Here's the configuration: 512Kbytes, floating point (or not...depending on the scinteific or commercial base bent), 4 serial lines which can connect to the 105, to a phone line, to a printer or lqp, and 1 other spare, using the telephone company modular phone jacks so that the user and or phone company can wire it up without special cables they have to get from us.   Also, there is a built in 1200 baud modem with dial out and automatic answer. Somehow, there is another connection so that it can be connected to a phone or relay so that it can be turned on by dialing into it. It comes equipped with the 105, but a user can get up to 3 of them. Also, the IEEE 488 connector is on the back.   The first version will be a fixed...and I MEAN FIXED version with 2 RL02's, and the next an R80 and RL02. The options are: floating point, a pair of RL02's mounted in a cabinet with a cable out of them, extra VT05's, an LA120 (for a printer), and possibly a serial lqp if we have one availble via WPS, otherwise, we recommend the one to buy if a user wants this. I want to mock this up within the next week and begin to help Lou write the brochure as a personal computer. Lou, can you get some brochures like this we can use as templates?   Note it has to have the WPS78 keyboard and we should get EDT modified to be compatible with WPS78 by then so it has really great WP.

When can we get this mocked up and running so we can demo and show the
brochure? (The current modem is only 300 baud, but we should get a breadboard on one that will go at 1200, or buy one out for the mock up)

SUBJECT: THE 3 RIVERS PER Q - A THREAT, TREND? FOLLOW UP:
2/1/80

Every university I've talked to recently (Newcastle, CMU, Purdue, U.
of Washington) have commented that they intend to get a number of PER
Q's. Also MIT's building their own.

Why haven't the folks in marketing asked about this?

When will we have a Nebula mock-up or a breadboard, working software
for this product? When could we get it to the market?

SUBJECT: HOW GOOD AND TIMELY IS NEBULA?

In stretching the Nebula schedule by 1-2 years longer than need be to get lower cost, I think we've really screwed up. Nebula ranks near the 11/60 and the 11/24 long product gestation time. Why didn't we do the work so the whole system came out at one time?

Would you compute the relative (to the 780) goodness of a Nebula system? (Here, you might assume 20 percent yearly improvements.) When should it have come out to be as "good as" the 780?

I understand we didn't come out with Nebula earlier because of high cost. What would have been the relative competitiveness if we'd introduced Nebula then?

Assuming finite product lives are a function of goodness, would you run two Burp analysis of the two cases?

The answers I get on the above don't feel good, so I'd like to match my analysis with yours. (I haven't done the Burp work, so

here we can
just interact to try various alternatives, based on different assumptions.)

Please forward results as you obtain them.

SUBJECT: RE: YOUR EMS ON NEBULA

I've asked Si (and you) to put a product positioning vs time picture in place for 16, 32, and 36 and include the low end terminal based systems. This should show how effectively we have moved in the vax space at reducing product proliferation by staying with 1 machine per factor of 2.5 price bands.

We have a powerful and important message:
1. Vax is the key to reduce product proliferation now and int the 80's.
2. Customers should move to it because it offers the most capablity as we demonstrate in comparison with other systems and show it with our products down to 24, et. al and other competitiors.
3. We have incredible range. Ten so far and will get better.
4. For our own good, we must get our customers to vax because of the fundamentally higher profitability with a single system such that we can limit the investment in the various 16-bit systems.
5. Also, for our own good, the longer we wait for the

customer
to switch... and they inevitably must as they run out of capability on the small address, the higher the probablity that when they switch it will be to other alternatives. These future alternatives will icnclude lower cost 370's and 370 look alikes, possibly the S38, and the lower cost micros as they get better operating systems and have lower cost.

At last, we are beginning to see what a really good family would look like, now let's capitalize on it and make a bundle... and get prepared for the massive onslaught of competition.

We just have to push this one through, as it has never been so right.
gordon

N.E.C. has a sales office in Lexington and they are making a spin writer which is an improved copy of the Perkin/Elmer Machine.

How does it look to you? What is the quality of it? Do we get one for evaluation? We can probably buy the head from them if that is all we want.

FOLLOW-UP 7/13/79

I visited BTL on Friday, and asked them how they were describing and managing
to implement protocols across all the nets, and machine types. They believe
the protocol has to be specified as an algorithum in a relatively machine
independent fashion - here they use a "C" description that has separate
interfaces to hardware and to the specific operating systems. Then any
protocol change can be made only once for all machines.

Surely we could figure out a way to get a common specification using some
common HLL such as Common BLISS, BASIC, + 2, C, or FORTRAN. Can't we? Is
anyone worried about having correct and common protocols across all machines.
Bill Keating would you sponsor a meeting with me and some of the developers to
educate me on where we are on what I believe is an essential development
strategy?

The way to go seems to be higher than high-level languages.

You should especially examine the work from the IBM Vienna Labs, and the
formal specs used in the formats and protocols manual (IBM SNA).

Vienna alledged to be working on optimizing compilers from provable linked
state-machine descriptions to particular implementations.

The problem with HLL's is that they imbed a lot of implementation details such
as how multiprogramming is implemented, buffering and other resource control,
etc.

The SNA specs are implementation independented, being couched as multiple
linked state machines.

SUBJECT: USING ENGINEERING AS A PROTOTYPICAL NETWORK USER

I believe the data network represents an ideal service business which
I hope you folks would consider. Within engineering, we have a
network with 256 + nodes. This requires a small staff to plan and
operate. With Ethernet, the size and growth will be even greater.

A Network service business would be:

1. Sale and installation of the network initially
2. Planning (continuous and forever)
3. Service (forever)
4. Network Mangement (forever)

Networks evolve forever and require much skill that few organizations
can get (just as it's difficult to have good internal voice network
management). Can I get you to use us as a customer? Can you consider
this as a highly desirable business?

As I understand it, the new CIS and COBOL on the 10 will really run circles around the VAX CIS and new COBOL.

What's your opinions?

What should VAX CIS for COBOL look like?

GB:ljp

PIONEER COMPUTERS

The first dozen computers were one-of-a-kind machines demonstrating the feasibility of programmed data processing. Each one added to the knowledge base needed for using and manufacturing computers.

The mid-thirties brought needs for increasingly complex engineering calculations. George Stibitz, designer of early Bell Telephone Laboratories machines, recalled:

> In 1937, Bell Labs began to need greater calculating power for development in mathematical form as a theory of communications engineering. The basic principles were expressed in terms of complex numbers because they nicely represent the characteristics of alternating currents used by the power and communications industries. Twelve girls (if you don't mind the expression) did nothing but calculate complex numbers with 8 place precision using desk calculators. The arithmetic of complex numbers when it has been converted to multiple operations with real numbers and carried out on desk calculators is even more

tedious and subject to errors than bookkeeping. Furthermore, the computing load was increasing rapidly (Stibitz, 1980).

By the forties, the need for greater computing power was driven by the demand for complex military calculations. The first true working computers were funded by various parts of the national war efforts on cryptology in Great Britain and to compute firing tables in the U.S. (Randell, 1980). To give an idea of the order of magnitude of the need, Herman Goldstine estimated,

> The human cum desk calculator (10 seconds per multiplication) would then spend about 2 hours on the multiplying; and with our estimate of a factor 6, about 11 hours doing an individual trajectory. This was a little right, perhaps a little low. The Harvard-IBM machine (3 seconds) required about 2 hours; the Bell machine (1 second, about 2/3 hour; and the Mark II (0.4 seconds) about 1/4 hour. The differential analyzer took, as we have said, about 10-20 minutes. ... None of these was sufficient for Aberdeen's needs since a typical firing table require perhaps 2,000-4,000 trajectories--assume 3,000. Thus, for example, the differential analyzer required perhaps 750 hours --30 days-- to do the trajectory calculations for a table (Goldstine, 1972).

Although academic, engineering, and scientific communities were skeptical that an order-of-magnitude change was possible, Goldstine arranged Army funding for J. Presper Eckert and John Mauchly to put together a team at the University of Pennsylvania and build a computing machine (Stern, 1981). Before the ENIAC was completed, Goldstine, Eckert and Mauchly met John vonNeumann and were heartily encouraged to progress with the stored program concept and a second report. The EDVAC report, written by von Neumann and based on the work of Eckert, Mauchly, Burks, and others involved with the ENIAC project, put down the realistic specifications for the general purpose, stored program computer (von Neumann, 1945). It excited the academic community, and led to the origin of a number of computer projects (Bigelow, 1980). Similarly, a report by Alan Turing in England spawned interest there.

By the time von Neumann was specifying the IAS project at Princeton, World War II was over and another meta-problem was needed to keep the government funding computing. Von Neumann identified the weather prediction problem. The equations for greater accuracy in prediction were known in 1911-12 but time consuming to compute. Von Neumann's first experiments were so successful that as a result the U.S. set up a statistical weather prediction service. No conceptual breakthroughs had been made: it was only a case of carrying out the computations more carefully and with greater speed. But even with the advanced fourth generation computers, the one week theoretical limit of weather prediction as understood as a subset of celestial mechanics has not been reached (Leith, 1981). The computer was then set on a developmental course of use for wide-spread classified and non-classified activities. The first users themselves were to invent new potentials ofr computing, a process that continues.

The twelve projects in laboratories and universities between 1945 and 1950 then convinced the scientific, government and business communities of the reality of potential of the stored program, general purpose digital computer. Most of these were directly paired to different manufacturers, so that by the early fifties, eight firms in England and the USA were building computers for sale.

BELL TELEPHONE LABORATORIES CALCULATOR I

George Stibitz of Bell Telephone Laboratories designed electromechanical (telephone relay) circuits for addition, multiplication and division in 1937. The Bell Labs Model I "Complex Computer," designed by Stibitz and S. B. Williams, was built in 1939. Controlled manually through a keyboard, the Model I was actually a complex calculator, not a computer. It was demonstrated by teletype -- the first long-distance data link -- at a 1940 American Mathematical Society meeting in New Hampshire.

Instruction Format: Manually controlled through keyboard

Technology: Electro-mechanical; binary-coded decimal

Project Leader & Members: George Stibitz, S. B. Williams
Project Dates: 1937-Stibitz started to experiment with relays; designed circuits for addition, multiplication, and division.
April 1939-construction of BTL Model I began.
October 1939-construction completed
January 1940-routine operation began (with multiplication and division only; addition and subtraction added soon thereafter)
September 1940-demonstrated using long-distance data link: teletype N.Y.C. to Hanover, N. H., American Mathematical Society meeting
1949-decommissioned
Number Produced: 1
Predecessor: (telephone relays, desk calculators)
Successors: BTL Models II-VI
Uses: Filter network design
Achievements: First fully operational electro-mechanical complex calculator. First in series of Bell Labs electro-mechanical computers; with Harvard Mark I, these computers set standard of reliability against which the much faster fully electronic computers were measured. (Later Bell Labs computers did early work in error-detection codes.)

Relay Breadboard of Bell Telephone Laboratories Calculator, 1939, Reproduction by and gift of George Stibitz, (D127.80).
"Communications Milestone: Invention of the Electrical Digital Computer", Bell Laboratories, ca 1980, Color, 3/4" videotape, 8 min. running time (V4.81).
p
George Stibitz recalls early computer development in this Bell Labs publicity piece. Stibitz, whose electromechanical calculator was a forerunner of the modern computer, demonstrates his first binary adder and documents the first long-distance data link.
George Stibitz Lecture, Digital Computer Museum, 1980, b&w, 3/4" videotape, 58 min. running time (V12.81).

George Stibitz's Pioneer Computer Lecture, May 8, 1980

Z1 and Z3

The Z1, a mechanical, binary computer was designed in 1936 and built in 1938 by the German engineer Konrad Zuse. Zuse and Helmut Schreyer's electromechanical Z3, built in 1941, was the first general-purpose program-controlled computer. Its program was external, coded on punched film. Zuse worked in isolation from the similar developments taking place in England and the USA: his work was unknown outside Germany, and until World War II's end, he was unaware of computer developments in other countries.

Memory Size: Z1, 16 words; Z3, 64 words

Instruction Format: Z3, 8-bit one-address instructions punched on film

Technology: Z1, mechanical; Z3, electro-mechanical, floating point, binary

Project Leader & Members: Konrad Zuse; Helmut Schreyer (Z3)

Project Dates:

1934 - Zuse started work on calculations

1936 - Basic design of Z1 complete

1938 - Z1 complete (machine never operated reliably)

1941 - Z3 complete (first fully operational model in series)

Number Produced: Z1, 1; Z3, 1

Successor: Z4

Uses: Z3 - rocket design

Achievements: Z3 - first general-purpose program-controlled computer

Konrad Zuse Lecture, Digital Computer Museum, 1981, B&W, 3/4"

P

videotape, (V15.81)

Konrad Zuse's Pioneer Computer lecture, March 4, 1981

HARVARD AUTOMATIC SEQUENCE CONTROLLED CALCULATOR (MARK I)

George Aiken began designing the Harvard Mark I in 1937.

The machine was built at the IBM Endicott facility in 1943 with design help from IBM engineers Benjamin M. Durfee, Francis E. Hamilton and Clair D. Lake. In February 1944, it was delivered to Harvard and by April -- seventeen months before the first electronic computer came into use -- it was in full-scale operation tackling ballistics problems for the Navy. This largely mechanical computer was controlled by a paper-tape external program. The Mark I had four tape readers, three for interpolation and one for sequence control. L. J. Comrie explained, "The brains of the machine lie in the control tape, which is code-punched in three sections. The first instructs the machine where to find its data; the second gives the destination of the data or answer; the third dictates the process."

Technology: Mostly mechanical (transfer between sections of machine by electricity); paper-tape controlled
Size: 50 ft long
Project Leader & Members: Howard Aiken; Grace Hopper; C. D. Lake, F. E. Hamilton, B. M. Durfee
Project Dates:
1937 - Aiken began design
January 1943 - completed machine demonstrated at IBM
May 1944 - machine operational at Harvard
1959 - decommissioned
Number Produced: 1
Predecessor: Charles Babbage's Analytical Engine (theoretical)
Successors: Harvard Mark II, IV
Uses: Ballistics problems; general-purpose
Achievements: First American program-controlled computer. With BTL electro-mechanical computers, established standard for reliability against which electronic computers had to compete.

ATANASOFF-BERRY COMPUTER

John Vincent Atanasoff of Iowa State College, aided by graduate student Clifford Berry, built the first machine to use electronic circuitry for binary calculation. A prototype

ABC (Atanasoff-Berry Computer; actually a special-purpose complex calculator) operated in 1939. A full-scale machine using a capacitor memory drum was built in 1942. Atanasoff's work is generally regarded as having influenced the ENIAC.

Technology: Electronic (with some electro-mechanical elements). Not program-controlled. Binary.
Capacitor drum primary memory; card punch & reader for secondary memory.
Project Leader & Members: John V. Atanasoff; Clifford Berry
Project Dates:
1936 - Atanasoff started work on memory and logic circuits.
1938 - project design complete.
Autumn 1939 - prototype computing element operating.
1942 - full-scale ABC machine operational (unreliable-card reader not reliable)
Number Produced: 1
Successors: ENIAC (logic circuitry)
Uses: Intended to solve simultaneous linear equations.
Achievements: First electronic digital calculator.

ABC Memory Drum, Atanasoff, 1935-1940, Loaned by Dr. Clair Maple, Iowa State University (X11.80).

*P*ABC Breadboard, Atanasoff, 1935-1940, Loaned by Dr. John Vincent Atanasoff (X12.80).

J. V. Atanasoff lecture, Digital Computer Museum, 1980, b&w, 3/4" videotape, (v10.81).

THE COLOSSUS

The British COLOSSUS machines were built in 1943 by T. H. Flowers and others to break the German ENIGMA code. These special-purpose machines used photoelectric readers with masks, some electronic circuitry, and some form of program control. The project has not yet been fully declassified, so its influence on computer development was limited to knowledge transferred by the personnel involved and is difficult to evaluate.

Clock Rate: 5000 pulses/second
Technology: Electronic circuits for counting, binary arithmetic, and Boolean logic; electronic storage registers changeable by an automatically controlled sequence of operations; conditional (branching) logic; logic functions pre-set by patch-panels or switches, or conditionally selected by telephone relays; photoelectric reader
Project Leader & Members: T. H. Flowers (machine design); M. H. A. Newman (formulation of requirements); and others
Project Dates:
January 1943 - project start
December 1943 - operational
Number produced: Several
Predecessor: Theoretical work by Alan Turing?
HEATH ROBINSON and other British cryptoanalytic machines
Successors: (indirectly) Manchester University Mark I
Uses: Cryptoanalysis-used to break Nazi ENIGMA code
Achievements: One of the first applications of electronic circuitry to logic. Thought to have stimulated later British computer development.
p

The ENIAC
The ENIAC was the first general-purpose, full-scale, electronic computer. Its vacuum-tube circuitry operated at 1000 times the speed of its electromechanical predecessors. The project team, led by John Mauchly and J. Presper Eckert, began work in 1943 at the Moore School of the University of Pennsylvania. The ENIAC solved its first problem in 1945. The machine's internal program was controlled by externally set plugs and switches; in 1948 a read-only stored program was added. This machine stimulated most later computer development.

Word Length: 10 decimal digits and sign

Memory Size: 20 words
Speed: 3 millisecond multiply
Clock Rate: (100,000 pulses/sec)
Instruction Format: Program by jackplugs and switches
Technology: Electronic; fixed-point; decimal.
Power Consumption: 174,000 watts
Size: 8 feet by 2 feet by 80 feet
Component Count: 18,000 vacuum tubes, 1500 relays.
Architecture: Master programmer unit; 20 accumulators; one high-speed multiplier; one divider/square rooter; three function-table units.
Maintainability: operating ratio 0.70 by 1954
Project Leader & Members: J. Presper Eckert and John Mauchly; J. G. Brainerd, A. Burks, T. K. Sharpless, Shaw, and others
Project Dates:
April 2, 1943 - proposal to Army Ballistics Research Lab
May 1943 - project funded
Summer 1943 - development began
June 1944 - design complete
November/December 1945 - solved Los Alamos problem
1946 - dedication
Number Produced: 1
Predecessor: Bush's Differential Analyzer; Atanasoff-Berry Computer
Successors: Directly: EDVAC, BINAC; and influenced many first-generation computers.
Uses: Intended for ballistics table construction; used on various scientific problems; design was fairly general-purpose
Achievements: First electronic, digital, general-purpose computer; first large-scale application of vacuum

"The ENIAC", John Brainerd pioneer computer lecture, Digital Computer Museum, 1981, B&W, 3/4" videotape, (18.81).

THE EDVAC

Before the ENIAC was completed, its designers, aided by mathematician John von Neumann, began work on its stored-program successor. The idea of a stored-program computer was publicized by von Neumann's 1945 write-up of the EDVAC team's discussions and by a 1946 lecture series at the Moore School. The EDVAC was not completed until 1951.

Word Length: 44 bits
Memory Size: 1024 words (delay lines) & magnetic wire secondary memory
Speed: Average: 846 microseconds add, 2.9 milliseconds multiply
Clock Rate: 997 kHz
Instruction Format: (3 + 1) address
Technology: Electronic, serial
Component Count: 3600 vacuum tubes
Project Leader & Members: Members: J. Presper Eckert, John Mauchly, John von Neumann, J. G. Brainerd, Herman Goldstine, Arthur Burks, and others
Project Dates:
January 1944 - theoretical work
Late 1951 - first operated
December 1962 - decommissioned
Number Produced: 1
Predecessor: ENIAC
Successors: EDSAC, IAS Computer, and other stored-program machines completed before EDVAC were influenced by EDVAC work in progress
Achievements: Stored program concept delineated in "First Draft of a Report on the EDVAC," although implemented on other machines before EDVAC

The IAS Computer
John von Neumann and others, among them several former EDVAC designers, started work on the Institute for Advanced Study's computer in 1946. The IAS machine, which embodied many EDVAC principles, was not completed until 1951. Interim reports detailing its architecture influenced a number of other laboratory and university built machines, including the ILLIAC, MANIAC, SILIAC, and JOHNNIAC.

Word Length: 40 bits
Memory Size: 4096 words (Williams tubes) & secondary drum memory
Speed: Average: 62 microseconds add; 713 microseconds multiply
Clock Rate: Asynchronous
Instruction Format: 1 address
Technology: Electronic, parallel
Component Count: 2300 vacuum tubes
Project Leader & Members: John von Neumann; Julian Bigelow (head of engineering group); Arthur Burks, Herman Goldstine, James Pomerene, Ralph Slutz, Willis Ware, and others
Project Dates:
June 1946 - preliminary investigations
Summer 1947 - design began
June 1948 - arithmetic unit operational
Late 1950 - extensive tests done, although incomplete.
Summer 1951 - Los Alamos problem run (60 days, 24 hours/day, approximately 1/2 dozen errors)
Number Produced: 1
Predecessor: Theoretical work on EDVAC
Successors: A number of first-generation computers were influenced by reports on the IAS Computer's architecture as the machine progressed; e.g. MANIAC, ORDVAC, ILLIAC, JOHNNIAC
Achievements: Disseminated computer architecture information to other institutions (Los Alamos, U. of Illinois, Oak Ridge, Argonne, Rand)

The EDSAC

Maurice Wilkes, who had attended the 1946 Moore School EDVAC lectures, led the development of Cambridge University's EDSAC. This computer, which ran its first program in May 1949, was the first full-scale, stored-program computer to operate.

Name: EDSAC (Electronic Delay Storage Automatic Calculator)
Word Length: 36 bit
Memory Size: 512 word (delay line)
Speed: (average) 1.4 milliseconds add, 5.4 milliseconds multiply

Instruction Format: 1 address
Technology: Electronic; 5-hole punched paper tape input, teleprinter output; binary coded decimal
Component Count: 3000 tubes
Project Leader & Members: Maurice Wilkes
Project Dates:
Summer 1946 - M. Wilkes attended Moore School lectures
October 1946 - work on project began
Early 1947 - work on EDSAC began
May 6, 1949 - first program ran
Number Produced: 1
Predecessor: Theoretical work on EDVAC
Software: Yes (EDSAC order code; subroutine library)
Achievements: First full-scale stored-program computer to operate. Beginning of microprogramming. Wired-in "rudimentary assembler and loader."

"The EDSAC Film", Cambridge University Mathematics Laboratory, 1951; narration added 1976, Color, 3/4" videotape, 10 min. running time (V3.81).

The EDSAC, the first full-scale stored-program computer, is the subject of this 1951 documentary. Cambridge University Mathematics Laboratory staff act out the story of a computer program from problem formulation through run, with memory contents displayed on EDSAC's CRT, to final results. Maurice Wilkes added an introduction in 1976.

P "The EDSAC", Maurice Wilkes Lecture, Digital Computer Museum, 1979, Color, 3/4" videotape , 2 tapes, 82 min running time (V13.81).

Manchester Mark I

A small-scale stored-program computer operated at Manchester University in 1948, a year before the EDSAC was completed. This prototype Manchester Mark I was built by F.C. Williams and T. Kilburn to test a CRT memory tube invented by Williams. A larger version of the Manchester Mark I (MADM) was doing useful work in the summer of 1949, and the machine was operating at its full scale late that year.

Word Length: 40 bits (prototype 31 bits)
Memory Size: 128 words (prototype 32 words) (Williams tubes)
Speed: (average) 1.8 milliseconds add, 10 milliseconds multiply
Instruction Format: 1-address
Technology: Electronic
Component Count: 1300 tubes; diodes
Project Leader & Members: F. C. Williams, T. Kilburn; (M. H. A. Newman head of section); D. B. G. Edwards, G. E. Thomas, I. J. Good, A. A. Robinson & others; A. Turing, programming
Project Dates:

Late 1946 - design of prototype began
December 11, 1946 - patent application for Williams tube memory filed
Autumn 1947 - Williams tube with 1024 bits operated several hours
June 21, 1948 - prototype version operated
August 1948 - development of full-scale version begun
October 1949 - full-scale version complete (Williams-Kilburn article)
Late 1949 - full-scale version operational
August 1950 - dismantled

Number Produced: 1
Predecessor: (indirectly) COLOSSUS; theoretical work by Turing
Successors: Ferranti Mark I, Ferranti Mark I *
Software: Yes
Achievements: Williams tube memory allows combination of small, fast, random access memory with larger, serial, secondary memory. Index registers.

WHIRLWIND

The Whirlwind, designed at MIT by Jay Forrester and others, was begun as an analog machine in 1944, before the ENIAC was completed. By 1945, Forrester had changed to a digital design. Completed in 1950, the Whirlwind was the first interactive, parallel, real-time computer. Core memory was developed for the Whirlwind in 1953; this was used as primary memory for most computers until the mid 1970s.

Word length: l6 bits;
Memory size: 2048 words;
Speed: Approximately 42,000 single address instructions per second;
*P*Clock rate: 1 Mhz; 2 Mhz (for arithmetic element);
Arithmetic element: Accumulator, A and B registers.
Instruction format: Single address 5 bit op code and ll bit addess;
Power consumption: Approximately l50,000 kw;
Size: Occupied Barta Building, Cambridge.
Component count: 5000 vacuum tubes and 11,000 crystal diodes;
Availability: >95%;
Maintainability: Used marginal checking of grid and screen bias voltage;
Project leaders: Jay W. Forrester and Robert Everett.
Project start: 1945;
Operated: November, 1950 with 256 words; and August l953 with core memory.
Decommissioned: at MIT in May 1959; operated at Wolf R&D from 1963-1973; Moved to Digital, 1974.
Use: Prototype for Air Defense Computer, precursor to IBM built AN/FSQ7 computer. Used to develop Linvill's sampled-data system theory.
Achievements: First core memory. First high speed, parallel computer for real time. Control organized in an array permitting diodes to be used for specifying register transfer operations needed for degining each instruction in what Maurice Wilkes later described to be microprogrammed. First use of marginal checking to detect weak components. Self checking procedure for faulty components. First use of cathode ray tubes for light pen input. Data-transmission via phone lines; vacuum tube process improvements.

Whirlwind Register/Logic Module MIT

1950,(D104.76);
Whirlwind Core Plane MIT 1953 (D29.73);

Whirlwind Core Memory Stack, MIT, 1953,(D30.73).

Jay Forrester Lecture, Digital Computer Museum, B&W, 3/4" videotape, 2 tapes, 84 min. total running time (V11.31).

Jay Forrester's lecture on the design and engineering of the Whirlwind; Third Pioneer Computer Lecture, June 2, 1980.

"See It Now" (excerpt on Whirlwind), CBS, 1952, B&W, 3/4" videotape, 6 min. running time (V1.81).

Edward R. Murrow features the Whirlwind computer, the new "electronic marvel," in this 1952 excerpt from the CBS "See It Now" news program. Jay Forrester, Whirlwind project leader and director of the MIT Digital Computer Laboratory, demonstrates the capabilities of the computer using paper-tape input, display scope, and teletypewriter output.

"The Whirlwind Film", ca 1953, Color, 3/4" videotape, Running time: 13 min. (V8.81).

The Whirlwind's structure is shown in detail as a scientific application program is written, debugged at 3 a.m., and run. This film on computer operations and applications was made after Jay Forrester invented core memory for the Whirlwind.

THE PILOT ACE (AUTOMATIC COMPUTING ENGINE)

Alan Turing's 1936 description of a theoretical computer, his work on British cryptanalytic machinery, and his Manchester University computer programming influenced computer development in Great Britain. He began designing versions of the ACE for the National Physical Laboratory in 1945. A team began detailed design of one of his versions in 1949, and the Pilot ACE was operational in 1950. This well-engineered machine featured high performance with relatively little hardware.

Word length: 32 binary digits

Memory size: Originally 384 words in mercury delay lines; later 4096 words of drum store.

Speed: Because of optimum coding this is ill-defined. Could perform at maximum rate of one instruction per 64 ms. Addition 32 ms. and multiplication 64 ms.

Clock rate: one megacycle/second

Arithmetic element: Arithmetic facilities distributed among a number of one and two word delay lines. No central accumulator.

Instruction format: S -> D, W, T, N. (Transfer from source "s" to Destination "d" beginning at time "w" ending at time "t"; Source "n" provided next instruction.

Technology: Miniature vacuum tubes and some germanium diodes.

Power consumption: 10 kw

Size: 1x6x12 feet one wheels and transportable.

Project start: October 1948

Project leaders: Edward A. Newman and James H. Wilkinson

Project complete: May 1950

Successor: English Electric Deuce

Software: No high level languages used, but highly successful matrix interpretive scheme was developed.

Use: Basic research in numerical analysis.

Achievements: First work of serious value in floating-point arithmetic led to development of floating point error analysis. Mathematical software carried over to Deuce.

Prof. Merril Eisenbud
New York University Medical Center
Institute of Environmental Medicine
550 First Avenue
New York, NY 10016

Dear Prof. Eisenbud:

I don't feel our group can perform an adequate review of Dr. Charnes. I suggest he remain in the General Engineering Peer Committee.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

GB:swh
GB1.S5.31

Enclosure - Charnes' Nomination Form

GB0002/42

DRAFT

. Design and implementation of first list processing language, IPL (with Simon and Shaw).

. Formulated early planning (goal) language approval to artificial intelligence. The approval was embodied in his language GPS.

. Designed and implenented numerous program language for artifical intelligence, better human interfacing, psychology experimentation control and simulation.

. Best known for view/modelling of human problem solving.

. Instrumental in the definition of computer science as both a science and engineering-based discipline by writings, behavior and work within ARPA and by providing the environment at Carnegie Mellon University.

. Let an ARPA sponsored task force which set the 5-year research direction in Speech Understand Research (1971). This work has been the base for most recent progress in Speech input output.

. Two books (author Bell) on computer hardware design including notations for describing digital systems.

. Sponsorship/leadership in building two multiprocessor computer systems at CMU.

I know that it is not time for the Annual Report. I hope we don't start working on it until the first of August, but this year we have bunched a very large number of products together for either product announce or product ship.

Every few years we dedicate the Annual Report to products. Could we, given that this is the year of an incredible number of products, make the Annual Report product oriented?

SUBJECT: NI ON MERCURY VERSUS CI. LONG (INTERIM) VS SHORT RANGE?

Every 6 months I make the following appeal:

Please, can't we get Mercury off the CI and put it on the NI?

Can I ask you to look at this again? I know it is largely a software issue, but I feel it is completely right and inevitable
instead of being an interim or transition. How it feels:

.Much lower product cost for Hg, now that we got rid of the BI.
.Hg could then be used for the communications on nearly all systems than simply confined to be used for Hydra because of the
extra cost.
.It is inevitable with NI. A user wants the comm distributed along NI over the space of a building both for hardwired terminals and for the interface to telephone equipment.
.It gets switching to all of our computers in a more direct fashion instead of going into a specific one and then using a virtual terminal to another computer.

.It's the structure for interconnecting to the 10/20 already and
they'll use it as it.
.Based on the use of DECnet, which VMS has shown that it supports
in Virtual terminal mode on the Software Engineering network, it
works.
.Architecturally cleaner interface to VMS and our other systems
by getting the terminal crap out of the OS.
.A single point to put the gateways for our systems such that we
can build only a single gateway, rather than building one for
each system (10,20,rsts,11/m,m+,vms,dsm, etc.)
.We would get the NI on Qbus and a real start at the long term
interconnect strategy.
.It is long, versus short term and as such it avoids doing
something (the CI) that has no meaning and is simply expense and
make work.
.There are going to be a significant number of systems out there
using the NI, and I'd like to be able to have our systems use it
and provide the proper interface. Hence, it gets us NI on all
systems sooner.

Can we please look at this again?.

SUBJECT: LET'S GO DIRECTLY TO NI-BASED COMM. WHAT'S THE PROBLEM?

Note the following memo from Alan, re the 20 and the NI. To reiterate:
1. Our goal is to establish NI as THE interconnect ASAP so as to avoid as many as possible competitive alternatives.
2. Only NI allows distributed comm, and the ability to have any terminal have access to any machine.
3. It addresses the combinatorial problem of having to support
h-hardware x s-operating systems x (terminal, international, and
computer company protocols).
4. We are resource limited as to being able to put Hg on CI for VAX and 20's and then support it forever.
5. NI is a must, already for every machine, whereas CI only attaches to central type machines in a single room. NI is used here for file interchange and other activities we still have to understand. We have to put all our resources behind

it versus splitting them into all possible alternatives.

Scott was going to start to run the experiments here to let us us understand if we could go this way.   I feel we must change and get the hardware to have the assist that the CI hardware has, assuming we have performance problems.   For earlier breadboarding, we might get some old Ethernet boards from Xerox that run at 3 mbits, or we could simply use other options like DMC's to check out.

Can we proceed with a plan which is NI based for concentrators,
and gateways, versus using the CI? This would come out first on VMS, followed by other systems that support the NI, including
the 20, rsts and m/m+.

Stan, how is your task force coming in terms of leading us to this goal now?

SUBJECT: JUPITER COMM STRATEGY MEETING

Yesterday I attended the Jupiter (2080) comm strategy meeting in Marlboro. Mary Breslin attended the morning part, too. I'm glad I went. It turns out that NI was not part of the Jupiter plan, and was generally viewed as some real neat, but over the horizon technology.

The major presentation was from Gary Passon, which recommended use of the CI Mercury as primary Comm interface. Given his perspective, it made a lot of sense. Since we are really several different companies who happen to share the same name, they hadn't heard all the rumblings about "NI by 83".

I spent 10 minutes outlining where I thought we (the corporation) were going. Despite the skepticism as to what and when it would be delivered, there was general enthusiasm for an NI based comm system.

Since they have and FCS target in the latter half of CY 82, none of the solutions, including Hg, looked good enough to avoid having to have a backup strategy in place. The FCS machines will hopefully be shipped with DN20s running DECnet heterogeneous virtual terminal.
A fallback position from that is either RSX20F (a-la KL10) or comm directly on the host Unibus. No decision was made there.

LSG is enthusiastic about participating in a company-wide

solution
to the comm problem, and to that end, Sharon Passon was charged to
coordinate LSG comm requirements with John Adams, and Gary Passon
and Fred Engel to work with Mary Breslin on technical issues.

Personally, I consider the meeting a success, and hope that the
coupling between distributed systems and LSG will improve rapidly,
so that we will, indeed, have a single comm strategy.

Subject: **Professor Nicoud's Small System Activities (i.e., SMAKY) with BOBST and Swiss Computer Industry**

To: Distribution

Date: 22 SEP 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

F/U 9/29

One of Nicoud's students attending a NATO summer school that I lectured at reported the above. He asked me why we were not interested in such a product?

His basic point is that with the partial demise of the time industry, the Swiss are open for something else. The small, personal computer fits this perfectly. It requires small, mechanisims and care in fabrication. If we were to start something in Europe, this might well be the best base...although there's little programming capability outside of England.

Dave Stone, can you confirm or deny this rumour?

Is England and/or Switzerland the place to do hardware engineering in Europe? Would Germany be better for hardware?

Where's the next European plant?

I also heard rumour of an HP, shirt-pocket, folding BASIC calculator.

SUBJECT: RE: KEN'S MEMO ABOUT NI

Good points. The NI is now Demmer's responsibility. Things like these printer servers, etc. are clearly NOT... plus all the things you have dreamed up. At this time, he has to make the whole set visible, but he can't possibly fund the whole environment as you suggest. We simply aren't putting this kind of money into it now.

Bill has responsibility to raise the issue along with your, etc. How you could think he has to build all those interfaces,
just as he should build all the modems for every marginal terminal we design is beyond me? Where do you get the ideas?

Have him raise the issue, but in the meantime, if you are counting on all those interfaces and components on NI, I suggest you get with him and decide how you raise the issue and get the funds.

SUBJECT: RE YOUR NOTE ON WHY NI.

Alan,

We must all recognize that we are in a highly vulnerable position with respect to getting NI to be a standard.

Ma bell and the carriers aren't going to stand still on not supplying data switching even though they have a past record of failure and non-accomplishment. Couple this to the fact that we are not coupled to any other wire service (IBM or cable tv), then the odds are pretty low of Ethernet making it. We have two choices:
1. throw in the towel now, say it's a bad idea ... too fast for the technology, not matched to cable tv (takes multiple channels), and is drastic overkill for data comm as we now know it; or

2. go like hell to make ni work. get others to adopt it, find applications for which it is unique and the other approach won't work. Also get the cost so that we can use it as an interconnect within a computer (I believe this will work once the technology gets there.)

I think we made an error in NI. It should have been debated more, also it got evolved significantly in commiettee without the above realism. All that is of course hidnsight.

(I am just a little bit pissed that you didn't raise this at the time of the design. I did, I hope you'll recall, when I pointed out to the whole DEC technical community that the way ma bell would do this was with a digital pbx, which they have running and I saw and asked you all to visit. It is called Datakit and I would expect it to be marketed. It is trivial, it uses the wiring, etc. Also, it is capable of going to 1 mb speeds, with special wiring back to the pbx.

Yes, question it continually as I do, but the sure way to make it fail is to stop work.

Frankly, I think we should put our heads down and get the thing to work... as we know it now. We have created a set of people all working on it too. As we work, if we can finally get going much more aggressively as though we intend to win, we should look around and be prepared to change the modem and interface protocol. The basic systems we can build will be about the same though.

Right now I want to make ni the standard for building computer nets and computer clusters and interconnecting the components of a computer to make a computer. If you, working on an alternative detailed design have a proposal that will let us do say the first 2 just as well, then I'll listen when the design is firm. You have a choice too, as a previous changer (along with me) we have a mercury that I haven't seen the design of yet and I believe we all have to get it done.

I don't want to cut off debate on whether we should switch or fight, but I believe we had best keep going like hell, until there is some alternative that is put together that has any meaning. Also, as we charge ahead faster than we have been, I hope, I expect us all to keep our eyes and ears open.

The most obvious worry is to build what no one wants or that is not what the competitive standards have brought out.

The less obvious way to lose is to ship nothing, while we chase all the standards.

What do you other folks think about this?

SUBJECT: DOES THE NOMENCLATURE PROGRAM HAVE NO CLOTHES ON?

Somehow, I can relate to this. Honest, I never ever
communicated
except by ESP on this.

We gotta do something, Mark does talk sense here. IBM isn't who I like to emulate, except in certain areas. We need discipline and changing all the numbers seems like a pain and high cost. I've been here before when we solved the world's problem in CAD by coming up with both EPLS and IDEA the super data bases in the sky that were to solve all the world's problems.

Honest, I do want to do something...but I'm certain not
clear
on the specifics.

It's comforting to find that there are two of us in this mad world. Hopefully that's all, because all it will take is to ignore or convince us.

I hope you supporters are even more solid and can answer the questions that mark raises.

SUBJECT: PRODUCT NOMENCLATURE PROGRAM

I have just spent some time studying the package of documents you sent me concerning the new corporate product nomenclature program (new model number system).

I have great difficulty with it.

It is generally agreed that we are running out of model numbers.
We are severely taxing the 2-5-2 system and have seen that the
five characters for the model number (of which only 3 are available
because the other two are "11" or such) plus the two subscripts
are inadaquate to our needs. Therefore it is clear that something
needs to be done soon.

My problem is not with the idea of change but with the system chosen. I find it cryptic and beyond comprehension.

A major part of my problem is with the use of an all numeric system. One major advantage to the current DEC system is the use
of letters and mimonics.

- The use of letters allows up to 26 variations to be expressed
  by each character of the name. The use of digits reduces this
  to 10. The result is that model numbers will need to be 2.6 times
  longer just to represent the same amount of information.

- Humans work with letters and mimonics very well. I am not the
  expert on this but I seem to recall that the best nomenclature
  schemes are a combination of letters and numbers; e.g. three letters
  plus three numbers.

- For the most part, the model number mimonics actually DO mean
  something. For example, everyone understands that an LPxx is
  probably a line printer or something to do with line printers.
  Memories are probably Maxx, comm devices tend to be Dxxx, etc.
  This system has been violated a lot of late and has become a
  bit strange but only because we are running out of room with
  2-5-2 and Dick Best has been forced to it.

  The advantage of the current system is that it makes it easy
  for people to remember at least half of a model number and
  therefore more easily find it in the price list or Dick Best
  list. As far as I can tell, the new system will force me to
  scan almost every line in a whole section of these lists to
  find something.

I have heard some comments that the new system is much like IBM's.

I would point out that just because IBM does something a certain
way doesn't make it the best way. This company was founded on
that idea.

I notice that manufacturing is staying with the 2-5-2 system.
I would submitt that actually the computer systems of manufacturing
are far more capable of absorbing the new system than are the
supposedly people oriented activities such as marketing, sales,
and our customers.

Maybe what we should do is start from the mimonic system we have
now, identify the problems, and expand the fields to meet our
needs. Maybe it should be 2-7-4.

Has anyone from Human Factors looked at this?

I don't deny that we need to change our current system to meet
our needs in the 80s. I am concerned that "the cure will be
worse than the illness".

Regards,

P.S. Someone quick tell me the difference between a 1419-B02
and a 1419-1201. I will send $1 via interoffice mail to
the first person who responds with the correct answer.

Allan T. Waterman Award

Date: September 9, 1979
Born: June 1, 1946
Education: U. of Michigan 1968, BSEE; Stanford 1969, MSEE; Stanford 1972, Ph.D.
Employment: Carnegie-Mellon University, Assistant Professor, 1972-1975; Associate Professor 1972-1975; Digital Equipment Corporation, Chief Architect 1975-1979; Technical Director, 1979-present

Sam has been involved in the understanding of Computer Systems both at Carnegie-Mellon University and Digital Equipment Corporation since graduating from Stanford. His work has included both analysis and synthesis of these systems on a widescale basis. He is extremely versatile and his interests also include algorithms, programming languages, and Computer Aided Design.

His major contributions are:

Understanding the way cyclic memories such as drums, disks, and all electronic (Charge Coupled Devices and Magnetic Bubble Domain) behave and control performance in various computer systems--this work came from his Stanford PhD thesis.

Measurement and understanding of multiprocessor computer systems. Was responsible for this work on Carnegie-Mellon's C.mmp, 16 processor multiprocessor system.

Comparison of computer architectures. This work was done for the Department of Defense and included various methods and measures of various architectures. This is the most significant evaluation of this type that has ever been carried out.

Synthesis of multicomputer systems. This work included Cm*, a system of 50 processors, which is now operational.

Chief Architect at Digital Equipment Corporation, and now Technical Director, responsible for assessing and guiding the direction of all DEC Research and Development.

Possible Future Contributions:

I believe Sam's immediate contributions will be in his role as Technical Director. This will apply his widescale knowledge of Computer Systems to determining the future direction of the systems we research and build.

SUBJECT: NEW CSD AT NORTHEASTERN AND US

COMPUTER SCIENCE DEPARTMENT NEED

Bob Fano (MIT), Max Mathews (BTL), Dick Karp (UC/B), and I were invited to recommend how their Computer Science Department should be structured. They have been operating in a fragmented mode for many years, with efforts in math, EE, industrial engineering, business, and in the technology schools. We recommended establishing a strong department in the Engineering school, together with strong components in electrical engineering, industrial engineering and math. The department should encourage joint appointments with the other departments.

The department should be heavily financed in terms of computing equipment, including having their own computer. These departments we call Computer Science are a misnomer because it is fundamentally an engineering discipline. Thus, by having equipment they get into the nitty gritty problems of machines, not just being lobbyists and complainers about computation facilities that someone should fix. Virtually all departments have their own facilities now. The Computation Center Director supports this too, with something like a 750! I trust they'll come for support, and given they get their act together, this would really be to our advantage to support this. It would be used both as a teaching and a research machine.

COMPUTATION CENTER

I was impressed by the new computation center director, Dr. Paul Kalagan (437-2335), and what they are doing with two 780s. One is for students, the other for research. They run 120 students on a 6 Mbyte machine and get decent response. They have VT100s and other CRT's, plus use some 120s as line printers. We ought to feature them in one of our ads...whatever happened to the ad campaign, Ask Any User? (We built a really great framework for VAX ads, and with the changing of the marketing guard, all the ad people, ideas and policies were changed. Why can't we have AD

compatibility and continuity and quality BOB and TED, instead of
the content-free crap we have now?)

PRODUCT CONCERNS AND IDEAS

. PORTABLE TERMINALS Since they are so heavily commuter based, they could really use portable personal computers so the students could prepare programs at home and bring them in or connect via phone to do editing. (Note, make it compatible with the TI editing terminal!) BILL PICOTT, when will our LA12 hold a program so that I can edit without a host?

. BOOK AUTHORS Two groups were writing books on using VAX languages and we ought to consider publishing them. Prof. Proulx is doing one on VAX assembler, complete with I/O etc. that is aimed at the assembly language course, that is substantially less architecture based, but more VMS based. MARCY, it would be worth contacting.

. COMPLETE MANUALS VERSUS ALA CARTE One professor was trying to get a set of notes together so that a student could easily use a system and succeeded in getting EDT down to 32 pages, plus collected all the right stuff from the various manuals so that the student (or he) didn't have to rifle the big collection (now about 4 feet worth that is held in an auto parts binder in the comp center). ARMEN, please send him the drafts of the book you have on pascal and on pl/1 to: Dr Kalaghan, Dr Proulx, Dr. Rasala, and Dr. Casey.

. GOOD AND COMPLETE COMMUNICATIONS EQUIPMENT They'd like

less
overhead in the communications hardware as they believe this
costs them 30 percent of the cpu and if this could be reduced at a small cost, the number of lines could be increased still more, say by 20 percent. Note that with a
600K configuration, they are getting 100 users at 6K each.
If they spent 60K to get 20 more users, then the cost would
go down to 5.5K...or about the cost of an Apple III. They
might decide to try a very large number of personal computers say spending 3K to 4K each to off load the VAX of
the big numbers of terminals. They had banks and banks of
Racal Modems. We really have to focus our Modem efforts so
that we get this business! We spend money doing the engineering of modems, but we don't build them. Similarly,
we sell a system, but don't get all the revenue. BERNIE, WE
HAVE A GREAT OPPORTUNITY TO REALLY GO AFTER CORPORATE NOR BY
REALLY FOCUSSING ON COMMUNICATIONS.

. SELL FOLLOW-ONS We didn't sell all they system. They recently went on to balance the system by getting it up to 6
Mbytes, as it had been thrashing. We don't watch these systems at a field level so that they become balanced. BJ,
please tell me that all our internal systems are balanced.
Also, given our massive use of BLISS, we ought to really tune it to at least get rid of all i/o and cpu time we can
by large memory.

. GIGI POSSIBILITIES The CS folks didn't want Gigi, cause they were into building their own graphics package on a

bottom-up basis using Teraks and other PC's. Here, we ought
to give them a few so they could get passed this low level
graphics crap and start using graphics.   This should be a
sales/product line issue. For sales promotion, why don't we
give a Gigi to every VAX system user to simply let them try
it. It would be substantially cheaper than a sales call to
try and convince them? Note, since they use the system
software such as EDT, I would think Gigi should be modified
so that it can operate with VAX. This hardware problem has
to be solved.

. PDT AS A PERSONAL COMPUTER They are going to experiment
here. Why not get them a bunch of PDT's, as they are using
11s and VAX's now and this would save them the bother of
having to switch to something else?

Subject: Thoughts on the engineering organizations
To Ken and Jack, Win

I'd like to strongly recommend that we make the following Vice Presidents of Engineering:

Jeff Kalb
Bill Heffner
Sam Fuller
Tom Burniece... I think (Grant must make the case).

Each of these play a significant and increasing role in managing and leading engineering. With the exception of Sam, each manage a large important site.

The model that seems to work best in running these organizations is to have BOTH a manager and a leader (eg. Hindle/Olsen, Smith/Bell (now Fuller), Demmer/Strecker, Glorioso/Kotok, Kalb/?, BJ/Mahendra Patel, Saviers/Riggle, Julius/?, Cudmore/?, Communications guy/Lauck).

Sam
I think that Sam can take my place in providing the overall leadership especially in a more divisional structure. Glue will be needed, and Sam has been doing this. He needs to be even more assertive in the future in light of more binding within each group being more independent. The pressure will be even greater to have more, shorter term projects. Sam should also develop some managers to delegate to- research groups, external research, architectural control, etc. so that he's free to work on the fires. I think the title will help facilitate his work, but he clearly deserves the tille because of his past performance.

I think the network of senior consulting engineers is quite good, and needs to be strengthened and even made more formal. I think Mahendra is probably the broadest (electrons to databases and human interfaces) and deepest guy in the company. He continues to amaze me, as does Riggle.

You see that Julius and Jim need some leadership help. I don't think Jim will get much in the current environment unless we give him more support.

Gordon
7/17/83
Dear Jack, Win, Sam, BJ, and whoever:

I had some observations which might be of interest, so as a stockholder will reel them off.

1. It's going to very hard to get much speed up in the AI area through parallelism, based on a very sketchy knowedge of this field when I bumped into some researchers. There needs to be a high level interface at ARPA. Sam should really spend some time with Bob Kahn and ask what you can do for your country.

2. Symbolics has taken the market from DEC and the KL, running LISP about 2x a KL. Furthermore, Tom Knight (a professor and consultant?) believes they can get a factor

of 50-100 speedup over a 3600 in 4-6 years using 100K gate arrays to go from 180 ns to 25-40 ns. They would also use multiple pipes to get the x 5 or so. Apparently, Mike Farmall of LLL may join them. (My view is that it will be difficult both in time and performance.) They may also be working on a smaller machine. The company looks like it is going somewhere, and I don't hear of anything that will stop them except maybe the IBM 801 out of Austin or perhaps the DECWRL system, if it is pushed. People need to try a Prolog to compete with the new Japanese workstations, and the best bet looks like a re microcoded Symbolics.

3. Ed Feigenbaum described a Mitsubishi PC that Sperry will market that has upward compatible graphics that looks super good. They and IBM apparently didn't get the same message that was in Maynard: "If god would have wanted color and graphics, he wouldn't have put us in the black and white, one dimensional world and made us sit at slow, dumb text terminals and word processors."

4. Am quite impressed with the PC's we have and with this industry. IBM has the best machine by far! At last, the users are winning.

5. It looks like there's a very good DEC WPS compatible editor on the PC. Given the memory size of the PC, the only reason not to buy it (and a PC) is a dramatic price difference between a single function (eg DECmate word processing) box. Note the enclosed essay attempts to say this.

6. Where are the VT200's? I've plotted the ships in this area and clearly the point of inflection has passed. I believed there would be few dumb terminals by 85, if you recall reading the Product Stratgy statement 4 years ago.

