while useful in the short term was not the best intermediate to
long term choice.   1j1

We have been looking at configurations in two directions - one
the features and cost of the 11/70, the other a configuration

based on very small 11/03 or 4 to take over for Line Processor,
display (terminal) control, and CLI.   1j2

The former is (somewhere in $15k-30k difference range for
comparable configurations) so close in cost to the 11/40 and
offers so much more both in bandwidth and memory capacity, that
our preliminary look indicates the 11/40 is already obsolete
for this type of application. The 11/70 offers other
advantages as well.   1j3

The other approach using the small 11/03 or 4 also looks very
attractive. It appears very cost competitive and to have nice
scaling properties. A think piece on these approaches is in
the works with costs. Either approach follows nicely on work
to-date.   1j4

I am sending this note now hopefully not premature, to share
the good news, after having had one sent out with some bad
news.   1j5

My only regret is that I have two 11/40's sitting on my floor.   1j6

NSW Protocols Weekly Status Report: 31-JUL-75   1

  JIM WHITE   1a

    Major Responsibility: DPS-10   1a1

    Accomplished Last Week   1a2

      - Continued debugging CLI/DPS/NLS system with DSM/CHI.   1a2a

      - Implemented most of the new DPS-10 features outlined in
      last week's status report.   1a2b

      - Sent memo to Stu Schaffner suggesting that the WM make
      available to tools, an INDEX data store called "FEPH"
      containing the tool's process handle for the FE.   1a2c

      - Touched bases with Rick Schantz regarding his progress
      interfacing the encapsulator to DPS.   1a2d

        Learned that he's working with Schaffner (whose DPS
        interface code he's using) but has yet to really get off
        the ground; the ball rests with Schaffner at the moment,
        but I indicated my readiness to assist whenever required.
        Learned also that he's ready to test the encapsulator
        with JBP's user Telnet code, as soon as it is made
        available to him.   1a2d1

      - Reviewed second draft of LLG's DPS-11 user interface spec.   1a2e

      - Annotated previously published DPS-10 storage breakdown
      and SNDMSGed it to Warshall and Carlson.   1a2f

      - Reviewed Doug Wells' NSW Protocol Meeting minutes.   1a2g

      - Wrote initial and final draft of reply to proposed Message
      Transmission Protocol Subcommittee, incorporating the
      comments of CHI, JBP, JDH, and RWW.   1a2h

      - Proofed Journal section of final report.   1a2i

      - Mailed a copy of the 22-NOV-74 PCP documentation to Marty
      Michael at Brown University, at his request.   1a2j

      - No debugging of CLI/DPS/WM system with Stu Schaffner this
      past week.   1a2k

    Scheduled Next Week   1a3

NSW Protocols Weekly Status Report: 31-JUL-75

   - Continue debugging CLI/DPS/NLS system with DSM/CHI,
   CLI/DPS/DEBUGGER system with KEV, CLI/DPS/WM system with Stu
   Schaffner, and CLI/DPS/ENCAPSULATOR system with Rick
   Schantz, as required.   1a3a

   - Complete implementation of new DPS-10 features and update
   DPSJSYS accordingly.   1a3b

  Queued   1a4

   - Code inter-host inter-process communication (this is not
   critical path).   1a4a

  Problems Encountered   1a5

   - System response (apparently the Network) has been
   extremely poor this week!   1a5a

   - Having to respond to the proposed message protocol
   adversely affected my ability to respond to DSM's debugging
   needs, primarily because installation of the new DPS
   features was abruptly interrupted with the source file in a
   state such that it couldn't be recompiled.   1a5b

LARRY GARLICK   1b

  Major Responsibility: DPS-11   1b1

  Accomplished Last Week   1b2

   - Journalized final (?) draft of DPS-11 user interface
   description.   1b2a

   - Prepared a note on storage management issues with DLR. 1b2b

   - Continued coding DPS-11 event and manager management. 1b2c

   - Began coding a message block allocation monitor to be
   shared by DPS-11 and CLI-11, which relieves the caller of
   ELF-level calls of responsibility for controlling access to
   message blocks.   1b2d

   - Learned DDT and debugged my first piece of code -- the
   process address parser.   1b2e

  Scheduled for Short Term   1b3

   - Continue DPS-10 => DPS-11 conversion.   1b3a

       > Install new VJSYS/VJUSR call mechanisms.   1b3a1

       > Remove subprocess and processor management.   1b3a2

       > Code data format conversion routines for PCPB8.   1b3a3

     - Shooting for a test of DPS-11 with CLI-11 by 1-SEP.   1b3b

Scheduled for Long Term   1b4

   Install DPS-11.   1b4a

Tripping around, (final?) Glossary to COM, QMR, start on 8.5 help
files: Documentation weekly report for week ending August 1

POOH   1

  This Week   1a

      spent monday and tuesday at the pentagon meeting with pople
      about the 66-1 document the are going to be revising at gunter   1a1

      spent the rest of the week getting ready for the gunter
      trip...working with DEX, talking with Larry Crain to make
      arrangements, looking at the documents we are going to produce   1a2