7. It occurred to me that there may be an extraordinary opportunity using the Trilogy technology. I think there's a finite chance that their machine is too complex to get working in a timely fashion. Sperry may not be moving fast enough. So why not be first? This should be

quite predicatable once you have the knowledge about the technology coming though. I would hope to see a first class team on it. Why not encourgage Sam or Bill Strecker to lead it out there?

8. Bill Krause of 3 Com would like to put his low cost Ethernet on the DEC personal computers. His product on the IBM PC is being sold by IBM. It looks like Ethernet may kind of make it in spite of DEC.

9. There's an incredible array of fault tolerant micro-based machines for transaction processing and it really pains me to think that DEC can't get this whole market given the tremendous investment in the Clusters! I've yet to meet anyone in the field that knows about it. (So much for Base Product Marketing.

10. Deleted (on second thought)

11. Will any of the fast VAXen ever make it out? Are you helping these folks?

12. Andy sent Jack and I a note at the beginning of the summer which essentially said: "marketing is and has been taking a bum rap for what is fundamentally an engineering/manufacturing problem... think about it". Having seen many other companies, I must partially agree! Also, having now worked with marketing folks of all denominations, I think the DEC ones are quite good.

13. Just for luck. Attached is an essay which gives my thoughts on this generation.

Mr. Bob Noyce
INTEL
3065 Bowers Avenue
Santa Clara, Cal. 95051

Dear Bob:

The enclosed is the result of my recent trip to Japan. I'd like your opinion, as I intend to publish this. Specifically I'm interested in knowing what's wrong, unclear, overly opinionated, etc.

Sorry it's so long.

Sincerely,

Gordon Bell
Vice President,
Engineering

GB:ljp

Enclosure

Page 6. Blind comment about a breakthrough is very suspect. We've been trying for about twenty years in this area and results of this research really don't address need or indicate hint of a breakthrough.

Page 13. Classification doesn't feel good. ILLIAC IV, is a restricted, forerunner to vector machines (e.g., Cray 1). What about the STARAN and friends? Data flow (admittedly non-existent, and suspect) may be a better computational model for X-tree.

Page 15. I'm really uncomfortable with thinking that is based on classifying ILLIAC IV (a single instruction stream) as a multiprocessor! It is a uniprocessor capable of 64 simultaneous operations on relatively connected data (e.g., vectors), stored in a restricted fashion.

Page 21. Dynamic microprogramming - how do we get this order of magnitude?

The misunderstanding about symmetrical multiprocessors is so enormous here that I have trouble believing these researchers will get anywhere. There is no real hardware cost, performance and reliability problem in building large symmetrical multiprocessors for <u>now</u> any arbitrarily large number of processors! Having been involved in several where p = 2, 4, 16 and 16, there isn't a limit say for p~ 1,000; caches and tandem switches (read the Benes book on switching -- otherwise we would never have the telephone systems we do) can be used. The small cost of switching varies pretty much as p+m, with only a small part being m x p. The comments in their first paper are strongly in error.

There is one, common problem for all these multiprocessor or multi-computer systems whether they be: symmetrical multiprocessors (Burroughs, Univac, DEC, CMU); almost symmetrical multiprocessors (PRIME); multi-computer networks with a common address space (Cm*); computer networks with fast message passing and tandem sharing of peripherals (Tandem); conventional, homogeneous or heterogeneous computer networks; and especially the tree-structured, homogeneous computer networks (so called, X-tree). It is:

> We have not yet found a way to utilize (program) them either by current or experimental (although there's a little hope at CMU using Algol 68 on Cm* and C.mmp) programming languages in any fashion <u>except</u> as:
>
> > independent computers;
> > multiprogramming as in transaction processing, real time applications or timesharing;
> > functional multiprogramming (e.g., front end, back end)
> > specialized applications (e.g., pipelining as in signal processing).

Overall, ignoring the above details, my concern is that the work (including design, construction and research) is too broad (from VLSI to applications) to get anything at all useful.

The money would be better applied to understand the use of existing multiprocessor and multi-computer structures. The "physical structure fixation" inherent in this proposal will detract from addressing computational models, parallel programming languages, doing good VLSI work, etc. If they really want to work on the O/S (another rat hole), language (essential) and general nature of parallelism (which I think is now concept-theory bound) then let's get them a reasonable set of Cm* modules so they can build their X-trees immediately without messing around in more low-level hardware that most likely won't work anyway (e.g., Berkeley's Prime) because it's hard (expensive) to get real engineers at universities and build something of this scope. The research proposal is quite good and the approach generally well thought out. The problem needs addressing. It's a shame that some of this didn't get done with COSERS (of which I was a member) -- even if the report ever comes out.

Fundamentally, let's not waste money on a research committee. Pick a good person as PI, and give them a review group to call on/visit/advise/etc. But make someone (who's had this kind of research experience) responsible for the work.

I'd recommend Eric von Hippel at the MIT Sloan School, part of the group of Roberts, Allen et al that studies research management.

P.S. Since there's no name on this as PI, why waste our time reviewing it?

Subject: **NSF Microstructures Conference**

To: Distribution

Date: 27 NOV 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 12/11/78

This three-day conference focused on helping NSF get its act together to go for more funding in VLSI and other sub-micron research. I didn't spend much time attending because I don't know the areas, but some of the tidbits I gleaned:

1. Electron beam exposure is currently the only way to get below two micron lines.

2. The complexity of

circuits even at four micron HMOS level are well-beyond CAD tools and designer capabilities.

3. IBM is into multi-layered IC's.

4. The Cornell (National) facility is only $5M funding over five years.

5. Stanford looks like the best place by far! Meindl is now collaborating with Forest Baskett (forthcoming head of Digital Systems Lab.) and their goal is to build a 1M gate structure in four years! I'd like the test chip to be a VAX, but they probably want to explore their own architecture. They have an industrial affiliates program. The cost is $15K/year. This seems worth belonging to. Meindl is impressive!

Jim Bell They've ordered a 2060 and want a corporation contribution. Can we use this contribution to prepay several years of the affiliates program?

6. It's not clear that Cal Tech is very highly regarded by others in the semiconductor area. This might be a good place to give up. I think we have to stay for another year. Stanford and Cornell may be better and we must help MIT succeed!

7. SUPREME (or something) Stanford University Process Modelling program is a program we might want to use. Jim Meindl says that this program is run by all major semiconductor companies including Intel and IBM. It's used for modelling the yields for processes so they can be tuned. Do we/should we use it?

8. Most universities aren't supplying graduates in semis, but some are. Let's tap the supply NOW! We're bent on buying expensive, fickle, trained artists who spend a few months or two years and then leave. Occasionally we try to "grow our own" but I know of little success. Effective <u>now</u>, I want a major <u>recruiting</u> campaign to get <u>new</u> MS/Ph.D level graduates by June! It's not clear where to recruit, but don't bother unless they've actually built msi level circuits. Some possibilities: Stanford, Cal Tech, Berkeley and U. of Cincinnati (Prof. Boyd). John Meyer, please put a Recruiting Program together! Any other places?

9. The EBEAM Mask Maker is used by IBM in the System 38 to get turn around time for ECO's down to three days. Wouldn't it pay for us to get one?

10. MIT is having a one-three week study group this January to examine if and how they can work on vlsi and some of us may be invited. I want to get some sort of collaborative effort with them. Let's make sure Paul Penfield stays here and consults as much as possible. We can not go on (or exist) the way we are postured in this area; we must have trained people and we must reduce the design from art to engineering -- MIT has to do this for us. Jon Allen and Lynn Conway are teaching a course this term using Conway and Mead's book and may need someone to process their wafers. Let's do this to get an involvement. Can we hire Lynn?

11. BTL is still pushing

bubbles and they have a product out with 256 Kbits/package, although it looks like there are only 68K per chip inside the package.

They are really targetting disks...just as I would be. The extrapolation is to a 1 Mbit in 82 and on to 256 Mbit with .05 micron bubbles. The 256 Kbit 80 chip assumes 1.5 micron bubbles, whereas now they are 3 micron.

12. The agreed upon cost is about $100/gate for LSI design. Bill Green/Joe Zeh, could we go back in time and plot the design cost for each chip as a function of physical size, (crowding), number of gates and the design technology? We need this model in order to understand how to get our own engineering priorities decided.

13. Apparently the 64 Kbit TI chip has 2.5 micron channel width.

14. TI, Fairchild and Motorola are all going in the gate array direction for a number of applications that used to be standard parts for what was mainly computer industry. We are not coupled into this activity worth a damn and I fully expect to get creamed by a machine that is made by a semi vendor or a competitor using standard semi industry supplied gate arrays. I would think we might want to see just what the competition is going to be, by looking at the technology. Watch out for high end, low cost CDC machines! Henry Crouse and Bill Green, do you remember TI? What are all the technologies they could supply us with? (I am getting a list via Carnegie-Mellon and would like to see if our assessments agree.)

15. Cy Levinthal of Columbia thinks it is a trivial engineering exercise to build a write once, read only memory of 100 to 10,000 billion bits using a shadow masking technique he's developed by looking which uses a SEM. Could someone go talk with him that understands materials?, SEMs, etc?

16. The Japanese have demonstrated a 50 Km link optical link running at 50 Mbit. It is limited by the number of cable splices which insert loss.

17. The TI Speak and Spell gadget uses 128 Kbit (i.e., 16 Kbytes) P. channel ROMs that cost less than $5. This is about ten times cheaper than we can do in two years with 64K chips. Why can't we look at ROMs for our software distribution problem?

18. General impression: IBM has the best research and does much for semiconductors (Broers heads the effort at Watson - and is good); BTL is second now, but more engineering oriented. The semis take these results and make money with them.

19. The most interesting two sessions were by Hans Zappe, of IBM Research, who described the Josephson device computer work. The statement was made by an NBS person that the vacuum tube dissipates about 1 watt, the transistor 1 milliwatt and the Josephson device 1 microwatt, hence it may be as important as the former devices. He described a 10 cubic cm. computer which has:

a.a processor cycle time of 1-2 ns, Pc has about 500K circuits;

b. a 256 Kbyte cache (1 ns access time, 2 Kbits/chip and 10,000 bits per sq. cm) the projected cache memory would have 4 Kbits/chip using 4 micron lines and have an access time of 0.4 ns;

c.main memory, being worked on in Zurich, would be 64 Mbytes, with access time of 15ns made from 2.5 micron lines organized on 32 Kbit/chip substrates.

The logic circuits currently are 5 micron and take 50-80 psec on switch and 400 circuits are on a chip. They are projecting 1,000 circuits per chip switching in 30-40 psec using 2.5 micron channel width. A 4 input gate switches in 32 ps and consumes 4 microwatts. The interesting points on curves he gave for switching were: 25/1/100; 5/.1/20; and 2.5/?/2 for line width in microns/gate delay in ns/power consumption in microwatts.

The whole thing is a packaging problem because it must be less than 2 x 2 x 2 cm, giving end to end transmission delays of 800 psec. Transmission is by superconducting transmission delay terminated delay lines, where the only loss is in the terminations. These are non-trivial to build and they are looking for ideas. Power is not a problem as the whole thing takes 6.3 watts (2.5 in the logic, 3.5 in memory, .1 to drive the outside world and .2 loss). This still requires a 19 Kw compressor to keep the thing cooled.

SUBJECT: VIEWING THE NYIT FILM ON COMPUTER GRAPHICS

As you may know, NYIT is doing really superb work on engineering some really great graphics products. Andy finally got me to see them, and they do deliver. Stangely enough, they are an OEM (as a university) and sell products to television broadcasters and film studios to do animation (cartoons) etc. A current customer is an animation studio in Tokyo where one of the employees is also employeed by Fujitsu! Their system is used by professional artists and cartoonists to do work.

Their artist's workstation runs on a 23, and their main machine is a 780 which they use for storing and processing images that go to tv tape or to film (as i/o). I believe we ought to use the stations internally for Industrial Design simply to reduce the labor in our product sketches. Also, it looks like this quite a reasonable alternative to the Genigraphics system we have to make slides.

They are doing/ have done software for Gigi and we've simply got to get this creative system running on the Professional!

I'll set up the 15 min videotape in Ken's Conference room for viewing at 11:45. Let me urge you to come and see this impressive
work.

SUBJECT: MORE COLLABORATION WITH NYIT

I hope we can get NYIT the PRO quick so as to get their impressive software up on it...and get them to sell it. They are an OEM and do like us.

Paul, I really want to see NO hand renderings of ID'd objects within 2 years. You folks should be "off paper" by then. Let me urge you to start. This is one of the few color rendering systems around.

EXT: 331-2289
LOC/MAIL STOP: LIO/LIO

MESSAGE ID: 5175069580

SUBJECT: NYIT / PROFESSIONAL

May 31, 1982 Avram Miller sent an ems to Gordon Bell re: NYIT. The
message ID is: 5165019344. Gordon then sent an ems to the operations
committee including Avrams ems. That message ID is: 5165019275. Chick
Shue, who is my Regional Sales Manager, sent me a memo with the above
memos attached requesting the statue of:

1. Gigi Software running on the professional (the packages NYIT wrote).
2. Status of Digital's potential use of NYIT's Paint workstation for our internal industrial design.
3. Digital's progress in repackaging NYIT's graphics to run on a professional.

To date I have been unable to reach Avram Miller to check his status on
getting NYIT a professional to begin software conversions. I have been
unsuccessful in my attemps to obtain a test unit, and would appreciate
any help or suggestions you might have.

Thank You
Gail

WPS USERS - Leave HP mode and type <CR>

I am quite impressed with both Dr. Schwartz and Gottlieb as researchers, but this proposal leaves me quite cold, even though I believe very much in the basic machine structure and approach to computing. The issue I have is simply:

The problem has been pushed much further at Carnegie-Mellon through the C.mmp and Cm* systems. This effort takes 3 years to get an experimental vechicle that is far inferior to either CMU system. Furthermore, I don't think the 8 processor system is worth building to investigate parallelism of the kind (several thousand computers) they're espousing.

The researchers are spending far too little time on the problem to make the necessary headway.

I see no evidence that the group is even capable of building even this modest hardware. Now, I am very sanguine about building this important experimental hardware in a university. It's non-trivial and requires more engineering skills than I see present in the research team.

They fall into the classic trap of mP and mC researchers in spending all their energy focussing on the switch. I have incredible faith in our ingenuity to produce large switches, but all the evidence is that it is extremely difficult to do work in parallel algorithms and to manage the distribution of the algorithm on multi-processors or multi-computers.

In short, ill-prepared but good people, and a half-hearted attack at a very important problem. They should go back to the drawing board and figure out how they are going to be able to get the resources that are necessary to make a significant dent in the problem.

SUBJECT: PERSONAL MESSAGE

I have to get this off my chest. If I am off base file it it
in
your waste basket.

I'm getting calls from the field re the need to counter OA
competition from
Prime & others. I've just returned from INFO 80 where OA was
the hottest
subject on the floor and in the classrooms.

We are going to suffer if we do not let some of our expertise
out to our
loyal customers who are aching to work with us.

Gordon, I have heard the arguments from all sides; I know where the marketing groups are and their fears of unleashing another TRAX; I am aware of the purist service disdain for DSM support; I know that the architects want a consistent evolution with a minimum if no migration conversion; and I know that all of them suffer from one major ailment, namely, parocialism. None of them are looking at the corporate picture. We need to move into the marketplace aggressively now! The barn will be beautiful but empty if we let those various groups worry about their individual goals, scorecards and empires at the expense of the good of the company.

We need a corporate statement re OA ASAP. We must respond to the demands of those customers who can help us enormously to maintain an image of leadership by working with them. IBM and the others are walking away with the show because we are chicken.

I am disgusted with the way our own people have dumped verbal dung over our EMS and WP projects because they have been willing to listen to our competition's derogatory evaluations rather than learn how to operate and use our products. Also, it is making me livid that so many are willing to criticize our human engineering and when asked how many hours of terminal time they have have meekly dive for cover.

We need another KO. This time in cunning marketing!

SUBJECT: OA: WE'LL GIVE IT UP RATHER THAN GET OUR ACT
TOGETHER

The attached memo from Jack is pretty accurate.

I attended a salesmeeting in Waltham where I heard that Prime was about to walk off with orders at MIT, Harvard and First Church cause we could say nothing about Office Automation or Mail, where we were headed specifically or generally.
We are using the product internally they must have. It is a set of 78's, 200's and EMS. We must get this package together
and sell it! (No, Word 11 probably won't be the savior, cause
it still doesn't address the Mail issue or the intercommunication
that offices must have!) Furthermore, given that our official
mail project, DECmail has not yet passed phase 0, it is not available within at least 2 years to address the credibility of us as an Office Automation vendor.

I have been advocating the release of EMS/VMS for quite sometime in order to get some experience with this sort of product in the marketplace. We have a couple of customers that are willing (Sandia) where we believe they could handle it. Furthermore, we have data necessary to evolve EMS/VMS to have a better human interface.

What we must do:
1. Stop knocking our products!
2. Get/don't get Word 11 ... it feels marginally relevant to the short or long term.
3. Tweak EMS/VMS and evolve it, while doing it right with DECmail.
4. Go flat out to get a great WPS system on KO that plays with DECmail, and that can be interconnected as a clustered system.
5. Put the whole marketing message effort together in terms of NOW (WPS Stand-alone, WPS Shared, and EMS/VMS) ... as the answer. Getting Word 11 would be frosting.
6. Continue Developing the ultimate, but don't sell it until we get it.

Doing 5 could make us the strongest vendor; telling the world
how bad our WPS is our selling futures in Mail, will only get us in worse shape.

It was truly tragic to listen to the First Church's pleas to have a product from us, and to the fact they had to go to Prime. Our product TODAY is better and is going to evolve to be MUCH, MUCH better, and we can't sell it! Worse yet, they'll
get locked in to PRIME!

We must note that:
for the near term (next 5 years), Electronic Mail will be
a Centralized Function! ... all systems are this way today, and
the economics of file costs and support force it to be this way
(This is in direct conflict with what I think the dreamers in Commercial Marketing feel ... we need to check the grass in MK.)
Hence, anyone who gets in with a system, will control a large set of bucks, including those for WPS. Like Mainframes which

are also Central, we probably can't get them out very easily. WPS, by contrast, can be dislodged by better products because the buying power is decentralized. Also, the "Apparent Support" cost is less due to the distributed nature of training being at a personal level.

Can I enlist your support so that we don't continue to look like jerks (although we may be)?

MESSAGE ID: 5171214578

SUBJECT: OA, RE-CENTRALIZED ORDER PROCESSING AND NETS PLAN?

Denny gave a pitch to the OC on having 6 regional centers to do order processing in place of the one we now have.

Al described a system for VAX's in local office to do Office Automation and Administration that did not include order processing.

I have not seen a corporate network plan that has anywhere the capability to handle traffic required for either system, let alone handle the growing traffic that's required among other functions including engineering and manufacturing.

The system we have, if you could call it one, is really outmoded and the new one for order processing is out-moded.

We need to ask who's responsible for the various parts within each of the organizations and then demand a modern, integrated, cost-effective plan.

(This would also be a good test vehicle for showing how we could provide this service to our customers who have or will have the same problem.)

The issues are: productivity without all the clerks, control by the responsible groups, getting the communications we need in place for inter and intra organizations and finally, understanding what we have to sell as a distributed office and information processing company by doing it right! (We'll save, be more productive, learn and sell if we do this one right.)

follow up 1/30/79

Take good care of Schalke (and Gonzales). Are they paid well enough?

Is Esling's salary enough and why is he a 3?

At the next salary review Ken asked for a complete distribution of our salaries. Do we have a compression problem?

The Salary Review Committee would like to see:

1. How can we make more visible key people (e.g, Keating, Fuller)?

2. How can personnel inform the management that there are poor situations where we're likely to lose people?

3. Can we report on what's happening regarding turnover (numbers and why)?

4. How do we/should we identify key people? and then not lose them?

Subject: **Attached Strategy Presentation to Operations Committee**

To: OOD

Date: 18 SEP 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1

Ext.: 2236

I've been asked to propose a more viable corporate product strategy, based on the attached first presentation. The Operations Committee is behind us, and there's considerable agreement of this strategy.

I want to work with a small group to refine the attached proposal before the OC Woods October 10-11. This'll also be given at Wednesday's EBOD. I'm not convinced of the exact details yet, but want to spend much time working this. The proposal has been given to Jack, John, Julius, and Stan. The working group has to be brought down to a more manageable size. Thus, I don't want to get into packaging, power, LSI, manufacturing or any memory technologies, communications, software, but rather want to have two groupings by product (size and application) and by staff.

There are one/two groups I'd like to work with:

Products		**Staff** (on call)
		Pearson (to record/help with)
8/11 micro	- Clayton	Puffer, Kur
11/VAX	- Demmer	Johnson, Fuller, Keating
10/20	- Fagerquist	Christy
Commercial	- Portner	Tomasic
Technical	- Heffner	

As a separate issue, Bob, please plan how we can do a below the line review of spending. It's nearly 1/2 the budget.

Please comment. We need to move.

Agenda for meeting on design of Office of Central Engineering, Wednesday, Jan. 9, 11 PM - Gordon Bell's office

Please peruse the attached working document on design goals and constraints so that it may be adopted and used as a working document. It was prepared by Gwen in consultation with me and the industrial designers.

Industrial design will have a presentation on the six items noted #1-6 on the goals and constraints document. They have highlighted these points as needing resolution before the project can be developed further.

MILL LOBBY: DESIGN GOALS AND CONSTRAINTS (9/14/80-gb)

G - GOAL: A VALUE THAT A DESIGN WILL ATTEMPT TO ACHIEVE/EXCEED.
C - CONSTRAINT: A LIMIT THAT A DESIGN CAN'T EXCEED.
I - IMPLICATION: A CONSEQUENCE, GIVEN A GOAL OR CONSTRAINT.

G.1 Create the appropriate image for the corporate headquarters
of a $2B computer company.

I.1.1. The appearance should make a statement about the company's emphasis on quality.

I.1.2. Computers should be used as much as possible for visitor login, control, etc.

I.1.3. Guests and employment candidates should be made to feel welcome.

C.1.1. Good control should be achieved over all traffice flow: guests, employment candidates, and employees.

C.1.2. The OOP should be appropriately insulated from irrate customers and vendors.

C.1.3. Separate toilet facilities for visitors from those that are "on the way" and most convenient for workers.

c.1.4. Create a "visitor" conference room.

G.2 Meet federal guidelines

C.2.1. Wheelchair entrance.

C.2.2. Energy conscious.

I.2.1. Appropriate use of natural light.

G.3 Clarity of intent.

C.3.1. One entrance, not two.

C.3.2. Don't make a maze for guests or workers.

I.3.1. Analyze traffic flow -- guests to Presidents area, to Central Engineering, off-site employees to conference rooms, and enployees in the mill.

G.4 Consider ROI

C.4.1. $300 for entrance and 12.1

I.4.1. Prioritize if necessary - avoid patchups like present bathroom floor redoing that is probably not in keeping with goal structure.
I.4.2. Spending money on paper is cheap. Properly design the space.

G.5 Maximize integrated workspace in 12.1 for Central Engineering.
C.1. Interior space without natural lighting is not appropriate left over space for engineering.
C.2. Two separated spaces by a corridor are not acceptable to central engineering.

SUBJ: **OFFICE OF CENTRAL ENGINEERING (OCE) DESIGN GOALS AND CONSTRAINTS**

To: Gwen Bell, ML12-1/A51
Paul Benigni, ML11-4/E53
Mary Jane Forbes, ML12-1/A51
Sam Fuller, ML3-5/H33
Mitch Kur, ML12-2/A16
Si Lyle, ML12-1/T39
Charlie Picarello, ML12-1
Larry Portner, ML12-1/T32
Dick Schneider, ML11-4/E53

Date: 1/5/79 Fri 3:00:43
From: Gordon Bell
Dept: OOD
MS: ML12-1/A51 Ext: 223-2236
EMS: @CORE

Definitions:
G - Goal: a value that a design will attempt to achieve or exceed.
C - Constraint: a limit that a design can't exceed.
I - Implication: given a goal or constraint, one of the consequences.
D - Decision: a value of a design parameter that has been

selected.
R - Remark: comment on a statement.
A - Alternative: some possible choices.
F - Fact: almost synonomous with an external constraint, eg., the OCE is
in the mill.
CF - Conflict: can exist between goal/constraint/ implication/fact and
demands resolution.

G - A well-designed open office that can and will be used as an example.

G - Measure ROI on all changes and designs.

G - Select from alternative designs before making decisions.

G - Keep within these goal statements and use them as a working document.

G - Keep within design guidelines established on a corporate basis.

G - Develop individual room/area design goals and objectives from these based on all of central engineering.

F - The OCE will be in 12-1.

<u>G.1 Be the central intelligence for central engineering, setting the style and pace for the environment for working as well as the work output.</u>

#1 C.1.1 Link OCE with all engineering groups.

#2 F.1.1 OCE includes the following:
Gordon Bell + 4 support
Larry Portner + 1 support
C. Picarello (war room manager) + 1 support
Si Lyle (product manager) + 5 support
Mitch Kur (engineering controller) + 1 support
Sam Fuller (technical director) + 1 support
Visitor work station
Conference room + waiting area with telephone

War room
Kitchen + food serving area
Bathrooms (also must service 10-2)

#3 CF.1.1 Given the present division of 12.1 the group cannot be contiguous unless the dividing hallway is removed.

I.1.1 Develop a war room for strategies that works as a communications and strategy center.

I.1.2 Provide an image of appropriate use of high technology for major high tech customers.

CF.1.1 "War room" will have to be secure and yet will have examples of new technology that may be interesting to customers.

C.1.2 Interrelate to corporate wide planning for DEC with appropriate links and connections.

G.2 Experiment with latest technologies in computing, communications, energy conservation, and building materials in order to improve productivity.

I.2.1 Record the process in order to learn from this experiment and make further improvements.

#4 I.2.2 Integrate use of ems, word processors, large screen video and latest communication modes into OCE for maximum use.

C.2.1 Use DEC machines to push their limit.

I.2.3 Willing to experiment with one of a kind and prototypes to better fit DEC machines into office environments.

R.2.1 Charter of Industrial Design does not include new machine adaptations and additional charter may need to be applied for.

C.2.2 All staff will be no more than l chair turn away from a terminal.

#5 CF.2.1 Use of inter-related machinery in mill will demand connecting with cables "dangling" and raises a special problem issue.

C.2.3 Minimize operational costs by reduced air conditions and use of natural lighting.

D.2.1 Use task vs overhead lighting.

D.2.2 Put switches on all lights.

C.2.4 Design for minimizing maintainence costs without exorbinant startup expenses.

#6 C.2.5 Conserve the basic mill structure, erring on the side of simplicity vs. Victorian refurbishing of any kind.

C.2.6 Look to new technology that minimizes energy and materials, eg., replacing paper with film, film with disks.

C.2.7 Be able to change over time with changing technologies and organizational structures while facilitating ongoing use.

<u>G.3 Satisfy human needs.</u>

I.3.1 Emphasize that humans are the masters of the machines. Integrate the use of machines and high technology with the visual, auditory, and physiological comfort of the individual.

I.3.2 Consider interactions and functions for assigned tasks to minimize wasted time.

I.3.3 Develop an integrated aesthetic style for OCE that fits within any corporate guidelines and also allows differentiation in "room" styles within OCE.

C. 3.1 Fit a variety of behavior patterns and individual needs, but confine individual tastes to discrete areas and use of nomadic items -- nothing attached.

CF.3.1 Consider the need for privacy and the needs for links and communication -- work out these conflicts on a generic and not on individualized bases.

Subject: **Organizational Computing Status and Plans (OCSP's)**

To: OOD, OOD Direct Reports,
Marketing Committee
Product Line Managers
Jerry Todd

Date: 18 OCT 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-
2236

follow up 11/1/78

I've recently had two very good presentations by Lawrence Livermore Laboratory and DuPont (Textile Fibers Division) on their current computing environments and what they think their organizations and computing use will look like over the next few years. We have yearly meetings among DEC internal users to give a similar view (DINCUS). In addition, there have been some very nice plans coming from Europe that characterize the use of computers within ITT and Olivetti (plus give details about their organization and buying habits). MIT has just sent us their 10 year plan/goal which is the best of the lot.

The OCSP's would be done by the appropriate product line(s) and sales responsible for an organization. In this way we can also get our sales and marketing people to really learn more about computing from our customer's viewpoint and what people do with machines.

I'd see the library as being key to our future planning, a way of understanding an organization when they come to visit us (without having to spend most of the time explaining it to us to get us up to a first grade level). They could become the most powerful sales planning, marketing, planning and product planning tool we could build.

For one, I think they are essential for getting much more insight into what's important so as to guide product development. (I rarely get to field and some of our engineers <u>never</u> talk to users!)

What do you think?

Could we start by cleaning up the above ones, sending them around and seeing whether they are useful?

SUBJECT: APPROACH TO DOING OFFICE APPLICATIONS

Was just looking at the whole OFIS architecture, going back to the note on this on Sept. 1, 1980. Wonder where we are.
I think we should be extremely careful in how we do the applications on the new OFIS architecture. It was my intent that there is a minimum amount of code in obm (Koala). The next level, the Generic Ofis Machine has a number of application primitives that should allow us to "program" more applications very fast.

Note, the Calendar should not be coded in the OBM, but most likely in GOM, in exactly the same way that the various calendars are now provided using list processing.

The GOM would include these primitives:
the editor
Digicalc interface components (input, program input, output)
a good forms language to allow users to fill in list

processing
 attributes easily
sort, math (via Digicalc),
database access, telephone control and access
graphics primitives

Would like to know how we are dealing withthese levels
so we can get the most programs in the highest level
so the user, oems, and us can get the variability and
productivity.
(This set of primitives would look something like the 4th
generation language that James Martin described.

What you think?

Subject: **THE OFFICE OF CENTRAL ENGINEERING**

To: Gordon Bell, ML12-1/A51
Dick Schneider, ML11-4/E53

Date: 11/7/79 Wed
From: Gwen Bell

After our meeting of Nov. 7, I have some comments for your discussion. In order to proceed on the project, I think the analysis has to take place at three levels: goal setting, targets and objectives, and design constraints and implications. In order to give you some idea of this hierarchy, I am outlining some a tentative schema and filling it in a little bit.

In order to get the program underway and some action. I suggest the following schedule:

December - review and establish goals and objectives

February - design review

March - preliminary final design -- purchasing etc. can start.

September - completion of phase one (built) to be lived in for a while.

GOAL: EXPERIMENT WITH LATEST TECHNOLOGIES TO IMPROVE PRODUCTIVITY

OBJECTIVE: Use DEC machines as much as possible.

DESIGN: Integrate use of ems, word processors, large screen video into the office. Use WPS/large screen as recallable blackboard <u>and</u> overhead projector.

OBJECTIVE: Use latest communications modes.

DESIGN: Test and try video links

GOAL: CONSERVATION

OBJECTIVE: Energy

DESIGN: Evaluate lighting, heating, cooling, kitchen, machine use, space use regarding energy conservation.

OBJECTIVE: The Mill

DESIGN: Conserve the fundamental mill structure.

OBJECTIVE: Human time

DESIGN: Consider interactions and functions.

OBJECTIVE: Materials
DESIGN: Look to the minimal; replacement of paper with film; film with disks etc. Use permanent or reusable materials when feasible to eliminate waste. Get rid of all paper!

GOAL: ADAPTATIBILITY AND FLEXIBILITY

OBJECTIVE: Change over time
DESIGN: Consider increments for evolving rather than static spaces.

OBJECTIVE: Fit a variety of behavior patterns
DESIGN: Observe and cater to individual behaviors within the structure and show how it can relate to a variety of needs.

OBJECTIVE: Change in technologies
DESIGN: A fundamental system -- connectors for a variety of new technological products.

GOAL: BE THE CENTER OF CENTRAL ENGINEERING

OBJECTIVE: Provide the central intelligence
DESIGN: Secure area where everything can be open within the group.

OBJECTIVE: Ease communication within the group
DESIGN: Ease of accessibility -- physical, electronic, or video between members.

OBJECTIVE: Set the style for engineering.

DESIGN: Let as much as possible hang out.

OBJECTIVE: Be where the action is.

DESIGN: Lot's of meaningful activity.

OBJECTIVE: Tie to the whole of engineering.

DESIGN: Communications and face to face interface.

OBJECTIVE: Relate to planning for all of DEC.

DESIGN: Appropriate connections.

OBJECTIVE: Image for outside guests.

DESIGN: Use and "sell" DEC products.

GOAL: INTEGRATED AESTHETICS

OBJECTIVE: Integrate machines/men

DESIGN: Look at machines with both a sense of humor and human use.

OBJECTIVE: Integrate machines/mill

DESIGN: Relate the mill as the receptacle for new technology.

OBJECTIVE: Integrate activity and space

DESIGN: Consider the use as part of the aesthetics -- with actors on the stage.

Reference: Translation of "Nikkei Electronics"

Dear Sir:

I understand that you are looking for industry recommendations concerning the translation of Foreign publications. Those translations would then be made available to the industry for a nominal fee. I recommend that you translate the periodical "Nikkei Electronics" which is published bi-weekly by Nikkei-McGraw Hill Inc, in Tokyo.

This magazine covers current electronics topics of prime importance to our industry computers. The editorial quality is high, because the text is original and in Japanese, the material is not available elsewhere. I would like to add that the advertisements contain technical information of significant value such as, technical specifications of products we compete with. I suggest that they should also be translated.

If you have further questions on this matter, please don't hesitate to call myself or Patrick Buffet at 617-493-2453.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

SUBJECT: KEN'S GRAND OFFICE PRODUCT ANNOUNCEMENT

Ken is asking us to discuss the announcing of all the office products in one, big package, including the following:

1. Standalone 278
2. Bundled DECword 11 using various configurations of 11's
3. Layered DECword 11 on RSTS
   (both 2 and 3 would include a drastically repackaged 11/23)
4. DECset for typesetting
5. EMS/VMS
6. High quality communications for local office intercomm. of parts using something until we get Ethernet

Si should get back to us on the 23 as to the configuration so that Dick and Ken get to work on the repackage. The principle
goal of all these packages except the large configurations should be: Customers must be able to unpack, assemble and install the configurations with NO outside help! Each of the component parts should be carryable by one person.

I'd like to look at DECset in terms of its compatibility with OFIS, useability, doneness, and systemness (does the buyer have to become a system integrator?).

Dave Rodgers and Si should lead us through the alternatives of
how we are going to interconnect the systems to one another and

how this will relate to our eventual Ethernet position.

SUBJECT: OFFICE REVIEW, 4/28

GB5.22

BOTTOM LINE
Based on the general interest and enthusiasm of the presenters, and
the apparent status of the projects, I'm quite impressed at the progress that's been made in forming a team and building products.
It's great to see that we're in one of the top slots from a product
standpoint. Staying there is now going to require an incredible amount of work and the delivery of what we've shown and are promising.
I look forward to a detailed technical review of the projects and
being a test site.

GENERAL CONCERNS ABOUT OUTPUT AND MY OWN BLOOD LETTING
The concerns I expressed were based on our (Youse and mine) inability
to define and deliver a quality product as promised. About 3 years
ago, engineering took over the management of the WPS and office

area. g">$ 2'% 2%:./u%q $%% !+   "b"k"i"j"j=)&& CO++RS#.-
'+W!   7MJ5   L<"!   2W#",2D:EA3   S   #   &   *   .
O!(!Q!W!S!"!"#"7"'derstand performance. I participated in the reviews and design until more pressing matters (eg. VENUS) called. I have tried to push the understanding of the human interface, performance and the features needed that will make us win.   At this point, I've failed.

Whether the architecture works must be decided quickly, otherwise we're going to build on a soft foundation. When will we know?

SPECIFIC CONCERNS RAISED AT THE REVIEW

TOO MANY IRRELEVANT PEOPLE causing rumours, leaks and selling of futures. Let's work this out so that we aren't an open sieve.

MY SUPPORT OF DECMATE- clearly has been and is there... because it's all we've got. I push for lower cost hardware and aim to make the DECMATE available at dumb terminal prices. My concern is that DECMATE can not compete because of the incredible difficulty to extend. Getting to a competitive hardware base where code can be written cheaply and correctly is crucial to our long term success. My gut

feel is that there are two options for a hot, feature laden, extendable WPS:

1 We do it on new, non-8 hardware in a transportable language, hopefully Koala. I like your approach. When will we know?

2 We BUY the hot product that is inevitable for the IBM PC! This will knock the 8 based DECmate out of the ring, and make the IBM PC the winner. Hopefully we can scurry around, buy and offer such a product.

URGENCY TO GET A VMS-BASED OFFICE SYSTEM (FOLLOWED BY M AND PRO)
Given my concerns above based on performance, and the sad lesson that we're learning about the Pro regarding performance, I believe the priorities have to be: reliablity, performance, human interface and features... which can always be added.

Again, we have to find out NOW whether the general architecture WORKS with acceptable performance especially on RSX and the PRO.

EVALUATION OF OFFICE PLUS
Really want to understand performance, reliability and extendability (cost of extensions) plus the goodness of the human inteface (including learnability). I saw not ONE metric, besides the time to check spelling, in the whole presentation... only features.

USING VMS AS A GROUP/DEPARTMENT/TEAM/PERSONAL MACHINE
I challenge all of you (Dockser, Marcus, Ancona, Hughes) to own and operate your own VAX with your current staff, and get it done within two months. This was possible with WPS200, albeit tough. If we're to have a reasonable market, it has to be self installable at some

point.
A good start would be for all of you to understand this. Who'll try?

All I'm asking is that you put yourself in the role of customer!

ROLE AND SIZE OF PRODUCT MANAGEMENT GROUP
I thought I heard there was one product manager for each function of a
basic product. For example, the manager of DECpage (a formatter),
Mary Leary, really admonished me for the concern that we had too many
product managers. Could I see the business plan and work around
DECpage just to get an idea of why so many resources are required for
a product? I didn't realize that our product managers are feeling
unloved... because I really do love them. And they are important too.

What I am concerned about is the responsibility and behavior of the
development group because I hold a development group solely
responsible for the success of a product. This means a developer must
know the technology, the use, users and competitors...ie. the market.
What I have seen happening is that the PM becomes the crutch and
excuse for not building great products.

GENERAL STRUCTURE OF THE GROUP
I'd like to see just what the make-up is, including developers,
technical leaders, product managers, writers, etc. when we meet. I'm
mostly concerned about the technical leadership there.

ADVANCED DEVELOPMENT
Dennis put on a great show. The CATV work is vital. Let's productize
DECtalk and the Teleconferencing products now... no cost

reductions,

just get it out. Cost reductions are trivial after we find out if
others can use it. If we're worried about the volume, get CSS to
produce it.

The spelling corrector was impressive too. Hope to see it soon.

LAST BOTTOM LINE
These products are vital to DEC. We've defined a great product set.
Also, our customers must be happy with what we've delivered because
I'm one of the first to know about this too.

I'm confident that if we deliver, Bob and Henry can sell 'em.

You have my support for any resources (except those that would extend
our commitment until we finish what we've promised).

SUBJECT: OFFICE AND CT/WPS SOFTWARE

I think we have a major problem in the Office Software area that we aren't facing. In looking back at the early architecture
document, I saw a goal of Q481 for field test. At our meeting
on Friday, I couldn't really get much of a feeling about whether we'll ever get a product for either VMS or CT. The whole SSC base was still being worked on as "insurance", independent of the decisions. Clearly there's no commitment for
it now given that the commit is for VMS, independent of the fact
that the people on board are small systems people, not VMS Kernel
folks. In short, the only glimmer of hope I saw was that the supervisor, Danielle, was committed to whatever the managers wanted to do.

The communications between the CT and OFIS has been about the worst I've ever seen. Clearly there's no real commitment in the sense of "we will win together" to get this software. I take this as a very strong personal failure. As such, I want to get a structure where this responsiblity is delegated in some fashion to a single individual who will make it happen
despite the fact that all the intermediate managers are overloaded.

This also comes in light of a discussion with a software engineer who wanted to leave DEC because as a former Boeing engineer we'll probably have to let people go too. Too much specialization, no risk, no commitment, top down, evolutionary
engineering (the next release) and total isolation from product/market. This again speaks to the need to get the software and hardware oriented to some business goal, not a come
to work goal or not a passing the Software Inspector General's
review goal. (We're dead if we add the bureaucracy in SW engineering to have software inspectors!)

I'm sorry for unloading these ain't it awful thoughts on you all, but I do want to get some thoughts out so we can move. Clearly Avram ought to be looking at outside software to get a decent editor and word processing package that can be shipped with CT!

I also saw the chaos of 3 software groups all doing their own thing with no overall direction. This made me feel very sick too at a time when we should be going balls out to get the product done. I think no matter what's said the office group really intends to show avram and put ssc and the clusters
on ct rather than fix ct.

The other thing about ofis is that it is done in the classic way that all our failing competitors build software: the marketing groups make their demands, the PM's formalize this into
a spec. and some poor unsuspecting sw engineer who's never implemented anything like this then rides off to try and build
it. The only answer of course is to leave because: the harware
wasn't what they think they wanted when they find out that it doesn't fit or perform well, or that others are leaving and they
don't want to be the last one there, or that it's really going to

be done in another country by a bunch of other people that have
NEVER built a word processing product, or that the spec will change, or that they are told they are going to have problems because all the groups outside are so bad (marketing, product prevention, hardware, etc.). What started as the hottest software group around is now bootrstrapped down to a near nil list. All that are left is a bunch of managers who yell at the
rest of the company, too many product managers who only know how
to interact with marketing folks, the human factors people, advisors, etc. ... but no co-workers. Are we at a point yet where is 1 engineer per 4 people managing, product managing, doing errands, writing, etc.? Bruce what are the actuals including a/d?

BJ,
This has to be fixed. We can not go on slipping the Office either implicitly or explicitly. There has to be an answer for CT, too. When I get back in a week, I'd like to start the
necessary meetings to decide on how this thing is going to be managed so that we get the products that I thought were promised and we desperately need!

MARY JANE FORBES EXT: 223-2236
LOC/MAIL STOP: ML12-
1/A51

SUBJECT: OFIS ARCHITECTURE DRAFT FOR KO, WPS, EMS: PLS
COMMENT

This is the architecture I propose we use for OFIS products. Please feedback so we can tune and formalize it. Parts would also be used in applications where compatibility is needed (e.g. an accounting system that would permit reports to be included in WPS documents).

The notions of architecture herein cover a range of base hardware/software systems on which we expect OFIS software systems to operate. The architecture extends to cover what some call applications, which I would like to call programs, but a more acceptable word to both us and our users might be called PROCEDURES. Since a program is the specification by which a machine interprets a set of actions to carry out a function, the word, "program" seems appropriate for all the machine levels, including those which end users may also specify. Thus, a user level program that a secretary might write to specify how a mail list is made would be called a Mailing List OFIS Procedure, and would be "programmed " on the Generic OFIS Machine, GOM, using List Processing Functions. We'll use the word, Procedures!

THE THREE DIMENSIONS OF THE ARCHITECTURE:

.MACHINE LEVELS as specified by data-types, operators and syntax for use by a procedure writer, ie. programmer (user) at the next level

.FUNCTION (CLASSES) ON DATA-TYPES (eg. files, communications, screens) within a machine level. Functions Classes are fundamentally PMS components. Roughly equal to Cobol divisions.

.RANGE OF UPWARD COMPATIBLE MACHINES with increasing functions.
The range of functions would be explicit permitting upward compatible products (eg. the file function might range over sequential, ISAM and multi-key ISAM). Cobol calls these levels.

Mostly the goal of the functions of a machine at a given level is
to make explicit choices and specify what the machine can do. Care is needed so that we don't select some very powerful low level function like DBMS such that all succeeding higher levels
require adding it. Also, there will be interaction between levels and within a level (actually a set of sub levels). For
example, the ability to display graphics will require a high function, within the low level HM. Subsequent machine levels will require the same higher functions. There are similar examples within a machine level that would depend on having an
advanced file system function in order to get an advanced function of another type.

THE MACHINE LEVELS

0. Hardware Machine (HM)
1. Base Machine (BM)- made up of o/s, data mgmt, a system programming language, such as Bliss, C, Pascal or PL/n, and utilities which system's programmers provide on a given system
such as RSTS, VMS, M, TOPS 20
2. Intermediate Common Base Machine (ICBM) for building OBM. Only exists as a common base that permits OBM to run on multiple,
incompatible BMs
3. OFIS Base Machine (OBM)
4. Generic OFIS Machine (GOM/GM)
5. Profession OFIS Machine (POM/PM), or for example, the Accountant's OFIS Machine
6. Organizational OFIS Machine (OOM/OM)
7. Individual's OFIS Machine (IOM/IM)

THE CAST OF PROGRAMMERS (PROCEDURE WRITERS) FOR THE MACHINES

0. Microprogrammer determines HM
1-2. System Programmer determines BM and most likely ICBM
3. OBM System Programmer writes OBM (or it could be done as another system programming language (a much extended TECO)
4. OFIS System Programmer builds GOM using OBM and GOM
5. OFIS End Use Procedure Writer (Programer) uses GOM to make specific packages for professions and sub-professions (i.e. POMs). Initially done within Engineering, then End User P/L's,
field and OEMs.
6. Organization Procedure Writer (group within a given organization in which WPS is installed. Responsible for tailoring OFIS product to the org. and using GOM (with some OBM)
7. Individual user may personalize using GOM

GOALS AND CONSTRAINTS OF THE ARCHITECTURE

G0. help us structure our thinking into a hierarchy of machines
organizaed by level, functional classes for a level, and a range
of upward compatible functions within a given level for multiple
implementations
C1. maximum clarity of the internal machines (levels). Documentation and architectural control of every level by function over the range.
C2. maximum flexibility to change how a given function is implemented without changing the specification of the function
seen by next level. Information about encoding is hidden!
C3. minimum programming in what is fundamentally assembly language albeit a system's programming language (e.g. BLISS, C,
Pascal)
C4. code freeze of lower levels asap such that all OFIS programming is done on the OBM and GOM
G5. minimum use of conventional procedural programming languages
including OBM . Preferrably use forms, decision tables and WPS
produced documents for "programming" that make up GOM.
C6. built-in ability to extend to foreign languages by non-programmers using GOM
C7. scope of applicability includes WPS, extended WPS, VMS/EMS,
and any OFIS knowledgeable programs. An OFIS knowledgeable program is one which shares the same file format in either or both a read and write fashion.
C8. range of hardware products include the 65 Kbyte terminal with
ability to buffer a single document or with a pair of floppies
for multiple documents, to a 256 Kbyte terminal with floppies and/or 5 Mbyte non-removeable disk, ... to VMS.
G9. program in the highest levels to get the greatest market leverage. Encourage organizations and end users to write

procedures specific to organization and individual in GOM and in
some cases OBM.
G10. program for the profession must be written where possible in
the highest level machine (GOM), and failing this using the OBM.
These would initially be done by End User Programmers, next by
the End User Product Lines and eventually the field or by OEMs
and perhaps even by users. Some professions will require new
data-types and hence extensions to OBM for performance. (Note,
that a procedure for a given profession can always be written on
the OBM but it might not be marketable because of performance.)

COMMENTS ON THE MACHINES

Hardware Machine (HM)
Explicit specification about each functional component and range
within the components is supported (eg. smooth scrolling and
margin settings for the VT100)

The Base Machine (BM)
A selected subset from all the available operating system calls,
languages, data management and other utilities of a given system
such as RSTS, VMS, 10/20, RT, M. Clearly documented what is
included and excluded for use by all succeeding levels.

Intermediate Common Base Machine (ICBM)
In the event that we believe that there will be a large amount of
software written that makes up the OBM, it would be worthwhile
formalizing a common base interface for implementing OBM. The

level is perilous. For example, if the first implementation of OFIS is on VMS, the temptation will be to use all the capabilites of VMS as level 1, with the implication that when operated on another machine, all the capabilites not in VMS must be made up in the level. The explicit notion of range is present in order to deal with this.

IN OUR CURRENT THINKING ABOUT THE ARCHITECTURE, I WOULD LIKE TO TEMPORARILY ABOLISH THIS LEVEL. It is imperative to work on the OBM and to find out how we can actually build the higher level OBM so that others can write programs that form GOM. If we work on the intermediate level, we'll just have meetings between system programmers and never face the OBM interface. For the first implementation of OBM, I propose it be on VMS, using all it's capabilities and we not worry about the intermediate level until the next implementation.

OFIS Base Machine (OBM)
This is the most important machine level, because it is on the OBM that we expect most programming to be done by the GOM and POM programmers who build these machines. Given our current thinking, this level would be programmed in some type of system's programming language such as Bliss, C or Pascal and would first provide a number of functions and procedures. It would also contain an interpreter, a compiler and possibly an interpretive compiler so as to isolate the GOM/POM programmer from having to

write the next level in a system programming language. It would also have a good debugger so that a GOM programmer could be productive. The editor functions (those that get a file and do string operations on the text file) would be pretty much along the lines of those in EDT, but in addition there would be program control capabilities like those in TECO. (Note TECO has been most successfully used as an editor writing language!)

Alternatively, a complete system like MUMPS is a reasonably good starting model for the OBM. MUMPS would have to be extended to better couple to the screen, to do better string operations, and permit the extension of more data types. Also, Mumps would ideally also be compilable, but this seems unnecessary, given the performance it attains on the EMS application. The real limitation of MUMPS for this level is the lack of extensibility for data types, forcing all extensions in terms of strings. The goal of OBM is to have a small, very high performance machine with a small set of primitives.

Generic OFIS Machine (GOM)
GOM is the machine for most end users, providing what is in the current WPS system. There will be a small version for what one might either consider to be an intelligent terminal if it is connected to a larger computer, or if standing alone it could be considered as part of the low end personal computer. The high end would extend over what we have or wish we had in today's WPS and include typesetting and VMS/EMS.

Programming to define GOM would be done in OBM and GOM procedures! OBM would be sufficiently rich as to permit the programming of list processing, math, sort, merge, table manipulation, forms capability to be programmed. These would not be defined in OBM per se.

Profession OFIS Machine (POM)
POM has a set of extended function data types that permit the system to be used by a particular profession. These include the data-types and appropriate operators for the profession (e.g. a specification using decimalized identification (e.g. para 12.5.6.1), accountant's spread sheet, table which can be manipulated and converted to grahps, legal type documents, two column multi-language for the professional translator, programs in a given language for the programmer, etc.). As WPS-8 currently exists, it is most ideally suited for the professional writer since it takes no additional definition of forms or procedures to immediately use. For example, the correspondance secretary would have a set of menus that only deal with a particular format of letters and it would permit their creation, editing, output on the letterhead and envelope both for individual and form letters, and filing for quick retrieval; the file system would include paragraphs and name/address files. Certainly this is well enough structured to permit people in the field to program on as well as some customers.

Programming at the POM level might be done by the GOM users in the case of straight-forward task like forming a system for the secretary or the correspondance secretary. In professions

which
require the understanding of a fundamentally new data-type like a
spread sheet or graph, there may have to be extensions to all the
lower level machines. Note that the goal is to have a sufficiently rich OBM such that extensions can be made at this
level without changing OBM and lower levels. For example, OBM
should be sufficiently powerful to permit a POM programmer to define tables data types and express the operators for them. The
user would then use the tables and the operators. A POM programmer, like the programmer who built the GOM, would program
the OBM and also use any capabilities of the GOM. Initially there would likely be exensions to the OBM for certain professions. In fact, we should segment our markets and initially go after users whose needs can be satisfied doing only
programs in GOM, and gradually go for those requiring programs in
OBM, and finally, we change OBM!

Organizational OFIS Machine (OOM)
Each organization including various sub-organization has a number
of forms or protocols. For example, an expense account form would be programmed (in GOM) for the whole organization and transferred to each user. Similarly, common filing and interoffice memo forms would be used. The implication is that we
would expect programming to be done for the organization as a whole and for various parts of it by what are fundamentally GOM
users.

Individual OFIS Machine (IOM)
This level is above POM, but if there is not a particular POM,
then it is the ability to personalize GOM. As a minimum, it

is a
set of user defined keys. Evolution would most likely be forms
that are common to a given use that are not part of a global organization. It is the highest level because it is next to the
individual and it is a personalizing function that one might apply to any lower level capability. In the limit, it might be
the ability to change all the menus as fits the workload. The
programmer for this level is fundamentally a GOM user, and as such programming for nearly everyone is in terms of the GOM.

FUNCTION (CLASSES) OF A MACHINE

These correspond or can be decomposed into the primitive PMS (for
Processor Memory Switch that Newell and I posited to describe hardware machines (HMs)). The PMS types:
.Processor- an aggrate of other components that interpret a program (procedure) stored in a memory
.Memory- main types for hardware: primary, secondary (files and
program swap), and tertiary
.Switch- can range from simple bus in hardware to selection of a
menu
.Transducer- anything that takes information in one form (bits in
a memory) and transfers it into some other form (character on a
screen)
.Link- transmission from one place to another (can make errors)
.K(control)- component that given an input, evokes an output (in
essence, a one instruction processor)
My first cut at the functional classes of OBM are:
.Program environment (P)- includes the language(s),
synchronization, how programs are stored. In particular includes

string manipulation primitives (similar to TECO those in TECO programs)
.Screen management and control (T)- two parts: command mode where a screen is put up and user interacts to produce parameters
to specify next action; and picture of output from a document for
interaction with in similar fashion when editing
.Communication (T) with other systems. Must include ability to
specify arbitrary protocols, by OBM programmer, ability to substitute strings to drive photocomp machines, etc. using VHLL
of OBM
.Data management (Ms/Mt)- files as we know them and ability to
access files in other formats
.Record Access (the data part of a primary memory accessed from
files)- the data-types that the system understands together with
the common procedures that operate on them (eg. string operations, table operations, graphs, voice i/o, images). Also
includes the ability to take in an arbitrarily encoded record and
to encode it in OBM format using OBM primitives.

The primitives vary with level by gaining increased functionality
by additional software. (eg. a disk becomes a file system). In
some cases functions are lost when a user visible feature like
smooth scrolling is not support by intermediate machines. The
issue of what the functional classes are and how they will evolve
with time, versus levels will be described in another document.

In short, please excuse me for writing such a long document.

I
didn't have time to make a short one and I wanted to get the model out for your comment, because I want us to organize and build according to it. No comment will be taken as approval!

SUBJECT: RE: OFIS ARCHITECTURE COUPLING

Appreciate the warning. The business of VAX agrees with my own concerns about making a very good system, hence the push to use suvax and get the work done. Somehow, I feel you are really wrong on the sizes and the structuring into conventional
languages. I offesr as counter evidence: good capabilities of

editors written in teco... albethem large; ems in mumps ... it
does virtually everything your demo did, plus ems and has a better interface ... but don't worry we would never stoop to or rise to working at this high of a level language; smalltalk
was written for a machine exactly the size of ko.

Right now, I simply want a dedicated group to go off and write
the first release of what has been called the ofis program in anyway they think they can be successful. I don't see coupling
them to anyone cause I don't see any base of knowledge that's doing anything except going to meetings like crazy.

I thought a small, dedicated group in R and D or in MR could have put a breadboard together by this time of these functions
but I was wrong. (My feeling is that there are too many people, too many ideas to get into one system, and no one who is capable of or has been assigned the leadership of this.)

Am quite sure I disagree with you re details of what I want to
see in GOM (Fundamentally hthis has to be a large set of menus
with the connection to the semantic routines in something resembling program calls. Have not figured out what the equivalent of this is for error returns or attaching semantics
to keys. There is a good demo of this in MK that I think shows how far one can go. It was done in a summer by a Harvard CS undergrad working for Jay Nickson. Such an approach
would let us handle the foreign language problem, and the tailoring problem. Both of these must be dealt with.

I strongly support George Poonen and 1 or 2 going off and trying to build a machine along the lines I outlined on VAX in
a very much detached fashion.

In answer to your previous memo. I want this group of people who are implementing the system on KO to go do it. They will write down things and have reviews and then you can talk with them. Also, there will be a person assigned to a formal port through which all other groups and persons can pass messages.

The OFIS program as it has been written down in the past, I will shortly declare to be defunct. It appears to be the dream of a set of people in marketing requesting, persons in product management and engineering management agreeing to and everyone saying that they can build a problem over an incredible range of size and applications. The fact is, we have strong evidence (given that the original wps 8 editor was designed and built outside) that our own abilities are strictly limited to something in the order of edt, a program editor (quite good, but not full wps yet). In short, in this
area, I must say that never have so many produced so little based on no fundamental knowledge. Right now I want to see a very small group build a small wps.

PS
On ICBM, we are ignoring this question. It may not run on every system. This seems like a very large rat hole into which we could descend.

pss
In the next few weeks, I hope the group demonstrates they can put together a credible architecture and plan. It is to be a very small group, with a leader. If the effort is successful, I want to replicate the methodology elsewhere. The plan will include formal interface requirements to other groups and systems, etc.

MESSAGE ID: 5176493421

SUBJECT: DISCUSSION WITH DICK DAVIES ABOUT OFIS

Two weeks ago I had a discussion with Dick and the managment group there after a demo on the progress over the last few months. My observations were that the demo hadn't progressed much, the base levels weren't broadcast and in operation there, the performance issue wasn't understood (maybe it was premature),
and the management didn't know how the product worked (eg. they couldn't tell me how the dictionary was organized or why it took so long to check a few words on a 780. On the basis or a previous, poor performing demo there, I asked Bruce and Bob Kushlis to check into the OBM and find out whether it was the base. The data we got was that an editor was made that outperformed EDT (which was written in BLISS)... therefore I ruled out the base language and system as the cause of their performance.

With Dick et al, I voiced these worries and concerns:
1. The UK is not known for office applications, and the use appears to be at least 3 years behind the US. Thus, there's no

way to get user feedback.
2. The UK culture in the office and the use of computers by managers and professionals is such that the lag may be more like infinity than 3 years. There's a possibility that they may be limited because using manual devices may be always beneath the average manager. Therefore, they have no cultural or role model for even conceptualizing the office design.
3. They have no understanding of the office or anyway of getting this. There's no research, specs, gut feel, market coupling, seminars, courses, consultants, people, etc. to have any rational basis for building the products they are chartered to build. In short, if they made a product it would like the million monkeys writing a Shakespeaare play.

4. They have no products running there to learn with. All in one wasn't up, DECword (which they brought) wasn't up, and all I saw was 78's and VAXmail... neither of which are close enough to office conceptually to give anyone a dream of what it should be like. Use is a way to get the vision.
5. Dick kept telling me about getting requirements, breaking new ground in human interfaces, etc. and then a product would follow. This prompted me to worry about the design even more. I don't understand this method of ever building products.
(I had a delightful afternoon with the designers (both... even though there are now 9 in the group) of All in one ... they surely didn't do it this way thank goodness.) The SICKNESS IN

THE SYSTEM IS THAT THE DESIGNERS OF ALL IN ONE HAVE NOT PRESENTED THEIR SYSTEM TO PEOPLE IN ENGINEERING!!!! (The Japanese know our every move, yet information in Charlotte doesn't travel to MK, ZK or Reading.)
6. I wanted to talk about
the technicalities of products and I expect every manager within engineering to know more than I do about these products. Anyone

who only has one product to manage should know everything about the product and competition. These people only knew that there were competitive products WITHIN DEC, spent lots of time on this
and Knew Nothing about their own products. There was no concept of competition. There was no concept of the ultimate office or even an interim office or even a modern office.
7. There's a very large group doing the work and in productization. This all seems too large and premature, given our level of understanding thoroughout the organization. Namely, a large organization is the greatest impediment to creativity and work when you don't know where your're going.

These were the concerns and Dick said he wanted to work on them. Today, I stumbled across an idea that might be useful to help: after the ALL IN ONE demo, I asked them about having really great book to explain it (their model and why it wins) to the world. They have no time to sell because they're building. I called Dick about him personally writing the book... only because I can't find the month to do it now. Frankly, I'd like to get Dick, assuming he can write, or one of his people and Dick to get the product there, take their pitch, model, notes, etc. and write a book explaining this. This would get them to a point where they have some basis for being involved in this project! If Dick can't find the time, then I'd like to get someone else within the incredibly fat (budgetwise) OFIS group to write this book and start to do the teaching that's needed to make us a first-rate engineering group for office products.

Right now I believe DEC is on the dawn of being able to market the products we have: DECmate, All in one, DECmail, DECset, DECtext (in europe), etc. together with our VIA, TP, DP. This with a little (lot) of work could make us # 1... marketwise.

The trick is to keep up this momentum and make ofis really great. This is going to mean very hard individual and team work. We have no choice, we have to get the job done.

JULIUS MARCUS DEPT: OOD
LARRY PORTNER EXT: 223-2236
BRUCE STEWART LOC/MAIL STOP: ML12-
1/A51

SUBJECT: JULIUS' COMMENTS ON THE OFIS PROGRAM: HELP

I think you ought to get a briefing from BJ, Bob Daley and Bruce as to why do it in the UK. My reading is simple: there is some talent and a team there to bring it in and get a product
out.

I am distressed too, but I am heartened by the fact that we are
building a group that I think can build a product now. This view
has gone from: give us money and we can do anything in two years;
to complete hopelessness based on the way we interact and define
things (including the way we did it in Hydra); to some hope by putting a small team together and giving them all we know about this area and asking for a proposal. You are now where I was a few months ago... dispair.

You can throw us back into the pits, but for now, I would like
to give tthe group a couple of months. They have produced more
in 2 weeks here then all the meetings over the last 6 months have produced between the marketing and product management folks. Honest, we do not need more input to define the product,
we need some understanding of how to build it!

PS,
My recent concern about the parameterized software package stems from the fact that it's schedule and budget driven versus
idea driven. So far, I would predict it to go the way of Hydra,
although it is about 1/10 as complex to build and having 1/10 the product requirements. My message:
get some idea about what you are going to build and how you are going to build it before embarking on major hiring and product schedule promises.

SUBJECT: OFIS IN EUROPE

I don't understand the logic behind doing software development
for OFIS in Europe. It is nine hours' time difference from the
source of the interim product, WORD-11, so there is absolutely
no ability to communicate between the documenters and the producers. It is nine hours and 6,000 miles, one quarter of the way around the world.

Furthermore, OFIS will be introduced very late in Europe because of the language; and we are not building a base of knowledge on which to build the future OFIS products close to the market where it will be sold.

I am personally extraordinarily depressed because of this and other issues. I feel it is impossible to influence projects, and this one makes no management sense to me. Since no one really cares about OFIS, maybe we should cancel it.

DEPT: OOD
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: OVERSPENDING ON OFIS/KO: RELAX A LITTLE

Somehow we must rise above what may just be noise. Fact, we are not hiring anyone. Fact, we have not, nor do we intend to fire anyone. Fact, our equipment and discretionary expenses
are pretty well frozen. Therefore, our overspending or not is totally predetermined and inevitable and I don't see that anyone can do anything about them or what they are! Also fact,
we are mucking around defing things and the ultimate priorities
aren't known now, together what the ultimate work plan will be.

My conclusion: let's not spend so much hassle trying to move expense budgets from one cost center to another just to try to

make a different manager look good or bad. At one level, I worry about our ability to manage a budget (and schedule), but
moreover I worry mostly about our ability to define and manage
and motivate. In the case of Heffner, I view starting up a new facility has been a challenge and we overspent. My conclusion is that maybe we want a single person that just helps in the starting up of these facilities, rather than having to take a really good line manager and to have to deal with this trivia. (It ain't trivia that I think he's built the best "feelin" facility so far, so I can't say totally turn it over to the bean counters and administrators cause they'll
build shithouses. On the other hand, he knows more about buildings
than he probably wants to or ever needs to know.)

My message: relax, let's do everything we can to hold expenses,
but I could care less who over and how under spends in the current environment. Also, I want us to spend our time defining
the work and approach and not the charter space so as to make the budgets be right!

TOM VLACH LOC/MAIL STOP: ML12-1/A51

SUBJECT: TARGET ARCHITECTURE AND PRODUCTIVITY FOR OFIS

Am concerned that we're posed to spend more than we can manage
in both wps and ems. Could you review for me what the productivity
in lines/person/day for the wps8?

As a rule of thumb, I would hope that our budget would get us about 30 additional programmers. This should produce about 300K lines of code in bliss.   Wps is about 100K lines of 8 code.

Why isn't the task fundamentally straight-forward given that we
have written programs like this many times before, we have user
specs and it should be possible to structure the work into many,
parallel, non-interacting tasks?

It seems like from an architecture viewpoint, we want to avoid
making details like the file system and file format known and available to the group writing the actual Wps or Ems application.
Instead, there would be a bunch of operators on it, pretty much
along the lines of the teco operators (delete a certain object,
get, put, etc.) which only the procedure or functions know about
and as such no one might know what the format was except the functions.

Have been thinking about various architectural levels and will send this seperately so as to get your reaction. Meanwhile, I think we have to seriously address the internals because I don't think any of us have confidence in our ability to build anything at this time.

SUBJECT: VLACH OFIS PROD. STRATEGY UPDATE 9/8/80 AND REDUCING HASSLE

This memo that went to the world bothers me. It is exactly the type of comitment that gets us in trouble. It moves all schedules out in what we feel should be some sort of reasonable
time frame. Yes, we should be able to meet these somehow.

I want Bruce to make the comitments under his name. Also, I want no schedules that aren't appropriately qualified. We have not agreed to a schedule on the small or large product yet or their phasing. Worse yet, I believe McKenzie and the project team has to make the comitement. I have not heard
them do it yet. We are not at phase 0 yet. DECmail is a similar problem.

We thus have to take the memo I wrote on reducing hassles and clean it up, shaving it to just the rules about who comits, and
publish and enforce it.
I would like comments from you folks about the rule and the corollaries cause I want to act to stop this crap before any more people get chewed up. All it will do is increase the meetings, with no attendant real work done! Please comment cause I want to get the rules down and out.

The result is clear: Tom is going to take a lot of crap from his customers if anything happens to the schedule (and I have no confidence that it won't, although I hope we can make it).

Rather than formally rescind it, because it supposedly was written
(9/8, with a 9/12 graph and I got it 9/17) before my 9/13 memo,
it seems like it should stand until we know something.
It is a reasonable target that I we should all go like hell to meet. It sure has everything so our P/L customers can't object!

Ohio University

Clippinger Building
Athens, Ohio 45701

Dear Dr. Raju:

Thank you for the invitation (July 6, 1979) to participate in your symposium. I'm sorry that I have made a previous commitment to be out of the country the preceeding two weeks. As such, I don't feel I can be away from here so long, and must decline your offer to speak and interact during the two-day October symposium.

As for ideas as who might speak on Computer topics, you might try: Dr. Jim Bell who heads our R and D Group and who has worked on curricula needs for DEC, or Del Lippert who heads our Educational Services Group here; or Sam Fuller, who is our Technical Director; our various Carnegie-Mellon (e.g. Bill Wulf, Dan Siewiorek) or Stanford faculty (Edward McCluskey, Forest Baskett).

Sincerely,

Gordon Bell
Vice President,
Engineering

SUBJECT: WE MUST STAY A MANUFACTURER, NOT BECOME A DISTRIBUTOR FOR OKI!

Unfortunately, I don't think there is an easy way out of designing and building low cost personal computers. We gotta learn, or decide that DEC should head for being a distributor and change the whole nature of what we do. Therefore, I say now is the time to get moving aggressively into this part of the very competitive arena. It's going to be really harder than anything we've seen. I don't think it is optional at all as it both threatens our main mid-range as an alternative computing style and as the mid-range comes down to be in a small box, offering even cheaper computing power.

It is critical that we hear from the troops everywhere in the company as to how we are going to pull together to stave off the forthcoming invasion of distributors such as TRW, National, and the company that imports the OKI.

The Foxhollow Inn
Lenox, Mass. 02140

Dear Sir:

Your Inn was featured in the Boston Sunday Globe, 1/21/79, and we would appreciate some additional information:

Do you have a meeting room which could be set up living room style -- at least 24' x 20'?

Do you have overnight accommodations?

Our meetings are usually two days in duration, with approximately twelve people. If you have the facilities for such a meeting, we would appreciate receiving a brochure, plus directions. Also, would you be able to handle our group April 25 and 26?

Sincerely,

Mary Jane Forbes

Dear Bill:

Enclosed are two papers I promised:

.   The Multi: A New Fourth (and Fifth?) Generation Computer Structure which I have submitted to Science.

.   A Taxonomy of Parallel Computers and definition of grains size

The first paper relates to the fact that COCOM should be aware of the incredible ease of building "Multi's"-- for multi(ple) microprocessor computer. The Synapse computer is an excellent example of this class (the Elexsi, a high performance multiprocessor, is not a Multi). My thesis is simple: this new computer structure is ideal from a cost, performance, cost/performance, reliability, maintainability, design and manufacturabilty standpoint, so much so that it could replace conventional minis and low end mainframes. The real kicker is that I believe the computer will lead directly to the general solution of the parallel processing problem. Whether it does is immaterial, because we do understand on thing about parallel processing: if a program is inherently parallel and important enough, then people can get it to run efficiently on a multiprocessor. Within 3 years, I expect to see a computer with 32-64 processors and 128 Megabyte memory all in a 2' x 2' x 2' box selling for $400K and delivering over 100 Mips! These computers while not totally trivial to build are easier to build than a large minicomputer, and are trivial to build when compared with a 100 Mip supercomputer (of which there aren't any).

The second point is about COCOM's position on approving the sale of IBM PC's in Russia and the notion of allowing a U. S. effort to help Russia build a factory to build PC's. Why are we allowing this? It should be observed that the PC is as cost-effective at Scientific calculations as a Cray, in terms of cost per megaflop, and more cost-effective than either a 780 or a 308x class. Most important, the PC has an 8088 which has a 20-bit address, permitting useful work to get done, unlike the toys made from Z80's or 8080's. Please do not confuse the 8088's architectural limit (20 bits) with implementation datapath (8 bit). The PC is perhaps a marginal issue, (although I clearly can't understand why we are actively helping improve computing in Russia) but when looked at from the following viewpoint, is a much more critical issue.

Professors Chuck Seitz (Computer Science) and Geoffrey Fox (physics) have built a multicomputer, which is a bunch of computers (processors and primary memories) interconnected in a hypercube the call the Cosmic Cube. It has 64 8086's with floating point. Each computer has 128 Kbytes of memory and is connected to six other computers by a fast serial line over which messages are sent to neighbors. So far they have a run a number of programs and demonstrated a factor of 64 speedup. Again, their examples all beat the Cray 1. They have some guidelines on how to code problems for the machine. For details, you might talk to them.

If I have a good factory, set up by the U.S. folks who can make reliable PC's, it is trivial to make 1 board that has the log (n) serial wires coming out of it for building a Hypercube. All I do is make 64 trivial boards (done by a good hobbyist), get the Cal Tech Software, plug in 64 PC's (an overkill because most PC's have bigger memory, and interconnect the wires. Now I have a supercomputer.

Although I open up some issues, I hope these thoughts are helpful.

Sincerely,

Gordon Bell

Subject: **Strategy Issues List**

To: OOD

Date: 16 NOV 78
From: Gordon Bell

Dept: OOD
Loc: ML12-1/A51 Ext: 223-
2236

follow up 12/4/78

On our meeting of the 13th, each of us aired problems for our areas that are important to the resolution of the products that back up the strategy. In order to get a timely resolution of these, I'd like to get a list from each of you, arranged by priority and with target date of resolution. There should be a separation as to what are intra-your-area versus inter-area (and these would include the other area of joint interest).

The list ought to be kept as short as possible, and the problems be named descriptively. This listing must be significantly less than ONE page! There should also be a one sentence to one paragraph statement of each of the problem issues.

In order to avoid hassling you, please either send the list or a date when the list will be sent to Mary Jane by December 4 in either paper or floppy form.

John Meyer	ML12-1/A11	Larry Portner	ML12-3/A62
Bob Puffer	ML12-2/E38		

In a prospectus on an EBAM, I ran across this:

"Oppenheimer is currently in the process of raising $30M in a R & D Partnership in which CDC is the general partner, to finance the development of a low cost GP coupler, fully compatible with CDC's existing product line."

In a recent dinner meeting with CDC, one of the principles commented that if CDC had brought out a low cost version of the 6600 or 7600 in "mini form", they could have taken much of the mini market. I declined to comment. I hope they don't do this, but they're probably exploiting their technology for lower end products...not a bad idea. They probably are looking at the gapping VAX hole.

Why would they use this method to find R & D?

Is it a way of encouraging entrepreneurship?

Is it something we should consider?

Portland, Oregon 97201

Dear Mr. Whitney:

I got your letter of April 2. Yes, I'd like to meet and explore the opportunities of an OMSI Pascal.

Although I won't be at DECUS, I'd like members of our staff to meet and discuss this with you. I'm asking Larry Portner, Head of Software, to do this. He'll contact you.

Sincerely,

Gordon Bell
Vice President,
Engineering

TO: Central Engineering         DATE:  15 June 79
    Managers                    FROM:  Gordon Bell/Larry
Portner

                                DEPT:  Central Engineering
                                MAIL STOP:  ML12-1
```

SUBJECT: Organization Announcement

In conjunction with Gordon's earlier memo concerning the Central Engineering Organization, we are pleased to make the following announcements:

> John Holman, presently Manager of the Computer Special Systems Product Line, will be responsible for the technical engineering activities that cross all of Central Engineering. These functions include: Engineering Information Systems, Central Engineering Services, Central Diagnostic Systems, Power and Packaging and Systems Evaluation. John will join Central Engineering on July 1 and will continue as Acting Manager of CSS until his replacement is installed.

> Grant Saviers, presently Manager of our Colorado Disk Development Group, will become Manager of Mass Storage Development. Grant is replacing John Kevill who resigned for personal reasons. Grant's appointment is effective immediately, he expects to be in residence in Maynard by July 1.

> Sam Fuller, presently Manager of Hardware Architecture, will replace Bill Johnson as Technology Director. The Systems Architecture and Technology Group will include: Central CAD Architecture, Systems Performance Analysis, Technology Tracking and Competitive Evaluation, Hardware and Software Architecture, Product Standards and Future Technology Committee sponsorship. Sam will assume his new duties immediately.

We are extremely fortunate to have people of this caliber available to undertake these key positions. Specific transition and integration plans for the involved people and organizations will be completed early in Q1 of the coming fiscal year. We hope that you will help all of us make the transition as smooth as possible.

Recently, it was announced that Bob Puffer will be moving to manage the Mass Storage Manufacturing operation under Jack Smith. We wish Bob well in his new job. We will miss his participation and contribution to Engineering.

Subject: **Organizational Changes**

To: Engineering Managers

Date: 6 JULY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

I am pleased to announce the following organizational changes:

Central Architecture and Technology Group

I am establishing a Central Architecture and Technology Group managed by Bill Johnson. Bill will report to me and have responsibility for: Computer Systems Architecture, Diagnostics Engineering and Technology Tracking. Reporting to Bill Johnson, Sam Fuller will manage Hardware Architecture, and Bill Keating will continue with his present responsibilities, including Software Architecture, Tools and Standards. These groups will be responsible to define and coordinate systems architecture and standards throughout engineering. This move will help focus the Engineering organization's attention on emerging technologies and trends and will also provide a continuing assessment of our capability in various technical disciplines.

R&D

Effective immediately, the R&D function under Jim Bell will report to Ulf Fagerquist. As previously announced in John Leng's recent memo, Ulf now reports to me and continues to manage DECsystem 10 and 20 engineering and product management.

Software Engineering will continue to report to Larry Portner with the exception of the changes mentioned above, and with additional responsibilities in the Commercial Group. Larry will continue to be a member of OOD and report to both Julius Marcus and myself.

<u>RECOMMENDATION</u>

Obtain a replacement for Si as a Product Engineering Group (PEG) manager for terminals and computers built into terminals.

Have that manager organize the work for maximum product autonomy, while building on common components and constrained by common architecture.

Build the best engineering team for Si's products!

This structure permits a team formed with Si to focus on the marketing, manufacturing and engineering aspects of products.

SI's OLD JOB

Si...

16-bit Qbus hardware
Also, VT278 hardware for WPS and Retail Products
16-bit Unibus hardware subcontract to Tewksbury

VT/LA and Terminal based hardware components (monitors/kbd)
Computing Terminals (CT), both hardware/software
Technical Director and A/D coupling

The following engineering (outside this area) is also associated with terminals and table-based, personal computing systems:

CT software
Disks, subcontracted and independently funded
WPS 278 software
VT278 software for Retail Products Group
Terminals engineering who are building 2 Computing Terminals
Modems for terminals
Special semiconductors and PDP-11 microprocessors

THE PROPOSED ENGINEERING ORGANIZATION (PRODUCT GROUP LEVEL VIEW)

Bell/Portner

(Product Engineering Group, PEG)
32-bit systems
Large computer systems
[Terminals and table-based (personal) computing system]
16-bit systems (part of Si's old job)
Networks, communications and distributed systems
Software
Mass storage
Semiconductors
Power, Packaging, Physical Interconnect

Technical Director (Standards, architecture, R&D)

(Engineering Administration Staff)
Administration
Finance
Personnel
Technical Operations
Strategic Planning
Corp. Product Management
Quality and Operations Analysis

Recording Secretary

SEVERAL POSSIBLE ORGANIZATIONS

Win suggests the following alternatives:

1. B/P manage the details of how to get Si competitive products

B/P

8 Current Product groups
CT
VT
LA
Technical Director
7 Current staff groups

2. Keep all computers together and all terminals together

B/P

7 Current Product Groups
16-bit
CT
VT
LA
Technical Director
7 Current staff groups

3. Combine CT and VT in one group and LA in another group

B/P

8 Current Product Groups
CT/VT Products
LA
Technical Director
7 Current staff groups

4a. One form of the Proposed Organization
B/P

8 Current Product Groups
Terminals and Terminal Based Systems
CT
VT/LA
Technical Director
7 Current staff groups

PROPOSED ORGANIZATION (DETAILED)

4b. Maximum autonomy for the various products

B/P

8 Current Product Groups

Terminals and Terminal Based Computing Systems
- CT
- VT
- LA
- VT278 (including hardware and ALL software)
- Common components (keyboards, modems, CRT's)
- Strong, Common Advanced Development and Architecture

Technical Director

7 Current staff groups

RATIONALE BASED ON MANY ORGANIZATIONAL DESIGN CRITERIA

Bell/Portner and Other Product Engineering Self-Preservation

Many Engineering Areas Need Our Attention

Technical Issues In Terminals and CT's Are Open
We need help here!

Protection From Me (and Passers By)

Strong, Autonomous Product Focus

Separation of Terminals and Computing Terminals

Strong and Clean Coupling With Si's Team

Strong and Clean Coupling With Manufacturing

Very Good Coupling For Shared Technology and Work

modems
power and packaging, including noise and radiation control
keyboards
monitors (although the LA's don't need them, VT/CT do)
use of roms for more intelligent terminals
common modules for terminals and computing terminals
including: comm., rom, some video, printers, mass store

architecture of communications to operate on non-DEC systems
architecture for use on DEC systems (badly missing now),
especially VT and VT (graphics)
human factors for much of the design, including editing
imaging based on dot matrices for fonts and graphics
common approach of servicing and customer installation
use and programming of standard VLSI

Printers have some unique characteristics

CT's are programming driven

Minimal Amount of Interaction With Other Parts of Engineering

Common terminal architecture interface with software

Mass storage (CT and VT)

Semiconductors (all, and all have unique VLSI too)

Ofis software (for both CT and VT)

Other operating system software for CT

The Revenues In These Market Directed Products Are Similar
to other product groups.

FY	VT	LA	CT/278	16-b	32-bit
81	.16	.16	.05	1	0.6
82	.2	.2	.06?	1.1	1.0
83	.22	.27	.13	1.2	1.5
84	.29	.3	.4	1.3	2.0

Having The 278 In The Group Is Desireable, Though Not Necessary

The Proposal Is Similar To Other Parts Of Engineering

B/P(level 2)

Mass storage (level 3)

CX (Level 4)
Big Drive Projects (level 5)
Controllers (level 5)
Specific controller project (level 6)

...
Large Computers

Venus Program
36-bit
Jupiter

...
Terminals and Terminal Based Computing Systems (Personals)

CT family of products
CT Product Management
CT Hardware manager
CT Software
CT product assurance

VT products
VT project

LA family
LA200, etc.

Components
Keyboards, monitors, etc.

Single VT278 mogul
Product manager
Software, including WPS, RPG, etc.
Hardware

Secretary
+---

The meeting schedule through calendar year 1981 is attached.

Jungle meetings will be scheduled to include the appropriate groups.
Please keep currently scheduled Jungle dates on your calendar unless
otherwise informed.

The initial meetings of these groups will be used to define the focus
and objectives of the groups so that agendas can be managed and the
time of the participants well spent.

* Sam Fuller's attendance is optional.

SUBJ: OOD ORGANIZATION ANNOUNCEMENT

Date: 5/17/79
From: Gordon Bell
Dept: OOD
MS: ML12/A51 Ext: 223-2236

TO: Operations Committee
Engineering Managers
Consulting Engineers
Product Line Managers

Effective immediately, Larry Portner will become Associate Head of Engineering. We will be jointly responsible for the management of Engineering. Under this system, I will focus on key products and technologies that further support the product strategy, and Larry will focus on operational management. Mitch Kur (Central Engineering Finance) and John Meyer (Central Engineering Personnel) will report directly to Larry. Larry will also assume direct responsibility for coordinating the activities of the Product Management Committee and working with this committee to implement a more focussed Product Managment and Planning process.

Bill Johnson will replace Larry as Manager of Software Engineering; Bill will continue to act as Technical Director until his replacement is selected.

George Plowman will assume additional responsibilties in the areas of Distributed Processing reporting to Bill Demmer as an additional step toward integrating our DECNET, communications and interconnect strategies.

The organization:

```
                           -------------------------------
                           |             |            |

Engineering Organization Goals and Constraints (10/14/80-GB)

General Principles of Organization Design

NG. Broadening or narrowing the organization
G.
Minimize # of organizational changes
G.
Minimize # of buyer/seller, matrixed based, and joint planning interfaces within engineering.
C.
Sole buyers of a given function should absorb the function
G.
Dominant buyers shall become main, planning (checking inteface) and preferably become service supplier to other PDE groups
G.

Minimize # of interfaces to marketing groups (buyers) for what is viewed by customer as fundamentally a single system (eg. Comet, VMS, disks, comm., database, Hydra, TP, etc.)

G.

Directly align hardware based systems with Mfg. as 1:1, versus 1:e, m:1, or e:m

G.

Minimize # of projects which have multiple uses

G.

Minimize # of programs (program is set of multiply dependent projects)

C.

All organizational principles adhered to in changes at the current level being addressed are transitive. That is, the next level should be able to use the same segmentation and design principles.

G.

Minimum # of sites for a given manager.

C.

No movement of workers.

General Engineering Related

G.

Maximize autonomy of product development groups (PDE), with minimum involvement of Office of Engineering (OE) groups.

C.

Minimize changes in high end where we are technologically most vulnerable and need greatest focus for long term

G.

Have a structure which supports the constantly evolving hardware changes in MOS, bipolar and ECL, with clearly identified responsibility for competitiveness at the base hardware (NOT SYSTEMS) level. Explictly understand how a broad organization structure will provide competitive base hardware. Recall our success is by providing both competitive hardware and software.

C.

Place all PDE expenses within PDE, versus OE allocations

C.

Do not add organization structure (overhead) over existing structure.

C.

Architecture with implementation groups.

Specific Projects and Programs

C.

Mass storage is supplier to hardware systems groups

C.

Semiconductor and Physcial Interconnect group are suppliers to hardware groups

C.

Provide clean structure for Terminals and TBS's, with minimum # of exptraneous functions

G.

Provide for the following explicit products and programs: Hydra, Comm. hardware, and Interconnect, PVAX, Office, and Applications (for Computer Products, Commercial and Technical)

C.

Design organization that supports the product strategy with clear alignment of responsiblity for various parts.

G.

Support product strategy by aligning parts with clear assignment to organization.

C.

Maintain standards and human interfaces across DEC supplies for files, languages, networks.

Address Current and Potential Overlaps

G.

Minimize hassle through organization to identify conflicts of: 8/11, 11Q/11U, 11/11, 11/VAX-11 co-existence, 32/36 co-existence.

TO: GROUP VP COMMITTEE: DATE: SUN 29 MAR 1981
20:43 EST
TED JOHNSON FROM: GORDON BELL
cc: MARY JANE FORBES DEPT: ENG STAFF
KEN OLSEN EXT: 223-2236
LOC/MAIL STOP: ML12-
1/A51

SUBJECT: COMMENTS ON WHAT AN ORGANIZATIONAL CHANGE MIGHT LOOK LIKE

Mary Jane will send around a memo which I suggested an eng./mfg./mkting segmentation (7/13/80) which we discussed at our July woods meeting. In essence, it was based on a level of integration approach. Semis, Pkg/pwr/physical/interconnect become technogy suppliers and are mfg.+eng. Mass storage is the same, except that it might also contain a product line to sell mass store products (I still believe in this). Similarly, the micrsos goroup would be at this level and be a combined group with both modules and probably now including the all the 11 systems as the next, competitve round are all based around the modules and semis.

Computing terminals, and dumb terminals would be a combined mfg./eng./mkt. group. All VAX systems would be a group, but containing NO mkting. The 36-bit is already a contained P/L. The office products group would be as is, but with product marketing support so that all product lines would sell office products.

It is even more essential to have a much better focus on

building
systems between the engineering and manufacturing groups.
Jake
quoted a figure of 3K to install a 30K system. The
responsibility
for this is spread all over manufacturing
and there is no way to get product design cost and focus
cause
the cpu and system manufacturing worlds are totally bent on
satisfying the 18 p/l's ... and the best way to satisfy
them is to have an incredible inventory, backed up
by an army of clerks. If you look now at Salem ad WM, there
is no mfg there, only clerks talking to one another and
swapping and communicating with P/L's. (If we establish
one more Group VP, or P/L, I believe we can safely predict
the
total demise of DEC as it consumes itself in communication.
(Can we have a Woods in Salem or WM and look at the
floor space now devoted to building?)

The stores would become part of the sales channel, and word
processing would be either part of market support in existing
P/L's or part of applications development as we know it now.

I think we should have learned something from our rpg and
wps p/l episodes:

.P/L, engineering, or any other type of group (especially a
new group vp level type group are costly as hell... I make it
about 10M or so just to have all the interfaces to the rest
of
the company (Rose Ann's 36-bit p/l is supposedly going to
cost 8m for example). These costs are more than the group
cost, it includes all the interfaces and inefficiencies of
the rest of the functions that now have to interface
with it. Therefore, I don't see having any more mkting group
vps.

.rpg, even with the best of products may not be viable.
Personally,
I continue to swear by a two tear market structure where
the tiers are seperate organizations and benefit by

the entrepeneurial drive of the small business person!
I don't think we have any particular knowledge about retailing that we could successfully build a channel like this.

.wps has a similar problem. To be successful, I believe we have to spend a fair amount in the product and manfacturing space. In doing this, it means that there is no way a start up product line can get the sales people and volume to make it. NOW WE ARE FACED WITH A BIG PROBLEM... WHAT ARE WPS AND WHAT ARE THE the other P/L's GOING TO SELL? Either we keep the P/L, lose money and the market or we figure out how to move the wps products through all channels. Frankly, I didn't work so hard to get a developement group so that we could get only 100M sales here. Given the spending of about 10M/year and the rule that product specific spending is about 1-2% for successful products, then we should be pulling about 500M to 1B out of this market per year!

(Buzz is good and the people are dedicated, but the channel is a straw and we need a fire hose!!!)
It is really crazy to talk about having a group vp who is going to run the office products, cause, as we know it, this implies selling through sales folks. I don't think any P/L is going to give up their sales folks, ergo, there's no way a group like this is going to be formed and make it. I see no way other than to consider office products as a new, fundamental product where every product group is encouraged (even required) to sell it. WPS could be effective as a P/L or not, depending on our leadership (or lack of it). (Did we learn anything from the time we had a distributed processing P/L?)

[The irony of our allocation process is that there is no way we can ever enter a new business without starting up a product line to lose money so that we can get the product done. Unfortunately, the baggage of spending to market before the product is there is costly and stupid. Yet, given our organization and behavior, this is the only way!!! Some of the folks who went to business school should of warned us about this logical inconsistency.]

You would think that any group could propose a new product area like wps that we could invest in in an incremental fashion, but since we have a product/marketing coupling scheme that is aimed at keeping our existing business strong, tthere is no way that the new product can be formed without this circuitous, costly and crazy route.

FROM: GORDON BELL

cc: KEN OLSEN
DEPT: OOD

EXT: 223-2236

LOC/MAIL STOP: ML12-1/A51

SUBJECT: AN EXPERIMENT TO REDUCE HASSLE AND CLARIFY INTERFACES

Am glad for the attached, comments by Dick. Allow me to comment.

I don't really agree with Dick in toto. His view, too much optimization and too much formality and ties with other groups.

My view, no explicit formality, anyone can comment and stop. Designers can meet virtually all the goals and constraints of a design, it is rarely that they ever write them down. Hence, people have no confidence in what they are going to build, therefore probe em so as to find out what's happening. We are all pretty frustrated. Our consensus style, our DEC right to be open and to be allowed to comment on anything, and the formalization of these rights into a set of processes where everyone must (or feels they must) participate in every decision is the final blow. I don't want to change these rights, but I do want to change how we engineer and what processes we use. I also want to place a lot more freedom to act back to the line development managers. They are the ones who we reward and penalize for our products ... somehow we've forgotten this. (This means they should worry, like Dick is, how they want to accept inputs and how they propose and are reviewed, and then they implement.)

Given all this, please let me make this clear: I don't want to change a thing about our processes or how we design... YET! I want to watch a couple of small groups and "help" them in such a way that I am not the bottleneck or approver. (I especially want to make sure they get some time to design by limiting their outside participation.)

-

WHAT CAN WE DO BEFORE WE GET ORGANIZED?

Therefore, I view it as an experiment (that incidentally has to succeed), and that if successful will be installed in every part of what is now one of the biggest bureaucracies outside of the federal or state government. The intent is get back to the DEC rule:

He who proposes, Does!

Consider these corollaries, on which I would like feedback:

If someone is to propose and do, then let'em.

If your want a proposal, then ask for one.

No committees or groups (outside of direct line staff groups) are allowed to propose... cause there's no one to do.

What you propose, will be reviewed... probably more than you want. Anyone is free to comment, as such there should be open flow of information, subject to need to know.

If you have inputs, then make 'em, but not such that the proposer/ doers are going to spend all their time responding instead of doing. If you've got no power by position, then there's a high risk of being ignored unless the ideas are good. If you have power by position, recognize you can stop and/or disrupt work easily.

If you are doing, then recognize that there are a lot of good inputs out there (and a lot of bad ones too), therefore, get set to handle input 'cause you probably can't live, nor should you live in this "suggestion-rich ... opinion-rich environment" without drowning in input.

If you are doing, and are part of a group (or team I hope) then you can get a hell of a lot more done by thinking by yourself most of the time, and occasionally with one or two other persons. The main reason to meet is to agree on interfaces and to review ideas and occasionally brainstorm if you're idea poor that day.

If you are part of a group of more than one, then allow me to hypothesize (and I believe I can prove it by numerous examples) that someone has to act as leader (ty-breaker... if you will)

Given that groups need leaders (probably cause I'm old fashioned) then ideally (but not necessarily, I suspect) the leader knows every aspect of the design! (This is only if you want to produce a great product (versus a mediocre one or one that a renegade committee specified or designed for you to build.)

If you really want to specify what a product is and how it is built, then be part of an engineering group. (Engineers build.)

If you want to posit, or gather inputs for, a desirable product or want to explain a product so that someone can buy it, or analyze the total financial aspects of the product, then be part of product management or marketing.

HOW DID WE GET WHERE WE ARE? MY VIEW:

A whole gang of people have gotten into the act to discuss and review plans that are cast or in some cases can not be cast because there is no one who has enough knowledge to even propose a rational course of action. I have just witnessed this later condition where an exceedingly large gang took over the definition of what a product was to be, when it was to be shipped and what the development cost was to be ... even before a single implementor came on the scene. There is no way to build a product like this, cause the person who we ultimately measure (ie the builders) had absolutely no say in it, or even if it were possible to be built. For starters, we are going to stop this nonsense (by senior engineering management).

In the case of what we are doing in a project in which I am involved as a consultant, we are not setting up to reject input or output or make them beyond review or approval, but we are setting up to make these exchanges controlled. There are a few, well defined ports where these exchanges will take place and the developers are off designing and are not obligated to have to answer to anybody on any question or to attend extraneous meetings. Whether they build or not, will be subject to whether they pass their reviews with a quality looking product. These reviews will also be the times when we make some of the hard trade-offs.

The software group is acting under a set of goals and constraints which will be reviewed at large, ad nauseum perhaps, but the guidelines for the design will be clear. They will publish the design at well defined intervals and will accept inputs then too, and will go through the review processes. The management part of the project, as opposed to the detailed architectural design and implementation group, is dedicated to making the product (and project) work. The project management part is concerned with dealing with other groups like advanced development, (which must focus on getting technical answers to problems the development group needs answered as opposed to being inner directed), marketing requirements, and gathering data that may be relevant to design decisions. We have operated for a week with only about 1/2 day of formal meetings with the outside, and the intent is to get this time down to 1/2 day per 2 weeks where there is a formal interaction. Furthermore, all the people work (hard) every day and don't go to other meetings or interact with all the other groups. As a comment, the management group, largely directed at working with other groups seems awfully large, but clearly necessary cause there appear to be numerous, necessary interfaces.

-

I don't see why all groups don't decide to operate this way, although I would argue for minimizing the interfaces to externalities. In particular it is interesting to note that several groups where there is absolutely no reason to have any other interaction, have figured out how to structure their lives so that all they do is meet. In one project, for example, not related to a shippable product, the group is able to churn itself in such a fashion as to produce no visible output in any well defined or structured way. (This one is because it is probably too large and leaderless and they have figured out that by meeting all the time they don't have to produce a plan, ot a product or anything.) They are frustrated too because the DEC culture has a lot of hassle according to all the rumours, so given that they don't have anyone outside to hassle with, or approve or review or interact with, they have produced a microcosm which is self-hassling and self-meeting generated.

-

Note, I am only slightly frustrated on this and I am not meaning to add to everyone else's frustration by talking about it. Instead of being frustrated, I am elated at being very near a few products and seeing very bright people who know how to design and will produce, given half a chance. (There are some depressing cases too where the groups are large, have some bright people, but have no record of ever having produced much. These too are ok, because all that's needed is a smaller a size and some leadership.)

How about it folks, want to speculate on the subject?

I trust you'll exercise your rights to voice opinion.

SUBJECT: RE: RE: OFIS ARCHITECTURE COUPLING

Just a note on your pss in your memo. YOu like the idea of a small group going off to do something. It struck a chord in me. I have been observing an increasing level of frustration at least in Software Engineering. IN part it is due to the need to optimize in every direction (i.e., make it good but be sure to be compatible with the other 10 groups out there and by the way make sure that CSSE and others have their oar in the water). It seems to me that Engineering has grown so large so fast over the past several years (that 20% exponential growth in SWE gets big fast) that we have to face up to a decision.

We can't optimize along every dimension very well anymore (if we ever could). IN the past we merely applied more energy and more meetings

and the probme went away. Si's giant flowchart of how SPU's and the

whole funding process is supposed to work is a good picture of

the complexity. Seems to me we are at a decision point. We either

opt for the small team approach where the primary constraint

is do something well and we relax the "listen to the world and

microoptimize for every interest group" constraint (means we

will probably develop some good but not terribly compatible

products or we will have to train our management to be a lot

smarter and a lot more top-down to allow us to continue to

try to optimize everything and still ship something.

My opbservation is that these guys in the small group that McKenzie

is running are happy as hell because they are going to be allowed

to have some of the constraints relaxed which means they probably

feel like they can succeed.

SUBJECT: ENGINEERING ORGANIZATIONAL CHANGE

We are taking the next step in the evolution of the Engineering organization. The increasing size and complexity of Engineering requires that we shift our focus to four separate product groups who will report to Jack Smith and me.

TECHNOLOGY, TERMINALS AND SMALL SYSTEMS - Jack Smith, responsible for:

- The Technology Groups - Jeff Kalb managing the LSI Group and Don Metzger managing the PTD and TOP's Group consisting of Will Thompson and John Holman
- PDP-11, Terminals and Workstations Groups consisting of Mike Gutman, Bill Avery, George Champine and Walt Hanstein

STORAGE SYSTEMS - Storage Systems will continue with its present charter under Grant Saviers.

SYSTEMS AND COMMUNICATIONS - Bill Johnson will be responsible for a newly formed group of the 32-bit, 36- bit and distributed systems consisting of Bill Demmer, Ulf Fagerquist and Bernie Lacroute. The present Software engineering organization will continue to report to Bill Johnson.

TECHNICAL DIRECTOR AND RESEARCH - Sam Fuller will work with me to help the groups achieve autonomy within the constraints of our highly compatible computers and product strategy. Each group will have adequate resources for advanced development and architecture.

We believe this change will strengthen Digital in several ways:

. By identifying these four groups for decision making, we enhance the probability that the issues will be addressed expeditiously.

. This clear segmentation of responsibility will position us to interact and link more effectively with our counterparts in manufacturing and marketing.

. In addition, corporate functional managers will have closer, more direct links to the individual Engineering Product Groups.

While it is our intent to decentralize the operating focus, Engineering must and will continue to be an interdependent organization. We are committed to the development of a quality organization and our people are the most vital ingredient in this effort. Success will require your enthusiastic support through this evolution.

SUBJECT: ENGINEERING ORGANIZATION THOUGHTS, PLS COMMENT

We hope the evening meeting this week will focus on goals and constraints and the problems we might try to solve with a changing engineering organization. Between now and the October meeting, we would like to further refine these so that it can be a working meeting where we finally resolve.

-32-bit. VMS direction and conflict resolution, HYDRA priorities, Personal VAX, Systems control, M/E alignment,

-Terminal/Terminal based systems. Hardware, Operating System(s), applications and market interface

-36/32 coexistence.

-Communications, networks and Interconnect program. More intense effort, including connection with terminals

-16-bit. We can organize to go to VAX, or alternatively we can end up with more 11's. EBOD direction was positive on minimizing 11's and we should support them with an organization.

-Semiconductor and Physical Interconnect orientation. We need technical leadership in both areas. Semis also require segmentation in order to support the various systems, by size.

-Applications and Office Products organization. The office is generic (across all markets and products) and we need

leadership
by size and market. Currently this is the P/L domain and we must
help structure it.

-Product, Program, Market and System Manager clear definition and
work following the organization

-Less staff work with movement of responsibility and work back
to the Product Development Engineering (PDE) groups versus Office
of Engineering (OE) groups. This includes all areas: finance,
personnel, operations, administration, technical, tops, etc. We
have to minimize the transactions that require a lot of
negotiations (eg. $2K contracts) and only cross fund efforts of
one person or so.

-Clean coupling with manufacturing in a true 2 x 2. Ken wants to
see this n x n, including Product Management, Field Service,
Software Support,etc. Our first priority is to get the proper
alignment with the manufacturing organization!

-There are two dichotomies: a larger (wider, in span of control)
Engineering organization, vis a vis what one might infer from
assigning each of the focusses to a unique individual; and
smaller organization (fewer PDE groups) along the lines spelled
out by manufacturing. We need to discuss this.

-Overall, we must have substantially clearer charters with
well-defined interfaces, and hopefully a minimum of these
interfaces both within Engineering and between Engineering and
the rest of the Product Lines. For example, we should be

able to
structure the organization whereby the system groups only interact with the product lines (versus Mass storage, semis, physical interconnect, comm/net/interconnect, and software).

Would each of you write down the thoughts you have on this?

What do we want to accomplish in our organizational tuning?

What are some ways we might restructure to make engineering management much easier to do?

GB1.S7.17

GB3.S1.48

There's an AMA organization chart book that shows that most businesses are very wide in terms of both divisional/functional reporting relationships. Although this may not be bad per se, it seems to me that it may be symptomatic of an out of control phenomenon and growing incompetence. I believe wide organizaions are fundamentally mainly American, because we all want to be nice guys and have direct control, although our European organization shares the same desire. On the other hand, CDC uses a deep pyramid of VPs housed in a 14 story executive building to get wide fanout to its working parts. Organization theory texts recommend a width of 5-8. Smaller widths turn out to be families and cluby, while wide organizations seem to become anarchies with no real way to operate in any kind of coherent or collaborative way. Certainly there's little reason to have any kind of boss in a very wide organization--either because there's no time to interact, or the staff groups are doing the bossing.