  Next Week   1b

      i will be at gunter for the next two weeks.   1b1

Bev   2

  This Week   2a

      Reviewed proofs from COM file of Glossary. Fixed errors. Off
      to isic again, this time for K-5's.   2a1

      Completed final draft of Quarterly Management Report, except
      for short blurb on NLS 7 to NLS 8 conversion.   2a2

      Revamped Sendmail Sample Sessions.   2a3

      Outlined documentation tasks for next nine months with Kirk.
      Divided up responsibilities among bev, kirk, pooh.   2a4

      Went over Help with Kirk; began working on CORE, then switched
      to Base file.   2a5

  Next Week   2b

      work on Help Base file.   2b1

      Complete and format QMR.   2b2

      Discuss packaging sample sessions with Jim Bair. Find out
      print runs. Send off to SRI printing.   2b3

      Discuss documentation technology transfer procedures with Jim
      Bair.   2b4

Kirk   3

  Done   3a

Tripping around, (final?) Glossary to COM, QMR, start on 8.5 help
files: Documentation weekly report for week ending August 1

       Re-did and un-did various AFMFormat program directives.   3a1

       Consulted on various ways of teaching and using DEX.   3a2

       Set up documentation schedule with Bev.   3a3

       Consulted on formatting various Air Force manuals with tables
       and different numberings.   3a4

       Discovered a search bug in Help, re-wrote (and simplified) the
       code in response.   3a5

       Got Bev started on writing description files.   3a6

       Introduced Jan to Help code.   3a7

  Do   3b

       Put the current list of development documentation on line.   3b1

       Finish getting Help files in order for bringing up 8.5.   3b2

       Work with Bev and review her help writing.   3b3

       Continue transfer to Jan of Help and Class-I user programs
       (which now includes Calculator?).   3b4

       Continue hassling with AFMFormat.   3b5

       Begin on Letter Program.   3b6

Concerning Shared Screens at OFFICE-1

In talking with KEV (and indirectly with CHI) it appears that the
nescessary modifications to TENEX to support NLS shared screens for
non-enabled users would take Jeff about a week to do. It would
require another week or two to get the changes through Tymshare.   1

It should be noted that this change represents a departure from
standard TENEX. It is unlikely that we could get BBN to pick it up
for standard release. This not only means that the feature would not
be available at BBN and ISI, but for each future TENEX release, the
edits and reassemblies would have to be repeated for OFFICE-1.   2

Concerning Shared Screens at OFFICE-1

Notes on the NSW Protocol Meeting June 11-13, 1975

Notes on the NSW Protocol Meeting June 11-13, 1975   1

by Douglas M. Wells   1a
(DWells at MIT-Multics)   1b

07/31/75   1c

SECRETARY'S COMMENTS   2

This meeting, which was held at SRI-ARC, was called to discuss the
NSW protocols. This was the first large-scale meeting at which MIT
and UCLA were prepared to be other than interested spectators. The
agenda announced included: a report on the the current
implementation status of DPS, a discussion of features which were
hard/impossible to implement on the other hosts (primarily Multics
and OS/360), a discussion of the File Package, and a discussion of
problem areas which might be handled in a re-design of DPS.   3

As the meeting wore on, however, it became obvious that the group as
a whole was uncertain as to the direction that it should be
proceeding. In particular, there seems to be no reference source
(either a written document or a particular person) to which specific
questions can be directed (with reasonable expectations of a correct
reply). The types of questions that keep coming up are of the form: 4

    Is feature X to be included in NSW?   4a

    Is it to be included in the first demonstration?   4b

where feature X is such things as automatic validation of Air Force
standard COBOL source format, or association of use-types with NSW
files. It is to be hoped that the appointment of COMPASS as
Technical Coordinator as of July 1 will help this situation
tremendously.   5

The primary result of this meeting, I believe, was the familiarity
gained with concepts of implementation of other parts of NSW and of
other operating systems. The fact that a day and a half were spent
considering how to interface the NSW file system to Network host's
native file systems can only indicate the magnitude of the problems
that were faced and (hopefully) partially solved.   6

[In the time between the meeting and the publication of these notes,
the Steering Committee has written a public letter to Steve Warshall
of COMPASS which goes a long way towards the defining of goals, both

long-range and immediate, of the NSW, It is to be hoped that
iteration of these goals will lead to a interesting and useful
product,]   7

These meeting notes have been prepared with the expectation that
some of the overview material is of more importance to non-attendees
than the particulars of some of the later discussions, Accordingly,
there has been an attempt in these meeting notes to reproduce more
of the substance of the first day overviews and status reports when
compared to the brief summary of the discussions that occured during
the last two days of the meeting, (It is also the case that the
substance of the discussion of the File Package and the other
protocols will eventually appear as protocol descriptions,)   8

Finally, it should be noted that the opinions expressed herein are
mine,,,   9

Notes on the NSW Protocol Meeting June 11-13, 1975

DAY 1: WEDNESDAY, JUNE 11, 1975   11

The meeting commenced at 9:00 AM. After introductions, Jim White
proceeded to report on DPS version 2.5. Jim explained that DPS was
currently coded and he was in the process of debugging. At the time
of the report, Jim was using the TENEX version of the FE to debug
the intra-host communication facilities of DPS.   12

                                                                    12a

For the benefit of all present, Jim then gave a overview of DPS: 13

   The Distributed Programming System (DPS) has a higher-level model
   in which the world is viewed as processes communicating with
   other processes. DPS processes remain undefined but are
   characterized by having associated with them such things as
   Procedures, Data Stores, and Processors. The Procedures and Data
   Stores are organized into Packages primarily for purposes of
   access control. Each package consists of one or more procedures,
   and zero or more data stores.) Furthermore, each process has one
   or more Processors. A processor is akin to an execution point
   moving in an address space   13a

   Among the concepts supported by DPS are: a Procedure Call to
   allow a program to call another program (possibly on another
   host), a Coroutine Linkage mechanism to allow two or more
   procedures to pass control back and forth among themselves, a
   Note facility to allow lower-level routines to inform
   higher-level routines that some event of possible interest to it
   has occurred, and a HELP return to allow a higher-level routine
   to provide assistance and additional information in anomalous
   situations.   13b

   DPS has a small number of Data Types to allow communication of
   information between processes. Data Types allowed include:
   INTEGER, BOOLEAN, BIT-STRING, CHARACTER-STRING, INDEX, EMPTY, and
   LIST.   13c

   DPS allows processes to interact in a number of ways. One process
   can create another (thus inferior) process. A process may be
   introduced to another, pre-existing process (by a different
   process that already knows about each of the two processes).
   Finally, a process may "splice" inself to another, pre-existing
   process (with no interaction with another process).   13d

The discussion which followed raised several issues about the
protocol: 14

  = because of the tree structure of processes encouraged by DPS,
  the relationships among "spliced" equivalent (pre=existing)
  processes seems unclear,   14a

  = the inclusion of the concept of processors seems to cause some
  problems in terms of simplicity of implementation,   14b

  = because the note facility (as implemented by the DPS NTEPE IPC
  message) is defined to send the note all the way to the top of
  the procedure call stack, the use of this information by both
  programs and human users seems uncertain,   14c

  = the actual use of the help facility (as implemented by a DPS
  co=routine call) seems unclear = particularly when there is an
  attempt to solve a real problem several levels down in the
  procedure call stack,   14d

Bob Millstein then gave a status report on the Works Manager, He
said that large portions of the WM were running using dummy
procedures for certain cross=net functions, He stated that since May
15, they have been using the Command Level Interpreter (CLI = the
TENEX version of the FE developed by Charles Irby) to debug the WM,   15

Following his status report, Bob proceeded to give the group an
overview of the Works Manager; an overview which he described as
"largely theoretical", i,e,, without considering an implementation
within DPS,   16

  The Works Manager takes a viewpoint of being a mediator in an
  interconnection of processes, The WM is a collection of
  non=identical processes sharing a common data base, The WM is
  primarily a resource allocator, In order to allocate and control
  resources, the WM arbitrates at request time to check the
  validity of the semantics of the call, and then may bless the
  request, The primary resource that the WM controls is the NSW
  File System, Other resources that the WM controls are Tools (on
  TBH's), and other WM procedures (such as the batch job stagers),   16a

  In order to provide an actual service, the WM has error report
  collection processes and needs the ability to communicate with
  other processes, The WM is viewed as one entity rather than a set
  of shared=goal entities, In order to remain simple, the WM

procedures want to be rather ignorant in regard to their
knowledge of the outside world,   16b

From the outside world, the WM appears to be a transaction
processor to which requests are sent. The transactions performed
are invocations of the WM Black Boxes described in previous
documentation. The WM queues requests that it cannot fulfill
immediately,   16c

To complete the tour of current progress, Charles Irby then
described the Front End as it is to be implemented under ELF. He
described it from a functional viewpoint: 17

The FE is currently envisioned as several processors (of the DPS
variety) running in one process which is spliced to the WM. To
emphasize that this was an implementation viewpoint, Charles
pointed out that the TENEX version of the FE now running (CLI)
causes each user to have a private process which is individually
spliced to the WM,   17a

Somehow at the beginning of time, NSW EXEC is loaded and begins
execution under ELF. This program/process creates a connection to
the WM and is given an initial set of grammars. At this point,
the FE is ready to provide service to human users at their
terminals,   17b

When a user indicates to the FE process that he/she wants to
start a session, the FE collects login information from the user
(according to an initial grammar) and then makes a procedure call
on the WM LOGIN function. At this point, the WM is aware of the
presence of the user and the capabilities/restrictions of the
user are known to the WM,   17c

If the user desires to perform some simple action such as
deleting a file, he must perform some action (as defined by the
grammar that he is using) to cause the FE to perform a
DELETE-FILE call to the WM, After this call, the WM will return a
"yes", return a "no, because ,,,", or will make a HELP call
indicating that more information is needed as, for example, would
happen if the name specified by the user were ambiguous,   17d

If the user desires to perform some more complicated action such
as running NLS, he must cause the FE to call the RUN-TOOL
procedure in the WM, If the WM will allow the user to use the NLS
tool, it will then choose a TBH on which to run NLS, create a

process at the TBH to run the NLS tool. Assuming things are still
going smoothly, the WM will then introduce the newly-created tool
process to the FE process and supply the appropriate NLS grammar
table to the FE. Now the FE uses the NLS grammar to allow the
human user to perform procedure calls (with arguments) directly
upon the NLS tool process.   17e