Digital both at the OC level, and within various organizations, seems to have evolved to a very wide organization with relatively low measured productivity (NOR/person) because we make much of what we sell. Also, we have the standard motivations of power based on organizational size and position. We also evolve larger by wanting what we think is the direct control that comes from ownership instead of subcontracting to someone. Engineering has evolved to be the widest organization, and similarly each PEG organization has become increasingly wide. Our rationale is to have high product visibility of our very broad product set. Larry and I've attempted to cope with the width by two techniques:

.
Focussing on PEG as the line organization responsible for the total output of the organization. Hopefully we, however, focused on the output. This allows some meetings to be reasonably small and productive.

.
Providing each of you 2 bosses for administration and product development functions. This means that there's a mix of interaction required among us, depending on the issue.

The reasons why we seem to build wide organizations include:

0.
We simply like the interaction with a particular individual. Or, we believe they must interact with us for some historical or idiosyncratic reason. We're afraid they won't be properly managed by a subordinate.

1.
Every PEG member has a number of projects and the desire may be to have a high level reporting relationship to give the project visibility, get understanding and power.

2.
The fact that we don't want to say no to anyone who might, for some good reason, report to us. Similarly, we believe we need the information and resulting clout of another direct report to help manage. (Perhaps, because we don't trust the line individuals.)

3.
There are common, centralizable service and support

functions that can be grouped to reduce or improve overall effort.

4. We're matrixed by other groups (finance and personnel) and go on to matrix these at every level. Note, this has been the rationale for why an individual can have 2, 3, or more bosses. We've only gotten to 2, despite pleas for 3.

5. We have co-team members, which together constitute a complete product business unit. These include marketing, field service, and manufacturing. In effect this is a product divisional cut at Digital's functional organization without a head.

6. We create a function that requires matrix co-ordination at PEG-level (eg. administration, space, computing, operations).

7. There is coordination required for our product strategy, requiring more help.

8. We want consistency across many dimensions. This requires many people to manage this.

I'm concerned that wider organizations perform poorly because:

1. There's lessened communication between levels.

2. In the spirit of team building, or because of individual interest, competence, or incompetence between levels, work gets smeared over several members. The result is lost time as we all work an issue.

3.

The organizational goal, in our case product development, is diminished by the supporting team member goals and processes, e.g., college hires, IDP, product accounting, control, space, the planning process. All of these problems are important and have to be handled, but somehow we've let the collection rise to the top above our basic product development.

4.

The goals of the individual development manager, whether it be me, a PEG manager, or one of your development managers becomes muddy. It shouldn't be: Our goal is to develop products -- this means we have to understand the products and the designers who build them. This also means we have to know these critical designers and how to help them. We can't have a situation where I know these people better than you do (although, there will be cases). To a first approximation, I believe all direct reports require an equal amount of time (if you take GB/LP together, then each Eng. Staff member has interacted about 2 X 1/18 or 1/9 with the head of engineering). Clearly, neither of us could have managed such a wide organization alone.

5.

We don't get the necessary PEG work done because of the large group size. In PEG work, the issues are: common products (e.g., Ethernet, services, the overall product strategy) and processes that cross at least half the organizations. It's a waste to use meetings to manage individuals by flogging or conflict. PEG will be used to evaluate products: in a critical fashion by peers.

(I'm getting very leary of the notion of team building and teamwork because our work is basically segmented to individuals who simply have a job to do. Often teamness means not putting up blocks, or calling time to ask'em/tell'em where to go.)

6. There are simply more people.

These are just some thoughts that have been forming over the last few months, aided by numerous discussions, Venus experience, observations and some of Ken's memos on management.

What you think?

There's an AMA organization chart book that shows that most businesses are very wide in terms of both divisional/functional reporting.

I believe this is mainly American, because we all want to be nice guys, although our European organization shares the same desire. On the other hand, CDC uses a deep pyramid of VPs housed in a 14 story executive building to get wide fanout to its working parts. Organization theory texts recommend a width of 5-8. Smaller widths turn out to be families and cluby, while wide organizations seem to become anarchies with no real way to operate in any kind of coherent or collaborative way. Certainly there's little reason to have any kind of boss in a very wide organization - either because there's no time to interact, or the staff groups are doing the bossing.

Digital seems to have both at the OC level, and within various organizations, evolved to a very wide organization with relatively low measured productivity (NOR/person) because we make so much of what we sell. Also, we have the standard motivations of power based on organizational size and position. We also evolve larger by wanting what we think is the direct control that comes from ownership instead of subcontracting to someone. Engineering, has evolved to be about the broadest organization, and similarly each PEG organization has become increasingly wide. Our rationale is to have high product visibility of our very broad product set. Larry and I've attempted to cope with the width by two techniques:

.

> Focussing on PEG as the line organization responsible for the total output of the organization. This allows some meetings to be reasonably small and productive.

Hopefully, we, however, focussed on the output.

.

Providing each of your 2 bosses for administration and product development functions. This means that there's a mix of interaction required among us.

The reasons why we seem to build wide organizations include:

1.

Every PEG member has a number of projects and the desire may be to have a high level reporting relationship to give the project visibility, get understanding and power. We simply like the interaction with a particular individual. Alternatively, we believe they must interact with us for some historical or idiosyncratic reason. We're afraid they won't be properly managed by a subordinate.

2.

The fact that we don't want to say no to anyone who might, for some good reason, report to us <?>. Similarly, we believe we need the information and resulting clout of another direct report to help manage. (Perhpas, we don't trust the line individuals.)

3.

There are service and support functions that can be grouped to reduce overall effort.

4.

We're matrix coordinated by external groups (Personnel and Finance) and feel we must matrix these at every level. Note, this has been the rationale for why an individual can have 2, 3, or up to 5 bosses. To my knowledge we've only gotten to 2, despite pleas for 3.

5.

We have co-team members, which together constitute complete product business units. These include

Marketing, Field Service, and Manufacturing. In effect this is a product divisional cut at Digital's functional organization.

6. We create a function that requires matrix co-ordination at PEG-level (administration, including space, computing, and operations).

7. There is coordination required for our product strategy, requiring more help.

I'm concerned that wider organizations perform poorly because:

1. There's lessened communication between levels.

2. In the spirit of team building, or because of individual interest, competence, skill or incompetence, work (such as space planning) tends to get smeared over several members. The result is lots of lost time.

3. The organizational goal, in our case product development, is diminished by the supporting team member goals and processes, e.g., college hires, IDP, product accounting, control, space, the planning process. All of these problems are important and have to be handled, but somehow we've let the collection rise to the top above our basic product development.

4. The goals of the individual development manager, whether it be me, a PEG manager, or one of your development managers becomes muddy. It shouldn't be: Our goal is to develop products -- this means we have to understand the products and the designers who build them. This also means we have to know these critical

designers and how to help them. We can't have a situation where I know these people better than you do (although, there will be <?>   To a first approximation, I believe all direct reports require an equal amount of time (if you take GB/LP together, then each Eng. Staff member has interacted about 2 X 1/18 or 1/9 with the head of Engineering. Clearly, neither of us could have managed such a wide organization alone.

5.

We don't get the necessary PEG work done because of the large group size.

I'm getting very leary of the notion of team building and teamwork because our work is basically segmented to individuals who simply have a job to do. There's no question of "teamness" because they have all the players, and the only thing we can do is cheer them as they run down the field! Often teamness means not butting up blocks, or calling time to ask'em/tel'em where to go. In the PEG world, the issues are: common products (e.g., Ethernet, services the overall product strategy) and processes that cross at least organizations. It's a waste to use meetings to manage individuals by flogging or pain conflict. PEG will be used to evaluate products in a critical fashion by peers.

LOC/MAIL STOP: ML12-1/A51

SUBJECT: SOME THOUGHTS ON CONTINUED ORGANIZATIONAL CLEAN-UP

As one of the diletantes in engineering, I am wondering whether we should only just have one? And I worry about me... cause I want to understand all products.

It seems we are spreading our basic products among more and more persons. Furthermore, projects are being managed and staffed with part-time persons-- a practice that is marginal at best. The result is that our whole management chain is defocused and has little or no understanding of the projects or products they manage, because the set is too broad. The only justification for this organization is because of the need for standards. Here, it seems to work for languages and other layered products, but this is the only area where it feels justified.

I'd like to see each part of your organization that is oriented to projects report as high as possible in your organization. Also, I believe we need increased project focus (versus level of effort) so that we can simply evaluate our output. Here, a project can be a product, a cad tool, 6 more nodes on the engineering network, the elmination of Journal vouchers, a One Week Turn Around Process for PWB's, etc. The point is that there is a resulting output, and a doneness criterion!

Several of our most recent project disasters have been caused by the burying of projects well below your level and you have not had the slightest idea of the disaster nor do you understand the product details. This is unacceptable.

It is vital that every product engineering manager understand the competitive situation in his product arena together with the status of every project he manages. Can we make the necessary changes to do this? Larry and I will be making several suggestions too!

Subject: Thoughts On An Associate Head of OOD

To: File

Date: April 18, 1979
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

I would like help in running OOD in order to free time that I might devote to working on more detailed implementation of the product strategy. In addition to the associate head, I would also like to leave the Operations Part in tact, to appoint a permanent secretary to OOD who would help in following up on dangling details, and most importantly, add the Product Manager Manager, as a supervisor for the Senior Product Managers. This would mean that OOD would consist of:

Me/the associate head/the permanent secretary

Operations (Personnel, Space, Finance, Central Svcs, EDP)

Technical Director (Arch., Tools, Diagnostics)

Product Manager-Manager

Manufacturing Interface (LSI and/or Mfg.)

Industrial Design, Packaging, Power and Systems Testing

Mass Storage and Semiconductor Memories

MOS CPU's, Small Systems and Terminals

Mid Range Systems, VAX Architecture and Interconnection & Networks

Large Systems

Software

In the next year, I believe the main things to be accomplished are to make the various groups more autonomous, minimize their interaction with each other and with any central support structure. They must be independent to a large degree, but yet we have to have the architecture in place so that the pieces they build work together when necessary. To me this means a central function which co-ordinates their plans, helps them resolve border conflicts across size, across technology, and across hardware and software.

Some of the issues I'd like help with:

Building a much better management system which includes
Long range planning
Control with Auditing
Making organizational structure changes (eg. better HW/SW integration)
Installing and repairing various processes (eg. EBOD, and especially moving from
Redbook to a continuous process with a 5 year horizon)
Putting in programs that cross organizational boundries (eg. DP, RAMP)
Organizational Development and Review
Specific organizational fires
Developing organizational interfaces with manufacturing and P/L's
Helping the Product Manager Manager get installed complete with planning,
and review

Subject: **Our Operating Systems: Can Anyone Else Make A Tree?**

To: ?

Date: 3 JAN 79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 1/17/79

Having drawn time line relationships of our hardware, software, languages, etc., let me offer the following observations at a time we need to be clear about future extensions to various systems. Since the future product strategy is based on the VAX ISP, there is much concern about whether a single operating system architecture (VMS) can be used over a wide range of system sizes, (single user...multiprocessor, Hydra, network) computing styles (timesharing, batch, real time, transaction processing). This concern is fully justified because:

0. there's no evidence (existence proof) that this has ever been done (e.g., 360, 10, 11);

1. systems are under constant pressure by our users and our own engineers, marketers, and field support people for increases in:

   a. file system;
   b. human interface;
   c. functionality batch, real time, transaction processing, timesharing;
   d. more languages with their implied needs;
   e. performance;
   f. reliability;
   g. distributed processing and network capability;
   h. market-specific functions --

commercial vs. real time.

2. all systems evolve in size 10%-20% per year. Although it is unclear how reliability and performance vary with time, increased sizes can place a higher swapping load.

In figure 1, I've tried to show a tree (taxonomy) of different system types. The basic thesis is that no matter what a system's roots are, they all tend to evolve to have identical functionality (e.g., RT as a single user to have Foreground-Background, and eventually batch when used in commercial environment; D as a real time system evolved to support IAS; M begot much of the IAS functionality and then M+ and SCS with cS an anomaly - as a compatible file-less sub-set; RSTS evolved from a single language timesharing to have batch and multiple languages; both the 10 and 20 operating systems evolved from timesharing to have batch, real time and transaction processing facilities.

We should fully understand what happened in the case of D, IAS, M/S, M+ and SCS in regard to building what I thought were to be a family of user-compatible operating systems.

<u>Possibilities for Family Members</u>

1. A single, time sequence of Fin???? releasees which will automatically have monotonically increased capability and functionality.

2. Subsets can be made by conditional assembly and system building in order to avoid the increases for all users. (E.g., 11M/S relationship). (A single version would be maintained).

3. Subsets can be made by dynamically loading (and/or distributing) the relevant subsets for particular applications.

4. Subsets can be formed both by conditional assembly and dynamic loading. This is perhaps the only way to get the reduced performance, number of processes, reliability needed to build truly <u>smaller</u> systems. I.e., various handlers, policy modules (e.g., schedulers, page management) will either be rewritten or written with conditional assembly to enable the reduced capability versions to be formed. (Multiple versions would occur.)

5. Branches for increased functionality that use common components and provide compatibility with a single user interface.

What Doesn't Work In Developing Compatible Systems

0. Sequential develoopment by independent groupd without explicit compatibility specifications (e.g., 11D - 11 M).

1. Parallel development by two groups, separated by more than one level of management, with the charter to develop two compatible systems (e.g., RT - 11/M).

2. Seeding a new branch through layering, using two independent groups (e.g., M - M+, M - TRAX, M - SCS).

Some Conclusions on VMS

Overall, I have several conclusions:

i. The only compatibility I know of, M/S was done by one group - furthermore we can only have a single VMS group, albeit one with groups working on independent branches.

ii. Taking a common base (e.g., M) will not automatically yield future upward-compatible systems.

iii. A new branch must have explicit compatibility constraints (i.e., a new release can't be both a super-set and a sub-set of the main branch).

iv. A new super-set branch should be identified in terms of specific, extended capability in order to avoid subsequent divergence with main trunk.

v. A sub-set branch must not introduce super-set, incompatibilities unless they go in the main branch.

SUBJECT: PROJECT TO DEMONSTRATE QUALITY AND PRODUCTIVITY

I am working in the Venus area to learn about quality and hopefully help demonstrate how it pays off in productivity.

The attached proposal seems like the best way to make the changes, and I hope to get the projects in place this summer to carry them out.

Right now, I'm thinking of a Monday Evening Summer Seminar Series (where all we serve is raw fish) that will have both speakers and case studies by our people on the processes.

Already there has been a positive effect, Will Thompson is establishing the project to get us the 1 week... which may turn out to be more like 4, versus the 8 (with unknown quality).

Also, note, I want to really clamp down on the engineers, as they have gotten unbelievably sloppy as the turn around times have gotten so long. The whole process bootstraps it's way down.

The corporate seminar may be a good place to kick it off, but right now I'm worried about being able to deliver at the intensity that's needed. Pete has had trouble getting any help from the groups to make a commitment on quality and productivity. However, I'm convinced it is the root of our whole future. BJ is the only group doing anything, or has the best understanding. Grant's group also does because of the inherent nature of errors on memories. We aren't limited by the rest of the company here at all.

As one tiny example, to demonstrate how quality and productivity
are correlated, I tried to get the journal voucher system changed
IMMEDIATELY so that we could get some instant productivity for
all our managers, just to show them we do care. So far, there
are no results: the system is apparently so bad and so
ponderous and apparently in the state of being redesigned that we
can't do anything. This is really sad and why it would be nice
to have a corporate focus and understanding about quality and
productivity. We really are fat (excessive= not quality), dumb,
and someone must be happy.

SUBJECT: PROPOSED ENGINEERING PROCESS BASED ON QUALITY & PRODUCTIVITY

A project is being organized in LSG to build a one week turnaround for correctly stuffed PWB's from SUDS input. The project crosses several organizations: LSG, LSG-Manufacturing, Physical Interconnect, Semiconductors, etc.

As we start to implement a one week fast turn-around project, the greatest use of capacity and hence, hinderance to turnaround, seems to be the correction of errors that should not exist at a particular stage, especially in design.

Currently it seems we have:

. too many changes on the first pass, indicating an incomplete design which we rush because turnaround is so poor because it's fixing too many errors

. too many passes to get FCS

. too many ECO's

Already it's clear we could change our processes to significantly
improve productivity and turnaround by:

. doing it right first where it's the least costly; and
. checking the output before forwarding the results to the next stage versus having front-end checks at each step (group) to filter for and correct earlier errors.

The steps of the entire process would thus be:

Design Engineering -

. Design using a functional specification and enter design into SUDS
. Check design (logic against functional spec) using either a structural walk-through or separate checking with full sign off by an independent designer or product support or diagnostics or quality organization
. Simulate the design
. Submit test data (topology, DC, AC tests, etc.) for testing final board

Drafting (beginning of one week turnaround) -

. Accept SUDS drawing, for PWB layout, subject to having a correct design with the two sign-offs by designer and design checker
. Layout PWB with guidelines from designer. Accept NO changes at this stage
. Using PWB checking rules, check PWB for manufacturability

. Prepare plot and drill tapes, check tapes and drills against SUDS

Manufacturing -

- . Prepare plot, checking plotter if necessary
- . Build boards
- . Check board continuity against SUDS
- . Burn-in and 100 percent check all IC's
- . Insert chips into PWB and inspect
- . DC test modules
- . AC test modules
- . Send correct module to designer

While these are major changes from how we do things today, I would
like to start now to make them as I see our designs deteriorating
under increasing complexity and module loads. We are hurrying to
submit poor designs because the system is choked correcting designs.

In case of modules made using wirewrap or multiwire, I believe we must
keep the same checking discipline: Design it right, check the design,
build it right, then give it to the designer to verify that his design
was correct! Now we're using these early breadboards to do the
design!! We have to eliminate the old style designs which are done by
wire guns!

Fundamentally, the proposal is simple:

.do it right the first time and check it...otherwise don't go to the
next step; and
.stop building breadboards we know are wrong and will not work and

that have to be changed.

I propose we start this today, and in no case do I expect it to not be
in effect, September 1, 1981!

What do you think?

LOC/MAIL STOP: ML12-1/A51

SUBJECT: KEN'S ALTERNATIVE MONITOR FOR THE CT

Ken just asked me to have us RELOOK at the CT monitor package BEFORE we commit to the manufacture of it within the next 2 weeks.
Will you establish what this deadline is so that we formally decide (probably at the Operations Committee) what the official
CT monitor package is?

Ken has made several sketches and Dick Gonzales is making a proto of an alternative. Ken would like Dick Schneider to get involved right now so that the package will also be appropriate from an esthetics and human factors viewpoint.

Ken is doing this packaging for the CAT computer AND because I've
constrained us to have only ONE monitor for our next computers
and terminals. We can't continue to blow or resources by massive
redo of electronics and packaging that only add inventory
and get us no new capability... hence I will not let us have many.

Before we get into the packaging redo, we ought to decide on what
is being addressed by redoing the CT package. I want Ken to
respond to this to us all by tonite, but my understanding is:

Make it small so it can fit on a clean desk and will look good.
Make it so it can be used by the professional too, but will be
unobtrusive, yet ergonomically sound
(I'd also argue that we want it small and useable with modular
desk furniture like the Westinghouse or mine. In this regard,
we need some method of mounting the tube so it can be taken off
the desk surface so as to get desk space and further
reduce clutter.)
It should be useable with both the CT and smaller CT (CAT).
It should (not a constraint but a goal) look very similar to the
larger color version that will be part of the next CT.

In this endeavor, I see the following steps:

Bill set the cutoff date.
Ken and everyone else will input goals and constraints (don't
just accept mine above).
You folks propose several alternatives and a recommendation
The OC will decide among the alternatives, based on how it

looks in various applications (You must quickly decide on just
what these are. Are they: clean desk, modular desk, seperate
terminal stand, secretarial desk/table, living room end table?
(In all cases, we have 3 times more cases: stand alone (with the
keyboard), with CT, with a smaller CT box.

Please by Friday evening get the whole design alternatives, end date, and criteria put together.

GB2.S8.30

January 9, 1979

Richard Palais
Professor of Mathematics
Brandeis University
Waltham, MA 02154

Dear Professor Palais:

I've sent your letter on to Jerry Witmore, who's head of our Education Systems Group. They're responsible for supplying the 2020 to AMS. You should work with him in any joint venture. Also, Ulf Fagerquist, head of our Large Systems Engineering Group, would be involved as a supplier, user. I would hope we could work with you as I'm impressed with TEX and would like to bring it in-house. Hence, we also would need an interface to the Versatec.

Let me urge you to consider a computer independent interface by using a simple intermediate computer (LSI-11) and a standard serial interface to the 2020. It would hold the conversion code and drive the plotter. Hence, all programming could be done at the user level. Alternatively, there is a Versatec interface or other standard Unibus interfaces that would probably work. Hence, I see no problem of needing new hardware.

Sincerely,

Gordon Bell
Vice President,
Engineering

Gordon Bell
Vice President of Engineering, Digital Equipment Corporation
Professor of Computer Science and Electrical Engineering (on leave)
Carnegie-Mellon University

Two highly distinct paths for establishing a national computer industry illustrate the high costs and benefits involved in achieving this goal. The most conventional approach to establishing an industry is manufacturing-directed licensing, starting with components in a bottom-up fashion. The ultimate goal of indigenous design is usually called "forward integration" of standard, components expected to have long life-times. In contrast, for rapidly evolving, or high technologies with short component life times a "top down" oriented user-based approach with the ultimate goal of indigenous design can be categorized as a "backward integration". The computer industry falls into the second category since many rapidly changing disciplines and technologies are required for building and using computers. By initiating a policy based on the second approach a country will not only rapidly establish an appropriate computer, <u>based on international standards</u>, industry but will become self-sufficient quickly, and with less imports than by taking forward integration manufacturing approach.

Backward integration necessitates the selection of one or more standard computer families and may even have a goal of establishing and indigenous architecture and programming language to further control inputs. It is desirable to <u>not</u> segment and control the market by size because emerging distributed processing systems are built more easily from a single general architecture. The adoption of an international "standard" allows rapid take-off in computational ability and is based on four criteria: 1) wide range of applications programs enabling immediate effective use; 2) cost-effectiveness and expandability as shown by various metrics and address space size; 3) availability of a family range from micro- to mainframe computer so that a small number of architectures (hopefully one), maximizes training, permits alternative computing styles to fit various problems, and results in a maximum cumulative learning curve; and 4) compatibility and accessibility through numerous sources of supply for peripheral equipment and software.

The poorest method for establishing a high technology industry is by government sanctioned, local monopolistic companies. For example, a company selected a high cost, non-standard, low performance basically obsolete computer for license from a North American that might have failed except for its exports to its foreign "licensee". This company then promised their government the following three-year, three-stage process: putting together sub-assemblies, and finally building sub-assemblies from imported circuit components under license. After five years, the local "manufacturer" was still importing finished goods, and no progress has been made toward local manufacturing. The computer was fundamentally unable to accomplish most of the tasks that were promised. The local company has a monopoly that has cost the country roughly a factor of two or $34M in balance of payments over the promised commitment and $50M over what could have been accomplished under a policy permitting competition for users and for manufacture. (See Appendix 1) Also, the users have paid a factor of 5.5 times or $400M extra for equipment because user applications, such as programming, maintenance, and operations costs (e.g. power and air conditioning) are several times greater for technically obsolete equipment. Certain applications are not possible, and where possible but not available, effort has to be expanded in doing applications.

Rather than using monopolies to establish industry, a simple policy could help establish local industry: each computer purchased would be approved by the government based on the total import cost prior to duty. The incentives to all would be clear and the system would self adjust rapidly! Alternatively, simple duties of any percentage, would work just as well, no doubt, avoiding bureaucracies, hassle and loss of productivity!

The Ongoing Computer Evolution

The computer has evolved more rapidly than any other man-made object as measured by improved price for a given component or by improved performance at a given price. By either of these measures, the rate of improvement is 20 to 30 percent per year. This means that if a given system at year (t) is 1.0, at year (t+1) it will be 0.8, and at (t+2), 0.64, and (t+3), 0.51. Every 3 years, the price halves. These measures have held constant for 20 years, and do not even take into account inflation. In contrast, nearly all consumer goods, such as automobiles, have increased in price at least an inflationary rate!

By the end of the seventies, computers have become all pervasive including many hardware technologies, some of which have necessarily evolved more rapidly than the normal rate. Major computer components are semiconductors, magnetic recording, conventional electronic sub-assemblies, various printing and xerography, video display, human speech i/o, analog i/o for process control and conventional communications. The software technologies are even broader, ranging from operating systems which administer computers to conventional computer languages in which application systems are written. Since computers can either supplement (and in some cases supplant) every other form of information processing, the almost infinite number of applications require broad technological expertise. Information processing includes all aspects of storage, transmission, switching, control, and processing. The software specialists must know the subject of the application deeply and unambiguously so that it can be made algorithmic and they must know the computer almost as well. In all fields, we continue to see manpower and training as limiting computer use.

Establishing a Computer Industry via the Forward Manufacturing Approach

The conventional manufacturing approach for establishing an industry usually cuts off external supply by sanctioning various firms to operate as monopolies and builds up internal manufacturing via licenses, joint ventures, and favored manufacturers. Only essential components and manufacturing equipment are imported. This approach is most successful when the evolution rate is low (i.e. automobiles, tv sets, radios) or where the ultimate goal is world market domination. However, in either case, the essential first step is the manufacture of all components, raw materials, and in some cases the equipment to manufacture components. For example, even though the Japanese have had the goal to dominate in computer manufacturing for 25 years, until recently they lacked the internal manufacture of critical components (e.g. semiconductors and magnetics) as well as software technology. If Japan, or any other country, starts with the goal of internal computer manufacturing to limit imports, the flow may well become increasingly more negative due to increased reliance on critical outside component and software suppliers. For example, had a country engaged in manufacturing transistorized and MSI based calculators in 1975 with imported semi-conductor components, in 1978 it would be possible to obtain the complete calculator for less than the imported component cost because with each new generation radically different parts are used. In a similar case relating to computers, more imports of raw materials occurred to build expensive disk memories and computer systems that were obsolete on completion. Purchase by??? completion date would have been cheaper since the price halves each 3 years.

Virtually every country that has operated a protected, computer industry (except recently Japan) has paid a significant price in terms of both imports and price to users. Computing with obsolete computers, has cost the country scarce resources to design, apply, and operate. This also defers economic gains of computing and facing critical applications questions. Only the government sanctioned monopolies (often owned by a few individuals) have profited!

Simultaneously establishing the manufacture of the critical base components, test equipment and component manufacturing equipment for a high technology product like computers is probably not feasible. Even manufacture of the lowest technology parts (e.g., printed circuit boards) is hazardous because these components may limit the final product as described in the calculator and computer components examples above. Manufacture of high technology components is generally not feasible because they evolve so rapidly that they do not achieve the learning curve without a significant market; require very high cost plant and equipment which is obsolete at a rapid rate: and require a highly skilled manufacturing engineering base to manage and interface with the design engineers. It's interesting to note that neither state-of-the-art (i.e. cost effectivve or least cost) disks nor semiconductors are manufactured away from their design group.

Since the critical resource for the manufacture and use of computers is educated manpower, their effective allocation has to be central to any effort in establishing a computer industry. If these limited numbers are utilized for manufacture, then there are few left to do the critical systems applications jobs. Reversing the allocation using the skilled manpower to use computers for significant and necessary tasks will lead both to a more rapid computer population and their manufacture locally.

Establishing An Industry By An Indigenous, Local Design

Most attempts to design, produce and sell computers either fail to meet their market and profit objectives or fail to be cost-effective over competitive alternatives. Many U.S. and foreign firms who at one time engaged in manufacture no longer exist in the market. Computers designed for special purpose (e.g. Military) have been shown to be particularly cost ineffective over their standard, commercial counter parts such that the distinction has finally disappeared.

While many of the scenarios described above have particularly poor effects on all aspects of an economy, a local indigenous design is likely to have the worst effect. The temptation is especially great because the art of computer design (architecture) is fascinating. By not adopting and backward integrating, untold resources are required to engage in hardware and software design that could otherwise be applied to implementing computers based on standards, or be applied directly to applications.

Establishing A Computer Industry Via the User-Directed, Backward Integration Manufacturing Approach

A policy that encourages using state-of-the-art computers to be applied in a standards-setting fashion will ultimately result in appropriate local computer manufacture. The selection of the right computer standards is essential, otherwise the situation is exactly what countries that do not have a computer industry fear--manufacturer domination.

It is interesting to note that until Japan adopted the approach of building computers to the IBM standard, its machines were uncompetitive (even in a closed market) and were ultimately withdrawn, requiring user program conversion.

The backward integration path was followed, interfacing with many manufacturers to license computer architecture know-how and hardware technology. Ultimate success occurred by an open market, by using the standard, by engineering near copies, and by its own large internal market. The standards for computer selection are:

1. Maximum range of applicability - germane to evolving applications. Leverage of internal resources can be gained by selecting the most appropriate machine family for the key range of applications.

2. Valuation balancing the conventional metrics for cost, cost/performance, and address size. A trade-off for larger address-space may offset short-term gains in cost-performance with smaller address-space.

3. Large family range of machine models from micro to mainframe. The utilization of one family versus a variety of machine-types maximizes the learning in terms of physical implementations, architecture, and software across all system ranges from the processor-on-a-chip (often called a microcomputer), through dedicated systems for special purpose use (often called a minicomputer) and to a large, shared, central system serving many users and managed by a staff (often called a mainframe). This would help achieve a critical mass of local experts.

4. Be available from numerous suppliers in a "standards-based" fashion. Ideally, each machine in a range would be the "defacto standard" machine. A defact standard has the following characteristics: a large fraction of installed units; well-defined system interfaces that manufacturers, users, and third-party suppliers understand; and many supply sources so that a user can build up systems by assemblying components via numerous fashions.

By using a standards-setting system, one is assured of having the latest models available, alternative competitive sources of supply and a method of intercommunications that has lasted and will last over time since it is understood and used by many different groups.

It is the "standards" approach that provides the method for backward integration into local manufacturing via the following steps.

1. Import complete systems and assign them to critical applications. This will help attract back any computer scientists and engineers attracted by the charisma of exciting problems using state-of-the-art computers who have left the country in what has been called the brain drain. During this period it is important to take advantage of the training systems now developed in North America, Europe, and Japan, just as the Japanese took advantage of these systems when their industry was embryonic.

2. Enlarge applications specialties to include special systems interfaces. Special hardware interfaces could be provided by users, the applications industry, and manufacturers. This would create the base knowledge for the ultimate design and manufacture of computers.

3. User and applications industry would begin to import "standard" alternative manufactured computer options (e.g., memory modules, disks, terminals) to minimize systems costs. Systems would form from components by having local final assembly and testing. By this time a critical teaching and research mass will have been reached at a significant level internally so that the appropriate computer scientists and engineers can be attracted and held. Training, research and development will be primarily nationally based, maintaining the continual need for international cross-fertilization of ideas. However, these critical nationally attained skills are necessary since many computing applications are culture-based.

4. A secondary supplier industry would develop based on both buying lower level components (e.g., integrated circuits,

disk drives) and interfacing to further reduced imports. Computer options would start to be manufactured locally both based on foreign and local designs.

If a user-directed policy were implemented, one might see the beginning of stage two within one or two years, followed rapidly by stage three. Finally local peripheral interface designs marking stage four could occur as early as four years from the time of the policy adoption.

During all periods the number of computers, useful local applications, and most importantly, computer scientists and engineers, who provide a strong intellectual base for the industry, would grow. Simply trying to assemble imported, likely-to-be-obsolete components with the manufacturing-based policy defers the applications that build up a critical mass of manpower, applications, and computers.

Appendix 1 - Case Study of Santioned Monopoly, Free Market Import and Backward Integration Strategies

In one country a sanctioned monopoly was set up to license and manufacture what was basically an obsolete computer. The following analysis of a five year period shows, in principle, the situation. It neglects any user loss of productivity because of poor computers, and any import duties (since the licensee was given duty free status).

Four cases are compared:

1. Monopoly (actual) - no manufacturing was achieved and licensee only imported finished goods.

2. Monopoly (plan) - the monopoly was to have imported finished goods the first year, put together sub-assemblies the second year, and assemble the sub-assemblies from components the third year.

3. Free Market Import - No controls, are assured. The most cost-effective system is imported.

4

. <u>Free Market Import with Backward Integration</u> - Case 3, except a policy which gives preference to minimizing import content is instituted. In the second and third year sub-assemblies are put together locally and in the fourth and fifth years sub-assemblies are built from imported components. The base design can only be changed each two years for new components!

A summary of the results of the four cases using various costs, markups, and market data is described below:

	Total Import (M$)	Local Mfg (M$)	Cost to Users
Monopoly (actual)	78.2	0	488
Monopoly (plan)	44.2	34.0	488
Free Market Import	44.1	0	88
Free Mkt Import with Mfg.	32.0	17.2	83.3

For the study, the market is assured to grow at 50%/year using the following units: 295 (first year, 443, 666, 1000, and 1500 (fifth year).

The following markups for sales and service are assured:

Monopoly (actual)	6.25
Monopoly (plan)	6.25
Free Market Import	2.0
Free Market, Local Assembly	2.5
Free Market Local Assembly and Sub-Assemblies (using imported components)	3.0

It is further assured that the following local content is possible.

Importing Finished Goods	0%
Importing Sub-assemblies	25%
Importing Components	50%

Year Price (Case)	Import Cost/ Unit (K$)	Total Import Cost (M$)	Local Mfg. (M$)	User Price (K$)	Total (M$)
Monopoly (actual)					
1	20	6	0	125	36.9
2	20	8.9	0	125	55.3
3	20	13.3	0	125	83.3
4	20	20	0	125	125
5	20	30	0	125	187.5
		78.2			488.
Monopoly (plan)

SUBJECT: RE: ISSCC - J-11 PAPER

NUTS!

Get the project done. Then write it up. It is behind schedule and is likely NOT to pass the ISSCC requirements for a working chip. All that we do is signal that we are TRYING to build a product. A paper on J would be in violation of spirit of ISSCC.

We still haven't shipped a T and now are in our 5th pass. Furthermore, we will have at least 3 more with a major redesign in store if I hear the signs right.

For now, we have too much work in Hudson to do to spend writing.

GB2.S8.34

Two Lieutenants: A Parable on A Parable

In the early days of the year 1979 there was a famous parable about two lieutenants who came back from a meeting with their commanding generals. One transmitted the message to attack a particular hill at 0700. Two got the message that there was dissension among the generals and that there was likely to be bloodshed if said hill were attacked. Two met with his group to plan a way to convince the generals not to attack the hill. The alternative plan would be delivered at 0700.

Here, endeth the first parable

Like any good parable, it is simple and has a message. The following tactical probabilities make other, interesting parables:

1. taking more than one hill, given both groups;
2. taking the hill, given both groups;
3. taking the hill or hills with only one group;
4. annihilation of the groups for the given attack forces;
5. annihilation of the generals' camp.

Furthermore, there are various situational rewards:

1. medals;
2. promotion for results at the hill or hills;
3. getting killed.

And one might believe that Two's troops included sergeants, and possibly women, who would:

1. actually go for the hill, as apparently directed;
2. go back to the generals at 0700;
3. retreat.

The final result of the attack turned out to be:

Lieutenant One's Group was annihilated and he was given a post humous dishonorable discharge.

Lieutenant Two's Group scattered. Some of the professional soldiers sold out as mercenaries, two sergeants were killed (possibly by their own troops) and got big medals, and the rest were captured, soon traded back and went home.

The camp containing the generals was captured while the generals were discussing Number One's bad luck. The general with the most stars escaped and went back from the fighting as chief of staff, bringing with him his promoted assistant, Two.

Moral, aside from being careful about getting involved with

people who fight and about knowing when to run, because parables are as complex as taking hills:
Given a few people and a simple situation, things never turn out to be as simple as one would think beforehand... or, complexity sure can kill a lot of people.

Given our interest and affinity to want Pascal, I fail to see why we're not using one of the many versions for the LA124. It's available on the 8080 and 11, and permits movement of programs (eg. LA124) to Tiny.

Why aren't we using it?

The strategy looks good, but:

1. Why don't we buy the new OMSI-11 Pascal instead of doing Micro Pascal?

2. Why staff so much on Pascal+ on VAX?

3. How are we going to keep compatibility among the products?

4. How's # 3 doing so far?

5. Will we be able to have Pascal+ be the base for the ADA run time system?

6. Why can't we bring in the current Pascal 11 now from OMSI for use internally (e.g. special LA's, new terminals)?

Who's responsible for watching/co-ordinating Pascal on VAX?

How's the project coming?

Can we get them here for a design review?

GB:ljp

October 10, 1978

Mr. Stuart Patterson
National Center for Atmospheric Research
Atmospheric Technology Division
P.O. Box 3000
Boulder, Colorado 80307

Dear Mr. Patterson:

Let me take this opportunity to thank you and your staff at NCAR for the fine hospitality and interaction on the 3rd. It was truly an honor to talk about VAX with such an outstanding group. The trip through the computation center and seeing the Cray 1 was a high point.

It was intriguing to speculate how we might use smaller computers (such as VAX), located within an individual scientific group, to provide similar levels of service (for over 90% of the users) to that obtained with the Cray 1. I hope Dawn can get some benchmarks and understanding of the NCAR user profile from you. Such a system will, of course, exacerbate the need for networking. Here, I hope you might avail yourself of some of the understanding we have of networking within the Denver office and also visit our network group.

In order to really get a better understanding of your future needs, I'd like to get you to write down and present us with various scenarios of how you see the NCAR computation needs developing with time. We could then understand and respond to your needs. Could I ask you to come and present this view some time when you're in the area? This would also be the basis of seeing whether we could help in the network area.

Again, thanks for the hospitality.

Sincerely,

Gordon Bell
Vice President,
Engineering

Mr. John Payne
National Semiconductor Corporation
2900 Semiconductor Drive
Santa Clara, CA 95051

Dear John:

I'm glad that there is increasing concern about National's future microprocessors. I'll be in the Valley during the week of the 10th of December and hope we can discuss the progress and direction then. I see three critical issues:

1. Get the 332 done and out by May
2. Establish the overall goals and constraints for the 532 project now. Follow this up within a month with a review of the functional specification and high level design. My target, is described below, but may not be aggressive enough.
3. Deciding on a longer term, hardwired architecture, which has 32000 data-type, operating system and language compatiblity to compete with the so called, reduced instruction sets, including MIPS Co.

The 532 described below is needed within two years, in order to be only a year late!

Here's some background data that we might start from:

```
      Machine Implm.  Clock
                                  Ticks/     Speed*   Mips
                      (ns.)  (Mhz) instr.
VAX
750         u       250    4   11         .75    .375
780         up      200    5   10        1.0     .5
8600        u4p      80   12.5  6**      4.2    2.1

32000
32032       userial 100?  10   27         .75    .375
32332                                    1.9
32532       u        30   33   15        4.4    2.2

Risc II     hardwire       83  12        8      2.0      1.0
(1.5)
MIPS Co."   250      4     4   2.0       1.0 (1.5)
```

* Note the 780 is commonly rated at 1 Mips, but actually runs less than 0.5 Mip when averaged over a long period. The rating comes from doubling the number which roughly corresponds to the number of 370 instructions which would have to be executed to do the same work.

** The 8600 (Venus) has a multiple stage pipeline, each of which is very complex to fetch (Ibox), Execute and do floating point. In addition, there's a special interface (Mbox) to interface the cache and memory.

Note the large number of ticks required to interpret the average instructions in the 032. Some recent benchmarks show that the 032 is probably able to keep up to a VAX 750 if you ignore the slow floating point in the 032 and use the same, poor UNIX compilers. I'd like to see the Whetstone numbers you have here.

The 532 above would use a package that would let you get all the 32 bit or possibly 64 bit data and 32 bit addresse lines in and out rapidly. The design should be incredibly simple and brute forced, not piplelined. Note most of the performance comes from the technology (3.3), the other performance gain should come from a 32-bit organization (2) and a wider microprogram control. The MMU should be on chip, like the Microvax chip, in order to avoid the package and handshake delays. I assume this can be done with double level metal, 2 micron CMOS, and most certainly 1.25 micron CMOS. I think it is also crucial to utilize Weitek in your planning to reduce the internal work.

I believe it is possible to build an ECL Risc that's 10-20 times faster than a 780 for programs (but may require 1.5 times the number of instructions) using a 25 mhz clock. This would have about 3-4 ticks per instruction, and could be implemented in CMOS. An article by Jean Yates is enclosed which describes the opportunity of Riscs.

While it is crucial to persue all three paths in parallel I would like to concentrate mostly on the first two on this visit to insure they are on the right track. Then we should explore ways to get a faster architecture.

Sincerely,

Gordon Bell
Chief Technical Officer

CMU SPICE ADVANTAGES

1. LARGE, CYCLE-INTENSIVE PROGRAMS CAN BE RUN EFFICIENTLY (NO SWAPPING OF N USERS)

2. MICROCODE TO EACH TASK

3. HIGH RESOLUTION GRAPHICS (PERMITS WORK ON VLSI LAYOUT)

4. NATURAL COMMUNICATION

VOICE AND VIDEO

5. EACH USER HAS A BIG COMPUTER TO SELF

6. RELIABILITY

7. EXTENDABILITY IS REALLY MODULAR

CMU ASSUMES

TIMESHARING IS ENDING

SMALL, HIGH VOLUME SYSTEMS WILL EVOLVE TO BE EMBEDDED IN TERMINAL

NO EVOLUTION OF CENTRAL SYSTEMS TO

SOLVE RESPONSE TIME; PROVIDE MORE; BEST SHARING

PROVIDE DIGITIZED AND RECOGNIZED AUDIO (AT + T FUNCTION?) -

STORE, TRANSMIT AND PROCESS VIDEO

(BECAUSE LOCAL TRANSDUCTION/PROCESSING IS NECESSARY)

<u>CMU SPICE SCENARIOS</u>

1. DOCUMENTATION PRODUCTION INCLUDING <u>ALL</u> FIGURES COMPLETE PAGE LAYOUT

2. PROGRAM DEVELOPMENT USING COLOR, EMACS-LIKE, CO-ORDINATION WITH TEAM/MANAGEMENT

3. PROGRAM DEBUGGING

4. VLSI DESIGN

5. MULTI-MEDIA COMMUNICATION (TEXT, FIGURES, SPEECH)

6. NON-INTRUSIVE COMMUNICATION

7. TELEPHONE ANSWERING SYSTEM

8. INFORMATION DISTRIBUTION

WHAT IS CMU CSD SAYING?

WANT / NEED? MANY MORE CYCLES/SEC; Mp; Ms (CURRENTLY 200 USERS SHARE 2 KA, KL, 3-780'S) TO:

DRIVE MUCH BETTER SCOPES AT FULL DATA RATE (Pc)

EMACS TYPE EDITING (Pc, Mp, Ms)

ABILITY TO MANAGE A TELEPHONE AND VOICE (Pc)

PICTURES (AND GRAPH) STORAGE, TRANSMISSION AND PROCESSING. (Pc, Mp, Ms)

WANT A CENTRAL FACILITY FOR FILES, PRINTING

DON'T SEE A NEED FOR A HIERARCHY OF CAPABILITIES OF PROCESSING

HOW DOES A PERSONAL SYSTEM DIFFER FROM A SHARED ONE?

. TO A USER, NO DIFFERENCE EXCEPT:
CONSTANT RESPONSE TIME
LOTS OF RESOURCES (Pc, Mp, AND Ms) TO THROW AT TERMINAL,
SPEECH, VIDEO

. IS ECONOMY OF SCALE OF WHAT MATTERS DISAPPEARING?
Pc -> 0
Mp -> 0
Ms = CONSTANT; SIZE INCREASES
.ECONOMY OF SCALE
.PERFORMANCE LIMITED BY MECHANISM
T.CRT -> 0
= CONSTANT; SIZE INCREASES
T.COMM = CONSTANT;
= INCREASING; UNAVAILIBILITY
T.LOCAL AREA NETS = ?

. LOTS OF RESEARCH QUESTIONS
MAKES EXPLICIT PROBLEM OF MULTIPLE, NEED TO CO-OPERATE/INTER-COMMUNICATE
DIST. DATA BASES
DIST. PROGRAMS AND PROGRAMMING
INTERFACING OTHER SYSTEMS

. IN SUMMARY
WE ARE TAKING LARGE SYSTEMS PROGRAMS THAT WERE EXECUTABLE ON CENTRAL SYSTEM AND BRINGING THEM DOWN TO OPERATE ON THE MANY INDIVIDUAL- AND GROUP-LEVEL COMPUTERS.

THE DEDICATED PROCESSING WILL PERMIT SYSTEMS TO BE BUILT WE NOW DON'T UNDERSTAND.

SUBJECT: FOCUS ON A MICROVAX PC

GB4.S1.42

We're driving like crazy to get 1 or 2 significant PC's based on MicroVAX and the Qbus. The first implementation is with Cutler's 2-board MicroVAX.

The options are:

. the disks, including floppy (for loading)

. the connection to an Ethernet and some other net (if necessary)

. Cutler's MicroVAX, followed by MicroVAX chip & board

. Two or Three Crt options:

  . low resolution - probably 15" monitor or CT-compatible screen
  . hi resolution - 19" monitor

. color (simple)

. Board to interface a laser printer to make a print server

We need to go back and address our technical market who are buying HP, Apollo, the IBM 9000, Sunworkstation, and are looking forward to the Apple Lisa.

Will you provide the box?

At this time we're trying to get 3 MicroVAX-based PC's.

1. Rainbow III - Barry will get CP/M to be transportable and move to a 32-bit micro. They'll probably do this for a 68020, which will be in the same time frame. This will be a portable operating system.

2. Pro 750 -

3. The Qbus-based PC's using your box.

If we play our cards right, the situation will be:

1. CP/M - It will evolve to be multi-user, and ultimately transportable to 68K - and MicroVAX.

2. UNIX - on 68K, Intel, 11's, VAX, IBM 370.

3. Vanity systems (eg. Apple, Atari)

4. One language, no O/S (eg. TRS).

5. DEC-VMS compatible - permitting dynamic movement of files and programs. Let's continue this and keep our compatibility, quality and coherence.

"TO" DISTRIBUTION:

ED KRAMER	KEN OLSEN	JACK SHIELDS
JACK SMITH		

WPS USERS - Leave HP mode and type <CR>

These 5 slides (definitions) may be of interest to you. They try to segment what and how computing is (and may be) done.

A TIMESHARING COMPUTER consists of:
.processor and primary memory,
.secondary memory for programs and data,
.communications links to other computers and to
.human interface terminals (eg. CRT and keyboard).

A timesharing computer is used interactively by several persons in a shared fashion. The computer belongs to a group, while the terminal ususally belongs to an individual.

A PERSONAL COMPUTER consists of:
.processor and primary memory,
.secondary memory for programs and data,
.communications link to other computers, and
.human interface components (eg. CRT and keyboard).

A personal computer is used interactively by one person at a time. The computer usually belongs to an individual. (LINC is the first to satisfy this defintion, if you ignore the addtional constraint that says a PC must be portable!)

A CENTRAL FACILITY (mainframe) provides:
.network communications among computing nodes, with conventions for exchanging data,
.archival storage for group and personal facilities,
.large, shared, central data bases,
.large, special facilities beyond group or person (eg. printing, plotting, high performance processing, electronic mail),
.general computation on a service bureau basis.

A GROUP LEVEL FACILITY (timeshared minicomputer) provides:
.ability to be part of communicating network,
.intra-group communications via the facility,
.shared programs and data for a single group,
.special facilities for the group (eg. microprocessor debug, simulation, printing, plotting, processing),
.shared, general computation for members of the group.

A PERSONAL FACILITY (personal computer) provides:
.ability to be part of communicating network,
.private programs and data for an individual,
.fast response for simple human interactive (eg. editing) tasks.

SUBJECT: MAKING COST-EFFECTIVE PC'S. LIKE SONY?

The SEG proposal to get a chip of the month out is vital to our success. The recent Sony announcement very likely is a result of intensive custom LSI. Note that they use VAX's and 4 years ago when I visited were already doing much custom work for consumer electronics. Their president, Iwama, was proud of the fact he had worked with Leo Esaki and that Sony was the first to pick up the Western Electric patents.

If you look at their recent, portable stuff, it is really VLSI intensive and probably CMOS to boot. It would not be a surprise if this is what it's all about.

Recently Avram showed that we have 2 x the chips as the IBM PC. We do more, but the issue may come to cost, reliablity and uniqueness or not. In this case, IBM probably had no customs. Clearly guys like Apple don't use customs, or if they do it's joint with another vendor.

Right now we are in an abyss that the chip a month program has to get us out of:
1. We believe we can do our own chips, yet we don't
2. We've cut ourselves off with working with the outside
   to any great degree

3. We don't use standard chips because of our uniqueness needs
4. We've stopped outside customs that gave us uniquenss in the vt100 and la120

SEG is going to need help and every product group is resposnible
for its own competitive destiny, without having the right skills, attitudes and sufficent targets.

Now that we have the PWB and cabinet turnaround times down, using the QTA, we have to have a CQTA!

Avram, What's your guess here vis a vis looking at their Typecorder and Word Processor? Is the Sony PC another breakthrough in cost and functionality?

SUBJECT: PDP-11 PROGRAM ENVIRONMENT ON VMS

Several events have prompted the following proposal:

1. Wondering what a 370 in a terminal would be and do, vis a vis use with a large 370 mainframe.

2. Speculating significantly better software support systems for our microprocessor systems. (Also noting that Intel is supporting their 8086's on VMS...smart people.)

3. Terrified at building the KO Jr. (65Kbyte + 2 - 200 Kbyte disks) and KO Sr. (256Kbyte + disks + 5 Mbyte disks) software on them.

4. Thinking about how we might get rid of 7000 PDT 150's.

5. Wondering how to build and debug software for intelligent terminals (especially the new ones for the commercial group).

6. Thinking how vax on a chip and in a terminal would work with a centrally supported type vax. Wishing that 11's were vax's, but remembering that vax does execute 11 programs damn fast.

Fundamentally, I'm proposing a bare, full function, virtual 11 environment for building 11 programs on vms. In addition, it might be sufficiently good so as to be useful for executing particular programs in production mode...though not a goal.

It would look like a simulator that was used at one time on the 10 to do 11 development before there was 11 software, and have:

1. The mass storage, terminals, and communications to vax with processor, including interrupts. It would run at faster than 11 speed for the small processors. Most likely it would have a terminal to control it and a terminal simulating the real one.