Following the status reports, the discussion moved to questions
about how the WM should be viewed by other components in NSW (in
particular, TBH's and the FE's). This discussion finally arrived at
the viewpoint that the WM is one entity which lives on one host
(until the implementation of multiple WM's - whatever that means)
and which requires some help from the TBH's, e.g., Local Name
Directory maintenance, file trapping. There was also some discussion
about the use of the terms authorization, revocation, and budget
with respect to the use of NSW Tools.   18

In the afternoon session, the subject of "how should the WM look"
arose. This discussion wandered through various side-roads without
ever coming to much of a conclusion. Along those side-roads,
however, several points did appear: 19

    - the WM takes a transaction approach rather than a process
    control viewpoint because the latter does not seem to lend itself
    to the problems associated with a user who has two (or more)
    tools active simultaneously, nor to the user who has multiple
    instances of himself/herself. (1)   19a

        (1) The notion of a transaction processor here is akin to the
        way that airline reservation systems (for example) handle
        requests. That is, there are one or more anonymous virtual
        processors which can handle any type of request. No
        information about a particular user is remembered in a
        processor.   19a1

        In a process-oriented system, however, a particular processor
        (process) is assigned the task of interfacing to a particular
        requestor. In this type of system information is not always
        immediately updated into a common data base.   19a2

    - the Black Boxes defined for use by the WM are such that even if
    a user process control type system were used, the global WM data
    base would still have to be updated at approximately the same
    points.   19b

Notes on the NSW Protocol Meeting June 11-13, 1975

   - in a hint at what multiple WM's might look like, Millstein
   offered the viewpoint that a single WM should control a user's
   session and that the updating and use of the various data bases
   of the multiple WM's would have to be synchronized in order that
   effective control of users (by human supervisors, in particular)
   could be maintained,   19c

   - finally, it was reaffirmed that the user should view the WM as
   his operating system supervisor,   19d

In an attempt to get back to the announced agenda, the meeting again
picked up the discussion of DPS as a protocol; specifically as a
protocol to be used in implementing NSW. This started as a attempt
to determine if the suitablility of DPS should be evaluated
separately from a WM viewpoint and from a TBH viewpoint. After an
obscure side trip to consider how the TIP accounting system handled
the problem of multiple-site data bases, the group got back on the
path and proposed two initial opinions: No, there should be only one
protocol, and Yes, DPS was designed to support the WM and a number
of special purpose features had been included in DPS in direct
support of a previous design of the WM. This brought up a point as
to whether DPS was targeted at the exact goal of implementing those
functions necessary to support NSW or as it was actually phrased:
whether DPS was at the same time, both too grandiose and too
restrictive, having, for example, both NOTE and HELP, and, having
both INTERRUPT and ABORT. [Secretary's Note: the interpretation of
these examples and the attendant discussion won't be explained here
and probably can't be explained at all.]   20

After a realization that such a discussion could easily take several
weeks, it seemed to be accepted that for the time being, we would
discuss only that part of DPS which was needed by the TBH's --
something which came to be called the TBH subset of DPS. After some
thought, it was generally agreed that the only readily identifiable
part of DPS which TBH's did not need to implement were the concept
of multiple processors running in a single process. In response to a
question about why the WM needed multiple processors, it was argued
that processors were an answer to two problems: concurrency of
execution on behalf of multiple users (to gain real-time speed) and
prevention of deadlocks. Because the WM may queue input requests for
transactions, it runs risks of creating deadlock situations,   21

In order to force a solution, Carlson then outlined four courses of
action which could be taken in the near future: 22

1) Throw out DPS and start over,   22a

2) Go through DPS 2.5 and remove, add, and change the primitives
as necessary,   22b

3) Accept DPS as is,   22c

4) Define a TBH subset and then choose 1, 2, or 3 above,   22d

This immediately led to a question as to whether or not there was a
strong commitment to DPS 3.0. The reason for this question is that
some of the people present felt that DPS is not organized in such a
fashion as to strongly encourage a interprocess communication model
of the world; thus if there is no commitment to DPS 3.0, then there
is a strong desire to fix the problems in DPS 2.75, but if DPS is
going to be altered later, then the various systems could live with
DPS as it stands today. Carlson stated that there was no strong
commitment to DPS 3.0; a statement which led SRI to state that they
had been previously given to believe otherwise.   23

In any case, it was widely believed that choice 4 above (choose a
TBH subset, and then choose something else) would eventually be the
necessary choice. At this time, Crocker proposed that that the
choice be 4=3 with the proviso that only the TENEX implementation
proceed over the next few months. The only real objections raised to
this direction was that NSW would again proceed along the path of
encouraging the creation of TENEX dependencies. [It will be pointed
out here that this issue was not resolved at the meeting and remains
unresolved today.]   24

Proceeding along the parallel paths of determining what portions of
DPS were to be in the TBH subset, and also of determining what
software was required in a TBH, the group drew up a list of
requirements for TBH's: 25

In order to support the WM, a TBH must provide: 25a

    = an encapsulator for tools (at least for "old" tools,   25a1

    = an interface to access files from the WM,   25a2

    = (possibly) to support version numbers for files (ala TENEX
    and ITS),   25a3

- to maintain a LND to provide a crash-resistant
correspondence between NSW file names and native file names,   25a4

In order to provide a background system to support NSW, a TBH
must provide: 25b

- a dispatcher to respond to ICP's on socket 25 and create DPS
processes,   25b1

- a File Package to move files in and out of workspaces, this
function was further divided into: 25b2

provision of temporary files (copies of NSW files and
local tool temporary files) in direct support of NSW Tools,

maintenance of Permanent Files (storage for NSW files),
[It should be remembered that this is really for support of
File Bearing Hosts.]

The group then expressed this list in terms of functional
requirements on a TBH: 26

1) must talk to WM,   26a

2) must use NS$_W$ File System instead of native one,   26b

3) must be able to tell somebody (as yet unspecified) that a Tool
has stopped,   26c

4) must be able to setup communication paths,   26d

5) must report accounting information both periodically and on
request.   26e

At this time, there was an attempt to consider scenarios of how an
actual TBH would function. In response to a proposal to consider the
B4700 as such a strawman TBH, a discussion about whether or not the
B4700-PDP11 combination should, in fact, be considered a TBH. The
primary argument for consideration of the B4700 as a TBH was that
there is going to be one of these beasts and thus it shouldn't be
considered special. The primary argument for not considering the
B4700 as a TBH is that it is so deficient in resources and
functionality that it might be better to consider that the B4700
uses special protocols to communicate with special purpose tools
(residing on TBH's). The result of this discussion was an

announcement by the WM group that they were not prepared to run
Tools other than on direct behalf and at the behest of a user; thus,
the IBS could not run a Tool on a TENEX, for example.   27

At this point, Carlson attempted to combine the two previous
requirement lists into one re-organized list. This new list stated
that a TBH must provide for: 28

  Communication paths with the WM.   28a

  Accepting a message to dispatch a tool acknowledgment   28b

    - acknowledgment   28b1

    - establish user communication paths   28b2

    - notify somebody (?) that a tool stopped   28b3

    - send accounting data to WM   28b4

    - translation of all file references into WM calls.   28b5

  Movement of Files   28c

    - Permanent NSW File System   28c1

      # interhost movement

      # intrahost movement

    - Temporary Files   28c2

      # true temporaries

      # copies of NSW files

The group then turned to a discussion of the consequences of using
DPS, both in the past and in the future. Crocker re-offered his
suggestion that DPS probably hasn't been the optimal way to go, but
that it probably is close; it probably doesn't solve all the
problems of NSW and it probably solves some extraneous problems. In
response to a general question about the state of the various TBH
implementations, Schantz implied that the TENEX Tool Encapsulator
would be finished by the end of June. Wells stated that much of an
earlier version of DPS had been implemented, and thus Multics had

12

many of the primitives of DPS 2.5 implemented, but that the
completion of the entire implementation was not particularly close.
Braden stated that CCN had not started any implementation, but that
the group was currently in the process of performing design choices
and evaluating implementation languages.   29

Continuing the examination of the consequences of using DPS, the
group considered the efficiency of DPS. Two measures of
implementation efficiency were offered: the number of network
messages, and the number of procedure calls required to perform a
function. It was also noted that two measure of network efficeincy
existed: throughput (bandwidth), and real-time delay. It was thought
by a few present that the use of DPS caused too many network
messages to be passed back and forth. [Secretary's Note: though this
issue of the large number of network messages required by DPS has
been raised periodically and was raised throughout the meeting,
there has not been one single instance of a proposed simple protocol
change (short of grossly modifying the Host-Host protocol - and thus
requiring all hosts to totally rewrite their NCP's and operating
system interfaces) which would reduce the number of network messages
necessary to transmit a file, for example. This would tend to
suggest that the number of messages used withing DPS is close to the
lower bound of messages needed. Rather, a number of suggestions were
made later as to how to reduce the number of procedure calls (and
thus network messages) in support of the File Package.]   30

For the remainder of the day, the group discussed the Interprocess
Communication Messages defined within DPS. Because these messages
(as well as the basic procedure calls within DPS) will eventually be
documented elsewhere, these notes will be limited to a brief summary
of the message's function together with the gist of any important
comments: 31

  INIPS - Initialize Process.   31a

      This message is passed after an ICP to the TBH dispatcher in
      order to get a DPS process running at the host on behalf of a
      particular user. Information included in the call provides
      data about what program to run, what userid to use, and some
      startup data to be passed to the newly executing program.   31a1

      This message is typically sent from the WM to the TBH
      dispatcher in order to start a tool process on the host. The
      program to run is usually an indication of the tool, the
      start-up info will be used by NLS as the user's ID.   31a2

INIACK - Initialize Process Acknowledge   31b

This message is passed back to the sender of an INIPS message
as an acknowledgment that the process has been created and is
running, or that such a process could not be started.   31b1

This message is typically sent from the Tool to the WM as an
indication that the Tool is ready to run.   31b2