2. Software environment to load, run and debug programs in the simulated environment. It would allow monitoring of the whole state including the files and comm lines.

3. Ability to load and monitor a real 11 when ready.

4. Fallback of a really good monitoring and support capability enabling control of a real, local 11 such as the KO or PDT or computer on a board (a harder case). This is double, but still tricky cause it requires vms to have a monitor to access all the state of the system and to be able to have breakpoints, etc.

It would be aimed at applications 2-5 above, especially 3 & 5.

What's the chance of getting something like this together out of the SSC effort in order to support the effort on getting lots of software quickly for the PDT 150, and the KO?

What would it have precisely?

Would it really make things a lot more productive...not

waiting for
disks, assemblies, etc. or having to have the software development
environment anywhere near the thing being developed?

What youse think?

follow up 3/9/79

I hear that we have all but announced this. What's the story? Why was this announced without Marketing Committee approval?

What are our options now?

Can we delay announcement and get the PAX in it (especially since there's a problem in semiconductor capacity)?

Certainly we don't need the 11/24 early...and, can we save some engineering money? We do need Fonz to be built in to other products. Could we give them high priority?

SUBJECT: KEN'S COMMERCIAL 11/23 PACKAGE

I hope you'll keep abreast of this. It looks interesting (provided we can remove the contact paper). If we do it, it should offer a significant payoff in terms of cost. The big saving I see is making the long box in a high volume plant
and then shipping the manuals, software (on disks) and frame from FAT. The disk drives would come directly from high volume.

The site merge of the parts would cut the inventory and wip down considerably. (It's too bad we simply don't simply assign an inventory carrying charge to PL's to encourage them to do the right thing.)

The package should be able to handle a 23B 9 slot backplane. We also might consider taking the DF03 modems out of their boxes and use a single PS (if the 23 one will do it), to further clean up and cost reduce the whole system.

Am anxious to see what the costs and a working system would look like.

Subject: **Post Mortem on 11/70 CIS**

To: Bill Demmer, TW/D19 Date: 3/12/79

Dave Rodgers, TW/C04 From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

I hope in putting the 11/70 with CIS away, you will write-up a history as you understand it. As I go back many years on this project, I find us always pushing against doing the extensions. This is understandable. However, some of the marketing people occasionally say this has been the problem on the project. My analysis is somewhat different, I believe any machine or architecture can be extended <u>once</u>. In this case, the extension was the second/third one beyond the original 11/45 and well beyond the range of the design options due to nature of the two extensions. Alternatively, was it because of two design options for mP and CIS?

We (I especially) learn from history. Is it too painful or too useless to try to make an internal history of the project that we can all learn from in the future?

Stan Pearson, ML12-2/E38
Bill Strecker, TW/A08
Mike Titelbaum, ML1-2/E65
Roy Moffa, ML1-2/H26

Although there are many arguments why we have to carry out this expensive chip development effort, the following summarizes my thoughts:

1. It's a classic follow-on, constant cost product for our module (DCG) business. Here, we have a large base built on the 03 ('75), and 23/24 ('79). Jaws (the proposed 11/70 on a chip), available in '82 would support this large, user base.

2. It would be used in many places as a major cost reduction. As an 11/70, the cost reduction at just the box (no memory) would be in the order of 9K! No other cost reduction project could get anywhere near this leverage.

3. There will be some obvious uses for it as it becomes available, based on the fact that the Fonz chips will create markets internally. These include use in the mass storage controllers, Hydra front end (Mercury), as special speech and signal processors, and the terminals (e.g., graphics) evolve to need this kind of power by then.

4. There will be many uses for standard 11 systems at the lower cost put in highly integrated systems. These would run RSTS, SCS, RSX, and TRAX.

5. It is the way to build our systems in this time frame using one engine. In retrospect, we could have probably avoided the 11/44 and covered the space with an 11/24 if the memory

space were extended to >128KW. The speed of the Fonz is adequate, but the memory space is not. A similar situation will no doubt exist as the need for the 11/44 follow-on (called 11/XX) is identified. This is the way to do it.

6. Just as the 8 is the really low end now, so too will be the 11 until we get the price of VAX systems down. I don't see this happening until '85 or so.

7. By identifying it, hopefully we can avoid doing enhancements to the Fonz.

8. It is getting to be clear that we can't get a VLSI-VAX in this time frame. The specific details will be forthcoming on VAX as we learn how difficult the project is. This is both a hardware and a software base maturity issue.

SUBJECT: WHAT IF THE 780 WERE REALIZED USING MCA'S OR NEW TTL/FAST LOGIC?

Let's talk tomorrow. Bob has been off doing a quick study as to how fast an MCA translitteration of the 780 would run. His rough answer: 2.5 x a 780. If we had done this, it would have shipped 2 years before venus, at a small fraction of the development and start-up costs. I am concerned that we don't understand how to compute time/cost/performance (that's why I wrote the little essay in Computer Engineering whichh apparently no one read). Anyway, the bottom line is that a 780/mca would have roughly a price/performance ratio of 250K/2.5 or 100K, where the 780 is the standard base. Venus will have price/perf. of 320K/4 or 80K. Since this ratio should get better at .8 per year, then a 2 year delay should be .8 x .8 or .64 either lower cost or higher performance.

The point of this is: We seemed to have screwed up in not making this product. Now, with some faster TTL coming out, maybe we could do a direct substitution of FAST ttl and get a speedup of say 2, with virtually no redesign, but by using the new parts.

Could you look at this one?

I think we ought to spend a little more time on the mca version too and see if the Stewart numbers can be improved any. I think these should be kept alive until there is some better feeling about Venus.

GB2.S6.50

Mr. Alec Peltier 15 August 1980
Special Assistant to Counsel General
Operations Branch
American Embassy
London
England

Dear Mr. Peltier:

Reference your conversation with Richard Goldstein on August 15 regarding Dr. Maurice Wilkes. I wish to extend my personal appreciation for your efforts on this matter.

I am writing to explain our situation regarding Professor Maurice V. Wilkes with whom we have made arrangements to join the staff of our Corporate Research Group.

Professor Wilkes has been a towering figure in computer engineering and computer science from the invention of computers until the present day. He is one of the small handful of men who originated the modern computer; he was personally responsible for the construction of EDSAC 1 which was working in May 1949. Some of the concepts first proposed by him, such as "microprogramming," have continued to grow in importance until today virtually all computers manufactured in the world are designed using this technique which he created.

For the last decade Professor Wilkes has been Head of the Computer Laboratory at the University of Cambridge (England), where he was previously Director of the Mathematical Laboratory for a quarter of a century. I will not attempt to list all of the honors and awards which he has received over the years; this information is available from standard reference works such as Who's Who. Suffice it to say that he has been one of the intellectual leaders and respected senior statesman in computing for the last three decades. He is a Fellow of the Royal Society, a Fellow of the Institute of

Electrical and Electronics Engineers, a Fellow of the British Computer Society, of which he was the first President, and a foreign associate of the U.S. National Academy of Engineering. He received the Turing Award and the Harry Goode Memorial Award, two of the highest honors in American computing. He has received honorary Doctorates from five universities in three countries, together with other honors from around the world, including recently being named as a foreign associate of the U. S. Academy of Sciences. In summary, he is a distinguished scientist and engineer of world reputation, possessing unique background and qualifications not available elsewhere.

Dr. Wilkes is urgently needed to run our research program on techniques for making computer systems more secure. This program is not only important for us as a major computer manufacturer, but also may have a significant impact on U.S. leadership in computer technology throughout the world. Dr. Wilkes' presence is necessary to move this work forward. Also, we need his interaction and leadership across all our research.

Dr. Wilkes is scheduled to leave England the last week of August and will start to work here September 2. He has made all personal arrangements including letting his house in London and renting a house here in Massachusetts. We were lead to believe several months ago that his visa was in order but he was told by your office a few days ago that it would be 1 to 3 months before he could get his permanent visa. This is totally unacceptable. Please check into this urgent matter, expedite, and return TWX the status of this situation. Your help is most urgently requested in this matter.

I have known and interacted with Dr. Wilkes for many years. We need him here. Won't you please, please help us? What other information do you need? I will be calling you and Dr. Brewster after you have received this.

Sincerely,

Gordon Bell

SUBJ: People to Place

TO: John Meyer   Date: 7/10/78
From: Gordon Bell
CC: OOD Dept: Office of Development
MS: ML12/A51 Ext: 2236

There are a number of people casting about for jobs either within OOD or in other parts of the organization. These are the ones I'm aware of:

1. Bruce--try Stan or Larry's (commercial organization). We discussed a job with systems (hardware and software responsibility). Also a job with customer/end use would be preferable. He needs to know how to motivate a set of unrelated projects...as distinct from a highly focused program which I believe he could successfully manage.

2. Stan Pearson--I don't know. Somehow we aren't giving him the strokes here. I've been awfully impressed with what he is doing in the RAD committee for example, but we've signalled that he has to go to line management. I believe we desperately need him in the planning role and we have to make this rewarding.

3. Peter Jessel--I can't tell what he wants to do. I believe he is good in focussed Advanced Development and might be good in R and D. Ulf should talk to him, as Jim has been unable to do anything. Whatever Dick is going to do the small systems areas might create a need. I said talk to both Dick and Bill regarding the systems job. (Here my reasoning is that if Dick's only customer is Bill,

maybe he should turn the function over to Bill.) Also, Peter might like to get more involved in end use (DCG, Stan, Commercial) as he believes the realignment will be more useful to product definition. He is also talking to Telco.

There are undoubtedly more. Please make a list of other people...the unhappy or the groping. Assign them to various people. I am tired of losing people who get in this mode and that we make find themselves. I expect them to be settled in or out of their current jobs by the first of September.

gb

Subject: **Doing Business With The People's Republic of China**

To: Carl Janzen, AK
Ted Johnson, PK3-2/A55

Date: 26 JAN 79
From: Jean Bow
Loc: PK1/E33

As a DEC employee, I would like to support DEC and help you in deciding about, and hopefully doing business in China. I'm going to China April 11 for one month and could present DEC products and meet people.

I understand from Gordon Bell that you are formulating our trade policy and that you will meet with me in regard to a possible assignment.

Should DEC Try to do Business with China?
Yes. China's desire to modernize her industry, agriculture, science and medicine via western technology has opened up a vast potential market for DEC. I believe DEC has the unique know-how and adaptability in building special systems (hardware and software) to solve difficult problems. Indeed, China has many difficult problems at present that could be solved by the innovative use of computers. Therefore, China should be given a chance to listen to what DEC has to offer prior to her commitment to our competitors, both U.S. and Japanese.

Making Contact
The purpose of my forthcoming trip to China is to visit my family, whom I have not seen for 30 years. I also intend to visit government research centers, universities, laboratories, hospitals and manufacturers. I am prepared to take courses here, if necessary, and give informal lectures on the practical aspects of our computers and how to use them. I do have a technical background as you can see (attached). For example, how to organize and manage computer data centers, how to teach practical mini courses on using computer software, and the difference between university and business data centers, etc. I will have opportunities to establish contacts and personal rapport with various key Chinese personnel. In addition, I will be able to plan and establish contacts in advance from Boston as soon as you can give me some guidance. Please take advantage of my enthusiasm. I want to help.

DOCNO8/21

Digital **Interoffice Memo**

Subject: **Peripheral Buy Out/Getting Co-operative Vendors:Versetec Case Study**

To: Distribution

Date: 20 SEP 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

F/U 9/28

Given our limited resources, particularly in PL Engineering, F.S. and Software Support, I'd like to suggest we limit our product offering higher volume, supported products. This would have precluded our offering the Versetec printer, for example.

0. We don't make much on it, and it adversely affects PLC.
1. It's expensive for the graphics user.
2. Customers don't buy it because it's too expensive.
3. We don't support it well because we don't have good margins (i.e., both poor hardware and software).
4. Versetec has a good product with hardware and software support.
5. We offer the obsolete (100 pt) version.

Therefore:

LET'S NOT DISTRIBUTE THE VERSETEC PRINTER BUT LET'S HELP THEM SUPPLY PRINTERS TO OUR COMPUTERS!

Everybody wins! Also we could offer Calcomp plotters in this same way.

Instead of adding a new printer to the VS60, let's co-operate to get a good product that we do not make. What other

products should be bought/attached out?
Why not just offer this and not process it through our books?

PEEBLES VIA J BELL

SUBJECT: GEORGE IS PROBABLY RIGHT

Somehow we have to get the personal VAX project going quickly in order to deal with this problem of one-ness and the built-in complexity that it might imply. The intent of the single VMS is to be able to run a program at any level so as to preserve programs, and more importantly data across the various systems. The thing that can vary is the user interface and the packaging of the system and the documentation to reflect the specific uses of the variations.

George is absolutely right on the evolution of a complex system.
It implies tons of manuals, and expensive system programmer experts, high support and massive overheads that only the CS depts can afford because the people are free and can deal with the complexity. Also, large organizations want them
to keep their staffs challenged.

Personally, I have had waged and lost all the battles in this regard by trying to get a manual written for a user (here, I have wanted to try the simple experiment of putting all you need to know if all you know is APL, BASIC, PASCAL, or Fortan,
and simply want to login, create, run (with a library), and debug your program in a single manual). This would have made VAX simple for all who touch it in 95% of the cases. Alas, it
doesn't cover all the intricies of the file system, loader, debugging, writing macro programs, user defined commands, and administering the system. Not only have I lost the battle, but
I found out that we can't even get manuals like this written because the typesetting system and writers are not enough in control of their words that it is a 2+ year project...instead of simply moving a few files from previous manuals around. We
are somewhere in the early 1970's in our manual writing and typesetting capability it feels like.

Yes...we need some work here, and a plan. The systems organizations
as we have them now will never deal with this cause there are hundreds of other issues like Dock Merge that have to be dealt
with. Somehow it is in the domain of the Technical Director of
SW, and we need real leadership here to keep us from going

down the current path that will inevitably mean a set of new systems to cope with the complexity.

PS
The IBM approach ain't right...cause it means no movement of computing styles, files, programs, and a mess in the complexity due to the fact that SNA won't be that good in solving the Interconnect problem. I still believe in the concept of where we could go, but it takes a belief and design to do it. The personal VAX is a start.
... assuming it starts someday. (The test is how big the manuals
are.)

George, I'm delighted you have bought some programs from the outside and potentially have saved us t to mkt and precious development resources. Given that we share a common problem/
vision here, how can you in addition help guide us?

Anybody worried about this besides George and I?

SUBJECT: RE. DEC UNIQUENESS

Read your note and will throw out a couple of comments-

Think we're striving for ease of use for our large customers by
expanding on the generality of the Operating System so as to

minimize their training,networking, interchange, etc, problems.
Unfortunately a by-product of generality is to give up some of
the "approachable,friendly, and easy to use" characteristics that the single function user can have in 11 Land (single user
is RT-11, T/S is RSTS, multi programmed real time is RSX...)I suspect that a large part of this ease of use is in the manuals
which are describing a smaller functionality and are therefor easier to read....

It's worrisome in terms of the single function prospect that we're putting so many eggs into the one Operating System approach
which by definition is more complex than a system dedicated to a
subset of the universe. The system your data base prospect gets
will not only be able to run DBMS-32 but also Transaction Processing, Real Time, Time Sharing, etc which is great for the
General Motors Programming Shop but complicates life for the single function guy. Maybe what's needed most is really good Tech
Writers who produce sets of single function system manuals?

It's even more worrisome that IBM seems to be trying to get where
we came from: the image of the S38 is Data Base; the 8100 is Real
Time; the 4300 is GP; etc. And they seem to feel that SNA will solve
all their compatibility problems? At any rate it seems intuitively
clear to me that whatever DB system you may develop on VMS just
has to be more complicated than say the S38 with its more narrow focus.Better manuals and prebuilt systems can help, but....

Maybe you've guessed by now that I question the one Operating System approach; you're right I do! On the other hand I don't advocate the chaos of the 11 Land where Operating Systems continue to proliferate, but rather a rigidly planned set of compatible, functional subsets of VMS. I would think this would return "ease of use" to the single function user while VMS would continue to be the GP system needed by the GM's of the world.

I'll also question the notion that 1 OS is easier to maintain than several(when blaspheming why not go all the way). I'll argue that there's a powerful synergism of complexity that more than makes up for the extra drivers and manuals. In five years we're going to need some pretty smart people to maintain VMS (Remember when OS370 went critical; ie fixing 1 bug was introducing 1.x bugs? or when the TOPS-10 solution was to throw away 1000 SPR reports?)

In sum then I'm suggesting that the multi function capability required by the one Operating System approach promotes ease of use for our large customers at the corporate levels but has to cost the single function user in terms of complexity. We can mitigate this to an extent with prebuilding systems and more precisely focusing our manuals but nothing's free;controlled additions to the O/S lineup could help on the ease of use axis.

Regards

SUBJ: NOMINATION: BILL JOHNSON, VICE PRESIDENT OF SOFTWARE ENGINEERING

TO: OPERATIONS COMMITTEE

Date: 2/16/82 Tue 9:46
From: Gordon Bell & Jack Smith
MS: ML12-1/A51 Ext: 223-2236

We would like to recommend that Bill Johnson be appointed Vice President of Software Engineering. BJ fulfils the agreed upon criteria*.

BJ has the largest engineering group, and due to the complexity of the interconnection of the components has the most difficult management job. In this regard, we are known for quality and creatively compatible systems. He is an excellent manager, managing by inspection, and knows what goes on in the products and within the projects.

The recent announcements of the 782, VAX Information Architecture, and Office are indicative of the performance of our creative and productive software engineering group.

BJ is pivotal to our product future.

Due to BJ's wide experience in both hardware and software engineering, he is a widely sought after person. He can handle a wide variety of future assignments.

* "Officer Criteria

Past (a) sustained, excellent performance in key positions

(b) major contributions to DEC

Future

(c) strong belief that person will make contributions in future

Future factor is the most critical."

CANDIDATE: Bill (B.J.) Johnson Sponsor: Gordon Bell

Jack Smith

CURRENT POSITION: Manager of Software Engineering

ACCOMPLISHMENTS: B.J. has been our fast track performer; in rapid succession he has been Manager of Diagnostic Programming, Technology Director for Central Engineering, and Manager of software Engineering. In all of these roles he has demonstrated leadership and strong technical and organizational skills. His role in software is to manage the largest, most complex (organizationally) Engineering group. He has increased focus in quality and advanced development, and software methodology.

He has put into effective operation Reading and DECwest. We believe that all groups are operating very effectively.

FUTURE: B.J. will continue to be a fast track performer. He is rapidly acquiring a broad perspective of DEC's business which when allied with his hardware and software technical skills makes him extremely valuable.

SUBJECT: HIRING FROM WITHIN AND WITHOUT, AND OUT-PLACEMENT

Bill Thompson really probed at me on the issue of approving many hires. I've been doing it, assuming that you folks are doing this within budget! At the same time, I know that we are going to have to let some people go, if things continue to deteriorate bookings-wise. Jack is dealing with his group and I'm approving the Nautilus expansion. I also approved a very strong technical person (and manager) for Sam, along with the 6 people for the California startup.

I had a request for a former general manager and VP which I think both Jack and I should look at, cause it looks like there will be good managers available with similar experience within DEC. It's unclear as to the quality because the person had been running their videodisc effort and hence I'd question his technical judgement and esthetics. The OC is asking members to identify high quality people for reassignment. They are also asking for the budget to be made 2 ways for FY83: one as is; one if some of the marginal people can be identified and put in a holding place for reassignment. This should also be done for engineering too.

In short, we gotta really put on the brakes. There are many people that are going to be identified for reassignment that we might have and that we want transferred. We do have to keep our commitment to the colleges and strong technical contributors because they are what really make the products.

Any managers are going to have to be screened thoroughly, and unless they possess very strong technical skills, I don't intend to approve them.

LARRY PORTNER FROM: GORDON BELL
DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: A PROPOSAL FOR EVALUATION OF DIRECT REPORTS IN JUNE

We recently evaluated the direct reports within engineering using the salary, proposed salary, and proposed stock. In addition, Don Ames provided the stock value available in 1982 on an if sold basis, treating all past stock grants as compensation. The data was suprising and useful! In addition, I believe we should have the total value of all remaining stock to be used as a guide.

We asked each person to rank order their candidates together with the justification of the stock shares. The criteria used were:

1 exceptional performance
2 criticality to continued success and who were not proportionally compensated or recognized
3 position in the organization and who might receive stock assuming they were doing an adequate job

The method we used for the evaluation was to:

1 have each person present their candidates in order of importance (what amounts to the LAST person that one would throw out of a lifeboat)

2 have the whole group comment on the candidates and collectively decide on the shares for the candidate. This of course required additional stock shares.

3 these new requirements were then merged back into the initial list so that we could compare across organizations, and

4 finally we made a single pass of the complete list from the largest number to the smallest number. At this time, the total number was reduced, as we found there were persons within each group that were reduced (this amounts to finding persons we didn't need in the boat at all).

We found that the past data was useful in a several cases: there were critical persons we always want in the boat with us and who are neither compensated very well nor who have many shares. Also, there were a bunch of harmless folks with us who are doing little to move the boat, and who would probably not be missed if they fell overboard. In fact, we found that we were paying some riders $120K, while our key people were only getting $60K. Since the initial recommendations were to add some more to the riders, in proportion to their position in the organization, the final recommendations came out nothing like this.

Therefore, I propose that in the June meeting, we come with the

personnel list which includes: name, salary, proposed salary,
percent increase, rating, stock compensation this coming
year,
remaining stock compensation for all following years, and the
proposed stock grants, together with the justification as to
why
each person occupies the critical position in the boat.

I recommend that we use a similar procedure in June.

Gordon

In addition, we observed that stock value to a person varies
by a
factor of 20 to 40. If a person is really committed to DEC,
then
the value is at least the spread x 10 x (2 - 4), or 15K to
30K
per 100 shares! If the person isn't committed, the value is
only
the spread he can sell next year, or about $750. When we
ultimately grant the stock, we should accompany it with a
sales
pitch!

SUBJECT: 16-BIT PROGRAM OFFICE MANAGER

We are very pleased to announce the appointment of Mike Gutman as
Manager of the PDP-11 Program Office reporting directly to Gordon
Bell and Larry Portner.

The Program Office covers the development of all PDP-11 based products from microprocessors to large systems for technical, real time and commercial systems.

The PDP-11 Program Office will be responsible for determining the
strategies for PDP-11 products, the line management of QBus and
Ubus hardware development and support, and the resource allocation of all hardware and software projects.

There will be a transition period as Mike works out of his current job in Storage Systems and he will take over the Program
Office on a full-time basis by the start of the 1982 fiscal year.
Mike will be announcing the PDP-11 Program Office organization at
a later date.

Mike came to Digital 7 years ago to help found the Components Group. For 3 years, he was Product Manager and then Engineering
Manager of the Memory Systems Group. For the last 3 years, he
has been Storage Group Product Manager.

He received both his Bachelors and Masters degrees in Electrical
Engineering from Worcester Poly Tech. He and his wife Lois have
4 daughters and reside in Framingham.

We look forward to seeing Mike in this challenging and demanding role and hope he can count on your support.

LOC/MAIL STOP: ML12-1/A51

SUBJECT: RE: PROMOTING CRAIG MUDGE TO SENIOR CONSULTANT

The criteria in my head is two, significant technical accomplishments. Strecker (11/70, memory hierarchies modelling
general case, and vax architecture), Kotok(10 architecture guidance, our telephone system, many 10 implementations, and the ecl gate array push), Cutler (11/M, VMS and now a new compiler technology that promises to be backbone of much of future compilers). I would like to meet with the senior consultants on this and maybe go over names of all the people we have that fit this highest category. Believe he has done very solid work on the 60 FP and WCS, and Nebula advanced development, and in Managing the cal tech inteface including the idea of formal ports. Although I don't believe we have to wait for Scorpio, I do believe the transfer of the MOS work into production this year could constitute a second major accomplishment. Certainly the book was useful too.

This issue is so hot that I want you to keep pushing but I think it is essential to get with the Senior Consulting Engineers to get a bit more formality. I'll get this set up quick!

Senior Consultants how do you feel on this?
Who are we missing?
What do you think the criteria should be?
(Note, I'm putting some pretty strenuous criteria that goes beyond promotion of full professor with tenure in the academic
world.)

I also consider both Riggle and Fred Hertrich to be fitting of the title, although Mike has a manager's title and Fred isn't in the company.

PLEASE LET'S JUST KEEP THESE MEMOS VERY, VERY CLOSE TO OUR BODIES AND POSSIBLY NOT MAKE COPIES OF THEM!

Can we try exploring this a bit more this way and then get together? Also, how about a telephone conference tomorrow?

GB1.S2.11

THE BASIS OF SUPERCOMPUTERS:
SEMICONDUCTOR AND PACKAGING TECHNOLOGY

RELATIONSHIP OF SEMICONDUCTOR AND PACKAGING TECHNOLOGY TO PERFORMANCE

Semiconductor logic circuits and memory chips and the ability to interconnect them densely is the basis for today's pipelined supercomputers. For the last 20 years, Cray has taken "off the shelf" transistors and integrated circuits and packaged them creatively, forming a very dense structure to achieve the fastest speed clocks and therefore, the fastest computers. In addition, Cray has also organized his computers from a number of computers, processors and functional units to operate in parallel, giving greater performance.

For machines just being characterized, the Cray X-MP (a quad, multiprocessor) and the Fujitsu V-200, the clocks are 9.5 ns. and 7.5 ns respectively. The peak performance of the V-200 is about twice the Cray uniprocessor for the Livermore loops. The speed difference is probably attributable to a better vectorizing compiler for the V-200. The clock difference is due to Fujitsu's impressive semiconductor technology and the packaging capablity evolved from Amdahl. The X-MP is simply an evolution of the low density semiconductors used in the Cray 1. Virtually all computers today use Japanese high speed MOS and CMOS memories.

A Cray 2 uniprocessor, appears to be a breadboard for the Cray 3, and will be delivered soon to Livermore. It uses the fluorocarbon cooling bath and has a 4 ns. clock. The commercial version, the Cray 3 might be ready by '86. NEC's machine which will be introduced next year has a 6 ns. clock. Cray is currently exploring GaAs for increased speed and lower power.

Since the V-200 is IBM compatible, with a large virtual memory, Fujitsu is likely to create a new market, and begin a major erosion of the U.S. dominated supercomputer market unless the X-MP can be parallel processed, or new, faster models introduced quickly. Because the V-200 and corresponding Hitachi machines are IBM compatible, they will make an impact on supercomputers as we have known them.

THE JAPANESE POSITION IN SEMICONDUCTORS

Japan's semiconductor technology lead is increasing. All major manufacturers have operated submicron facilities for up to three years. Since these facilities represent a discontinuity in equipment for cleanliness, lithography, handling, etc., semiconductors are likely to be our technological blindside <u>unless</u> a major discontinuity is introduced to offset their effort. Today, the Japanese have closed the gap in manufacturing equipment by introducing their own, non-exportable equipment. The tight coupling between producer and consumer of semiconductors within a single company in Japan is also another interesting facet.

Note the situation in these directly critical semiconductor areas:

1. <u>CMOS for RAM and gate arrays;</u> Japan is several years ahead because U. S. suppliers were slow to make the transition from NMOS to CMOS. The best U. S. gate array supplier, LSI Logic, uses Toshiba chips. Toshiba has the most advanced CMOS facilities today in both manufacturing and research.

   While today's supercomputers are <u>not</u> CMOS based, one company, ETL is basing its future on a large, CMOS gate array.

2. <u>evolution of ECL;</u> Current and projected ECL gate arrays have continued to outperform U.S. produced devices. While efforts in this area are decreasing, evolutionary devices could enable the current Japanese supercomputers to be "evolved" again with relative ease.

3. <u>revolutionary HEMT and revolutionary GaAs devices;</u> The Japanese continue to build and describe high speed circuits at various conferences. Cray is working with GaAs; however, chip manufacturers are required to make the technology viable.

4. <u>packaging;</u> Trilogy's ECL circuits and packaging represented the most advanced design, but is currently "on hold" because of the company developed a design

that went beyond their ability to manage and process the complex design. Only a few efforts exist outside of IBM and are aimed at the necessary interconnect and packaging densities.

While not directly relevant, these areas are of similar importance:

5. conventional microprocessors; These are dominated by U. S. "Semicomputer" manufacturers quite likely because the Japanese are unwilling to make the architectural and software investments when the return is so low. It is much easier to copy the architectures and produce compatible chips.

Microprocessor Opportunity and Potential Blindside

Because of the low cost, reasonable speed (compared with minis and mainframes) and rapid rate of progress compared to conventional computers, the microprocessor represents two technological opportunities that could impact supercomputers and represents a unique opportunity for the U.S.:

5a. The PC provides about the same number of floating point operations per dollar as a Cray for a number of scientific problems, whereas a mainframe is an order of magnitude more expensive. High performance, scientifically oriented micros, would provide cost-effective computation for a much wider class of users, and it could reduce the dependence of some supercomputer users by offering an order of magnitude better performance/price.

5b. A substantial number of multiprocessors have been built which provide substantially better performance/price than large computers. Also, several multiprocessor computers have been built which provide performance that deliver power in the same range as supercomputers, but at substantially lower prices.

6. microprocessor peripherals; While not directly relevant to supercomputers, peripherals indicate the state of the art in design complexity. Many of the

major chips are designed in Japan such as the NEC graphics and disk controllers for the IBM PC.

7. <u>Computer</u> <u>Aided</u> <u>Design:</u> CAD has been developed by U. S. Universities. The programs move almost instantaneously across all borders, creating an even more powerful industry in Japan.

Today's CAD systems are aimed at chips or small, board-level systems. CAD for large systems appear to grow exponentially in complexity and size. An opportunity exists in this area, if simpler methods can be found to deal with the large system size without increasing the CAD or designer complexity. In this way a larger number of ideas could be explored without requiring the massive engineering resources of the large, Japanese companies.

8. <u>electro-optical</u> <u>technology;</u> Some effort should be made to access the likelihood that this technology offers for both computation and for interconnections.

RECOMMENDATIONS TO MOVE TO TECHNOLOGICAL PARITY

Several alternatives have been suggested to establish submicron facilities, beyond those at AT&T and IBM. The Semiconductor Industry Association, SIA, has recently focused on long term research through its research company, SRC which is supporting basic research in universities (and supplying additional engineers).

If the technology for future supercomputers will come from the SIA member companies following an evolutionary path based on CMOS, then the current direction must be acclerated. If the technology requires evolutionary materials and circuits, then an additional effort is required because of the commodity focus of the semiconductor industry.

We recommend following as many of the following alternatives as possible:

1. Startups. An entrepreneurial energy driven, industrial/venture capital financed company, such as Picotech, proposed by Integrated Circuit Engineering Corp., ICE, a market research firm in Phoenix. This would be located in the New Jersey and New York area and presumbably "pull" technical people from AT&T, IBM, RCA Labs, etc. to produced 0.5 and 0.25 micron chips. With the right leaders, this would could be the "best" solution. A facility in Silicon Valley would lack people with submicron experience.

1a.Picotech, Japan would be an interesting alternative. A company would be formed in Japan which would draw on the experienced semiconductor leaders and utilize Japanese process equipment.

2. An SRC or national effort.

a. Form an effort as part of, but in addition to, Microelectronics Center of North Carolina, MCNC done in conjunction with Semiconductor Research Company, SRC.

b. Some other SRC initiative directed at an aggressive submicron chip facility.

c. A National Laboratory for Submicron Device Circuits.

3. Synergy with VHSIC Phase 2. Use VHSIC's second stage results which are targetted at producing the first 0.5 micron chips beginning in two years. The first VHSIC phase obtained 1.25 micron chips within a 3 year timeframe because this was simply a transfer of technology from commercial advanced development to an expensive military line where the government can pay an order of magnitude more for chips. Since current facilities are not in place for submicron fabrication, the effort is unlikely to be successful in time for making competitive supercomputers.

4. Industry. An incentive program which would establish submicron facilities in ALL current semiconductor vendors who are working on high speed circuitry. A special effort should be directed at sorting out the viability and timing of GaAs. If VHSIC is involved in GaAs, the experience gained in this effort should be made available to the commercial industry in order to have cost-effective chips.

5. CAD aimed at small systems could be extended for sets of chips which are necessary for supercomputers.

6. Revolutionary, But Trivial Microprocessors for PCs and Multis. Providing substantially better microprocessors than currently exist or are likely to evolve. The evolution of microprocessors from Intel, Motorola and National has been slow. The key parameters for building effective computers are address size and floating point performance have improved much slower than the semiconductor parameters would predict. The architecture for micros has followed the time worn evolutionary paths of minis and mainframes, and this is not appropriate now because the memory speed and internal clock times for micros are almost identical, given a poor mismatch between processor and memory.

Today's micros need to be abandoned and a simpler load/store architecture that is characteristic of the Cray designs is needed, but with floating point arithmetic and large virtual address. Both Stanford and Berkeley have built the MIPS and RISC chips which are small in transistor count, but these need to be available for widescale use. A program to make this transition within 2-3 years, providing 10 - 20 million instructions per second would have far greater impact on supercomputers than any other factor as described above for use in PC's and multiprocessor structures.

It should be noted that these multiprocessor computers do not provide a lasting uniqueness, but rather, lower the barrier of building supercomputers. Furthermore, any country can make a substantially better micro than those on the market (and in development) today, and with known interconnection techniques achieve substantial parallelism. This represents another technological blindsiding giving a 2 - 3 year lead.

7. <u>Packaging.</u> This crucial area needs to be examined seperately and an action plan formulated.

Follow-Up: 7/9/79

Several of us visited ATT's Picturephone Meeting room in Boston. It is one of a dozen (Atl, Bos, Chi, Det, La, Ny, Phl, Pgh, Sf, Wdc) or so linked together by full duplex color video channels. Apparently up to 4 of the rooms can be connected for an even larger conference. The cost per hour varies from about $150 to $390 (NY to LA).

The rooms hold 6 at a table, plus about 10 in a row behind, and another row of chairs can be installed. Apparently 24 have made it in a room, assuming the air conditioning is on better than when we visited. It has the following:

. 3 cameras that are voice actuated that cover pairs of the 6 at the table
. 1 camera to give a panorama of the room, when no one is speaking
. 1 camera with tilt and zoom to cover a presentor at a whiteboard area
. 1 camera with zoom to cover back or top lighted viewgraphs or opaque stuff
. 1 camera on a slide projector
. 1 camera can be brought into the room for special use
. a tv videorecorder for input or recording the proceedings of a channel
. a Tektronix hardcopy output of the incoming channel
. several consoles where the camera channels can be selected
. 2 tv screens for viewing incoming and outgoing video

Each of the participants wears a neck mike, hence there is great audio. The numerous cameras make for lots of action to hold attention of the conferees. The person who manages a transmission has little to do, and in fact can do nothing and the voice actuation and presentor can do it all. This means there's not another person in the room to manage the conferencing.

I talked to people at BTL Friday and discussed the changes to subsequent rooms. Hitachi is building a digital encoder to get the color tv down to 5 MBS so it can use the regular network. There was some notion of a large (60") screen, which seems essential because the 2 TV screens were only 25" or so. Also, it would be worthwhile having some automatic or easy to use videomixing so that static material such as slides or viewgraphs can be mixed with the conferees.

What I would like to see:

. Let's make a concerted attempt to use the existing videoconference facility of AT&T's...and log our reactions, find out its use and limitations.

. Put in place these rooms as per what BTL will provide and a network among the NE sites assuming it pays on the basis of transportation costs (the worst case).

. Work with BTL to see just whether we can get down to a cheap, 50 bps link so that it can also be used among widely separated domestic facilities (eg. ML-CX).

AT&T hypes it for: product introduction and sales, especially to multiple sites; personnel interviews...it looks very good for this in certain cases where the interviewee has a hard time coming to visit; design reviews and technical problem solving between two groups; staff meetings such as regional sales or service (note with 4 sites, the travel time could be significantly reduced in our case). It has even been used for depositions.

Why can't these be identical in terms of power supply, electronics, and overall package? I assume they differ by a rom for the different positioners. I don't see why the form factors aren't identical such that either could be put in a cabinet slot.

What you say?

Certainly we must abide with PPC decision to not announce PL/1 or make a product commitment at DECUS.

Since we often describe R+D efforts, it seems totally appropriate to discuss your work as such and get feedback you might want.

I believe a talk on "The Structure of a PL/1 Compiler for VAX" or "PL/1 Code Generators for VAX" or "An Experimental PL/1 for VAX" would be good and should get on the program. Let's describe the work.

SUBJECT: HOW CAN WE GET A REALISTIC GEMINI/SCORPIO/NAUTILUS PLAN?

Having just looked at the potential competitors, it's clear that they are based on the emerging 32-bit micros (Motorola and its Japanes licensees, Intel, Zilog and its partner) which will permit the construction of systems that are competitive with all systems we build up to and including the 780 and multi-780's! Also, these machines will be available BEFORE Gemini, Scorpio and Nautiuls!

I'm not confident that we're going to get the competitive machines of Gemini/Scorpio/Nautilus, even within the normal 6 quarter slip times. Is there a meaningful basis for producing schedules since there are many undefined and very high risk parts? Is the management overcommitted too? We ought to not overlook these signs:

HUDSON

1. Tiny has had 5 passes and will require a complete redesign... it is also several years late.
2. J is behind schedule.
3. We were just surprised to have to design our own very complex rom/ram for the microcode. This a very advanced design.
4. BI looks like an even more risky and complex chip than the now 3 chips of Scorpio.
5. DECSIM has slipped and parts are one year late. It's needed.
6. We are behind in hiring and we are constantly adding people to maintain the schedule. A/D resources have to be used.
7. Plans and commitments are made independent of the doer because hiring is behind the commits (I.e. he who plans does not do).
8. A complex organization with lack of project role clarity.
9. All effort is on MOS, little involvement in the gate array.
10. Scorpio is the FIRST state of the art design we've tried.

PACKAGING, POWER AND PHYSICAL INTERCONNECT

1. Management is only by level of effort with no measureable programs.
2. No reporting of direction or progress outside the organization
3. No evidence as to doability of technology cause there's no communication or project.

MID RANGE SYSTEMS

1. Large FCC workload

2. A non-zero work backlog for CI, the 750 and other projects.
3. Lack of systems manufacturing interface and rapport (not critical until there is something to build)
4. Lack of recognition of the incredible work load ahead implied by the Gemini/Scorpio/Nautilus Program (too many CPU designers and no systems, and option module designers)
5. A PP/PI plan (wish) without a manufacturing engineer
6. A requirement for a sophisticated engineering process and no CAD gurus or managers
7. A basically arcane engineering process with process responsiblity buried 2-3 levels below Demmer
8. Lengthening project gestation times, giving less competitive products without the accompanying understanding
9. A Nautilus plan requiring the use of chips at the limit of their capability AND well beyond the needs that all other users will put them to. This was same problem with the MCA!
10. A Nautilus plan requiring a sophisticated CAD CHAS-like system for: drawing, communication, much checking (due to chip use), q/c, project scheduling, testing, etc.
11. A Nautilus plan of sufficient length to burn out people

WE HAVE MANY POSITIVES
The Hudson folks are working hard and are very good. Also, CHAS was just released on schedule and may be a breakthrough in tools that even MOS designers may use.

We have very talented designers, and they can do very good work if we don't overcommit and frustrate them. They can be frustrated by:
1. changes, false starts and lack of resources at the beginning,

2. a long project caused by poor planning and poor processes,
3. a long project because we can't get it manufactured.

The managers are very good with fine records of accomplishment both on technology and to schedule.

The architecture and the software are ready, and we have: VAX, VMS, BI, CI, NI and SI products. We have a SUVAX prototype. It is clear what components we must have. These are our real aces!

The system possiblities are quite clear, even though our planning is yet to catch up with this. (I don't advocate building a planning staff as it's too late.)

Bill,
I do not have an answer, but certainly have a concern about the enormous work load ahead and the underlap and overlap of organizations, products and projects... amounting to lack of clarity. None of the negatives taken alone are a problem, but the collection of them is frightening.

The project set is larger than the original VAX Project!!

We need to be calm. We need to understand. And, we need a believable plan!

SUBJECT: PLUTO'S GREAT. LET'S SELL IT WIDELY AS THE COMM. COMPUTER!

It was great to see Pluto in operation yesterday. It looks like we finally have a Corporate communications server product after 10 years of trying to get one. The mechanics too are a landmark and the ability to stack and have 96 lines in a small space is really great. We have a basis for future communications system products using the packaging to eliminate the intermediate cables.

It's the first unpack and stack system.

It's clear to me we ought to consider selling it as a communications computer in other than NI contexts without the UNA. In this regard we'll clearly want the J in there as line speeds increase. Also there'll be a demand for higher speed lines and doing interfaces to high speed common carriers to couple LANs. Similarly, you're planning the multidrop hdlc to get the cost per terminal interfaced down even further.

I think it's time to take the cover off it and start talking to people like the phone company and OEMs who need good communications hardware. Clearly we ought to be able to clobber the 8100 and the other IBM kludges that do comm! Let's do it. There clearly has to be a market for it as our customers have been building communications systems for years with our relatively crude hardware. Now they ought to be able to do much better! Let's figure out how we can sell it. Clearly there'll be a demand for other components that can stack on it like a disk. It's by far the neatest package I've seen from Digital. Congratulations.

SUBJECT: GETTING A REAL START ON PLUTO, GATEWAYS, ETC.

Pluto scares me. I see lots of paper and little real content on its
REAL (future vs. past) competitiveness, or what it is, or most
importantly, how it's going to be built. Now I see a second Product
Manager: US Paper!

For starters, I'd approach it as an evolutionary design by building it
now using current hardware (DMC lar serial line interfaces),
then evolve to support UNA and the Protocol Assist Module/line units.
In this way, you have an automatic backup to a standard 11 with a UNA,
cause all that PAM, etc. hardware will demand very large diagnostics
and a big handler change.

Also, the folks building the CATS and the old 10/20 DN may know
something that could be used to design this.

The sequence:
1. Get a host (10/20/VAX or whatever)/Pluto environment using today's hardware that supports PLUTO SW development, down line loading and debugging. (Decide on how to handle the multiple host development/down line loading and debugging environment).

2. Get a PLUTO environment that works with 1.
2A. Buld a PAM SW interface
3. Develop and TEST as concentrator while
3A. developing and testing a separate, parallel RJE (line printer part).
4. Replace the standard D(L,H,...Z) with the PAM.
5. Replace the DMR with UNA

We're doing the review soon. At that time, please give me a demo of 1 and 2. Note that this base software 1 and 2 has to be done and has to be completely general before you can build any gateways, servers, repeaters, etc.

Bill Johnson, ML21-3/E87
John Kevill, ML3-6/E94
Pat White, ML12-3/E51

I'm appalled at the lack of any PMS Architecture of VAX. (I saw Bernie's input to Mass Store.)

Surely there are more ways than SBI, CMI, ICCS (only 1 version?), Unibus, and New I/O Bus to interconnect the range of VAX systems to disks? What about Massbus and the inevitable Nebula Backplane?

This will be a good lesson (case study) in losing money. There are now no standards!

Ulf and Bill, please get together to help, not sink, John (and Bill).

As an aside, Bernie suggests no CCD in HSC or no optimization. This, I believe is only because there is no performance data on VAX, our customers are in honeymoon period and not yet complaining.

Founder and VP of R&D, Prime Computer 1972-1979
Under Bill's technical leadership, a significant minicomputer company was formed that grew from 0 to about one-half billon dollars revenue. The Prime minicomputer had the FIRST computer implementation of a 32-bit, virtual address with Multics style computing at a fraction of the cost. The entire product line which Bill managed, before leaving consisted of wide range of compatible minicomputers which were used for a wide range of applications (general purpose to office automation).

In 1978, VAX was introduced as a 32-bit minicomputer; today all minis and micros have been extended to 32-bits, but Prime was the first to extend the addressing of small computers and provide a virtual memory program environment.

Commercial development, in 1975, of first token-passing, local area network. (The first implementation of IEEE 802.5 will occur in 1984.)

Citation

For technical vision and leadership in computing that established the first minicomputers with large virtual addresses and the first company of a new industry of distributed, co-operating workstations.

6a

Founder, Chairman and CEO, Apollo Computer, 1980 - present

Under Bill's entrepreneurial and technical leadership, a new industry has been formed based on powerful, fully distributed workstations. The Apollo environment typifies distributed computing of the future.

The Apollo Domain environment provides computing directly at the user's Workstation, thus avoiding the response-time bottleneck of timesharing for what is highly interactive work. In addition to the workstation, the environment consists of a token passing ring (similar to IEEE 802.5, but at least 4 years earlier) to interconnect the stations. A 48-bit name space permits all workstations to communicate and share resources (especially files) with one another.

Apollo was the FIRST company to provide this environment. Now 150 new workstation companies have been formed to compete with some segment of Apollo. In addition, traditional companies such as IBM and DEC are attempting to provide similar products. Apollo still maintains the leadership position.

6 explanation

The Apollo environment is the FIRST commercial implementation of the fully distributed cluster outside of a laboratory environment (Xerox Palo Alto Reseach Center; Ethernet interconnecting Alto workstations). This kind of environment will be the main style of computing of the 90's. Only two companies appear to be providing products which are similar, but less extensive than the Apollo environment (eg. SUN Microsystems, Silicon Graphics). A proposal in 1979, at Carnegie Mellon University, SPICE, offered such an environment, but only now is it partially operational. The Apollo product(s) constitute a system formed from hardware (various workstations), a local area network, and distributed operating system-- any one of which are a significant.

The above examples illustrate the engineering difficulty necessary to make the Apollo Domain Environment and set of products, i.e. the work is well beyond what can be done by 100's of startups or capable research groups. Bill lead this effort!

Apollo started in '80, and introduced their first product within the first year. The company has just reached $100M annual sales, and should reach the billion dollar level by 1988.

1980-Apollo Domain, Distributed Computing Workstation Environment

Demonstrated vision and technical leadership to found a company to develop a computer system that is generally viewed as the successor to time sharing. See "Architecture of Apollo Domain."

1975-Prime Token-passing local area network

Delivered first, commercial high speed, token passing ring local area network. See Reference Manual for Primos.

1974-Prime Virtual Memory Minicomputer

Delivered first implementation of large, virtual memory on a minicomputer. One of first companies to do systems programming in a high level language (subset of PL/1). See Reference Manual for Prime 400.

7 additonal

1973-Prime
First product with demand paging on a 16-bit minicomputer. See Reference Manual for Prime 300.

1968-Honeywell
Consulted on the 16-bit computer that ultimately became the Series 16 minicomputer.

1968-NASA
Demonstrated demand paging on a minicomputer.

1968-NASA
Pioneered in the use of higher level languages for implementing operating systems by using Fortran as the implementation language for a NASA system.

1966-MIT
Pioneered a first course in systems programming with text.

7 next page

Bill has demonstrated exceptional technical vision, followed by leadership to implement the vision resulting in two key 'firsts" in computing which others have followed.

In the case of Prime, a recent study (which will be published shortly by me in Computer), showed that of 100 companies that began making minicomputers in the early 70's, only the startups Prime and DG remained autonomous. 75% of the companies failed. Only 8 companies succeed to any degree: Prime, DG, DEC, IBM, HP, Interdata, Harris, and SEL.

In the case of Apollo, they were clearly first and everyone is following. In this case, I expect a much more brutal fallout of companies. Of the 150, I expect only Apollo and perhaps 2 others will win. I expect DEC, IBM and perhaps 2 of today's computer companies to produce products that will compete with Apollo.

Bill's leadership as an engeering entrpreneur should weigh heavily in favor of his becoming and IEEE Fellow, because I believe this combination of superb engineer/leader/entrpreneur is who we want as leaders and role fellows in engineering.

Enclosed is a set of notes I took from a lecture Bill gave to the IEEE Engineering Management Chapter (12/83). It shows why Apollo is no. 1, and why Bill would be an asset as a Fellow of the IEEE.

Bill Poduska: On Apollo
Lecture to IEEE Eng. Mgmt. Chapter, 12/13/83
slides, (comments), [GB comments]

THE APOLLO BUSINESS PLAN

Business Plan
$100M by 1985. (Will achieve 4 Q run rate by early '84. Poised to be running at $1B by 1988.)
Marketplace
Computing Professionals, especially engineers. Productivity based, and the natural successor to timesharing. (3.5M engineers who potentially could be

twice as productive is the market goal. This amounts to 100B market. Trick is to convince public to part with money. This was easy because the buying decision is initially under 100K and is incremental. Model was positied by various universities including CMU. Take advantage of micro and evolving, poor performance of timesharing.)

Product

Network of dedicated Computers. The technology of the '80's. (MIT taxonomy: It's a NEW product to an OLD marketplace. It's a Workstation with 16 Mby VA, 4 Mby Mp, 154 Mby Ms, 1000x1000 x 1 to 8 planes x 2 for image backup. Operating system allows paging over a 12 Mbit/s LAN with 48-bit address in full transparent mode. pages: 1 Kby, average of 4 pages transferred. Apollo's own LAN has 280 nodes. Is busy 10%. Price: $40K monochrome.)

(Product strategy: [straight from computer engineering. Introduce a product, go up in performance, go down in price and form a wedge of **compatible, LAN'd** products.] '81 monochrome 40K; '82, color, flt pt, 100K; '83 desktop mainfram at 10K to 20K; Oct 83 fully compatible TTL version of 68K giving more Whetstones than a VAX 780. Soon a 100-150K product. Easy to add a node. They are predicated on NO BACKWARD INTEGRATION. THEY ARE A SYSTEMS COMPANY...). [RECALL WE MAKE WHAT WE SELL, NOT WHAT WE CAN BUY.]

[They simply exploit mini lethurgy and inability to move on micros. Apollo is clearly working on an ECL version!]

People

Used seasoned Professionals and entrepreneurs. Now 1.3Kp. (Company started in 5/80 with FCS 3/81 to Harvard. The Operating Committee has 8p with 3 Prime, 2 DG, 2 DEC, 1 outside Computer industry. Six had been founders before. The average age at startup time was 42! The average age for all startups is 32! Bill is now 45. Apollo ONLY hired quality people... most of whom had done it before.)

[Apollo is simply going to pick off the cream from DEC, Prime, etc. (I believe DG has its act together and is not vulnerable now.) in much the same way that the mini folks (DEC, DG, Prime) used Honeywell as the basis to start to build their companies. The issue of the average age of a company, particularly the top management is quite interesting.]