CALPE - Call Local Procedure   31c

This message provides for calling a procedure local to the
receiver of the message. Provisions are made for masks to
minimize the amount of data that must be transferred over the
Network. There is also a priority associated with the call,   31c1

This message is used by processes to call procedures in other
processes. The WM will always have to make this call upon a
Tool; if the Tool uses files or the like, then the Tool will
have to call upon procedures in the WM. The priority has no
use in NSW, but was included at the request of Dick Mandel at
ISI; the priority must always be set to 1 when used in the NSW
environment.   31c2

RTNPE - Return to Local Caller   31d

This message is the acknowledgement that a call has taken
place and furthermore that the called procedure has returned.
Provision is made for standardized reporting of the
success/failure of the call, as well as the cost of the
procedure invocation.   31d1

This message will travel from the Tool to the WM. If the Tool
has made any calls upon procedures in the WM, then this
message will go from the WM to the Tool. Among the types of
returns that can be made are: success, failure, abort, and
temporary return (co-routine linkage).   31d2

RECPE - Recall Local Procedure   31e

This message allows for the continuation of a procedure which
has previously performed a temporary return.   31e1

In the TBH subset of DPS, the use of this call is restricted
to cases wherein the procedure to be recalled is the

outstanding call that most recently sent a RTNPE message,
i.e,, there must be a stack discipline maintained with respect
to outstanding temporary returns, It was agreed that the WM
would never make such calls on a TBH, and that the only place
that such non-stacked calls could originate was in the grammar
supplied with a Tool, (Thus if a host chooses not to implement
this feature, it need only make sure that grammars for tools
that it supports do not use the function,)   31e2

NTEPE - Note to Local Caller   31f

This message is originated by some procedure currently
running, It must be sent to all procedures in the call stack,
An event, as well as a description, is associated with each
note message,   31f1

It was noted that the events used in this message are
currently defined in such a manner than the eventids must be
globally defined, i,e,, there must be a registration list
within NSW of all events used in notes,   31f2

The meeting was adjourned at 6:45 PM,   32

DAY 2: THURSDAY, JUNE 12, 1975   33

The meeting reconvened at 8:15 AM. The first part of the morning was
a rehash of some of yesterday's discussion together with the
introduction of a number of ideas which still remain unresolved. Due
to the fact that there was little discussion on each issue, only the
issues are listed here: 34

  - It was agreed by all TBH implementers that the note facility
  (NTEPE message) could (and would be implemented).   34a

  --> we don't seem to have a model of notes, and in general, of
  "unsolicited messages,"   34b

  - one use of a note created so far is that a particular event
  will cause the associated message to be printed on a user's
  terminal by the FE,   34c

  --> it seems that for DPS 3.0, it is desired to reconsider the
  IPC messages that pass between DPS processes,   34d

  --> It seems desirable to set ("wire") the limits of all DPS
  implementation choices. The primary examples here are the lengths
  of character strings, and the range of allowable integers,   34e

  - it seems desirable (though no one seems to know quite how to
  implement) to define the queue length for unprocessed DPS
  messages between processes,   34f

  - Packages are the access control mechanism in NSW. It is to be
  considered out of the ordinary to attempt to revoke access to a
  package after a process has opened the package.   34g

  - Millstein says that the WM is not going to use DPS internally;
  what it will use was not stated,   34h

  - Millstein says that DPS does meet the needs of the WM; this
  seemed to be an affirmation that the WM can be implemented using
  DPS to communicate with other network hosts (TBH's for example), 34i

At this time, the meeting was directed towards the question of: Are
we missing a statement of what NSW is, what the WM is, what the
requirements of the system are? The general consensus of the group
seemed to be that we were missing these primary descriptions, and
that the lack of these primary descriptions caused the descriptions

16

of the FE and the tools to be fuzzy, also, Amidst the general
discussion, Millstein repeated parts of his earlier description of
NSW and the WM, namely that the purpose of the WM (and thus that of
the NSW) is to control resources; the real problem to be resolved is
what are the resources to be controlled, and what control is to be
placed over the resources,   35

As a finale to the discussion about general NSW issues, the group
attempted a discussion on two further issues: 1) should there be an
NSW, and 2) how should we proceed from the current state, There were
no apparent conclusions to this discussion,   36

From this point until the end of the meeting, discussion centered
around specific protocols, in general, and the File Package, in
particular, The resolution of these issues will be described in two
separate documents (a description of PCPB8 and a description of the
File Package), but discussions of side issues, as well as points of
general interest in the FP, will be summarized below,   37

    Braden pointed ourt that his experience at CCN has shown that
    there are two schools of philosophy about files: One school
    believes that files should look like a paper tape; the other
    school believes that files should look like punched cards, This
    leads to the stream vs, records controversy which shows up so
    clearly in the File Transfer Protocol (FTP),   37a

    In determining how to process a file that is to be shipped across
    the net, it is important to determine if the file is being
    transferred to be stored at the foreign host or to be used by
    some tool at the foreign host, (The underlying premise being that
    almost all conversions performed upon filess are irreversable and
    cause information to be lost, If a file is to be shipped for
    storage only, it should only be converted by reversable
    transformations,)   37b