Money

Venture financing to be a public, profitable company. (The company is now selling at $32 with 22 Msh, giving a 700M market value. 80% of the people in the company are shareholders. 60 are Millionaires via the stock.)

MANAGEMENT PRINCIPLES

Risk

Use time line management; have plan A, B and A+. (Tradeoff cost, functionality NOT schedule. Be able to work with a slower part, but if a faster one comes along, also be able to exploit it. Not all breaks are bad. Whenever people work hard, they end up getting lots of good breaks too.)

Organizational focus

Functional based

Products look like organizations [Conway's famous law.] (Take lots of time for organizational design.)

Management is a contact sport (Air hostilities, but get the hate out in 24 hours.)

People Principles

Justice and share the rewards

Fun (Don't think that it's the end goal that's it. Achieving the goal is ALL the fun.)

Excellence!

TOOLS AND MEASURES (PREDICTION VS FACT... have a plan)

Money

P&L and Balance Sheets (are your friends. Understand and use them.)

People

Oranization Chart with names and dates (Put responsiblities here.)

Time

Schedule (has names and resources on it)

Time Line Management for resources
Bad Tools
Marathon Staff meetings that are problem solving sessions. (Charlie Spector taught them to have short, 2 hour, meetings that have problem identification and reporting. No problem solving on line. People are to do this.)
Committee design reviews

THE ENTREPRENEURIAL STEP

New ideas
Market driven, technology driven, Opportunity (exploit some pathological phenomena such as lack of parts, or high prices)
The Business Plan (note the first slide)
Business
Marketplace
Product
People
$
(Poduska as VC: business plans must be less than 10 pages. Have never read or known anyone who has read a business plan over 10 pages long. Go for Grade A people only. Grade B people with a grade A plan loses. Grade A people have fire in the belly and steel in the eyes.)
Selling the Plan
Value of the investor. (The VC system works!)
Seperate investors and management. (Keep the investors independent of the management! VCs know nothing about management. A business without management is useless, and VCs are now beginning to realize this more and more.)
Everyone must win
Pace and timing (Be in it for the long race.)

RISK AND REWARDS

Rewards
Ego- achievement
$- capital gains (Watch for $'s not for the % of the company. Control always rests with the management, NOT with votes.)

Risks
Ego- failure
$- no way (People may be out of a job 3 months.)

ELEMENTS OF SUCCESS AND FAILURE

Success
Ego drive
Faith in the idea
Trust in the people
Humility and humanity

Failure
Misjudgement (technical and people)
Mismangement
Unrecognized success (giving up too soon
Lack of courage

People
More important than the idea
More interesting than bits, bytes, nanos

Q&A
lots, eg.
Q: How will you keep Apollo from becoming large and lithurgic?
A: The key is to use some form of entrepreneurism. People like the personal challenge of proposing something and the freedom to carry it out with the corresponding risks and rewards.

Other thoughts (by GB)
My simple model of computer generations has to be extended to include people (leadership) and new organizations as I see incredible new highs and lows of performance.

Apollo is an archetype of the phenomenon that creates a new generation and industry... even though it is simply a replacement (New product to old market) designed to eat a large segment of the mini market. It is clear that old organizations rarely make it from generation to generation (eg. BUNCH to build minis). This can be seen by looking at every level of integration and systems including: logic technology, computer, software and various peripheral vendors. The notable exception is IBM who has moved out by significantly stronger leadership at the top.

Mr. Bill Pohlman
INTEL
3065 Bowers Avenue
Santa Clara, California 95051

Dear Bill:

It was good to talk with you again on Tuesday regarding your kind offer to write a chapter for the update of Computer Structures by Professor Dan Siewiorek. You will of course be free to publish the chapter elsewhere and to get any other co-authors involved in the writing. We would encourage and urge the publication in the regular technical literature. I'm enclosing a copy of Computer Structures and a copy of the recent PDP-10 paper which may be useful as models.

I believe the article should cover the interaction of technology, architecture and use surrounding Intel's 8008...8086. The peripherals chips and bus are of interest too. I don't believe the 8086 should be more than 1/2 the chapter and the article should cover all the Intel machines back to the 8008 and any other machines that are relevant to the evolution of the microprocessor. The 8080 should be emphasized, particularly because it became a standard.

We need a first draft by September 1. Although the size is up to you, I believe that it would take 10-15 book pages or up to 45 typewritten pages to do justice to the subject.

If there are any questions, please contact me or Dan Siewiorek.

Sincerely,

Gordon Bell
Vice President,
Engineering

follow up 3/8/79 (OOD Mtg.)

Given the strategy, we need the above. Can you get someone to deal with this and give us a report at OOD in early March. Both Al Crawford and Bob Grimes have made commitments and have policies with respect to VAX (see the attached). I think we need a similar set of statements and we need to know who should make them...and implement them.

I don't have any detailed thoughts, but would like to get a general direction such as:

0. Probably plan to minimize the buying of more 10's. Buy VAX's instead.

1. Let's look at applications which we say will always run on 10's unchanged! Let's not rewrite them, but use them till we don't need them or they're obsolete (e.g., PC Layout).

2. Establish a network so that as work builds up on a given 10, we can off load it on VAXs and place new work there rather than having any kind of massive migration program. For example, the new PC Layout program should be moved to VAX because we're out of 10 address space. This will free up a lot of 10 capacity.

3. No programming anywhere in anything other than VAX languages (common Bliss, Fortran, Cobol, APL--betting on the cum of a good, compatible APL, etc.)...but specify!

Whoever is going to manage this would have the whole thing planned, and all I want you to do is to identify the person or persons within engineering.

OBSERVATIONS ON GENERATING COMPUTER GENERATIONS

ABSTRACT

We've implemented thousands of species of the computer in a few, basically evolutionary technologies. These technologies mark the generations. The evolutionary process is cyclic and includes the technology, the architecture and implementation of species, followed by use which in turn generates increased demand for better technology, permitting evolutionary new computer structures.

Since new generations spring from new technologies and often different people, a new generation most likely follows the time-worn path of early pioneers. New generation builders tend to relearn the same lessons about technology limits,

architecture, its evolution including the "wheel of reincarnation" for specialized functions, multiprocessors, etc.

Subject: **Portability and Waterloo's Widget, Watfor, Watfiv and Watbal on Series 1**

To: Bell Heffner, Bill Keating,
John Leng, Jerry Witmore

Date: 31 MAY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

CC: OOD, Gus Ashton, Denny Doyle,
Ed Fauvre, Win Hindle, Ted Johnson,
Andy Knowles, Gordon McConnell,
George Plowman, Ron Smart, Bob Trocchi,

follow up 6/14/78

I just talked with Professor Wes Graham at the University of Waterloo. He believes we're not too responsive in selling these products when compared to the system he put on (ported over to) the Series 1. Still, he wants this software on VAX.

His people have made 4 trips to IBM to train 100+ salesmen/trip and IBM has sold 100 Series 1 systems as a result of his products (we've sold less than 100). He would like us to get interested in pushing the products on 11's. (He'll also send us data as to the number of systems that run his software--even though he believes three times this number should with some reasonable selling and promotion!) Is there any way we could do this and at least give the customer the option of an 11 over IBM? IBM is also mounting a major sales effort to push this product.

As an aside, he said there is a faction within IBM that was pushing a 32-bit architecture for Series 1 that is now saying "I told you so" when we announced VAX! We apparently sucked IBM into a small, low end, 16-bit architecture -- when others within IBM think its too little, too late.

Portability and DEC

These systems were written in a portable way and moved over to Series 1 in a rather straight-forward fashion! Portability is being used more and more (e.g., UC/San Diego with PASCAL, Bell Labs with Unix and C). (Note much 10 and 11 software has been "ported" from other machines too!) Somehow, not only are we not developing portable software internally, but we often have multiple redundant efforts for software (e.g., many 11 Cobols and a new non-ported Cobols on VAX+ 10). Although Cobol may be the wrong example, there have to be good examples (e.g., the new Editor).

This year (FY79) I, again, want from Software Engineering:

1. Clear statement on where we (numerically) are vis a vis the language used to implement systems together with a policy!

2. Portability considered on each piece of software (i.e., what systems it is for and when will it move.

3. In DECnet, especially, there could be a complete overhaul of software, tools and policies considering high level languages and testing.

SUBJ: POST OFFICE AND MAIL COLLECTOR

Date: 2/28/79 Wed
From: Gordon Bell
Dept: Office of Development

TO: Don Alusic

Al Crawford MS: ML12-1/a51 ext: 223-2236

George Plowman

Follow up: 3/16/79

I hope that your Post Office program will deal with the problem that is now bugging me: I have two places to look for mail since the ARPAnet isn't connected to our systems.

Is it possible to have some background jobs in Post Office that will go out to specific computers like CMU10A and pick up my mail on a periodic basis?

Also, I would like mail delivered to the user community there, but the Post Office does that, I gather.

GB:mjf

Post v N Computing: A 10 YEAR, DIRECTED RESEARCH PROGRAM AND NATIONAL FACILITIES AIMED AT PARALLEL PROCESSING

A Draft Outline*

Proposal(s)**

Gordon Bell, DEC

George Clark, Harris

Bruce Delagi, DEC

Sid Fernbach, Consultant to CDC

Bob Lillestrand, CDC

Red Phillips, Univac

13 August 1982

ntive references to previous and ongoing work and bibliographic references have been omitted. While we believe the general is correct, specific tactics such as the applications to focus on, will be subject to change with the final proposal(s). We now th conceptual and detailed critiques.

The final proposal must come from the program group dedicated to produce the results. Thus we solicit:

- o sites
- o individual researchers and a program director
- o applications and other research projects

1. Some Critical Global Questions

2. Why use CDC's Advanced Flexible Processor?

3. Rough Budget

OVERVIEW

egan as an exercise by positing a computing environment we believe is attainable in 10 years based on parallelism
c of the single, von Neumann machine and then asking ourselves:

Are we doing anything significant to understand and build this environment?

overwhelming:

most industrial research appears to be aimed at incrementally improving today's products and processes; while

academic research is aimed at basic research and the mechanism of getting grants, producing papers and Ph.D's.

f this program is to develop the technology and build next generation computers by establishing several National Laboratories
cience and engineering research within the U.S. military, academic and industrial community. This technology is essential:

1. for defense;

to improve the declining computer and semicomputer part of the U.S. Information Processing Industry which now constitutes
d supports much of our economy directly and via exports; and

3. as a basis for
uch of the 21st Century Industries.

echnology position in the computers and semicomputer industry is a national crisis. As such, this necessitates these unique
program:

1. collaboration
nong national science, defense, university and industrial applied research, often called technology, in a fashion not unlike the
ISIC program;

2. National

boratories so that limited machine and people resources can be shared, unlike the VHSIC program;

3. a large, fast

twork including access both for experimentation and to extend the program to other research sites;

4. construction of

ototypes by industry for evaluation within the research community;

5. technology

nsfer by industrial residents at the laboratories;

6. tighter

upling of application (need), architecture, construction and use by co-location in order to rapidly engineer, build and test ideas. is speeds up migration of ideas to use by applying engineering resources earlier.

will be the hub of a goal directed research program aimed at new VLSI-based, highly parallel computing structures. Parallel ems, including: specialized processors and hardware algorithms, multiprocessors, multicomputers, dataflow and high speed ork based meshes will be built and evaluated. Evolutionary projections show a performance increase in processing of only a 1) to 11 (Fig. 2) over the next 10 years. In contrast, the Japanese Fifth Generation Research Project, is aimed at producing high llel computers with a factor of 100 to 1000 more computing power for conventional and Knowledge Based computing systems .

goal of the program is VLSIzation, the ability to transfer an algorithm, simulated within the computing environment, to VLSI the foundry time in much the way programs are currently compiled. By it's nature, this structure adds inherent parallelism to e national facilities would also support the goal that computers would do a substantial part of the VLSI design. Research in the ting structures we target will rely on accomplishment of these goals.

er generation is marked by concurrence of technology and needs causing a new computing structure and resulting in new use. driving need is for the ability to transmit, store, and process (understand) the same information as people, including voice, es and images. Images are a major data type of this research program because of the links with people. The research need is hardware and technology and by the potential of Knowledge Based Systems requiring much higher performance. These must be gnal processing to assimilate voice and images.

ould be organized in 3 phases, covering roughly a decade, in order to focus the work in a timely fashion. Generations have en 7-10 years and consist of two periods: specification and construction; followed by use and evaluation. The immediate he most powerful, high speed network of general purpose computers would start the program in the use and evaluation phase. n application of this facility would then be applied to produce new VLSIzed computing structures by the end of this first phase. se would apply these newer structures, forming the basis for new designs in the final program phase.

MOTIVATION FOR THE PROGRAM

the combined Information Processing Industries is now declining relative to Japan. While there are many reasons for the re noteworthy and represent the motivation for this program:

1. The U.S. (and rld) funding for basic and applied research is large. This mechanism produces far more results than can be applied.

2. There is NO S. effort or policy aimed at systematically examining the basic research results and refining them so they can be applied to oducts. The cost to do applied research on even a small fraction of the basic research is usually far greater than the original work d is well beyond the scope of a single company or a laboratory. Furthermore, most laboratories doing research can only carry eas to the paper stage because of the engineering nature of the final stages to build and test the idea. Thus, overfunding search relative to applied research means a "spilling" of knowledge that forms the basis of a significant industry.

3. U.S. companies ve not worked collaboratively to develop these technologies because of legal and cultural reasons.

4. U.S. industry s been especially short sighted in its funding of this phase of research. Now, many short term, mundane product opportunities g. another Z80 + CP/M based personal computer) exist to attract resources resulting in further decline. This is further fueled by e venture capital market and increased R&D tax credits which in turn produce even more mundane products.

5. An inadequate pply of people and equipment exist to carry out the work in industry and the research organizations.

6. A research ogram aimed at parallelism requires interaction and co-location with a user community.

ne effectiveness of the Japanese collaborative research programs and believe we must emulate them. Both France and the U.K. d programs aimed at the next computer generation. Note the past and present programs in the Information Processing area:

1. Pattern formation Processing- voice and vision

2. VLSI- improved
ocessing characteristics (eg. 64K and 256K rams resulted in a 2 year lead over U.S. industry)

3.
Supercomputers- high speed technology

4.
Optoelectronics- just established

5. Standard
nicomputer for NTT- Fujitsu, NEC and Hitachi

6. Fifth

eneration Computer- Fujitsu, NEC, Hitachi, Mitsubishi, Matsushita, Oki, Sharp. ICOT Lab and 10 year program were established. e first phase builds Relational Database and Prolog machines.

7. Local Area

etwork standards as part of the Fifth Generation.

8. Next

neration research and technology program.

THE RESEARCH PROGRAM CONTENT

ECTIVES

dertaken with the expectation that the confluence of the disciplines of parallel processing applied to image processing, and ineering, and implemented using VLSI will prove fertile. It, and the resulting VLSIzation process, that of first understanding am and tasks and then VLSI'ing them, may well be a major characteristic of the next generation computing systems, which the e Fifth Computer Generation.* The establishment of a quasi-competitive, but coordinated program of research using common es is intended to stimulate a national understanding of such systems and their potential application.

ed at a fundamental understanding of parallelism and its application to a class of problems critical both to the growth of the stry in this country and to the maintenance of a preeminant US position in intelligence based military systems.

AND USING THE FACILITIES: PHASE ONE

focus will be on installing and applying parallel approaches to image procesing and logic/circuit/process simulation problems, flow. We think it is vital to understand the range of dataflow from theory to practice across a wide range of applications. In its dataflow can be viewed as a formalized, generalization of pipelining that is conventionally used for graphics and image process. eral form, dataflow looks appealing for logic simulation, signal routing, and conventional array processing type tasks where a rallelism exists, but cannot be exploited due to the difficulty of expressing algorithms in conventional languages. It is indeed ataflow-specific machines <u>will not</u> exist, instead dataflow languages will enable programs to be written for large, multiprocessors. l be based on a high performance local area network to interconnect the central machines, including:

. supercomputers,

. experimental achines (dataflow and conventional multiprocessors and multicomputers), and

. the CDC AFP.*

erate with <u>fixed microprograms</u> to simulate several computer structures including dataflow computers. This will enable begin now and to understand the limits and use of dataflow architecture, for example. These efforts must be put to the test of applications in order that the tradeoffs discovered be relevant to solve.

), believes that the current generation, number 5, is based on powerful personal computers interconnected via local area
Japanese are working on the sixth generation, beginning in the late '80's.

have real applications on which to "benchmark" various designs. The following applications cover some of the possible ary and industrial problems: scanning electron microscopic image enhancement, automated assembly inspection, target ligital system design and construction (eg. logic simulation, routing and IC signature analysis). The actual applications should be final proposal.

l results have focused on using a dataflow architecture to examine its limits, the network and facilities we envision are much and will be used as alternative ways of computing.

ELOPMENT OF THE CENTRAL FACILITIES

hat the central research facilities will be enriched further over time by including, as additional research tools, the fruits of the program particularly focussed on realizing more powerful forms of processor interconnect and process (or operator based) ation. It is expectd, further, that several realizations of parallel solutions to specific application image processing problems will d (in VLSI) and included in the central research environment.

NG PARALLELISM: PHASE TWO

hase of the program here proposed, the principle results will include a deep understanding of the dimensions and metrics that ace of parallel computing - costs, performance, programming expense, and reliability. The proposed facilities provide a rich set ealizations for parallel computing - ranging from tightly coupled multiprocessors to conventional Local Area Networks. We do t the kind of interconnect for switching is a particularly fruitful area of study because it is really an economic issue that shifts with ulation, market demand, and supply. Thus, the goal is to provide various structures for evaluation and use very rapidly, but not interconnect possibilities!

and knowledge engineering efforts are expected to yield their most important results in the last phase of the program. stones are established throughout the research effort: discerning the computational (and data management) primitives rrent rules-based expert systems languages, establishing an effective integration of image and symbolic information into a e (consistent with the data management primitives noted above), realizing a VLSI implementation of a highly parallel, post von puter structure for expert systems, trying it out on (say) a SEM analysis problem, a fully automated VLSI design, and finally on an or (semiconductor) process/crisis management (or threat evaluation and reconnaissance mission). These will, in turn, provide ing needed for a second VLSI implementation of the expert system engine above.

ingredient of effective VLSI implementations supporting the research goals of this program we need the 1990's VLSI equivalent he Guttenberg Press but of the linotype machine and the automatic typesetter. The process would be completely controlled by small group. The most important element of this program then is the development of the capability for (fully) automated VLSI om representations of parallel algorithms simulated on the parallel computing facilities proposed. At first, this will likely be by conventional supercomputers and the dataflow machine simulators running at the central facility.

design capabilities will be made to stand the test of real use in VLSI implementatins of (at least one) dataflow machine. The achine will be based on the measurement and analysis of simulated dataflow machines running applications as noted earlier. pabilities will be also tested in VLSI realizations of IC signature analysis dataflow algorithms and the mobile object identification jects implemented previously. The culmination of efforts in image encoding and compressions will be a special purpose VLSI that provides full motion video-conferencing within the bounds of a 56 Kbps phone line, for example.

A FACILITY TO UNDERSTAND AND EXPLOIT PARALLELISM

applications usually result from having new, higher performance computers allowing solution of problems that previously were y intractable. Performance increases in computing come from two sources: technology improvements and increased is program is aimed at understanding and exploiting parallelism to gain performance.

s to parallelism in two ways.

nmodity processors allow the low cost construction of the most cost effective systems. That is the Mips/chip of microprocessors rips the densest, high performance ECL gate arrays.

Second, VLSIzation is an inherently parallel process - standard algorithms are off loaded.

pts to improve performance through highly parallel structures has been relatively disappointing. We believe the major reason progress is the high real and personal cost to build and evaluate parallel structures. This program supports systematic research nt on the following alternatives. In this regard, we posit this fundamental hypothesis: <u>in order for a new computer structure to a user, and hence ultimately developed and exist, it must offer an order of magnitude improvent in performance over his d of computation.</u>

OCESSING (AND VLSIZATION)

order of magnitude or more speed improvement has resulted from looking at the execution times of particular work and then are to carry out the function. VLSIzation is a realization that this evolutionary process exists and is an attempt to formalize the

s of "off-loading" using special function hardware:

1. Floating point

rdware versus a software interpreter

2. Channels, I/O

ocessors and I/O Computers versus interrupt and hardwired I/O

3. Display

ocessors

4. Array Signal

ocessors

5. Front end

ommunications) and back end (disk, file and database) computers

g from a computation on a particular kind of data occurs.

n a requirement for a new computing structure. The function is then "off-loaded" in specialized hardware that operates in e general purpose computer.

eral purpose, very high speed system, the resulting, specialized structures can be totally simulated before they are committed to n this way the designer can interact with the structure in a quickly iteractive fashion instead of waiting at each iteration for system (re) integration.

ORS

w computer class is formed, there are strong arguments to build multiprocessors for performance reasons. Invariably, others rformance Uniprocessors at the same time and deliver more power via the strictly sequential approach. Multiprocessors were e early 60's, with Burroughs probably delivering the first one (B5000). By the early 70's Burrough's, CDC, DEC, GE, IBM and uilt 2 - 4 processor multiprocessors. Unfortunately, these were either used in an asymmetrical fashion, or at most they were nary multiprogramming environment. In no cases was parallel processing of a single task provided.

n investigated parallel processing of a single task with a 16 procesor multiprocessor and showed that for various tasks speed-ups By 1975 two 16 processor systems were built by BTL and at CMU. The CMU system was predicted on the 11/40 minicomputer, ord the construction, and speed-ups of up to 10 were observed in various algorithms.

d Flexible Processor is an ideal machine to investigate the use of multiprocessors and multicomputers since the interconnection puters is via very high speed local links (ultra LAN) and shared memory. It can be used in many ways, including:

1. a 16 computer ultiprocessor;

2. a 16 processor ultiprocessor;

3. a fixed, rpreter for particular structures (eg. dataflow); or

4. a particular, dicated pipeline processing configuration (eg. image processing).

ories are building systems with up to several hundred microprocessors.

multiprocessor, the successor to the S1, with 16 supercomputer class processors. As soon as the processor's available, it should the multiprocessor case for evaluation, since the processors are both tightly coupled and have very fast inter processor mechanisms. This should be within the next three years.

ffering a 64 processor multiprocessor which requires investigation. We strongly recommend the installation of this machine in rder to work on the multiprocessor problem.

artz, et al at NYU has proposed the Ultra-Computer, a multiprocessor with up to 16,000 VLSI microprocessors. Just as soon as we easonable number of processors together, construction should begin on this very large multiprocessor.

hat one can produce conventional parallel processors which should be able to deliver up to a factor of four, for specially coded ctor of 10 is possible, but there has to be a significant amount of research to make this automatically possible. Studies continue amounts of parallelism in algorithms that we have no way of exploiting.

t the optimistic (Fifth Generation) projection for computing power speed-up over the next decade could be accomplished simply parallel processing using multiprocessors and not by semiconductor and packaging technology if a significant effort were ubtedly the dataflow language is an important part of this effort to represent, control and thereby exploit this form of

TERS

een done formally with arrays of tightly coupled multicomputers where independent computers (Pc-Mp pairs) operate and communicate with one another by sending messages. By 1980, CM*, a multicomputer system based on the LSI-11 with 5 clusters of 10 computers was constructed, and speedups of up to 30 were observed for particular problems, including tion. Because there is less interconnection among the computers, it is more difficult to predict the performance: the algorithm ully partitioned across computers rather than distributed in memory.

FP, we believe that other multicomputers should be constructed and used, particularly those with several hundred computers. l support the construction of several, (say 6) different multicomputer alternatives.

CHITECTURES

dataflow computers have been proposed, only a half dozen computers have been built. The performance of dataflow ot understood, although the use of dataflow graphs and languages to express parallelism is promising. In particular, dataflow most useful in expressing signal processing operations. For example, the AFP is programmed using a dataflow-like representation essing tasks. Individual computer modules can be assigned to various processing stages of say a digital filtering task. The AFP also deal to simulate static dataflow architectures and their application. It would be microprogrammed to be a general purpose ne using separate computer modules in a functional fashion: matching store, switching, processing, and i/o.

AND CONVENTIONAL LOCAL AREA NETWORKS

works, LANs, are systems which normally allow the physical distribution of functional, server components to cover a local ea (eg. a building, or campus). The functional servers roughly correspond to various parts of a shared system: person servers rkstations/terminals), file servers, print servers, and communicatins servers. The communications is via message passing le the curent 10 Mbit/sec LANs are relatively slow, they are well matched to today's, slow terminals, personal computers and for networking.

ve also posited that LANs can be used to provide high performance, parallel processing. We too believe higher speed LANs are nterconect architecture for new computer structures. The higher speed, 100 Mbit/s LANs will be the basis for interconnecting puters in a hierarchy as shown in the facilities section (Fig. 3).

tra-LAN as a major architectural component and standard for truly fast, highly parallel structures of this next generation. Note at interconnects the AFP provides transmission at about 2 Gbits/sec for each computer node connected for the tightly connected us, the AFP would be used for some studies of this type of LAN-based architecture.

the hierarchy of three LANs is summarized:

Ultra-LAN	2 Gbits x p	AFP's processor intercommunication; as first basis for an ultra-LAN architecture
Fast-LAN	100 Mbits	Facility computer intercommunication and center to remote sites, forming a single cluster
LAN	10 Mbits	Individual workstations to form centers

CESSING FOR KNOWLEDGE BASED SYSTEMS

widely agreed that Knowledge based Systems can exploit parallelism. For Rule Based Systems, it is believed that many rules can parallel. The research will be aimed at first answering the question, and then simulating and evaluating the resulting structure. sed to simulate such a structure, provided this approach looks worthwhile.

THE RESEARCH PROGRAM FORM

l, DIRECTION AND RELATIONSHIP TO ONGOING RESEARCH

e, together with a board of directors would contract the research in a fairly structured fashion. While research of this type is not e today in computer science, we believe it can and must be done effectively by a joint industry and computer science research t. Industry can be effective at providing facilities and systems that have been traditionally absent from the research laboratories. the major motivation for the proposal.

the research project is to provide a large infusion of computing systems to support existing, more basic and unstructured work, ics.

ould not be to change the nature of the existing unstructured research to be highly focused and goal directd, but rather to nal resources so that both the structured project and unstructued work could co-exist and complement one another.

uld be aimed at very similar research targets in order to get the benefit of "friendly competition". Similarly, several approaches ined within a center. This approach was successful in the mid-70's in speech research and should be the "model" direction. peech research resulted in few, commercialized industrial or military applications, because the research coupling between ndustrial research was poor. Unfortunately, the final transfer phase of research was terminated before the program ended.* It een basic research and applications research that the program is fundamentally addressing. It is interesting to note that NEC ed development operating separately, but concurrently with the ARPA program. The result is that NEC provides recognition

e that a better model to follow is VHSIC. It is crucial that the participants be able to exploit the technology for commercial and tions propitiously. Unlike VHSIC, we believe that the work should be done at a few sites with movement of personnel.

OFFICE

is research is a fairly close weave. The environments are, indeed, established anticipating that unexpected leverage and will yeild significant results not included in the program plan. However, it is precisely the existance of a structured program and n of its several work flows that will enable this to occur. The program office is responsible for the successive development of the ources as it can find them and coordinating efforts so work can easily build upon what came before.

munication with Allen Newell and Raj Reddy at CMM.

ffice will set adequate standards so that ideas meet no unnecessary boundaries between the workers and the worksites in this , stable agreement on the common rules, language, workstation, the network and the general computational support structure he most important contributions of the program office, the goal is to use this commonality of interface to allow pyramiding of reful not to pyramid risk.

ses applications to test ideas, and uses realizations of those ideas to build the next generation applications. It even uses these emselves to acomplish future generation realizations fueling the next cycle. The central facilities are the place that application ng ideas, the realizations themselves, and the applications for testing ideas all come together. This must all flow forward rather k into a deadlocking interdependencies. The opportunity and expectation for people to build on each others work as it becomes key. In the natural uncertainties inherent in this ambitious program of research, there must be enough alternative paths so an use their wits to find a critically helpful piece of another's work or another's facility wherever it may turn up.

ffice must have the ability to facilitate the construction of important engineering breadboards so that systems can be rapidly built We envision utilizing the industrial sponsors for this breadboarding.

ffice is deliberately kept small to force most standards to be developed collaboratively with the groups doing the work. The g for the parallel computing facilities is very light in the expectation that site personnel will be provided by the host institution. le, Appendix 3, provides a more detailed breakdown.

EFICIARIES

as conceived in order to improve this flow of basic and applied research into industrial research and eventually into products. ficiaries are those who use these ideas to eventually build products. Products will not come directly from this program.

and, virtually everyone will benefit by the program:

1. the U.S.

chnology will be drastically improved - thereby improving defense and the economy;

2. the

searchers will be more effective and productive by having more meaningful work;

3. certain

search will be published; and

4. researchers

ll still migrate from the coupled programs, being attracted by venture capital, and build higher technology products.

ANSFERING THE TECHNOLOGY

tive means of technology transfer is through the transfer of people. Program sponsors will each have the right to place people in the program. It is expected that assignments be for a three year interval and that the assigned person return to the sponsoring epared to produce the competitive products of the late 80's.

operative working environment among the members of a project team, intellectual property rights for the work done as a team ies of the host institution will be controlled by the policies of the host institution. However, each program sponsor will have the xclusive license at reasonable terms.

the transfer will occur when the sites and industry collaborate on fabricating a design that a site has specified.

, chips produced as part of a research project would be licensed to the sponsors. The "rights" to chips and software produced as ch program are indeed not clear at this time and vary among the institutions. This area would have to be worked out between and the program.

sms for technology transfer include sponsor access to prototypes, distribution of published technical reports and invitations to ars.

e held quarterly for program sponsors with invited speakers from universities, government and industry.

kers the organizers of the seminars will have the freedom to draw on the wide range of topics encompassed by the program,

. Pattern and

age processing applications

. A. I. algorithm

search

. Multi-

ocessor architectural developments

. CAD/CAM

ftware systems

. VLSI design

ocess advancements

FACILITIES

ERARCHIES OF AREA NETWORKS

ould be organized around at least central research computation centers containing a variety of production and experimental ems (nodes) interconnected via 100 Mb/s links and forming the central facility for a hierarchical set of closely coupled, high ocal area networks. The centers will be linked to several campuses via the highest available links so that they could be used in a on "as if local" computation centers.

contain supercomputers, AFP's and experimental computers.

proposing ARPA-net II. This must come into operation relatively soon, to be used to interconnect the more remote research to gh bandwidth, such as several video channels would be needed to avoid limiting the interaction between sites. Here, the goal ovide only millisecond delays between processes operating on separated machines.

CILITY

cts would be designing many VLSI chips, the facility would need a way to build state of the art VLSI chips from mask design. this plished by a multi-year committment of appropriate existing capacity to the needs of the program.

ould start immediately and be coupled to existing computer science and computer engineering research facilities and programs. n is strictly on the basis of the intensity and quality of work in VLSI, image processing, parallel computing and AI. Either more or Berkeley Laboratories would be ideal sites for the computation center which would link to Stanford, SRI, and MIT, MITRE or Lincoln Laboratory could be the basis of an East Coast facility. Los Alamos has the largest network of s and support computers including storage and image production. If a central site were Los Alamos, this would force the nd installation of high speed links to other sites.

ENTERS

ery imcomplete list of application centers is included as an example of how work would be contracted by the program office to rs throughout the country.

DELIVERABLES

mpassed is broken into three classes shown in the Deliverables Table. Within each class there are families of projects and finally emselves. The program runs about ten years broken into rough phase transitions at the end of 1985 and 1989. The work in the the research environment and work standards in place and develops the first generation tools and applications. The second several machine realizations that use the tools and runs the test bed applications. In this phase, the research facilities are he machines realized by program efforts. These are in turn, the base of the second generation tools and applications. Finally, provides refinements and solves the hard problems that depended on the new understandings generated in the first two phases .

MOTIVATING SUMMARY

e motivation for this approach is timeliness and effectiveness:

1. THE RESEARCH

OGRAM SHOULD START NOW

2. WE NEED

OUPLING OF INDUSTRIAL R&D AND APPLICATIONS WITH COMPUTER SCIENCE RESEARCH

3. WE CAN BUILD

N EXISTING RESEARCH PROGRAMS AND COMPUTERS

at we start now on the research program, as our computer science research has been drifting these last few years as both mputer science research have both gotten large, diffused, and independent of one another. Significant industrial research Bell Labs and Japanese companies is non-existent and there is no coupling of basic and industrial research. For example, we better coupling of Bell Labs work to the Japanese computer industry via NTT's, ECL, than between Bell Labs and the U.S. lustry. Furthermore, both the academic and industrial research communities are now poorly coupled to real applications. We ogram focus of some of the existing research efforts into a goal directed system will enhance their productivity and enable the a vital Information Industry for the 21st Century.

APPENDIX 1

SOME CRITICAL GLOBAL QUESTIONS (AND ANASWERS)

1. Why is the tablishment of national facilities the correct way to attach the parallel problem?

. No single lab now has critical mass or focus in anyone area - currently all resources are difused.

. The lab(s) and programs operate together to do the work.

. Users, architects, and builders must couple.

2. What impact ll this proposed program have on existing research facilities? Programs?

. The intent is to build on, and extend current facilities by additionla resouces. We believe that this program is close enough to some of the existing.

2a. What about the extra space required for these facilities?

. We don't ow.

3. How will this effort help the basic problem of a shortage of qualified researchers?

. It is hoped that a "program" will stimulate the demand to produce more researches over the long term.

. Short term, the focus should increase everyone's effectiveness.

. We hope to apply industrial researchers to the problem that are now difused and often operate as a sub-critical mass.

4. Who is supposed to benefit from this proposal and in what specific ways?

(See Section on Program Beneficiaries)

5. Is there a nationla crisis and exactly what is it?

(See section on Motivation for the Program)

6.What evidence do you have to support the level of funding which is projected as being adequate to achieve the goals?

This is really a draft outline for concrete proposals. From this we expect specific sites to be established and operated in very rgetted areas: such as parallel knowledge based systems, high performance parallel processing and parallel image processing.

7. What, exactly is the overall objection of the program?

(See the first sentence of this document)

APPENDIX 2

WHY USE CDC'S ADVANCED FLEXIBLE PROCESSOR?

e AFP has demonstrated high performance in digital image and signal -

s. For example, a processor system can transform the every co-ordinate of a million point picture in 1/30 second. Several
operation today. It includes various support software including simulators.

e design, build and then use. A machine as fast and general as AFP would require at least 5 years to build. By using the current
l purpose research tool, we can gain at least 5 years on starting such a program from scratch. To illustrate, consider the several
cts that could use AFP today to simulate architectures. Since we need to evaluate these architectures by using them, we could
benefits and drawbacks of these machines five years (or so) sooner by adopting the AFP as a hardware simulation base.

ovides a very fast, flexible, microprogrammed set of up to 16 computer modules for experimenting in various parallel computing
rious type. A single, AFP microprogrammed processor provides the following capability:

. 20 to 800
ops in 16 parallel, 16-bit arithmetic and logic units

. Microprogrammed control

. Access to 32
egaword (256 Megabyte block oriented memory)

. 2 X 1 Gbits/sec
mmunication with neighbors in ring

processor and multicomputer structure are both provided since, the sixteen processors can be interconnected both to a common
memory and to adjacent processors.

us be used as a tool to study several different computer structures that we believe are much of the basis of the next generation.

so highly parallel, including having functional units with side effects, we believe it will not be imcroporgrammed to any great nvision is that it would operate in several configurations, with fixed microprograms to behave as:

1. Set of

croprogrammed pipelined, functional units within each processor. Four units can be initiated every 20 nanoseconds, although average of seven units operate in parallel for most problems. Because of the difficulty of programming this highly parallel ucture, the most important benefit, or side-effect will be understanding in how to do it effectively. Because the croprogramming so heavily pipelined, we believe a better understanding of dataflow techniques for expressing algorithms will sult from the use. Nearly all high performance machines are pipelined; hence, we believe AFP is a good vehicle to get a better derstanding of pipelining.

2. 16 processor

ltiprocessor with shared memory and very fast interprocessor intercommunication. Here, the processors will be programmed be particular ISP, such C. If C could become the basis of the machine, then UNIX could be run.

3. Set of 16

mputer Modules microprogrammed for particular functions. AFP was designed to be operated in this mode for image ocessing.

4. A dataflow

mputer. This is a special case of item 3 whereby particular computers are programmed to behave as the various functionla units a dataflow computer.

5. A set of

ecial, parallel processing architectures using individual, microprogrammed processors as the functional units of the particular uctures. In this mode, AFP turns out to be a very good emulator of relatively complex VLSI chips.

6. An

perimental Ultra-LAN based architecture. To examine how computers can be coupled effectively and work together on a task, e AFP looks like an ideal for study.

APENDIX 3

ROUGH BUDGET

xpenses are estimated at approximately $18M/year running from 1982 through 1989. Equipment is expensed as delivered. In three "competitive but collaborative" groups are charged with each project family.

SUBJECT: 784/PPA AT STANFORD

GB5.48

I think we made some progress getting Stanford to get their act together so it can be used. It's clear to me that CMU is 10 years
ahead in thinking about parallelism, especially applied to multiprocessors (ala C.mmp and Cm*).

The vision is pretty much along the strategy (dream) I outlined for
PPA: get a 784 in now so that the ultimate software writing and
testing can be started instead of waiting two years till PPA arrives.
The 784 should "simulate" the ultimate machine with n processors and
be able to output what the actual running time would be.

The users there would include:

1. Heuristic Program Project's Machine Architecture Research. This 3 year program, with Bruce as one of the team members, is aimed at examining the performance and parallelism of AI applications as the basis of the next generation architectures. This work is badly needed because I view we have NO understanding about LISP performance, the desireability of special P's for LISP, whether or how LISP can be extended for mP's, etc. This work would also include running on PPA to verify conjectures.

2. John Hennesy's Single Assignment Language for Multiprocessors.

   VAX is currently the host; having PPA would let them accelerate their research by several years. I believe this will turn out to be the way to get performance from mP's. This is also probably the path to build a "parallel LISP" -- not by starting from each of the baroque dialects.

3. Dave Cheriton's distributed processing is quite different, but PPA could be the best vehicle for experimentation because it can provide the most rapid communication.

4. Many applications: Tom Binford - Pixel and image processing; Hennesy - circuit and logic simulation; plus many others in computer science, electrical engineering and the center for integrated systems.

5. Jeff Ullman - experimentations in parallel algorithms.

Bruce is coordinating the 784/PPA procurement and our part of the
program both within Stanford and DEC.

SUBJECT: STRATEGY (OR BETTER CALL IT DREAM) FOR A HOT MACHINE

We appear to be making excellent progress in the design of
PPA (the 32
processor MicroVAX) which would have the power of roughly a
CRAY 1.
The performance picture doesn't appear to be appreciably
different
than what is given in the attached EMS.

It is becoming increasingly clear that the real limit to PPA
is the
problem of either modifying existing programs or re-
programming to
take advantage of parallelism. Therefore, we must have a
strong
program which puts 4 processor machines in the hands of users
so that
the programming can start. Otherwise, the acceptance in the

market
will be delayed two years until the real machine is in the market.

THE DREAM FOR PPA
Would like to see the following timetable:
    Q184 Ship several 784 (quad mP's) to the test sites so they can be
        used for parallel program development during the next 1.5
        years:
        CMU-Joint development. CMU to use in their Supercomputer
           workbench, and to test the parallel processor AI machine.
        LLL-Debug phyics programs for the Cray mP, and the S1 (16Pc).
        LASL-Physics applications.
        LBL-Physics applications, but move the techniques they've
           learned on their Midas system over to VAX/VMS... help us.
        Illinois-Get them started on our system versus doing their own.
           Kuck knows more about compiling for these machines than
           anyone around.
        NYU-Some bright folks. Save them from trying to build their
           ultracomputer and get them to work on the hard problem of
           software. Currently they plan an 8 Pc in 3 years on their
           way to 16000 Pc's.
        Cornell-Ken Wilson, Nobel Prize winner, has been advocating.
        Stanford-Might get them to want one for AI.

MIT-Might get them to want one for AI, etc. We really need
someone to work on parallel processing for AI languages.
Concurrent Prolog and Scheme (a LISP) dialect are candidate
languages which permit expressing parallelism.
PURDUE, YALE-Has work in this area.
Q384 Ship really good software so that applications can be
developed on PPA. This would include the ability to "simulate"
PPA such that a user can run at 4 x 780 speed and measure the
performance as if it were on an n processor machine.
Q185 Ship first MicroVAX PPA to a test site.
Q385 Ship PPAs to test sites. Verify that PPA matches the results
that were obtained by the 784 and that their software really
runs as predicted.
Q186 Begin shipping PPAs at a volume (eg. 780) rate, thus creating
a new level of price/performance, and performance (for this
price band) that has been heretofore unattainable.

What you think?
Are there other places? (eg. Schlumberger)

SUBJECT: BETTER COST, PERFORMANCE AND PERFORMANCE/$

GB4.S1.24

Cycles for the Masses is beginning to look up. The following table
indicates we have some very interesting possibilities for competitive
machines everywhere. It also shows we are in a new computer
generation, the Fifth, as the cost decreases by a factor of 10 or
performance increases by a factor of 10. This gives a factor of 5-50
in performance/cost over where we are today. Note the following
table of machines.

	Time	Price($M)	Perf.	Mflops	flops/$	# Users
Microvax W/S	85	0.01	0.9	0.45	45.0	1

Scorpio	85	.04	0.9	.45	11.0	5- 500
780	78	0.4	1.0	0.5	1.25	5- 500
790	6/84	0.5	5.0	2.5	5.0	5- 500
Nautilus	4/85	0.25	4.0	2.0	8.0	5- 500
dual proc.		0.4	8.0	4.0	10.0	
PPA	6/85	0.25	40.0	20.0	80.0	5- 500
Titan (proto)	12/83	0.1	10.0	5.0	50.0	1- ?
KL	74	0.75	1.3	0.66	0.9	10- 500
Jupiter	+30(mos)	0.75	6.0	3.0	4.0	10- 500
Cray 1	76	10.0	40.0	20.0	2.0	50-1000
with vectors			100.0	200.0	10.0	
Cray 2/XMP	85	10.0	120.0	60.0	6.0	
with vectors			300.0	600.0	30.0	

Notice there are several ways to get a performance:

1. Supercomputers (eg. Cray) operate in batch mode. At LLNL, a large user gets a maximum of 1 hr/day. Therefore, if one of our systems can deliver only 1/8 to 1/24 the performance, the price performance is likely to be better with a Supermini depending on the problem. In a real environment, most users would rather have something else so they can escape from the center.

2. Supermini, operated as a personal or with a small number of users.

3. The new, powerful microprocessor based personal computer with 750-780 performance. This gives a user the most power. I believe our technical marketplace wants this.

4. The new, shared, Supermicro such as Scorpio - These computers have the best cost/user, but will the added sharing be worth it versus the low cost PC's? This is quite attractive.

5. New, specialized facilities such as PPA, a 32 processor based on MicroVAX, FPS-164, XYCAD for high performance batch. All are quite interesting.

Performance/price depends on the fraction of a system that can be dedicated to a user. With MicroVAX PC - the price may be in the don't care range 10K-20K (or 10% of a professional's salary) but the performance is at 780 level. Therefore, work will migrate both from supers and superminis.

We have some incredible opportunities. It would seem desireable that
we first simply consider Titan and PPA as purely computational
processors, although Titan would eventually be a PC when it has
software. They would be operated as servers running, say Fortran, to
off-load KL's or VAXen via CI.

This VLSI generation is going to generate many more kinds of computers
than ever. Supers, Mainframes, and Superminis are all going to feel
the impact of Supermicros, PC's and interesting specials.

Bottom Line

We've entered an era (the Fifth Generation) driven by the powerful
microprocessor and this drastically changes the price,
price/performance and maximum performance of the systems we can build.

The numbers should reinforce the gut feel that the Fifth Generation is
going to be exciting.

SUBJECT: DISCUSSION WITH RAJ RE PPA AND DEC/CMU RELATIONSHIP

GB5.26

Just talked with Raj an hour or so He says that Kahn and Adams
say the money's in the bank and they are going ahead with CMU part.

I had pushed Allen re the notion that they would go someplace else with our ideas. Raj said no. They only discussions they
are having are with Fairchild building a proprietary chip with
th new Fairchild 1 micron CMOS technolgy. CMU would do the architecture and Fairchild the implementation. It would be based around the Forgie/Newell ideas.

He also talked about Intel's interest in supplying a 432 redesign which Intel ispnding a 100M on, courtesy of Siemens. apparently it has caches everywhere to make it perform.

He discussed the PPA concerns:
want more bus bandwidth so that on next go around 256 Pc's

are
possible.
Want to have a 10-100 x Cray on the 3rd version, by 1992. He wants us to think about evolving the design several times and to try and plan for it.
Wants 1 Gigabyte or so.
Worried about cache size too small

He needs a letter from one of us (It should be from BJ/Demmer/Strecker)
describing our intent and how we want to work with CMU. Raj will
send a template via Siewiorek this week.

He now buys into the 784, provided we can get a big, shared memory. I concur. We somehow have to get a memory of reasonable
size. Is there any work here? What's the limiting factor? Here, they would take it with the small one, provided we can get
an upgrade soon Tom, can you help here? This has to be a problem
that can be solved, and really must be solved to have a good running system (suitable for either production or simulation of PPA).

Preliminary Draft for Commment by Digital Engineering Community

HEURISTICS AND COMMENTS FOR BUILDING GREAT PRODUCTS
Gordon Bell, Vice President, Engineering

Product goodness is somewhat like pornography, it can't fully be described, but we're told people know it when they see it. If we can agree on heuristics about product goodness and how to achieve it - then we're clearly ahead. Five sets of dimensions for building great products need be attended to (roughly in order of importance):
. a responsible, productive and creative engineering group;
. product and design metrics (competitiveness);
. design goals and constraints;
. product evolution, revolution and death; and
. the ability to get the product built and sold.

ENGINEERING GROUP
As a company managed primarily by engineers, groups are encouraged to form and design products. With this right, are responsibilities.

The Team must have:
. a_chief_designer/chief_programmer_to_formulate_and_lead the resolution of the problems encountered in the design; No matter how large the project, it must be lead from a "single head". We often make two errors in leadership: having no clear technical leader/problem resolver, and abdicating to a committee.

Committees do not do design! They are never held responsible, nor are they rewarded or punished. Committees can review.

. management who understand_the_product_space_and_who_has engineered_successful_products; The two most important jobs are:
  . making sure that everyone knows their job; and
  . setting and reviewing work on a timely basis, ie. MBO.
. team skills and resources to implement the proposal so that we adhere to the cardinal rule of Digital, "He Who Proposes, Does"; A plan must include the chief designer, team, project organization and resources (eg. computers). Supporting skills and disciplines are essential in the respective product areas, eg. ergonometrics, acoustics, radiation, microprogramming, data bases, security, reliability.
. an_understanding_of_the_design,_design_production_(eg. CAD) processes,_and_manufacturing__processes; Learning curves apply to all processes! The organization must be staffed with people who understand the product, the design process (CAD and management discipline) and the production introduction process. One or two out of three isn't enough.

Behaviorally, the team must:
. do_it_right_the_first_time; Being correct has the highest payoff everywhere: timeliness, quality, lack of rework, and mfg. cost.

. execute_the_project_in_a_timely_fashion; Virtually ALL of our projects are late because we start too late, don't get it done on time because some critical invention is required, take too long to get it introduced, etc. For the very long, very late projects, the failure is lack of planning, tools and organization. Finally, people burn out. This suggests we:
  . limit_projects_to_two_years_by_a_small_team. We often make an aggressive business plan, then hire the team. They then find out they have neither tools nor technology to do the project.
  . not_predicate_a_project_on_scheduling_inventions_in_the_design, process_and_CAD_areas. If we can't see how to do the work in 2 years, then let's not start the project! This means the product must be cut down to fit the tools, people and process. Advanced developement is to insure that we can do development.
. have a_written_design_methodology that includes: all design processes in the form of manuals, design conventions, conflict resolution, criteria for task completion, PERT structure, etc.;
. be_open_and_have_external_reviews,_and_clearly_written_product descriptions_for_inspection; For new product areas, we require breadboards in addition to the above heuristics. When the

product gestation time equals the generation time, a full advanced development effort is the only way to be successful.
- start_small,_be_reviewed_and_grow_on_its_demonstrated_success;
- learn, in order to handle the increase in complexity that comes with technology. Until there's a formal sabbatical program, individuals would do well to consider taking the equivalent of a semester of technical courses each 10 years.

PRODUCT METRICS KNOWLEDGE includes:
- products_for_which_there'll_be_no_competitor;
- all_product_cost_metrics (cost, cost of ownership, cost to operate and use);
- all_product_performance_and_cost/performance_metrics; These are the goodness measures of a product and tell how easily it will be to sell, and if we have improved. Cost and performance is measured against a state-of-the-art line represented by the first shipment of a more advanced product. Alternatively, when there's no direct comparison, the time goodness is determined from the day the product could have shipped. For example, because of parts availability, Nebula and CT could have shipped two and three years ago based on component availability.
- reasons_why_the_product_will_succeed against present and likely future competition; sure success in the market is to introduce a needed function (eg. 32-bit address) by which all other products have to be measured.
- major_competitor_products by cost, performance and functionality; This should cover the past and future five years.
- leading_edge, innovative, small_company_products;
- productivity, quality and design_process metrics for projects.

DESIGN GOALS AND CONSTRAINTS
Design constraints are generally set as various kinds of standards. These are useful because they limit the choice of often trivial design decisions, and let us deal with important free choices, the goals.

Goals are vitally important because they target our uniqueness.

Poor "mind-set" standards can create poor products, even though they may have made sense at one time. The historical English measures is a good case in point. Currently, the 19" rack and the metal boxes Digital makes to fit in them, and then ship on pallets to customers, act as constraints on building cost-effective PDP-11 Systems. This historical "mind set" standard often impedes the ability to produce products that meet the 20% per year cost decline curve.

. Goals_and_constraints must be_written_down_and_updated_from_the day_the_project_starts. Virtually every product failure and period of product floundering is a result of no clear goals and constraints since everyone has a different idea of the product.
. A_product_can_only_have_a_few_goals_and_constraints. The ranking is usually: it must work and have improved cost of ownership, be the shortest time to market, highest performance and lowest cost.

We must adhere to standards which we either follow or set!
. If_a_standard_exists,_follow_it_or_change_it_for_all! We lost the IEEE Floating Point format. It is likely we will eventually have to support it.
. If_a_standard_is_forming_go_all_out_to_set_it. When formed, then follow it. We didn't make DDCMP a standard. When HDLC came, we didn't use it. The result: expensive, low performance products.

Standards can be grouped into four distinct sets:
. DEC Engineering Standards; These cover most physical structures and design practice for producibility, and assimilate critical external standards, such as UL, VDE, and FCC.
. professional society, industry and area information processing standards, from EIA, CBEMA, ECMA, ANSI, ISO etc. such as Cobol '74, Codasyl, IEEE 488;
. defacto industry wide information processing and communication standards such as IBM SNA, Visicalc;
. standards implied by the architecture of existing DEC products to insure our customer software investments are preserved include:
    . architecture of computers, terminals, mass store and communications links; Our current ISP's include 8, 11's, 10/20, VAX, 8048, 8080, 8086, 68000; VT52, VT100, keyboards, Regis; MCP; HDLC, CI, NI, SI.
    . physical interconnect busses for computers and for interconnecting them CT, Q, U, NI, CI, etc. These insure that future system products can evolve from component and computer options between generations.
    . operating system interface file commands, command language, human interface, calling sequence, screen/form management, keyboard, etc.

. Products_must_be_designed_for_easy_translation_into_in_any natural_language_since_we_are_an_international_company.
. All_products_must_have_be_customer_installable_and_maintainable.
. Portability_is_an_important_goal. Personal computers must be portable! We must achieve this for all systems ASAP!

WHEN TO CREATE, WHEN TO EVOLVE AND WHEN TO STOP PRODUCTS
Engineering is responsible for designing evolutionary products in our markets AND for producing products that are natural to our tradition of supplying the most interactive, cost-effective computing. If a new product such as personal computing emerges and we do not have a product, engineering has failed, independent of being asked for it!

Given all the constraints, can we ever create a new product, or is everything just an evolutionary extension of the past? If revolutionary do we know or care where product ideas come from? The important aspect about product ideas is:

. Ideas_must_exist_to_have_products! If we don't have ideas to redefine or extend a market, then we should not build a product.

It is hard to determine whether something is an evolution or just an extension. The critically successful products are likely to occur the second time around. Some examples: PDP 6,KA10,KI10,KL10,2080; Tops 10,Tenex,TOPS20; PDP5,8,8S,8I/L,8E/F/M; OS8-RT11; 11/20,40,34,44; RSX-A... M, M+; TSS-8,RSTS; various versions of Fortran, Cobol and Basic follow this; LA30,36,120; VT05,50/52,100, 101 etc.; RK05,RL01/2.

. A_product_tree_MUST_be_maintained_by_each_engineering_group showing roots, gestation time and life.

Goodness_and_Greatness = NO CRAPPY PRODUCTS!
All products whether they be revolutionary, creating a new base, or evolutionary, should:

. be elegant and high quality; Russ Doane's working definition is: "every feature contributes two benefits", like a double pun. Quality means no excess. Elegant, high quality designs, do double duty with a minimum use of resources. Quality is also the absence of errors, by being right the first time so that it doesn't have to be inspected or redone.
. offer_at_least_a_factor_of_two_in_terms_of_cost-effectiveness over_a_current_product; We have classic failures because a CPU cost has been minimized, only to find the total system cost has barely changed 10% and the total cost to the customer is only 5% lower! If each product is unique then we will have funds to build good products.
. be_based_on_an_idea_which_will_offer_an_attribute_or_set_of attributes_that_no_existing_products_have; For example, the goals and constraints for VAX included factor of two algorithm encoding and also offering ability to write a single program in multiple languages. VT100 got distinction by offering 132 columns and smooth scrolling.
. build_in_generality,_and_extensibility; Historically we have not been sufficiently able to predict how applications will evolve, hence generality and extensibility allow us and our customers to deal with changing needs. Extendable products also permit mid-life kickers to products. We have built several dead end products with the intent of lower product cost, only to find that

no one wants the particular collection of options. In reality, even the $200 calculators offer a family of modular printer and mass storage options. For example, our 1-bit PDP-14 had no arithmetic ability, nor could it be a general purpose computer.

As customers used it, ad hoc extensions were needed to count, compare, etc. and it finally evolved into a really poor, general purpose digital computer.

. be_a_complete_system,_not_piece_parts; The total system is what the user sees. A word processing system for example includes: memory, keyboard, tube, modems, cpu, documentation including how to unpack it, the programs, table (if there is one, if not then the method of using at the customer table), and shipping boxes.

. be_a_great_system_because_the_components_are_great; We should not depend on system markups and software functionality to cover poor components and high overhead.

. if_we_don't_make_it,_buy_it; We must carefully decide what components to make versus buy. It is very hard for an organization to be competitive without competing in the marketplace, hence unless we sell it, we should buy it.

Product_Evolution

A product family evolution is described on page 10 of Computer Engineering along the paths of lower cost, and relatively constant performance; constant cost and higher performance; and higher cost and performance. In looking at our successful evolutions:

. lower_cost_products_require_additional functionality_too; A lower cost product, with constant performance or constant function is risky because a new customer base and new way of marketing may be required. Some other company may, however, be successful with the concept. The PDP-8, based on new technology, was radically more successful than its higher priced predecessor, the PDP-5, because it was 2/3 the price and 6 times more performance. The PDP-8/S was a failure at 2/3 the price and 15 less performance than the PDP-8. There are similar stories about the LA 34, VT50/52 and PDT as replacement products.

. constant_cost,_higher_performance_products_are_likely_to_be_the most_useful; Economics of use, the marketing channel and customer base are already established and a more powerful system such as the LA120 will allow higher productivity (see Computer Engineering for the understanding and economics). In the 11's there was a successful evolution: 20, 40, 34 anChied 44. Not the 60. The 11/70 was probably our greatest success; it was billed as a mid-life kicker to the 11/45-55.

Revolutionary_New_Product_Bases

. A new product base, such as a new ISP, physical interconnection, Operating System, approach to building Office Products, must start_a_family_tree_from_which_significant_evolution_can_occur. The investment for a point product is so high that the product is very likely not to payoff. In every case where we have successful evolutionary products, the successors are more successful than the first member of the family. Point products with no follow-on will probably fail all roi tests.

Product_Termination

. A_product_evolution_is_likely_to_need_termination_after successive_implementations,_because_new_concepts_in_use_have obsoleted_its_underlying_structure. All structures decay with

evolution, and the trick is to identify the last member of a family, such as the 132 column card, and then not build it. This holds for physical components, processors, terminals, mass storage, operating systems, languages and applications. Some of the signs of product obsolescence:

    . It has been extended at least once, and future extensions render it virtually unintelligible.
    . Better products using other bases are available.

SELLING AND BUILDING THE PRODUCT

"Buy in" of the product can come at any time. However, if all the other rules are adhered to, there is no guarantee that it will be promoted, or that customers will find out about it and buy it. Some rules about selling it:

. it_has_to_be_producible_and_work, AND be useful to software; This, although seemingly trivial rule, is often overlooked when explaining why a product is good or not. If it is a piece of hardware that requires software to support it, the hardware must be available to the programmers who must support it. Software engineers approach new hardware with much caution! The often ask: is it significant? is it needed? why isn't it compatible with the past? If a hardware is viewed with distrust by software engineers it may be met with the same distrust by customers!

. a_business_plan_with_orders_and_marketing_plans_from_several marketing_persons_and_groups_needs_to_be_in_place; Just as it is unwise to depend on a single opinion in engineering for design and review, it is even more important that several different groups are intending to sell the product. Individual marketers are just as fallible as unchecked engineers. This rule can and must be violated for revolutionary products!

. never_build_a_product_for_a_single_customer, although a particular customer may be used as an archetype user; predicating a product on one sale is the one sure way to fail! Paraphrasing a remark by former GM executive Charles Wilson: if it's good for General Motors, it may only be good for GM.
. it_must_be_done_in_a_timely_fashion according to the committed schedule, price and functions as previously described;
. it_must_be_understandable_and_easy_to_use. The small size, complete hardware books were the DEC trademark that established the minicomputer. We must revive these such that a particular user never need access more than one.   Simplicity must be the rule for our documentation.

What heuristics are missing? What heuristics do you disagree with?

What heuristics could be removed? reordered?

Could I please have your feedback before this becomes a final draft?

3/13/82 Sat 19:47:01 GB3.S2.5

OTHER PREMISES AND CONSIDERATIONS

1. OUR BASE PRODUCTS ARE OK, EXCEPT THERE ARE TOO MANY. GO FOR BETTER

LONG TERM STRATEGY. SKIP HOLE FILLING WHICH INCREASES CLUTTER.

2. WE'RE SUPPORTING TOO MANY SYSTEMS.

3. NATURAL PRESSURE THROUGH SALES, DECUS, MARKETING AND DEVELOPERS

REQUIRES ALL SYSTEMS TO BE SUPPORTED AND ENHANCED FOREVER.

4. NATURAL MARKET PRESSURE FORCES MORE GENERALITY INTO EXISTING

PRODUCTS. THIS DETRACTS FROM MOVING TO APPLICATIONG.

5. A "GREAT SYSTEM" WILL ATTRACT LANGUAGES (COMMON, EXOTIC AND

SPECIAL APPLICATIONS) AND APPLICATIONS BY EXTERNAL USERS AND THIRD

PARTY COMPANIES. TOO MANY SYSTEMS BY A MANUFACTURER WILL DETRACT FROM

THIS NATURAL MAGNET.

6. ALTHOUGH WE DON'T HAVE A PRECISE UNDERSTANDING OF VAX ACCEPTANCE,

IT FEELS LIKE "A GREAT SYSTEM" (LOVED BY KNOWLEDGEABLE USERS,

INSTALLS EASILY, WORKS AND IS EASY TO USE). IT'S EXCITING

ARCHITECTURALLY AND FITS WITH 11'S. THERE'S PRESSURE TO EXTEND IT

WITH MORE PERFORMANCE AND AT LOWER (11/34) COST.

7. EVEN WITH TOPS 20, THE 2020 HASN'T FOUND ITS NICHE YET.

draft press release

DIGITAL ACCELLERATES 32-BIT STRATEGY

ST. LOUIS, MO -- 23 MAY 83 -- Digital Equipment Corporation announced today that it is accelerating its program for moving users of its 36-bit products over to its more broadly-based 32-bit architecture.

Speaking at the Spring symposium of DECUS (Digital Equipment Computer Users) held at the (name of hotel) here, Winston Hindle, Vice President Corporate Operations, told 00000 members
of Digital's users group that the company has decided to" divert its development resourcEs away from a follow-on 36-bit machine and into accellerated development of hardware, software and communications
capabilities to enhance our already-formidable offering of 32-bit products.

"It has taken longer than originally planned to develop a follow-on to our existing DECsystem 10/20 family and it looks like
we're still three years away," Hindle told the users. "So, we have decided instead to shift some resources and speed up the development
of software and communications tools that will allow DECsystem 10s and
20s to be more easily integrated into our corporate architecture.

"We think the needs of our customers would be better served by concentrating our high-end development efforts around our more broadly-based VAX architecture," Hindle said.

...hype VAX, clusters, LANs....

SUBJECT: PRICE VS. FUNCTUALITY FACTS

We (you) could add much insight to BOD (us) by taking a number of the products which change in price or function (you have a metric) and plot log (price) vs. log (volume) for a given functionality (e.g. LA30, LA36, LA34), and (DS210, VT78, VT278 [projected]). This should begin to answer some arguments and might give us great business insight re predicting volumes in turn of coefficients of elasticity (e.g. 20% lower cost doubles volumes). Then, we might also use price not cost to set operating points for factories rather than redesigning every product for 20% lower cost. These kinds of things are probably only done in only in business schools, but since I'm only an engineer it probably doesn't have any application to us...or does it? At least the data shouldn't hurt anyone and would make me feel better about affects if price, functionality on volume.

SUBJECT: WHEN DO WE MEET ON THIS?

I got the Celi/Lomicka report.

Please get us (and your users) together to settle on the goals.

My priority is: quality (i.e. works), time to market, performance, range (print-no buffering to graphics server)... cost. Please select type 3 using an F (J's an upgrade) for the base work, with the option to go to type 2 if a limited product is possible -- but wait till it runs to decide. We'll use the MicroVAX board when it arrives. I don't see why we have to use Seahorse I since the processor isn't doing anything except routing. I assume the main controller is a 68K.

We need a product . . . yesterday !.

SUBJECT: REDUNDANT PRINT SERVER EFFORTS FROM NOD

GB5.20

The only 4-8 laser print controllers / print servers I know of are:

1. Craig James, John Celi, Roy Lomicka, Mickey Smith -- Printer group

2. Baum, Conroy, Feinberg, Friday, Fultyn, Laurune, Lint, Samberg --
Consortia of people who have a working prototype .

3. Brian Reid, Forest Baskett - Western Research Lab A/D project

4. Ron Criss's Server Group under Bernie (wait>2 years!)

5. Barry Folsom -- Omninet Shared Printer (get it soon)

6. CT clusters -- has/had a print server project?

7. MicroVAX / Seahorse I -- Server

8. Office ? Old typesetting group on LN01

9. A VAX based print/plot server that Marlboro uses for its

computation network.

I really don't expect to ever see a modern DEC print server that can
print graphics, multifont as a product given our perfect record of
producing nothing in this area, (including the LN01) there are
undoubtedly more internal efforts at each site to serve comp centers
and CAD groups.

Is there anyway to get a product? Or more engineering budget to
support these redundant, folks?

SUBJ: PRINT STATION WE MUST REDIRECT IT

TO: JIM CUDMORE
SAM FULLER
BILL JOHNSON
JACK SMITH

Date: 6/13/83 Mon
From: Gordon Bell
Dept: Eng. Staff
MS: ML12-1/A51 Ext: 223-2236
EMS: @CORE

The attached memo fairly accurately reflects our meeting.

At the meeting, I felt we should continue on our present course to build the current print server interface, while having a simpler controller built in parallel for software development.

Today, I feel we should DROP the design because the product and project are so far beyond our capabilities. We would go on some kind of buyout or to a much simpler plan. One of our software groups has an operational breadboard of a printer, and this might be the basis of a product, too.

A MUCH SIMPLER PRODUCT AND PLAN

We might change the project, reflecting a much simpler product structure on which the group has a chance, to implement. There is no way that the current group, with this set of specifications, abilities and processes could ever come close to building an operational design in anything under 3 years, not ONE. In general, the approach is similar to the recent redirection to get a Personal VAX based on the Qbus, and that approach we should have used for the PRO, Pluto and VS100... all of which are roughly 2-3 years late, and uncompetitive using better tools and a more experienced staff.

In making the change, we should in parallel train people in hierarchical design for complex systems, and provide them with the managment and process tools to be successful. I see a problem not unlike Jupiter. (I suspect this may be the reason why the LA200 has taken many years and will never ship.)

The approach:

- Clarify the distributed organization, and make sure there is adequate management to undertake this complex projectt.
- The print server should be renamed to be an Ethernet-based Print Station to more properly reflect its function and structure. The product functions have to be drastically cut.
- The server will NOT queue print jobs, but operates as a printer attached to Ethernet. It doesn't have a disk or console. Seasoftware permits very nice debugging from remote VAXen. Fonts, and station programs are nicely stored on a remote VAX.
- The station will be based on Seahorse I (followed automatically by II). Seahorse I operates in prototype mode TODAY with a VAX, Seasoftware, an NI, and a Unibus to Qbus adapter.
- The hardware for this first product should be greatly simplified so that we can get a completely debugged system up asap. This would correspond to the current products on the market. Fundamentally, the design approach is several stages:
   1. get the product built as quickly as possible in software, while using rigorous design methods with

specs. We will ship this unless it's too slow. If it is too slow, then microcode Seahorse to have the bitblt function. This will get the text-only print mode to be clearly acceptable.
2. when we understand the functions well enough and the amount of processing they require, selectively move the functions into hardware.
3. replace Seahorse I with Seahorse II (for cost reasons). A bounded version with MicroVAX, NI, etc. may be considered when we understand the current design space AFTER building a product.
4. VLSIzation of a function such as line drawing or bitblt might be considered when we understand performance.

. acquire and use the Adobe system for graphics description and font generation. It may be run partially in the station.

TODAY, USING THE LN01

C-T.printer-

PROPOSED STRUCTURE

```
C...C
!___!__ (Ethernet)
 !
 T.print_station
```

Where T.print_station :=

```
------- (Ethernet)
!
K.qna Pc Mp K.laser-T.print_engine-    (Pc :=
Pc.Seahorse!Pc.Microvax)
!_____!__!__!___(Qbus)
```

and K.laser is a double buffer memory which alternates between printing and being loaded by the processor. Pc accesses the Mp.

The current design has two gp processors and their associated busses, neither of which do very much except talk to each other and prepare work for a third, microprogrammed processor, which also controls a complex chip for line drawing. This design is based on one MicroVAX, and no special hardware in the first, potentially slow implementation. There are several ways to speed the design up:

- doing more operations in the hosts in preparing documents
- microcoded pixel operations
- some form of the current microprogrammed machine, or one special hardware operator to do a time consuming operation

WHY I THINK THE PROJECT HAS TO BE REDIRECTED

The reasons for this are not whimsical, but based on several previous projects, including Venus, Jupiter, VS100, Pluto, HSC and PRO.

- There's no definition or spec on what the system is supposed to do. Likewise, functional specs are non-existent for each hardware and software sub-component.

  The sketchy hardware specs are non-hierarchical, incomplete (memory sizes or locations aren't given, busses and links to busses are missing, etc.), conflicting, informal, etc. There isn't a manual for the various microcode machines or the hardware. I've seen nothing on software!

- There's no analytic data backing up any of the design, nor is there any data showing how each of the subsystems must perform.

- The design I see is incomplete (as reflected by the lack of specs), even though there's hardware coming. Flaky, incomplete hardware is a giant millstone! As such, it is precisely in the state of Jupiter when it was cancelled, even though much hardware was built and some of it running for 2 years.

. The design is far too complex to ever operate with this level of rigor in the organization, specifications and tools to carry out the design.

. The printer group is evolving to take on this major software effort, while lacking software engineering personnel and practices.

. We should have done PRO this way. Put on the Qbus, get the software operating, ship, and then cost reduce if necessary with a new bus, accelerators, etc.

. The VS100 and Pluto have similar structures: seperate 68000's, accelerator hardware with microcode and specialized software. ALL have taken more than 3 years, NONE perform acceptably, nor do we know why. On VS100, two of the processors are now acknowledged to be redundant.

I'm not advocating a large organization. This one is already larger than DECwest, and the project is of similar size. The quality of the project is over an order of magnitude poorer in every respect. As such, it is unlikely to ever reach completion.

Jim,
I think you have to lead us through this one. We badly need this printer. If it's available outside, and the project can be entirely software, then that's the easiest way out. Alternatively, we can go the painful route of training the people rather than giving up on them and never being competitive or able to build complex systems. Frankly, I think there are enough bright engineers among the intellectually bankrupt management structure that it's worth what will be a very difficult project and process. Success is probably some combination of the two.

Since the distribution of function and the need to print what our workstations produce is such a key part of the product structure, I have no choice but to help. What do you want from me?

ATTACHMENT
The attached memo fairly accurately reflects our meeting.

At the meeting, I felt we should continue on our present course to build the current print server interface, while having a simpler controller built in parallel for software development.

Today, I feel we should DROP the design because the product and project are so far beyond our capabilities. We would go on some kind of buyout or to a much simpler plan.   One of our software groups has an operational breadboard of a printer, and this might be the basis of a product, too.

A MUCH SIMPLER PRODUCT AND PLAN

We might change the project, reflecting a much simpler product structure on which the group has a chance, to implement. There is no way that the current group, with this set of specifications, abilities and processes could ever come close to building an operational design in anything under 3 years, not ONE. In general, the approach is similar to the recent redirection to get a Personal VAX based on the Qbus, and that approach we should have used for the PRO, Pluto and VS100... all of which are roughly 2-3 years late, and uncompetitive using better tools and a more experienced staff.

In making the change, we should in parallel train people in hierarchical design for complex systems, and provide them with the managment and process tools to be successful.   I see a problem not unlike Jupiter. (I suspect this may be the reason why the LA200 has taken many years and will never ship.)

The approach:

- . Clarify the distributed organization, and make sure there is adequate management to undertake this complex projectt.
- . The print server should be renamed to be an Ethernet-based Print Station to more properly reflect its function and structure. The product functions have to

be drastically cut.

. The server will NOT queue print jobs, but operates as a printer attached to Ethernet. It doesn't have a disk or console. Seasoftware permits very nice debugging from remote VAXen. Fonts, and station programs are nicely stored on a remote VAX.

. The station will be based on Seahorse I (followed automatically by II). Seahorse I operates in prototype mode TODAY with a VAX, Seasoftware, an NI, and a Unibus to Qbus adapter.

SUBJECT: SOMEHOW FINDING $'S TO BREADBOARD THE LQP/SHEET FEEDER

I really liked what I saw. Somehow we have to move post
haste
to get a breadboard to see if there are any flaws in it and

how hard it will be as a project. The intriguing thing is that
we could take the WHOLE Spinwriter lqp market away from Diabolo,
NEC, Qume and C Itoh. This ought to be a major incentive to go balls out and get it. Also the add on ribbon/belt market would be enormous.

Let's get to working breadboards immediately. What will we NOT
do in order to get this one?

SUBJ: The Centronics Quietwriter--Is it for us?

Date: 8/21/79
From: Gordon Bell
MS: ML12-1/A51 Ext: 223-2236

TO: Jim Bell, Dick Clayton, Henry Crouse, Bob Glorioso, Gene Jones, Walt Tetschner, Art Williams, Bill Zimmer, OOD

Although I'm enthusiastic that the Quietwriter could be a major alternative to the Selectric or daisy wheel impact printers, it is important that we do a thorough evaluation. Right now it looks good, but then at this stage of engineering, many things always look good. It seems like the alternatives can be ranked:

	Selectric Dot Matrix	Daisy Wheel		Quietwriter
quality	1	2	1?,2?	3...but rapidly improving
noise	4	3	1	2
font variability	4	3	2	1
graphics ability	3	3	2?	1
reliability	3	4	1?	2
best cost	?	?	?	?

So the issues are: the cost differences may not be significant, the Quietwriter's quality is unknown, but unless it gets to Selectric level, it is probably not worth pursuing, and it feels like Dot Matrix will come up rapidly because everyone is working on it in one form or another. I resent the fact that we have to really evaluate the Quietwriter because life would have been soo simple proceeding along the matrix path.

I hope this adds some balance to my position. Let's go flat out to evaluate the Quietwriter, cause it could be significant for the short (5 years?) time frame. We do need the quality most likely for mail and for personal communications. In the long run I believe dot matrix will win.

LOC/MAIL STOP: ML12-1/A51

SUBJECT: SHEET FEED VS. ROLL OR FOLDED FORM FEED: AN OPPORTUNITY!

If we could go to ALL sheet feed it seems it would offer incredible opportunity for us.

Having only sheets, permits:

0. Handling all kinds of paper including envelopes, thereby allowing us to get rid of the lingering typewriters in the office.

1. Any paper can be used.

2. It's right. It avoids the cruddy roll paper where it's impossible to get to be 11" long. It avoids the messy bursting and stripping required in the folded/form feed.

3. It's unique and represents a competition knock-off.

4. By using cartridges, paper types can be switched early.

5. Eliminates the "box" or "roll" and is easy to place anywhere.

6. A different style/shape of printer can be made!

What do you think?

SUBJECT: WE HAVE TO SELL PRO'S AND CI CLUSTERS

GB6.3

Jack,

I think we need a major amount of help from you in regard to selling
PRO and the CI Clusters. For starters, we really need an audit, by
your committee about what's been going on. The goal is to make much
more sales and PROFIT. My analysis follows.

CI CLUSTERS PROBLEM
A lack cluster announcement considering that we have a major product.
I think the problem is that there's NO product manager for Clusters,
and it simply gets done somewhere in the bowels of VAX base products
marketing. Note clusters is:

- hardware options on the 750 and 780
- some cable and a connector (probably a Product Manager for it)
- VMS 3b.n, part of a release
- HSC which is clearly and seperately hyped

Note the absence of anyone who cares whether this works as a system,
or that this collection can be sold as a significant system whose
whole is greater than the sum of the parts. Rick Case's memo showed
that we could promote it as the whole which is at least equal to the
sum of its parts in terms of performance! Colorado recently just

tried it all together. (There was no one there who took the system
responsiblity.)

Fundamentally, we need your help to judge what so far is an non-existent act, and then help us get it together.

PRO PROBLEM (OPPORTUNITY)
PRO was late with its software, and it has been poorly advertised
internally. Rumours abound. For example, it's incompatible with RSX
and VMS, and there's a new PRO out soon on the Qbus. (This one hasn't
been started yet.) All of these problems mean poor sales.

It's vital that we have a set of products that get customers onto DEC
standards and files. PRO has great compatibility with Operating
System interfaces and file systems with VMS and multi-user RSX. A
great variety of programs from Fortran to third party software run
compatibly across the PRO-RSX-VMS trio. No other system or vendor has
the compatibility across PC's, team, group and mainframes like PRO
does. PRO will still ship about $100M this year, but is below plan
and still needs more care and pulling.

Again, I think we need an audit, and help from your committee.
Please help.
Gordon

MESSAGE ID: 5202115201

SUBJECT: CI CLUSTERS, OUR HOTTEST PRODUCT. NOW WHAT?

It's incredibly disturbing to see such a lackluster approach to the marketing and sales, especially since we seem to need the revenue.
The announcement should have been front page news!

In Colorado, they're running a maximum configuration VAX Cluster with:

    12-780's
     4-HSC's, with
         2 x 24-Dual ported R81's (over 20 Gigabytes)

It was very impressive in terms of performance and reliability... now that it has been tested. Also, American Bell has some running and gave a very strong endorsement at DECUS.

Recall that 5 years ago HYDRA was started as the most important project to build a competitive (especially with Tandem) system, providing high reliability and incremental upgrade. Also, we

have a
unique product in the HSC disk server. IT's HERE now.

While one might observe that we're following Land's guideline that
"marketing is what you do when you don't have a product", since
    1. we've put all of our marketing and sales attention on PC's
    2. VAX clusters are good enough to sell themselves.
However, I think we need someway to tell the world we have this unique
product. Also, it might be possible to get sales from competitors
like IBM because of our uniqueness.

Marketing and Sales Committee, is there anyway to promote this great
product?

How about at least a review at your committee?

Can Rose Ann get this marketing charter, given the clear marketing
failure to date?

EXPLICIT PROBLEM

WE ARE POSED TO SPEND TOO MUCH IN ENGINEERING!

REAL PROBLEM(S)

1. THE RELEASE OF NEW PRODUCTS CAUSES HIGH START-UP EXPENSES IN OTHER AREAS.

2. WE HAVE TOO MANY OVERLAPPING, INCOMPATIBLE BASE HARDWARE AND SOFTWARE ARCHITECTURES.

. OUR CUSTOMERS/SALES PEOPLE CAN'T DECIDE

. WE DON'T HAVE THE SALES VOLUME (GIVEN A LOWER GROWTH) TO HAVE COMPETITIVE PRODUCTS

. PRODUCTS ARE 1/2 STARTED (OR 1/2 DONE)

. WE HAVE NO PLAN FOR IMPROVING COMPATIBILITY AND SAVING OF OUR OWN, BUT ESPECIALLY OUR CUSTOMER'S SOFTWARE INVESTMENTS

3. WE HAVE NO FLEXIBILITY FOR ANY ESSENTIAL PRODUCTS (E.G., LOW COST,LETTER QUALITY, ELECTRONIC TYPEWRITER).

4. WE HAVE NO FLEXIBILITY TO RESPOND TO ANY THREAT FROM WHAT COMPETITORS USING 21-BIT MICROS MIGHT PRODUCE!

5. WE SAY WE WANT APPLICATIONS, BUT WE INVEST ELSEWHERE (ESPECIALLY BASE SYSTEMS).

IMPROVING THE INTERFACE AND STRUCTURE OF SYSTEM'S MANUFACTURING
AND ENGINEERING

PROBLEMS
The gestation times for system products has been increasing to unacceptable levels, given the rapid change in technology. Our competitiveness is decreasing, given our organization structure, processes and the interface between engineering and manfacturing! Recent major slips in Nebula, Comet, the 24 and 44, together with gestation times of 36 - 60 months for products involving no special lsi are typical. In contrast, comparable complexity products are released in 12 - 18 months shorter times in the mass storage and terminals areas. The interface in the Large Systems Group (MR) seems to be fine, given co-location and a clear, manufacturing organization. It is unclear how the Distributed Systems Group (Lacroute) is aligned with its Manfacturing counterparts... although it is clear, the product gestation times there are too long.

Similarly, the productivity in manufacturing is not increasing at all, despite higher quality products, customer merging, and a higher materials percentage.

ACTION

The responsible folks (Hanson, Thorpe, Demmer and Gutman) need significant help in rethinking how we are going to build competitive products. Larry and I would like a one day Woods with you to review and brainstorm this issue. Shel's needed.

SYMPTOMS AND OBSERVATIONS ON LENGTHENING PRODUCT GESTATION TIMES

. gestation times have risen from 12-18 months in the mid 60's when we were all in 1 building and built our own modules, to 24 months when we had multiple sites and used conventional I/C's, to our present 36 months when conventional I/C's are involved and when many plant stages are involved. For Comet, 17 manufacturing groups were involved in a product built on our gate arrays... and the gestation time, already 5 years is still not complete (the floating point unit isn't out)! Nebula has taken 60 months, whereas the 780 only required 30 months. Let's cut gestation time in systems by 12-18 months.

. engineering has lost several key designers because they do not get the key engineering reward: Seeing a Product Ship. (Computer designers may be like mathematicians, in that they do their best work before age 30. They can continue in an uninterrupted fashion at this rate, given they have continue to design. These long gestation times impair getting the competitive designs from these few, creative individuals!)

. there is a major misalignment of goals between engineering and manufacturing. Engineering is measured on product competitiveness (cost, performance and timeliness) while manufacturing measures are inventory and capacity.

In the specific case of Nebula, there is not a joint goal of shipping Nebula on the newly revised and elongated schedule.

. technology for manufacturing can not be applied. We need drastic rethinking in the way we manufacture and test modules, but there's no one here to couple with at the system's level. For example, specifying and testing modules would produce drastically better quality. I believe IBM manufactures this way, and the result is a factor of three better reliablity at the module level. In order to do this, we must have co-operation, together with better specifications from both organizations.

. we simply aren't getting enough performance from manufacturing. Given that Nebula is shipping in May, and has been operating for two years, we should be able to estimate the costs quite accurately (no more than 10% ... not 25%!)

. there is a major misalignment of organization structure between engineering and manufacturing. While Larry and I do not know every design engineer, we do know the whole management chain and the KEY designers for every major project. For Nebula engineering: B/P, Demmer, Croxon, Breslin (Nebula program), Barry (cpu), Okin (designer)... 7 levels below KO).

For Nebula Mfg: Smith, Hanson, Thorpe, 16-Bit Program Manager (with no line responsibility), Several Plants reporting via different paths with divided responsibility which engineering must co-ordinate, New-Product Start-Up group, Nebula Startup, head, Nebula start-up engineers, coupled to Nebula startup workers, given the project is distributed throught the volume plant. This is a chain of at least 9 people, many of whom have no ability to direct either via power or funding.

. clear manufacturing organizational responsiblity is not present to cover the plants and groups within a plant on a product basis. Note the above, unclear responsibility and escalation path with respect to problems and schedules.

. we are evolving to a very large manufacturing size and bureaurcracy because of our apparently unwritten rules to build everything ourselves. This strategy should be under constant review. Response times of large organizations generally decrease and we seem to be no exception. We are following in the tradition of NCR and Burroughs, and are evolving completely counter to an organization like Apple which has $300M sales for 1500 people, for a productivity of $200K per person, versus our $50K. Apple and the Japanese solve many of the response time and organizational drive problems by the two tier supplier structure based on subcontracting ALL SUB ASSEMBLIES. IBM gets higher productivity by massive automation.

. THE SYSTEM has evolved to be completely unresponsive to new products and the number of organization levels has caused us to arrive at a point where escalation via either the engineering or manufacturing chain never occurs! (Recall the basic statement that our gestation times are lenghtening, yet no one is telling us this except a few impatient engineering troops as they walk out the door!)

. we are not staffing the start-up teams with people with computer systems understanding. Our systems are becoming more complex and manufacturing people must be skilled in electronic systems manufacturing (modules, sub-assembly, systems integration, firmware, software, manuals and testing). It is ludicrous to have the Nebula manufacturing manager come from the GE Turbine Division! In contrast, this would never happen in disk manufacturing.

. we have an estimate from TEAC (Japan) of 6 months to get a customer mergeable unit equivalent to the RX02. Our schedule is 14 months. (I just looked at an equivalent system product with an aggressive? 122 week schedule!)

We almost have adequate gestation times for mass storage and terminals where there is clear alignment of products with the organization. Bill Hanson's response is "Boy are they going to have problems when they get big!". A better reaction would be: "Let's learn from them, segment and have clear responsiblity and alignment of products with the organization." In this way we get focus, response time and lower costs via learning curves.

. we have a similar set of problems solely within the engineering processes surrounding the design, fabrication and testing of basic products. (We intend to make these processes competitive.)

. we have a similar set of problem interfaces in the software release process. (We intend to solve this.)

. manufacturing management attitudes toward change appear to be fundamentally top-down directive, versus define and then provide a framework to solve the problems which are beyond a single individual's ability to solve. Fundamentally Engineering Management does not believe that the Top Down Directive approach to the troops 9 levels down will solve this problem! We believe the structure is fundamentally wrong, and the troops can not fix the system no matter how we command them to... only we can start the fix, i. e. lead, then they can tell us how.

Now is the time, but are there any leaders?

Thanks for inviting me to speak. I was grateful to accept for several reasons:

.I wanted to thank BJ and John for putting this on, and you for attending. Even though I love products a lot, I've come to realize that they cannot be built without these processes. We now spend significantly more to develop the processes than the products.

. I wanted to communicate with you since the plumbing operation I had about 5 weeks ago, and to say that I'm doing fine. I drove to see the doctor today and don't have to go back for amonth. The only stress we have here is trying to convince Gwen to cut down on butter (which we eat very little of), but the DR. was of little help becasue he wouldn't even agree that I should change my diet. Given the cost of being in a hospital, I tried to get a modular jack implant at the same time, but apparently these aren't available yet from the telephone stores. I could have used one since I got back.

A friend called today and asked whether it made much difference given the technology to remain in touch: telephone, electronic mail and wps. I feel in touch, even though I couldn't get Ken to build me a portable DECmate while I spent almost a month in the hospital. It is great to be home and to have the conveniences of wps and ems also its nice to reaffirm how much can get done via telephone and a few meeetings.

In general, I feel quite good and things should be more normal in another month, although I feel fine now. I believe I operate my life at a constant pain, call it isopainer lines where what I measure is about 1 bell's worth. That is, I'm feeling fine physically, but this now gives my psyche time to think and act. I'm trying to work on only a few things right now that are either quite interesting from a life long standpoint, or that have to be fixed. The PPA's in the former category, and getting us a Workstation that performs and is cost-effective during my lifetime is in the later. I'm glad the workstation group is there, because I sure want very hot response time from it. On the other hand, we've trying for about 4 years to get one, while I've watched PERQ, Apollo, IBM, HP, a dozen companies including people who've worked here and are now building them at Apple and Masscomp.

I feel like I'm talking to an already reformed group who understand complexity in design and the whole notion of Quality Design Methodolgy, and the real sinners (the folks who muddle through because they build simple things and are able to ultimately get the mods made that will ultimate let a system hobble around) aren't here. I made several calls and threats to try to round them up from the low end and the disk groups, but to no avail. Dave Cutler and I were discussing this this morning and he's giving indivdual instruction to his hardware folks who are beginning to realize that hardware and software design are pretty much the same.

Subject: **Proposal/Clarification of New Product Announcement/Commitment Policy**

To: Marketing Committee

CC: OOD,
Si Lyle, MR1-1/M42
Jerry Witmore, PK3-1/M40

Date: 20 FEB 79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 3/2

I'd like to change what is apparently our policy with respect to product announcements.

Apparently it is:

1. Marketing Committee has to approve whether a committed project (e.g., Comet) can be discussed with customers if it involves price and delivery.

2. A Group Vice President can permit a project (e.g., Dolphin-36) to be described. We have apparently sold (are committed to) Dolphin-36 to Intel, Schlumberger, BNR, Phillips, Mobil and several universities. This seems strange.

Let me propose:

The Product Manager is responsible for maintaining a statement of what we can say to customers and to the field about <u>all</u> unannounced products. Changes to the policy should be approved by the PPC.

GB:ljp

D I G I T A L INTEROFFICE MEMORANDUM

DIST:

Dick Clayton	ML12-2/E71	Jim Cudmore	ML1-5/E30
Bill Demmer	TW/D19	Ulf Fagerquist	MR1-2/E78
Bill Hanson	ML1-4/P11	Win Hindle	ML10-2/A53
Bill Johnson	ML3-5/H33	Ted Johnson	PK3-2/A55
John Kevill	ML3-6/E94	Andy Knowles	ML10-2/A52
John Leng	MR1-1/F35	Bill Long	ML10-2/A57
Si Lyle	MR1-1/M42	Julius Marcus	MK2/C37
John Meyer	ML12-1/A11	Ken Olsen	ML10-2/A50
Stan Olsen	MK1-2/A57	Larry Portner	ML12-3/A62
Bob Puffer	ML12-2/E38	Jack Shields	PK3-2/A58
Bill Thompson	PK3-2/C12	Jerry Witmore	PK3-1/M40

We've been waiting to get the 11/23 out quickly via the stores. Apparently, if we price lower, there's going to be a conflict between the TOEM and store products.

Ken's suggested having two products. I'm opposed to this because
I think the TOEM should get the deal too because he is locked in.

Is it feasible to have the dual product strategy?

insurance office (SB and LB agents)

EDUCATION TOOLS AND PRODUCTS (By location) indust, secondary, primary, home, college

HOME
MILITARY ENVIRONMENT PRODUCTS
Language-ized products (for country)
Specialized Products (for customer)

This even simplified to the extent that in the case of office products, we want them on virtually ALL products just like Fortran or Cobol. Thus, Office sells to base systems and has to be a part of the technical generic products.

THE NEED FOR THE RIGHT PRODUCT GROUPING AND LEVELS
We must have the right number of product groups and levels to balance the wonderful compatiblity our customers love and we sell and product redundancy (for example, we have editors for:
   system programmer,
   office,
   typesetter,
   technical professional,
   education market)
against too many interdepencencies. Grouping and managing the right groups gets focus on products we sell, not the ones we buy either internally or externally. We must recognize a trait in engineers to want to redesign the base (eg. new logic, new ISP, new O/S, new lanaguage and programming environment) before they start to design they product! This is especially easy to rationalize when the measures and rewards permit and encourage trivial product differentiation.

With the exception of the first level, EVERY level OFFERS a

product both to the inside and outside creating interdependencies. The wise builder will take layered products,
the foolish will build the base over.

Rewards have to be based on elegant products we sell, rather than
the trivial re-invention and evolution of someone else's product.

DATE: SAT 10 APR 1982 1:07 PM EST
FROM: GORDON BELL
DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: DATA ON REASON FOR PRODUCT LINE MANAGERS

Ken's read once memo has the essence of an idea we want to use to
base our resegmentation of products and markets on. I tried to
make a chart, but rather than doing it as a SWAG, let's get the
study task force to give us the poop so we'll have it Tues.

Here's the chart we need:
Table of Products versus who distributes them. The table gives

%'s for each PL.

The P/L groupings:
PL90, ASG, CSS, Network systems (Jack Shield's new P/L)
Joel, Barry x 2, Jake, Rose Ann, TPG
Tech OEM Systems, Comml OEM systems, Micros
LDP, EDU, ESG, GSG
Telco, Mfg, CIS, Publishing, Broadcasting, office

The Product groupings:
ASG, LA, VT, Decmate, XT, CP/M
Disks, tapes, printers (shows % where CSS is low vol. supplier)
16 bit: boards, iron systems for unix, rt, m, rsts
32-bit: board (Microvax), Workstations, real time, commercial,
high reliability
36-bit of all kinds
Communications components and systems (DECnet, Ethernet, pluto, etc.)
Office Software
Product line unique software (here the entries say how it's done:
referral (EDU), DEC-built (DECset), DEC 3rd party joint (Eng).
Special hardware
Special software

I think we'll find something we've shown before: successful P/L's have a small number of products and/or customers. End user P/L's have to add value, understand the products (we use the word applications) as in Engineering. Products which go to ALL P/L's as in a cash cow mode (the 11 now?), can also lose if we let it.

We've got to keep this drive going to clean up the product and distribution act so as to focus on how we get the most products to the most customers. I'm convinced we have the products and more are coming.

SUBJ: PM...MANAGER AND STRATEGY (OR INTERCONNECT) COORDINATOR

Date: 2/28/79 Wed
From: Gordon Bell
TO: Bob Puffer
Dept: Office of Development
MS: ML12-1/A51 Ext:
223-2236
cc: OOD

I talked with Ken about the Pm...M job. He wants it to get done by a routine approval at a not too distant OC meeting. He would like it pre-sold and written down. Included would be the duties and a process description about who approves. (The POTS process would be assured, and written in too, if not through, by then.) He is worried about taking things into manufacturing before they are ready...so NO is a necessary part of it. Can you hold this discussion and include the PM's that report to OOD? Since a number of us will be absent on Thursday, it would be timely to hold the meeting and keep it to a small group. As a separate issue, we should get a candidate list, and their standing (i.e. who thinks what) in the environment.

It is increasingly clear that we need someone (Strategy Program Manager, Strategy Coordinator for?) to work on tieing the loose ends of the strategy together. Of highest priority is the Interconnect, which I believe is not going well at all. There is no schedule, priorities, etc. and virtually every group is involved but in a pretty nebulous way. In this later regard, I believe interconnect is of higher priority than several of our terminal or system products, because it is the only way to get at what IBM is doing. The whole ball here includes what the hardware is, then the software and finally what systems and when various device support will take place (e.g. serial connection to the unit record devices, such as line printers). This person is needed now before the final Red book is put to bed.

Any candidates?

Subject: **Product Managers: How Many?**

To: OOD

Date: 25 SEP 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

I'd like a simple measure and understanding of how many PMs we need so that we can proceed to fill critical slots. Rather than being coerced by Dick who must make an offer now to an outstanding candidate, I'd like to get some quick measures. John and Ulf have similar needs so we can look at the data on Thursday.

For starters, I'd certainly like a simple set of metrics from each of you at a +/- 20% guess level in a table listing:

1. The PM's, PMM's, and PMMM's in your area.

2. What products and model variations each is responsible for;

3. What is rough $ volume as per 78 product results and 79 forecast and $/PM.

4. How many were sold.

5. Number of P/L customers.

6. How large the engineering group,

its budget, is for each product and percent spent on PM in the area.

As a side benefit, this'll help us focus on just what each of us is responsible for.

(In the case of PMs in other groups such as DCG that are managing our products, please note that the budget or management is someplace else.)

SUBJECT: PRODUCT PLAQUES AND OC WOODS COMMENTS

There is universal concern about making an environment that supports engineering. The minutes will be forthcoming, but the immediate items:

1. Five task forces are going to be created to help us, headed by five members of the OC. They are: organizational interfaces, processes (redtape) that impede engineering products, interfacing to determine products, the lack of resources ($, computers, space), and a look at our organizations.

2. We want to kick off an awareness program of building a substantially better company so that we can be more competitive. We brainstormed a set of rules, and these

will be polished and then discussed with our staffs, who in turn will discuss them with their staffs. Here, I'd like to append the relevant rules to the memo on "Heuristics for Building Great Products", together with your input, and then use the two documents (OC, and Heuristics) as the base for discussion within engineering.

3. I presented the Transitions in computing, together with targets of where we should be. This took 1.5 hours and people were very attentive.

4. At the April Woods, we will present the Operations Committee with the Base Plan, in the form of several plaques that can be posted on the OC Conference Room wall... and at the various sites responsible for the implementation. This was done in 74, as we outlined the projects to 79. The old ones are in my office if you want to look at what they are. Then, there were only 2 plaques, the 11 system models over price (log scale 1-100K) and time, and the 3 families of single user, rsts, and real time operating system. Now, we would use the new price bands. For the components, there is not a range, but instead a point price, and hence let's use trees to show them (where position of branch represents price, leafs are products, or process and start of branch is start of design, the death of product or process would terminate the branch). This is represented in the DEC computer family tree poster where we have the 4 basic computer families.

We will produce the following 15 or so plaques, each of which would show products in the next 5 years (end of 86), and starting in beginning of FY80. The plaques would reside in the OC Conference Room, and be the basis of subsequent reviews and discussion.

- 36-bit
- VAX hardware systems; VMX capability, user capability including languages data management, nets, etc. (2-3 plaques) Here, I'd like to see enough plaques so as to show the whole family, complete with all products.
- 11 rack and stack and boards; 11 operating systems (2)
- Personal computers including pdt, 278 together with a line for user capabilities such as tms
- Office Products Systems
- LA's, Printers and VT's
- Communications Hardware; Communications/Networking Systems. It's not clear how to represent. One method might be to show three or four bands for DEC (including cx/dx), DEC via NI, IBM and International interconnect capability. Within each band, there would be each of the operating systems (rt, m/m+, ias, rsts, 10, 20, vax, 8) together with the products (eg. phase III, 3270). (2 plaques)
- Disks (where the families, as I understand them, are RK, RP/RM, R8x, RL, RX, Aztec),
- Tapes,
- Chips (here use the 3 or 4 basic processes as the different trees, with branches showing evolution to different geometries and chips or chip sets (eg.

Comet)
as the leafs)

- Packaging. Trees will help to show the forest.
- Power. Trees can probably help here too.
- Physical interconnect (various trees would show new structures such as substrates). There would be a pwb tree with branches representing new capability which are both layers and spacing/line width. Here, we also want to represent on the same graph our capabilities for laying out these in CAD.

These graphs should be the main foil of the presentations, as it enables us to talk about the what, where and when of our prodcuts in many cases. It would also show the risks of unacceptable gestation times. Also, B and C would show where we get by increasing investment. There may be others, but these are the necessary ones. In many cases we have them done, or have data to get them into this form easily.

5. There is also an agreement to review each major group once per year at the Operations Committee, in terms of the plaques.

6. There was a discussion of marketing the low end products, but there was no proposal, nor a resolution. It's clear that the engineering priorities are to drive to get great products. When we've got them, I'm convinced the

marketing will fall out of this.

Overall, it was the most constructive meeting we've had for sometime... albeit intense.

SUBJECT: PRODUCT STRATEGY VS BUSINESS AS USUAL

I certainly believe Bill has posed the right questions. We continue to have to make short term decisions, such as the WS200 based on the 8, that further erode our capacity our ability to provide good service and take customers down a path that we ultimately can't support or deliver according to their expectations.

Ultimately these users will probably want to switch.

When IBM made the 360 decision they didn't support all their past machines... as such there was a risk. Honeywell moved in to support the 1401 base and it kept them going for awhile.
Univac and Burroughs have a hodgepodge of oldies, none of which are particularly effective, but could have been consolidated
to give better overally support. Their customer, the government
has been locked in to them with no alternative. Now, the government is saying we are going to only buy the 370''s because it is available from many sources.
IBM has been doing their product introductions generatlly right in a business sense by knowing when to stop previous

products. This is just another reason as why they are number 1.
(As an aside, the government trend to 370 as their standard computer may have business implications mightn't it? Would others make the same decision, especially in light of an alternative source of supply from Japan?)

In our case, we lock people in. To the extent we lock them into something that is not in their long term best interest, they will have to change. When they do change it will be with a vengence to the best thing that is available then. Propogating all our oldies increases the likelihood of their eventual loss as a customer.

It is especially disheartening to see us lock in potential users to vax, to put out machines I can't really get enthusiastic about, and to not get the personal vax out. In this later one, there are emerging a several machines that users will flock to.
The interest in the Perq is very high, with all the universities ordering them and the Navy attempting to outfit its newest nuclear carrier with it. Meanwhile, we can't get it out.

Somehow, it might be useful to frame this as a classic business strategic question of old versus new product line... but the answer is even more tricky because of the effect of lastingness of software. (For example making only vax processors and letting the add-on market supply the rest might be the best way to go.
In this way we can supply the whole market with everything, past and future.)

SUBJECT: 32 BIT MARKETPLACE - SOME VACATION THOUGHTS

Ken has been admonishing us not to lose our lead in the 32 bit
market. Have we an agressive enough marketing, engineering and
manufacturing strategy with supporting implementation priorities
to achieve this? Or, in our usual attempts to partially satisfy
everyone are we risking high leverage future business with
allocations being made on individual tactical needs not any
strategic thrust?

An example or two of such things (primarily as "food for
thought") might be:

a) Marketing-Manufacturing: Should we continue to open up a
new plug compatible (VAX) memory and disk business as we are
currently allowing or should we consider closing this off at the
expense of permitting greater penetration on the 11/70 and
DEC10/20 systems.

b) Marketing-Engineering: Is there a strong enough marketing
swing to 32 bits such that we could re-evaluate the actual

need
for new high end PDP-11s and DEC10/20s? (eg, Right now our
priorities are such that we are cutting back on the DECnet
X25
type coexistence support and deferring VENUS options in order
to
maintain our plans for new DEC10/20 CPUs.)

c)   Any other view across our marketing strategy that would
shed
more light on the strength of our current 32 bit strategy as
we
are implementing it versus what it might be if we wanted to
set a
clear goal of maintaining our leadership position.

SUBJECT: RE SW PRODUCTIVITY AND A JOB SHOP CONTROL SYSTEM TO
DO IT

My hot idea for the greatest boon to productivity is still
a shop floor control system that forces the whole project
to report on the status, including writers, printers, sws,
managers, product managers, etc. This would let everyone
know without having to get together to bs about the project.'

Venus still is the best place to install this project where
everyone is on the machine and we could reduce the need
for many of the meetings etc just by having a program go
looking at all the files, tasks etc and where they are.

In this way we get every day an automatic update for the state of the design.   I've been asking to understand the "state of the design" for a year... we know much about it now.