There was then a short discussion (unresolved) about the obligation
to install "old" tools (i,e,, tools that do not understand NSW
protocols), An early resolve to include only "new" tools and to
upgrade outside resources into "new" tools, seemed to be slipping,   38

    The proposed model of transferring files is: there exists one
    process which desires to transfer a file across the net, This
    control process must create a File Package process at the origin
    host to send the file, and it must also create a File Package
    process at the target host to receive the file,   38a

The original Black Boxes document created by COMPASS is not
equivalent to the File Package proposed, In particular, the File
Package does not address issues of where the file comes from, nor
what conversions must be performed.   38b

The file is accepted as the smallest unit that the WM is supposed
to deal with.   38c

Transmission of files (for use at the target host) seems to cause
particular difficulties when the source is a stream-oriented host
and the target is a record-oriented host. One specific problem is
that the maximum record length must be computed by examining the
entire file.   38d

It appears that in order to cope with the transmission (and
conversion) of files between different types of hosts, several
file descriptors will need to be associated with
files/specific-transfers. For example, a tool requesting a file
for use might specify a host-dependent descriptor (readable by
the FP on the same host) indicating how the file should be
formatted for use, e.g., blocking factor, record size,   38e

A discussion of issues within pPS transfer protocols was resolved as
follows: 39

 - PCPTXT will be dropped in favor of PCPB8.   39a

 - PCPB72 will not be adopted.   39b

 - PCPB36 will continue to exist, but it will be negotiated into
by some as yet unspecified mechanism.   39c

 - Limits were placed on many types of items -- INTEGERS have 32
bits of precision; LISTS, BITSTRS, and CHARSTRS have a maximum
length of 16,777,215 (2**24-1).   39d

 - PCPB36 will be altered in some way to make it equivalent (in
terms of allowing long strings and lists) to PCPB8.   39e

The meeting adjourned at 6:30 PM,   40

18

Notes on the NSW Protocol Meeting June 11-13, 1975

DAY 3: FRIDAY, JUNE 13, 1975   41

The final day of the meeting began at 8:05 AM.   42

This final day of the meeting was characterized by general
acquiescence to the resolutions of the discussions of Thursday, and
some worry about use of the File Package by the WM. The majority of
the day was spent in further discussion of issues within the File
Package and the WM interface to the FP.   43

   A description of how the WM was currently dealing with the
   conversion of files for the B4700 and TENEX led some present to
   express concern about the amount of detail being built into the
   WM about the operating systems. This discussion culminated in the
   use of Maps (file descriptors) as information to the various File
   Packages in peforming transformations.   43a

   The introduction of a question as to why the WM couldn't use the
   already existing FTP servers at the various hosts led to another
   discussion about the problems of converting between
   stream-oriented and record-oriented files. The horror tales
   related about use of FTP seemed to convince everyone present.   43b

   In the last discussion of the meeting, Millstein raised the
   question of whether the concept of "appending" to files was a
   useful concept to implement at this stage. Pointing out that this
   required all File Packages to implement the concept, the meeting
   seemed to decide that the ability to append to files was a useful
   addition.   43c

After a promise by MIT to publish the notes, and a promise by Postel
to produce a new PCPB8 document and a new FP document, the meeting
was finally adjourned at 3:30 PM.   44

Notes on the NSW Protocol Meeting June 11-13, 1975

Glossary of Terms   46

  B4700.   46a

      A Burroughs 4700 computer at Gunter, which will be connected
      to the ARPANET. The initial goal of NSW is to allow
      programmers to write and debug programs for this machine using
      the sophisticated tools (such as NLS) developed at the various
      nodes. The B4700 will be connected to the ARPANET via a PDP-11
      front end processor running under ELF.   46a1

  BCPL.   46b

      The language in which the Works Manager is being coded.   46b1

  Black Box.   46c

      A software concept analogous to the engineering term of the
      same name. This term is mostly used in regards to implementing
      WM functions.   46c1

  CLI - Command Language Interpreter.   46d

      A TENEX program which acts as a Front End.   46d1

  DPS - Distributed Programming System.   46e

      DPS is a set of protocols and standard packages for supporting
      cooperating processes and procedures. Several Levels of DPS
      are distinguished: DPS 2.5 is that version currently being
      implemented on TENEX; DPS 2.75 is a slightly modified version
      of DPS 2.5 which, when finally specified, will be implemented
      on TENEX, Multics, OS/360, and ELF; DPS 3.0 is the alluded-to
      next major revision of DPS.   46e1

  ELF.   46f

      An operating system for the DEC PDP-11 computer. The FE runs
      under ELF, and the B4700 IP interpreter runs under ELF.   46f1

  FBH - File Bearing Host.   46g

      A host which will provide permanent storage for files in the
      NSW file system. FBH's and TBH's generally require the same

support programming, but a distinction is made to allow TBH's
which do not wish to retain files on a permanent basis.   46g1

FE - Front End,   46h

The component of the NSW software system which interfaces the
user. It is this component which tailors the user's interface
and calls for the execution of tools.   46h1

FP - File Package,   46i

A component supplied at each TBH to enable the WM to transfer
files among the various TBH's.   46i1

Grammar,   46j

A tool-specific interpretable table that is supplied to the FE
so that is can translate user requests into procedure calls on
the actual tool running on a TBH.   46j1

Gunter - Gunter Air Force Base, Alabama.   46k

Location of the Air Force Data Systems Design Center (AFDSDC),
the group which will be the first user of the NSW.   46k1

IBS - Interactive Batch Specifier,   46l

A procedure in the WM which interacts with a user requesting a
batch job to guarantee that all necessary information is
provided.   46l1

IP - Interface Protocol,   46m

The protocol used in communicating with the B4700 from TENEX
(via a PDP-11).   46m1

L10,   46n

The language in which DPS and NLS are written.   46n1

LND - Local Name Directory,   46o

A table maintained by each TBH in which correspondences
between NSW Files System names and Native system names, The

purpose of this table is to allow a degree of recovery if communication between the TBH and the WM should be severed.   46o1

Multics.   46p

A operating system for the Honeywell Level 68 computer, The MIT group is developing this system as a TBH.   46p1

NLS - Online System.   46q

The text manipuation system developed by SRI-ARC, This system is being developed as an NSW tool to run under TENEX.   46q1

NSW - National Software Works.   46r

This project.   46r1

OS/360.   46s

An operating system for the IBM 360 computer, The UCLA group is developing the CCN 360/91 as a TBH.   46s1

PCP - Procedure Call Protocol.   46t

A previous name of DPS.   46t1

TBH - Tool Bearing Host.   46u

A network host which acts a a tool purveyor.   46u1

TENEX.   46v

An operating system for the DEC PDP-10, The BBN group is developing this system as a TBH, The WM is being implemented to run under TENEX.   46v1

Tool.   46w

A non-special functional element in the NSW, Any service or function which is to be supplied to users of the NSW, but which is not inherent to the design of the WM is configured as a tool.   46w1

White Box.   46x

A function which differs substantially from a Black Box (q,v,)
by having its functionality more visible,   46x1

WM - Works Manager,   46y

The component of the NSW software system which acts as a
operating system supervisor, This component is being developed
by COMPASS,   46y1

WMO - Works Manager Operator,   46z

A portion of the Works Manager which controls the operation of
some aspect of its work, e,g, there is a WMO for controlling
B4700 Batch jobs,   46z1

1

NLS IS SUPPOSED TO BE AN INTUITIVE SYSTEM

The following "bug/feature/unfeature" confused me enough so that I
lost a journal item from my initial file.   1

   Given a branch which is at the top of the screen, a Move Branch
   causes the screen to be refreshed relative to the new locaction of
   the branch, and not relative to the old location of the branch.   1a

   The "moved" branch is still at the top of the screen.   1b

   Moreover, what is much worse, if the branch to be moved happens to
   fill the screen, NOTHING HAPPENS on the screen.   1c

   My intuitive understanding, and NLS IS SUPPOSED TO BE AN INTUITIVE
   SYSTEM, is that on the screen when an entity is moved, that entity
   disappears.   1d

   And in fact, if the entity is not at the top of the screen it does
   disappear.   1e

JBP has taken the time to explain to me the system rationale for this
counter-intuitive phenomena: 2

   The screen is refreshed relative to the current location and the
   top of the screen is the current location.   2a

   Therefore, if the top of the screen is moved, the current location
   is changed; but if something in the middle of the screen is moved,
   the current location does not change.   2b

In summary, I think that a MOVE should always be the same as a COPY
follwed by a DELETE.   3

NLS IS SUPPOSED TO BE AN INTUITIVE SYSTEM

Supplementary to (26222,)

Sent via SNDMSG to Millstein@BBNB, Schantz@BBNB, and Carlson@ISI.

NLS Backend / Works Manager File System Interface; Comments
Supplementary to (26222,)

Introductory Comment   1

   This note is a supplement to the earlier memo "NLS Backend / Works
   Manager File System Interface Requirements" (26222,) and is
   prompted by some comments by Charles Irby concerning the earlier
   document, References are to NLS statement numbers of the earlier
   memo and titles correspond to those of related sections in that
   document, The only substantive change is the suggestion that the
   semaphore contain some additional information, namely the date and
   time the semaphore was set, which may be accessed by the WM
   functions,   1a

Current NLS Use of File JSYSs-- (26222, 3)   2

   Charles points out that we do filename completion in NLS if
   requested by the user, This feature may be omitted in NSW,   2a

Simultaneous Multi-user Access to Files-- Locking Mechanism and File
Data Validity-- (26222, 6b1)   3

   The statement 6b1 maintains that "a file is locked by changing a
   bit in the user settable word,,," While we indeed use a bit in
   the user settable word to indicate the file is locked, we also
   store other information such as the ident of the user who has the
   file locked,   3a

Functions Needed in the WM File System or Foreman by the NLS-BE--
(26222, 7)   4

   The semaphore value should either be a null list if it is not set
   or a list containing the id of the user who set the semaphore and
   the date and time it was set, The definition of READSEMAPHORE
   should be modified accordingly, This information should also be
   returned upon OPEN and upon unsuccessful attempts to SETSEMAPHORE,   4a