Now, I think we want a tool that gives the instantaneous state of the design at all times and for all projects. This target comes directly from the fact that as engineers, information is our sole product and that information is in a computer at all times. Furthermore, the target of the compete set of information we are trying to produce is known, Therefore, it must be possible for a program to tell us how close we are to completely generating the information.

Can I get anyone interested in the notion of the Engineering, Job Floor Control System???

Think of the creativity we can release when we don't have to have the tedious meetings with all the tedious schedules and dates just to find out where things are? Why should the engineer have to tell someone what is already in the machine? (This is like having to fill out the forms again and again when the system already knows it.)

                                             LOC/MAIL STOP: ML12-1/A51

SUBJECT: PRODUCTIVITY VIA FEWER, BUT HIGHER QUALITY MESSAGES

Messages are often more expensive to read than to send!

Today's
incoming mail prompted these suggestions:

0. When writing, THINK FIRST OF THE READER. Will he understand, waste time, be discouraged or moved to action?
1. Too many messages are being sent; MANY MESSAGES CAN BE CUT OUT. SEND MESSAGES only ONCE, NOT BY EMS AND MAIL.
2. Messages need not be distributed so widely. CUT THE LIST! CIRCULATING a single document IS A GOOD ALTERNATIVE TO REPRODUCTION. Much of what we reproduce and distribute is neither timely nor requires filing, only adds cost.
3. A physical distribution list of 10 pages with a message of 1/4 page is not uncommon. Knowing who's on a distribution list is essential for short lists, but for general announcements, a list can be summarized (eg. 525 key people, or number by group and site). THE DISTRIBUTION LIST MUST BE NO LONGER THAN THE MESSAGE!
4. Many long distribution lists are also wrong. Gwen used a 3200 item mailing list with 500 duplicates or errors. Fixing the list gave an immediate 15% productivity increase! CLEAN LISTS.
5. Let's all STICK TO ONE PAGE FOR PRINTED MESSAGES! A one page, printed EMS body carries 46 lines. A 24 line screen is a nice size for messages requiring fast response.
6. A several page report requires greater time for a reader because of its complexity. A SUMMARY IS REQUIRED so that the reader can plan his time.
7. DIGEST, ABSTRACT, ANALYZE AND CRITIQUE INFORMATION WHEN "PASSING IT ON". Just got a thoughtful set of "press clippings" from an announcement, but would have liked one

page which analyzed how we did instead.
8. SEND SUMMARIES: MAKE FULL REPORTS AVAILABLE ON REQUEST (eg.
trip reports, clippings, backup tables, experimental data).
9. MINIMIZE SENDING VISUAL AIDS as written messages since the
media are different. If you want the viewgraphs to be read,
then re-edit to increase density and understanding.
10. If you can't be interesting, BE reasonably CORRECT. Even as
an injuneer, I have lo tolurance for mistspellings and poor
gramer, unless it's an off-the-wall EMS message.

Hope this is helpful.

Warning: Violators will be persecuted!

JIM LAWLESS EXT: 223-2236

LOC/MAIL STOP: ML12-1/A51

SUBJECT: WHAT'S THE RATIO OF DEVELOPMENT COST/NOR FOR A PRODUCT

We have Burp metrics for all products showing 1 ~ 2 percent for this
ratio. It's unclear whether this ratio should be small or large.
Until Jim Lawless challenged me, I thought the ratio was just the same

fraction, say f, we spend on engineering.

The percent turns out to be a function of the product development time and product life. There's no doubt, a formula, but I didn't try to derive it. Try this case of DEC growing 30 percent each year, a product development that takes three years and then is produced for five years:

- The product costs (1 + 1.3 + 1.69 = 4) x f to develop.
- The product revenue is (2.2 + 2.8 + 3.7 + 4.8 + 6.3 = 20).
- The development cost/nor ratio = .25 x f.
- If f = 5.5 percent, then the ratio is 1.375 for all products, since our Burps include a 100 percent overhead in them.

Subject: **Our Market/Product-Positioning/Growth Dilemma**

To: Marketing Committee
OOD

Date: 3/19/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Right now we must be especially concerned about the large 3+ decade price range of systems required in our many, varied (applications) markets. Consider the following viewpoints.

<u>We've got to lose market share</u> which in turn usually means higher costs overall, and possibly lower profits because:

a. DEC future growth at 26%/year is lower than the past 36%/year growth (see Fig. 1).

b. The technology improvements continue to open up a new low end at an increasing rate. Note the range increase as shown in Fig. 2, and the range factor, ignoring the terminals and 10/20 is plotted in Fig. 1. Prices of low end <u>systems</u> decline at 10% to 20% per year, limited only by the mass storage capability whether it be ram, bubbles, tape, floppy, etc.

c. Over most of our market price range (i.e., applications) the market growth rate is constant or increasing.

d. Our market and sales strength seems to be (ordered) in the following price bands:

i. 100K-250K (11/70, 2020, 780)
ii. 40K-100K (11/34)
iii. 1K-2.5K (terminals)
iv. >400K [both bands 250-625-1.6] (36-bit)
v. 16K-40K (low end 11/34 box and OEM RL based, plus Datasystems)
vi. 6.25K-16K (PDT, WP)
vii. 2.5-6.25 - almost non-existent, except for hardware-only components; small PDT's are here and the new WPS should be

e. Note, the market share,

base and growth is highly diverse over our range of interest, as shown in Fig. 3.

f. It's impossible to grow enough to keep market share in all these price areas. Therefore, we should understand the ultimate deleterious effect. By contrast, see Fig. 1, all our competitors (except IBM - who has divisions) seem to be in a narrower range, growing faster and are more profitable.

<u>At last IBM has noticed us</u> and is descending over the price-performance space like a bunch of locusts whose population is growing exponentially. For some time it's clear we've been exempt from IBM competition as they used to have really crappy products in this space. Now they're interested in the same growth, system size, and computing style we see.

a. The <u>useful</u> (i.e., 148-class with 0.5 Mbyte memory) 360/370 has come into the under 250K, mini market. Figures 3, 4, and 5 show how this series has stopped at the price boundary as more software is added and larger memories have been needed. Now even IBM can't fill all these primary memories with operating system and the cost has broken through with the lower cost/byte memory. Also, with the latest announcements, they have for the first time, machines that are competitive with the 10/20.

b. They have a mini with the Series 1 positioning at the 04/34 (one of our key strenths). The new enhancements get the price down to broaden its coverage into the 03. They may go after chips here, too. They'd really be smart to get an independent semi-house to make chips available.

c. The System 38 is targeted at the 11/70 class machine, our highest revenue earner.

d. The 8100 is targeted both at the 34 and 70 to do the system's off loading that many of our minis are sold for.

e. They're building user personal computers in the 5100.

Costs to engineer systems of a given price are increasing with time from several perspectives as can be seen in Figure 6. (I'll verify these costs later.) The cost of the minimal mini is rising from the situation in 1972 where it was built from standard MSI components.

a. IBM and semiconductor technology opportunities are raising the ante at the higher ends by using gate arrays to build higher performance, more cost effective (lower cost) systems. These cost proportionally more because:

i. Special gate arrays are required, increasing the number of circuit types.

ii. The machine is higher speed by more parallelism and is therefore more complex.

iii. More RAMP features are required.

iv. Mid life extensions should be built in to protect and extend the investment.

b. Intel and semiconductor technology opportunities are raising the ante at the low end because we must have DEC ISP chips for small systems. Gordon Moore has observed that the number of man-months/chip to design a chip is doubling every 2.7 years. These chips aren't taking advantage of maximum densities, either.

c. Our product size, system structure and diverse markets engender almost unbounded commitments (see the typical situation for the Large Systems' area shown in Fig. 7). The total number of products announced, is approximately the product of:

base hardware x
special front-end, back end hardware x
operating systems x
network options x
applications and data base hardware and software options x
any CSS products

i. There are many base hardware systems, tending to include other special hardware each of which has to be tested in a combinatorial fashion.

ii. Depending on the system size and the dedicatedness (versus general purposeness), we seem to take on a lifetime system enhancement-support commitment (see attachment for large). For example, only recently have we been able to decommit TOPS 10 enhancements on KA10's.

d. We have multiple families, all of which our customers expect, to be evolved and their ranges expanded forever! This means that whatever problem we think exists above, it is actually 4 x worse. Or ignoring ranges that have only one product in them 2-3 x worse than first glance.

There are several reasons to focus on <250K systems.

a. With the newly announced Federal Channel standard, the price line is 250K to define a mainframe. The 780 is excluded.

b. Various government groups can purchase computers under 250-300K without OMB approval.

c. For many large organizations, a selling price under $250K doesn't require the authorizations that a $500K purchase requires.

d. IBM isn't as strong here now as they seem to be headed for.

DEC's ability to introduct new products is actually more limited and more expensive than we think because all products tend to be marketed through all groups.

The expanding 3+ decades range of products presents a problem because:

a. Field Service, Software Support, Sales and Manufacturing are faced with much of the product introduction complexity and costs (paralleling development cost) that engineering faces.

b. Although we design many products, the introduction cycle and ability to absorb is clearly one limit.

c. With the high rate of growth and turnover in all groups, including sales. For example, it's impossible to believe that no matter how we segment, a salesman is being asked to cover and leave too wide a range.

d. It feels like we need the much better segmentation according to size, because costs over the whole P and L vary greatly by size! In engineering I'm attempting to have much clearer segmentation through funds firewalling and organizational segmentation! (I feel we need the same in the other organizations.)

SUBJ: HOSTILE FEELING TOWARD OUR PRODUCTS. **READ AND/OR DESTROY**

Date: 2/28/79 Wed
From: Gordon Bell
TO: Distribution
Dept: Office of Development
MS: ML12-1/A51   Ext:

223-2236

The following was typed on a Selectric, last Sunday. It came direct from my heart: "Can we get better products?

As a DEC user, I'm frustrated because I'm now using a Selectric (that's never failed!). My WPS78 is down, the second time in a month. It's the VT52. I know the more it's worked on the more unreliable it will get with all of its screws, connections etc. (I suspect electric discharge as the culprit.) I long for a replacement.

I can't call into EMS because either it is down, or my terminal won't answer it properly. (I can call CMU so I think it could be EMS.) However, it is clear that the infamous acoustic coupler may be the culprit, because I have been able to tweak a knob and get it to work before. Now, I don't have the time.

We're going to get killed with more products like these. If I ever had any doubt about quality and duty to make things work as highest priority, being a user sure makes things straight.

I hope each of you have a terminal that you personally use...we have to.

P.S. I'd been looking forward to (wondering about) a single universal terminal to get rid of the two I have. Now, it's clear I need three terminals because with this quality, two isn't enough.

P.S.S. I tried it later on, and the WPS works now. Clearly a static discharge that put it in an untenable state. (I lost the file I was editing...which seems strange.)

P.S.S.S. EMS was apparently being worked on; why should it answer?"

SUBJECT: RE: YOUR MEMO OF NOV 8 "WINNING HIGH END CPUS FOR THE 80'S"

Am excited about VENUS and the incredible progress it made and
certainly and don't believe BJ or anyone else seriously thinks
that Venus isn't going to be a major product. Just replacing all the SBI based 780's in the same floor space to run the current peripherals is probably going to seperate it from Nautilus.

As to the follow on work and what we base the next machines on,
that's the subject of some work, but I don't see waiting around
very long to decide. BJ has to go balls out to get the next VAX's started to get us back in the ball game competitively and see if we can regain some of the losses like ATT who are leaving us. I believe the key parameter of a design is simply
how well it is documented and how robust it is. I believe we can not screw up Nautilus in terms of documentation hierarchy, because this will turn out to be the key parameter as to what we re-realize (Nautilus or Venus). I want an expert
system that will do this design, therefore, we need a minimum amount of information so that an expert program can handle it.

As to SAFE, I simply have asked BJ to make sure that it is not conducted in Marlboro because you folks have lots of work and the next technology to do right now. Also, I'm pretty convinced that there aren't a plethora of interesting non-microprogrammed machines around, and I certainly don't want more than one of them. Forest is building a very fast machine, and if he's successful, then we'll build many... and they'll do much of what VAX is used for now!

If you want to explore this space, then I'd like to get it focussed somewhere in either BJ or Sam's organization.

For now the party line:

1. VAX is it. We're going to extend the architecture as long as no extra state or wild new data paths are implied (don't want to make the same mistake as the latest KL enhances.)

2. We're going to implement VAX's like crazy using some aggressive technology and good engineering. We need some decent CPUs!

3. The PPA looks like an interesting machine that can be used to get more cycles. We're going to build it.

4. TITAN is our next architecture, especially if it turns out to benchmark as well as I think it will. At the small size, it should really out compute just about everything.

5. Strecker is looking at whether there are any techniques to enable VAX to be implemented for direct, not microprogrammed
execution in order to get more speed.

Just visited a number of customers and they love VAX and want a high speed follow-on. Inside, we piss and moan about needing
a new architecture because VAX is too hard to do, and every group wants to throw it out and start over. Unfortunately, I see no evidence that VAX is particularly hard to implement as compared with every architecture I see (Cray, 370, Eagle, Prime, 6600, Jupiter (a super complex ISP))... I do see a major need for good engineering when implementing VAX because it can't be done in an undisciplined way.
Meanwhile, if direct execution of an architecture turns out the way to go, Forest will tell us quite soon.

SUBJ: A Competitive Set of Products

TO: OC
EMC
PEG

Date: 8 NOV 1982
From: Gordon Bell
Dept: Eng. Staff
MS: ML12-1/A51 Ext: 223-2236

BASIC SITUATION
.Businesses/products have been added. We're in too many now!
.We have poorly managed existing high priority projects.
.The result is a major slip in competitiveness across the board, this in turn causes more, short term, poor products to form.
.We must FIRST, staff a winning set of products, then backfill,
as needed with short term and less critical, less competitive ones

REDUNDANCY IS THE CURSE: when two (poor) is less than one (great)
.VAX and the 11
By slipping J, we can not start MicroVAX products. The result is that J is too little, too late and MicroVAX could be too late
.VAX and the 10/20
By slipping the high end products, we've merely deferred the question of the next 36-bit machine
.Industry Standard (or not) and 11/PDP-8 Personal Computers
Surely all the time we spent on channels would have been simpler

with fewer products. Learning curves say that we'll pay 20%
more for having 3 personal computers than one great one.
We need a competitive follow on to the PC 350 with 32 bits
.The question of a 68,000 product will probably come up soon too
.11 Systems and Boards for Systems are generally overlap

WHAT WOULD I CUT?

Why bother with the repackages of VAX's to get cost? Cut the prices as needed. I don't see speeding up the 780 versus PPA!

Clearly reduce 8, 11 board/system/PC, 36-bit to get the critical essential, competitive products staffed.

Admit to not doing something, such as the small PC, or cut one of the 3 PC's to get a low cost one in a different price band! Why two on top of each other?

There are redundancies in the typesetting/office area, and we might face having a strong LDP, ESG and MDC, versus weaker ones which include MEDICAL, ECS, Typesetting and Small Business.

The overlap in commercial and the COEM products can now be reduced when the need for product uniqueness for a channel is removed.

GETTING OUT OF THE PRODUCT MALAISE: ENTER, THE NEW DIGITAL

I think we have to build substantially more aggressive, competitive products. In many cases, the groups aren't really aware of their competitive position... but the NEW DIGITAL should fix this as we demand that they be responsible.

Now is the time to act to have great products.

THE COMPETITIVE SITUATION IN PRODUCTS

I only see only two competitive products, and they are based on futures: Nautilus and MicroVAX (2-2.5 years away, but look good). We have major competitive problems in virtually every area:

<u>VAX</u> (2 years away from possibly catching up)

VENUS is twice 780 cost, but it now looks doable by June 84!
NAUTILUS looks like an excellent 780 replacement, but 2+ years
NAUTILUS II, Jan. 86 FCS must start now (2-4) x Nautilus
NAUTILUS III, Jan. 87 FCS must start now (2 x Nautilus II)

SCORPIO CLUSTERS are essential. Having invested in this interconnect and software, we can now make it payoff!

SCORPIO-BASED Systems are simply not aggressive enough in cost and content. We will miss a major window without the options.
LOW END VAX needed against new micros, to be solved by MicroVAX
The projects must be started.
BOARDS AND CHIPS require a major investment and commitment to
behave as the competitors do

WORKSTATIONS are 2 years behind Appollo and with less power
WORKSTATIONS with Color are needed too
MICROVAX based WORKSTATION must be started

LARGE, PARALLEL PROCESSOR BASED ON MICROVAX. Risky, but could have very high payoff in getting us back to be recognized
as a leader in computing that we had when VAX was new

<u>PDP-11</u> (Major underpower now; parity if Jaws attains speed)
Sales indicate a complete movement from the 11!

Is it the products or are we not selling them? cost too low?
A new operating system for boards is too little too late
We can not fund both board and boards for systems
Opportunities for 11 upgrades exist!

BOARDS
See PDP-11. Require a 32-bit product. Many 16-bits don't equal 32-bits!

PC's
IBM, HP and everone else has 68,000 based machines
How can we win with having so many, particularly if they are me too or technically inferior? marketing? distribution? mfg?
MicroVAX PC 470 could provide the edge, but it isn't started!
Very Low Cost PC. Can we? Do we offer anything at all?

TERMINALS (Can we do fewer, better?)
VIDEO: Not leading in technology or cost
PRINTING: Budget, work, strategy and need are all incongruent!

UNIX

We have a strong development group, and they'd like to build good products.

LSG

We've sold what may be an unbuildable product, added new customer commitments and converted VAX customers to the 10/20, but are a bit closer in having a way to let customers compute on other DEC machines. We could probably learn from Honeywell and Univac who have similar, but larger 36-bit products and customer bases. Burroughs, CDC and NCR experience relevant?

LDP

We sell VAX systems. People buy their lab equipment elsewhere.

No awareness or drive to the real time aspect of laboratory, and propagating MINC, which was a significant product for us.

ECS

A major leadership gap exists because it's predicated on having and selling the lowest cost personal computer. We've never had this, and we NEVER will for an extended period of time.

We need a winning way to sell products here and we need some products, but aren't working on the critical ones.

ESG

Buyout is fine, but customers want integrated systems.

MDC

Real time equipment appears to be needed to win

SMALL BUSINESS COMPUTERS

Another Market without a product! (Remember the stores plan?)

WORD AND INFORMATION PROCESSING

Products can compete, but we don't seem to sell enough

to pay
 New WP/OA products are not visible enough to see competitively,   but given the age of current products, we must have follow-ons!
 There are major overlaps which Julius is addressing now.

follow up 4/2/79

How can we get together to get TPL to be more aggressive in managing the peripherals that go into TPL? Engineering is not very good about planning product phase-out of these products that have to be "added-on", i.e., disks, tapes, and perhaps even some terminals. Right now, for example, we are clogged in the disk area because we still support RP02's as a standard product. This gets in the way of manufacturing etc. Nevertheless, these products still have to be available to add-on to systems in the field. Rather than manufacture again, we should buy back and refurbish. We can use new disk subsystem trade-ins to get the old products back. Grant Saviers has expressed ideas about such a business. Let me urge you to talk with him, because it could really mean high profit to the corporation and much satisfaction to our customers.

As a separate issue, I would like to urge us to explore how some of the low volume software (e.g., APL) could be TPL'd or CSS's. We get these low volume packages and they clog the engineering support and budget system. However, we believe they can be profitable if managed as a small business. The way it is now, they all look like losers.

Could I implore you to meet with Grant on the peripherals business; and Larry and Jack Mileski on the low volume software business?

SUBJECT: THE DILEMMA OF NEEDING MORE PRODUCTS (>1 PAGE) F/U
2/29

I have strong empathy with the products your customers are requesting.
It seems as you improve the coupling, the effect is to get more
requests. We should all be very uncomfortable with sucking too much
out of the advanced development pipe for products, because that's
going to take us increasingly down the tubes. I wonder whether there
are any alternatives?

At the high end is there any way to get work started in the RP07
follow on? (There are currently no high-end products after the
07...unless it can be shown that gangs of 81's will do it (is the 81

adequately funded?)

In the low end, it feels too tight with 8 requests for 2 or 3 project
funds...and the need as nearly as I can tell is for low cost floppy
for most. The RX02 cost makes us really uncompetitive in the store.
We need cost before anything else too. I can't see why we don't
simply only pursue cost reduction in floppies, getting whatever
density is relatively free (adding no more than 5% - 10% to system
cost). I have trouble understanding the need for Aztec because of
size. We haven't packaged a floppy in anything other than a 19" rack,
so why bother? The RL02 looks great - it's cheap and will fit in
anything that our floppies fit in. Maybe you should wait on Aztec
until we have a small systems package that requires something other
than a 19" form factor. Could we package a pair of RL02's on any
other way to make them appear less bulky (e.g. a foot stool)?

In the midrange, somehow the 180 MB removeable is the killer in the
budget. As far as I can tell because we had been buying out that
capacity drive in the RM's an I don't understand why we don't
continue?

I hope there is an effect of the NI, but right now, I don't believe
the details are well enough laid out to comment.

The LSI plan still looks non-existent. I don't buy what I've heard.
It's too NIH, too product specific and too custom. Somehow

it feels
like we need more commonality than the 2901, and the 8080 across
disks.

Can ROI be used at all as a measure of goodness? Don't all disks or
tapes taken alone has incredibly high ROI? When you look at the ROI
of a system, given a year longer and with the disk tooling, I believe
the picture changes. Is it worthwhile to ever run an ROI on a disk
alone? In essence, let's go back to the make/buy criteria guidelines
we made several years ago (the memo is attached). In summary, the
only reason to make them is if they are good enough to sell alone in
the OEM market, OR we have to get the source of supply. Can you help
your systems customers a bit more by giving them the option of make,
buy, buy with option to make (for second sourceness or for source of
supply)? They might have chosen say 2 disks that are buyouts versus
one later that is apparently cheaper. At this point you have to look
at the ROI like crazy because of the field stocking/spares, and number
of system issues when you introduce two versus one.

I don't think your system buyers are going to help with funds. They
are going to continue to spend their budgets for
Processor-Memory-Controller (PMC) kernel products and to take what you
give and complain.

Is there anything besides a big $ transfusion to help?

Subject: Make vs Buy Guidelines Update (from 3/5/76)

To: File

Date: 3/28/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

What DEC SELLS not what it BUILDS is the more important issue for continuing success. In a rapidly changing industry where technologies can quickly become obsolete, it is essential that DEC maintain flexibility and not become over committed to any particular technology or process. As we make more and more of the items we sell, we become more rigid. Opportunities in the marketplace can be delayed or lost forever. Opportunities to cost reduce by building more inside will stay with us. The following guideline is intended to help us focus on these issues.

1. DEC wants to build unique products that offer specific advantages

to its customers. Profitability alone is not sufficient.

2. High ROI by itself is no reason to build anything (e.g., it robs resources from other, more essential projects).

3. The general rule should be, if we don't make it now, buy it.

4. Proposals to build must explicitly demonstrate that:

    a. project will result in a quantum jump in technology or

    b. needed to introduce (or confine) a vital technology to DEC or

    c. present or developing vendors are unable to supply demands of ON-GOING high production item.

5. All proposals to build should address and be screened by at least the following criteria:

    a. DEC's forecasted needs exceed the volume of at least the smallest economically viable vendor.

    b. DEC's engineering resources to accomplish task is at least comparable to vendor.

    c. Incremental NOR/employee will be above the corporate average for the effort. [We should strive to increase "PRODUCTIVITY".]

    d. Hardware products can be sold through the Components Group. [The product is inherently good enough to stand on its own.]

e. ROI analysis of not only the results of pursuing the project
but the corresponding results when using the vendors part.

f. Level-of-integration of the project. [We should tend to
increase level-of-integration-focus on MAKING what we sell--NOT what we BUY.]

g. The resulting incremental NOR to development cost ratio
compare with Corporate NOR to total engineering ratio budgets.
[Won't become an engineering sink.]

6. We must have a "buy out" advocate to test analysis (in Manufacturing, Purchasing, and Engineering?).

7. Proposals to "make" must be explicit with respect to the level-of-integration covered (i.e., which parts). "Making" is not a carte blanche licensing to make everything.

SUBJECT: HEURISTICS FOR GREAT PRODUCTS: 5, WITH 30+ DETAILS

HEURISTICS FOR BUILDING GREAT PRODUCTS

Products goodness is somewhat like pornography, it can't fully be described, but we're told people know it when they see it. There are lots of heuristics in the book, Computer Engineering. Since quality and competitive products must be our number one focus in these next generations, these heuristics are intended to help us.
Only the five following need be attended to:

- .a responsible, productive and creative engineering group;
- .understanding product metrics (competitiveness);
- .understanding the design constraints;
- .knowing when to create new direction, when to evolve, and when to break with the past; and
- .ability to get the product built and sold.

ENGINEERING GROUP
As a company whose management includes mostly engineers, we encourage engineering groups to form and design products. With this right of organizing, there are some responsibilities:

- .understanding leadership who understands the product space and who has engineered successful products;
- .having skills and disciplines required in the respective product area, eg. ergonometrics, acoustics, radiation, microprogramming, data bases, security, reliability;

.having skills on board to make the proposal so that we adhere to the cardinal rule of Digital, "He Who Proposes, Does"; Approving a plan, based on no implementers violates this.

.having open-ness, external reviews, clearly written descriptions of the product for inspection;

.as a corollary of being prepared with leadership and skills, we occasionally enter very new areas, requiring research and advanced development; Product commitment should not be made until fully operational breadboards exist.

.as a corollary, start up groups with no previous or poor previous track record, may need review.

PRODUCT METRICS

Since most of our products are evolutionary, engineering is responsible for knowing their product area, in terms of:

.major competitor cost, performance and functions together with what they will introduce over the next 5 years;

.leading edge, innovative small company product introductions.

DESIGN CONSTRAINTS

Design constraints such as acoustics, radiation, are basically useful because they limit choice of often trivial design decisions. We should meet the following design constraints, and if unacceptable, go about an orderly change:

.DEC Engineering Standards covering most physical structures and design practice for producibility; These assimilate the critical external standards such as VDE, and FCC as rapidly as possible.

.information processing and communications standards, such as Cobol, Codasyl, IEEE 488, EIA;

.information processing standards as determined by the key
supplier, such as IBM SNA;   For example, all eight
versions of VISICALC we are implementing, should be
compatible with external VISICALCs.

.the architecture of existing DEC products; For example,
future editors should be compatible with the past editors,
unless it can be shown experimentally that there is a
significant (x2) benefit to change. These include:

.ISPs of the 8, several 11's, 10/2, VAX-11, 8048, 8080 and
are likely to include a 16-bit micro;

.physical busses for interconnect; Fundamentally this
insures that future products can evolve.

.file, command language, human interface, calling
sequence, screen/form management, keyboard, etc.

.we must not be undone by historically poor standards which
constrain us to poor products; Currently, the 19" rack and
the metal boxes we put in it, and then ship on pallets to
our customers, act as constraints on building
cost-effective PDP-11 Systems. This "mind set" standard is
impeding our ability to produce products that meet the 20%
cost decline. A target should be the shipment of systems
in cardboard boxes which the customer assembles.

.ability to be implemented easily in any natural language,
given that we are selling products in all countries.

WHEN TO CREATE A NEW PRODUCT DIRECTION OR WHEN TO EVOLVE THE OLD

Given all the constraints, can we ever create a new product, or
is everything just an evolutionary extension of the past? Also
do we know or care where product ideas come from? There are a
whole set of places to look for products, but that's another

set
of heuristics, and the object of these heuristics is simplicity.
The important aspect about product ideas is:

- .Ideas must exist to have products!

It is hard to determine whether something is an evolution or just an extension. If you look at our family tree of products, like the one for our computing systems, and which every product group should have and maintain, the critically successful products all occur the second time around. Some examples: 6,KA,KI,KL,2080; Tops 10,Tenex,20; 5,8,8S,8I/L,8E/F/M; OS8-RT11; 11-20,40,34; RSX-A... M; TSS-8,RSTS; various versions of Fortran, Cobol and Basic all follow this; LA30,36,120; VT05,50/52,100; RK05,RL01/2.

Some heuristics in designing good products:

- .all products whether they be revolutionary (we have yet to have any that are really in this category), or creating a new base, or evolutionary, should:
  - .offer at least a factor of two in terms of cost-effectiveness over a current product; If we build unique products that do not compete with ourselves, then we will have funds to build really good products.
  - .be based on an idea which will offer an attribute or set of attributes that no existing products have; For example, the goals and constraints for VAX included factor of two algorithm encoding and also offering ability to write a single program in multiple languages. VT100 got distinction by going to 132 columns and doing smooth scrolling.

.build in generality, and extensibiility; We have not, historically been sufficently able to predict how applications will evolve, hence generality and extensibility allow us and our customers to deal with changing needs. We have built several dead end products with the intent of lower product cost, only to find that no one wants the particular collection of options. In reality, even the $200 calculators offer a familty of modular printer and mass storage options. For example, our 1-bit PDP-14 had no ability to do arithmetic or execute general purpose programs. As it began to be used, ad hoc extensions were installed to count, compare, etc. and it evolved into a digital computer.

.build complete systems, not piece parts. The total system is what the user sees. A word processing system for example includes: mass storage, keyboard, tube, mdoems, cpu, documentation including how to unpack it, the programs, table (if there is one, if not then the method of using at the customer table), and shipping boxes.

.a new product base, such as a new ISP, physical interconnection specification, Operating System, approach to building Office Products must:

.start a family tree for which we expect significant evolution to occur on, otherwise the investment for a point product is so short term and hence is likely to not payoff. In every case where we have successful evolutionary products, the successors are more successful than the first member of the family.

- a product family can evolve several ways as described on page 10 of Computer Engineering; The evolutionary paths are lower cost, and relatively constant performance; constant cost and higher performance; and higher cost and performance. In looking at our successful evolutions:
  - lower cost products can't get by without adding functionality too, as in the VT100;
  - constant cost, higher performance products are likely to be most useful, as economics of use are already established and a more powerful system such as the LA120 will allow more work to get done;

- a product evolution is likely to need termination after sucessive implementations, because new concepts in use have obsoleted its underlying structure. All structures decay with evolution, and the trick is to know what the last member of a family is, such as the 132 column card, and then not build it. This holds for physical components, processors, terminals, mass storage, operating systems, languages and applications. Some of the signs of product obsolescence:
  - it has been extended at least once, and future extensions render it virtually uninteligible; (For example, PDP-8 memory addressing and ISP was extended three times.)
  - there are significantly better products available using another base;

SELLING AND BUILDING THE PRODUCT

Buy in of the product can come at any time. However, if all the
other rules are adhered to, there is no guarantee that it will be
promoted, or that customers will find out about it and buy it.
Some rules about selling it:

- .it has to be producible and work; This, although seemingly trivial rule is often overlooked when explaining why a product is good or not.
- .there should have been a business plan that several different marketing groups have contributed to in terms of ordering and selling; Just as it is unwise to depend on a single opinion in engineering for design and review, it is evenn more important that several different groups are intending to sell the product. Individual marketers are just as fallible as unchecked engineers.
- .never build a product for a single customer, although a particular customer may be used as an archetype user. Predicating a product on a sale is the one sure way to fail!
- .it should be done in a timely fashion according to the committed schedule, at the committed price and with the committed functions.

Now isn't it clear why building great products should be so easy?

Are there any heuristics that should be added? or are patently
wrong? or need clarification?

Comments please!

The first paragraph with the 5 points says it all, but in
case there's need for detail, there are another 30 or so

which
follow... in the words of Mies van der Rohe, "God is in the details".

SUBJECT: ARE OUR PRODUCTS/INTRO STRATEGY WRONG IN LE?

Have just learned that one can't buy an 11/23 in Europe because P/L's and Europe have determined that small systems are too expensive to sell. DCG is the only outlet and it is OEM mainly. Some of my university friends would like them and I think there would be eventual payoff by letting them know that DEC does build microcomputers, something that they would never otherwise know. There outlet is via the reseller.

It seems to me we ought to consider the following:
1. Stop development of small systems because they clearly can't be marketed through our current channels.

2. Build a channel for small system and only or predominantly sell them through this channel.
3. Treat this as a special case of good times, and not introd.
the product at the systems level at all. Let the resellers eg. Plessey have all the 23 modules and let them sell the 23's instead.
4. Offer 02's at the systems levels (apparently they exist) and
then price an upgrade kit to 23's when the board becomes avail.

Given that the recent set of poor market showings in PDT, 78??,
03's?, and now 23's at systems levels, should we do some rethinking? Eg. form a low end product line? Make only a single PL responsible for a product (eg. Minc)?

I am experiencing the same proble in the introduction of the personal VAX...namely ESG is clearly the lead P/L, and it would
be good to introduce it there first. Also, I think in this case
we have a real leadership product as the Personal Professional
Computer for the serious computer user with a big problem or work that they want to run.

Someday we ought to discuss these issues calmly.

BRUCE STEWART LOC/MAIL STOP: ML12-1/A51

SUBJECT: WINNING, GREAT PRODUCTS: A CONSTRAINT ON OUR PRODUCT STRATEGY

After having approved a P/L plan at the December review of the LR Plan by the Operations Committee, one of our P/L's has just reduced their commitment to sell products in excess of 10% over last year. This amounts to a 90M$ reduction in NOR and a 4.5M$ reduction in engineering spending may result. The reason for this that was given was more competition and that our new products being introduced in early 82 have slipped a bit, plus they don't look so hot (when they come out).

In this case, I don't expect anything of the Product Line and it's possible that there may be other new products and that it's too hard to sell anything. Hence, the NOR may slip more.
Where we end up in sales is purely a game of chance because the only way that they can sell anything is if there is some feature that seperates our product from everyone else.

I believe they are right, and probably should go even further and suggest we close down the factories unless they get these kind of products. Unfortunately, they were part of the large mass of product managers, engineering strategists, and marketers who partipated in the generation of the product strategy. With such a mass, we clearly have a question of who is responsible. I want to make this clear:

I hold the engineering manager for a product, or product area solely responsible for the success of a product.

The issue then is what went wrong?
The products, now don't look good enough to be bought without what others might think of as marketing. In this case, the area looks "commodity like" and we don't have anything to

differentiate us. This is clearly our responsibility!

Therefore, I want us to stop building products that we do not believe are going to be great products. This means no mid life kickers, unless, like the 70 they enhance performance and really extend the product life. The new products in this example are fundamentally cost reductions, and golden rule products in a new, questionable market area. (Please refer to p12 of Computer Engineering for the economics of why products should evolve along performance rather than price... in a constrained engineering budget if you haven't read it.)

Therefore, the constraint on products are: fit the strategy; and
NO CRAPPY PRODUCTS. WE ARE ONLY GOING TO BUILD THE BEST PRODUCTS WE CAN!

(In the ensuing several months, I want to review several of the things we are doing against this criteria.   I know buy in and all those groupie words are nice, but when the going gets rough, the nice folks who buy in are the first to sell out. When that happens and we're all that's left, it's clear to me that the responsibility is once again solely ours for the generation of good products. If we don't think we can do it then maybe we should just sell ones others build or perhaps buy they product from Tokyo or wherever and avoid all the risk and hassle.)

In our presentation in April, we have to be honest. If the product is marginal, then let's not do it... independent of who's bought in... cause it's clear who's the first to sell out.

PS
The NOR reduction episode happened on Monday. On Wed. evening we
met with Andy about the Technical Group use of CT. He's not buying, cause it isn't good enough. This I respect! It's regretable that one of our customers had to tell us that our prouduct isn't good enough!

PSS
I don't want to hear the issue of we aren't spending enough money, and what do you expect. In the disaster areas, we have
spent incredible amounts of money, it's just that it's all been
to get marginal and/or half-done products.. The new rules will
stop this: we won't do any of them; someone of you have product
area responsiblity and you must make the appropriate proposals
(and breadboards) to get us good products.

Please join me in building quality products.

Any problem with the clarity or rationale of going this way?
Comments, please.
Are the rules clear?

GB2.S5.19
7 June 1983

Professor John Zysman
Assoc. Professor of Political Science
  and Director of BRIE
University of California at Berkeley
Berkeley, California 94720

Dear Professor Zysman:

I thoroughly enjoyed your BRIE conference several weeks ago, Saturday. Many thanks for letting me attend, and I'm especially indebted to Regis McKenna for inviting me. I hope that BRIE can make the essential inroads to some form of reciprocity with Japan through its various approaches.

Several years ago when visiting Brazil, I outlined a development policy for going into computers. They, of course, didn't follow it, but instead went the traditional evolutionary path, making all the errors and it required significantly larger investment. Furthermore, it ensured their delay into modern computing. A copy of the paper is enclosed. I'm sending it because it's really on the industrial development of computers.

I didn't understand then that it had any bearing on the current industry in the U.S. and abroad. Ironically, the paper most applies to Silicon Valley today, for what's happening, is based both on a backward (not like the Japanese forward) integration policy where standards are adopted to minimize development, and maximize added value. That is, it called out what's now happening. We see: the Multibus, C, the 8086 --> 68,000 --> ? (virtual memory), several operating system (UNIX, CP/M, MDOS), and languages, etc. as standards.

Also there are generic applications suppliers such as typesetting, WPS, spreadsheets, graphics. Applications industries are springing up based on the knowledge of a field of application - the clearest and now the most difficult being CAD or VLSI CAD. Finally, there are the integrator-distributors (eg. Convergent Technology, Osborne, each Japanese company, Digital, IBM). This is a complete fragmentation by levels of integration to gain expertise, take a few risks and share rewards, unlike anything in previous computer generations where system suppliers virtually did the whole job. This is what traditional suppliers of all types didn't really foresee very well. This is why an Apple can grow at an unprecedented rate. Also, I doubt if many of them see it yet!

The observation about this industry restructure in the 4th and 5th generations (VLSI) as being quite different from the transitions through the evolutionary 2nd (transistors) and 3rd (integrated circuit) generations might be useful in your work. I think I see it clearly.

Again, thanks for a stimulating day.

Sincerely,

Gordon Bell

Professor Francis Lee of MIT is going to spend his next year's sabbatical in China at Peking and Shanghai Universities.

He wants to set up a version of his lab installed there.

There is also an order for 11/70's, 11/60's, and a PDP-10 that he's getting together.

He wants our help in the bookkeeping of this order. Can we get someone from sales to interface with him?

Subject: **Professor Lee's MIT LSI-11 Microcomputer Lab**

To: Distribution

Date: 24 JAN 79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 2/7/79

Professor Francis Lee gave me an update of the status of his Real Time Computer and Control Course. He told me that many of the other universities were really jealous because they turn out 600 students/year (more than CMU, Berkeley, Stanford and Illinois combined) and use LSI-11's!

The course:

1. Taught in PASCAL (not UC/SD) and when the programs run into performance problems, they go into assembly language.

2. Problems start with oven control and move to motors and displays. The later requires microcode in WCS. They also use 1 Board 8080's for some problems.

We'll be invited to see the lab and we should get structured to take advantage of their results. Let's take advantage of this work!

He wants to export the lab (including the 11 WCS that the Commerce Department is sitting on) to China when he goes there on sabbatical.

Shouldn't we try to export this system in order to get more students hooked on 11's? (With this, Tiny and Fonz are critical!!)

SUBJECT: MY READING OF MCNAMARA AND WHAT PROJECTS TO DO

His comments are: Engineers want to create; Be on the best team; and Be rewarded. This means: 1. Shorter cycles; 2. Be more graceful about cancellations; 3. Improve facilities; and 4. Pay more attention to education.

The only thing I commented on to our management was that there were projects we obviously can't do, due to budget restrictions... this may be a graceful way of saying that we should kill some products.

All my issues are totally in line with McNamara:
Engineers want to do very good products and complete them.
You might look at the forecasts
versus actuals of the software sold. Somehow quantity isn't always the answer.
1. The 4G funding is really obscenely large. The only good thing about it is that something like this is needed because the phase review process just about kills any creative ideas that might come out of our engineers. However, the large list was awfully mundane and redundant.
2. Redirecting the software effort in office is simply taking the lead from the troops who have all left the project. Your latest leader there is hurt because he has a marginal record of management of software engineering, and we have not given him even more to do so that he has an excuse to fail. I was sold on him until you told me he was pouting because he didn't have the works. This effort has been a mess to date and I don't have much hope, given the latest leader comments.
3. I still say DECalc is immoral and should be illegal if there were decent laws applying to software. If this were a hardware question that we owned, we would have sued the company (as we did in the case of Lockheed). This a poor copy of an original. McNamara says do great things.

For some reason, we can't really innovate very effectively in new areas. I think it may be that we are too decoupled from the market, or it may be that there isn't the right front end case where people can invent and propose. I see lots of copying of the mundane (eg. >= 2 mail systems per operating system; or 4 new office type editors on VS, CT (2), and VMS), but not a really good 4 G effort that takes advantage of VMS. I had endless conversations with Don WilWilson et al, but got nowhere except to see a copy of the

Visicalc work (and a poor one at that!).

I also thing the DECset was a collosal mistake that we should try to extricate ourselves from. Talk to our internal users (eg. Patti Anklan). I have no ego needs to think that we can beat Knuth or Brian Reid at typesetting; I know these guys and they are very, very good.

Then, there are the Japanese. I predict they'll be good.

Avram is buying out. I think that we should do more of this. Since we have a strategy of compatibility between CT and VMS, it's clear we should have the system run both on VAX and CT. How are we going to handle this?

What about ADA? Here, we've really spent a lot of time and nonow with Ike gone, I see that we have no unfair competitive advantage. Pascal, which is mucho late on VAX and which was tolerated (even though Cutler told you to knock it off) and should be reviewed.

Subject: **Reasonable Promotion for VAX Now; and NCC**

To: Bill Demmer, Bernie Lacroute

CC: Win Hindle, Ted Johnson,
Andy Knowles, Ken Olsen

Date: 28 APRIL 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

I've now talked to a half dozen potential customers of VAX. None have really heard about it. The technical summary is excellent! Let's produce them in mass (in small manual version) and ship them out at NCC and other places. Flush any notion of the slick brochures -- use the summary so our potential buyers will keep the information.

Given the knowledge of our salesmen on VAX, their reluctance and temperament to sell, the lack of any ads, and any deep central market support in the fragmented P/Ls -- the machine has to sell itself. The manuals are good and can, but they have to be made and distributed!

Our first few users are happy; the machine is really great -- but we have to do something to keep the sales happening by themselves and allow our customers to order machines easily!

Subject: **PROPOSED ANSI BSR X3.67 SPECIFICATION FOR I/O CHANNEL INTERFACE**

SUMMARY

We are strongly against this standard because of its past, present and future cost and performance merits. In addition we speculate that it will be useless, unenforceable and have a deleterious effect on computer architecture and the computer industry. The standard doesn't specify controller designs; thus two conforming controllers will most likely be incompatible and useless across systems of different manufacturers.

Technically the standard is poor and contrary to the current and future technology design alternatives (e.g., easier to specify serial links). We believe it requires extra hardware over alternatives, and the partitioning of logic appears to significantly increase software complexity. It seems to have the worst cost/performance characteristics of the interfaces we know. We aren't planning to use it on any of our future systems. We believe future i/o systems will be message-oriented and the various i/o control functions (including diagnostics, file management) will migrate to the subsystem.

The standard may be unenforceable due to the nature of parallel interfaces. Fundamentally, it is a syntactic specification and there must be semantics too! Since the standard doesn't cover the specific controller/device designs, it is inadequate to make controllers that will work across mainframes made by different manufacturers. Even the Japanese, who originally adopted it and proposed to extend it, seem to have abandoned the standard.

The standard, per se, may wipe out several mainframe vendors if they adhere to the letter and intent since only IBM, IBM plug compatible vendors, and the Japanese, who have IBM compatibility, benefit. Because of the standard, (not as it stands -- but rather making identical IBM controllers) all designs are forced to that of IBM. Since IBM has significantly higher volume, and the knowledge for manufacture, significant manufacturing and field learning means much lower costs. While the effect might possibly be to reduce IBM's prices here, the effect on other mainframes may be annihilation. Lower costs from other vendors are because they are not IBM compatible! Overall, the standard seems to be at the expense of other users and non-IBM vendors.

There is a high likelihood that the standard will cost the computer consumers more. Any savings have already occurred as IBM has lowered prices and redistributed prices to be more competitive on a component-by-component basis. Even if IBM compatible controllers, not covered by the standard are put on other mainframes, the software is different and the market here is negligible when one considers the myriad of low volume operating systems. By supplying low volume components that have to be backward engineered into designs, the cost will most likely be redistributed (and hidden to the users in the form of unreliability and user-supplied system design and integration).

The standard, if misapplied to other, smaller peripherals where the interface is a high fraction of the cost, would most certainly increase prices. Any cost savings, for disks, are artificial simply because the add-on vendors are not paying for software (i.e., diagnostics, file systems and operating systems). The net effect will merely be a rebundling of costs. As the mainframe vendors supply parts to the standard, any technology gain will be slowed down.

The computer industry is complex and this form of standardization is very likely to effect its performance adversely. There are standards that can be made in the interface area which may be of higher priority and provide greater impact for the future. Although the proposal has been in the environment for some time, the goals, method of implementation and effects have not been stated and analyzed.

DETAILED POSITION

We've been against this interface for a number of years, and the feelings about it are now more intense that there is a possibility that it might become a computer industry standard. The concerns are:

1. Technically, it is poor and contrary to the direction of current and future technology and design alternatives:

   a. Extra hardware. It introduces another component, the i/o processor (Pio) - i.e., the IBM Channel into systems. This concept isn't used in either minis or our larger machines like the PDP-10. Virtually none of the successful larger computers use it (e.g., Univac's 1108, and the CDC's 6600 and 7600 derived computers have a simpler interface that is driven by peripheral computers). This is illustrated in fig. 1. The figure doesn't fully illustrate the magnitude of the problem. The hardware in the whole 11/34 support computer (used in DECsystems 10 and 20) is less than the hardware needed to support two ends of a channel interface! For high speed devices usually only 1 disk controller is attached per Pio, creating a second needless interface and more hardware (Pio + K vs K).

   b. Extra software and software complexity. We "conjecture" that the additional i/o processor, with its different ISP (Instruction Set Processor), introduces an extra level of software that doesn't exist in other operating systems. This occurs because the processor isn't a full computer (e.g., the CDC computers), nor is it totally passive (e.g., a wire) and hence requires supervision and constant intercommunication between Pc (the Central Processor) and Pio. Pio doesn't have enough capability to diagnose itself. The result may be that IBM's operating systems are larger than those of other manufacturers.

c. <u>Poor interface cost and performance</u>. Of the interfaces which have about the same number of wires, this channel has the poorest cost/performance characteristics. This is shown in figs. 2 and 3 where we have tried to evaluate the relative interface costs now (and in 1980). In addition to the interfaces, other costs for the i/o sub-system include: Pio (the IBM Channel) - DEC doesn't have them; the controller (about the same in the 2 cases) and which can vary from a few circuits to a cabinet of logic; interfaces to device(s); and the device.

For low cost devices (e.g., serial teletypes) this interface cost is nearly all (95%) of the cost of the controller even for the Unibus.

d. <u>Inadequate performance lessens future utility</u>. The performance appears to be inadequate for the faster disks and non-rotating memories (e.g., solid state and magnetic bubble devices) that are likely to appear in the near term. It is still unclear how the non-rotating devices will be connected. They may be integrated into the disks to cache disk accesses (in which case we do need faster device data rates between Mp and K); or they may be integrated into the primary memory system in which case no external busses would appear; or they may require higher data rate busses (e.g., Massbus).

e. <u>High speed serial is more appropriate to the future</u>. We believe DEC and the computer industry must go rapidly to serial intercommunications, that are message oriented in order (a) to improve reliability, (b) provide true interconnectability by being truly specifiable, and (c) to provide more freedom in equipment location. The fiber optic technology, for example, significantly increases reliability by eliminating common mode noise, by being specifiable, and by having clearer definitions for each component.

This serial approach is supported by semiconductor technology trends of 60-100% increase in complexity per year with only small increases in power dissipation and pin count. The cost of power, semiconductors to drive cables, cabling, and air conditioning is increasing at least as fast as inflation.

A high speed serial interface such as those used by the communications industry for digital communications (e.g., T1 through T4) is probably the only good, well-defined (enforceable) interface due to the precision and simplicity of the electrical specification.

f. <u>Future</u>

functional migration. With the greater logic complexity there should be significant migration of functions to the secondary memory systems. As a minimum, this would include the diagnostics, memory access optimization, and error/fault management; but we believe it will also include the file system and possibly a database management system. This transition will probably occur by 1980. The "channel" concept will be archaic and inhibit the migration.

g. Against future integrated packaging trends. We believe it is possible to include a complete, 500 Kword DECsystem 10/20 in the base of a disk cabinet by 1980. Here we would not have a channel, an interface, a controller; instead, a single interface to a few drives would be integrated into the design...and take up much of the space. It would be ridiculous to add a needless structure to provide an interface point that would dwarf the hardware.

h. Against future integrated memory hierarchy possibilities. Some of the memory hierarchy alternatives described in (d) would be impossible using the proposed bus structure.

2. The standard may be either unenforceable, or unusable.

a. Parallel interfaces are perhaps unspecifiable. The nature of a parallel interface, timing, and the states at both the channel (transmitter) and controller (receiver) is such that the number of states is essentially infinite, and unspecifiable. It's hard to believe that a specification can cover all of them...or even the problem of electrical transmission. In effect, all the incorrect (error) states have to be specified too.

For example, although we (and other vendors) have been delivering controllers to meet the Unibus specification for 7 years, we consider the specification barely adequate, and only within the last year did we feel progress had been made in getting it clear enough for a design specification.

b. Devices have to be specified also. The channel interface per se, does not cover device to device compatibility. It covers only a few status bits in the devices. Hence, there is no guaranteed compatibility among the "standard" controllers.

Any amount of movement of intelligence would negate compatibility of what is a syntactic specification. Devices need additional syntax and specific implementations would cause additional meanings to be needed. (A good example of this is microcomputer PL/1 dialects. Several companies use the syntax of PL/1 for languages which are semantically incompatible. and even two programs with identical syntax give different results.)

A new device with different capability requires additional commands, thereby introducing semantics to what is a syntactic standard. For example, the movement of the error correction function between the device and a program in primary memory requires a totally different approach than with existing controllers. Note that a program in the central processor, or a program in the device controller, or a program in the channel may carry out a given function, and still meet the specification but can be totally incompatible. By convention, IBM places this function in the controller (except for errors in data fields), whereas in our small computers, we place all of this function in the device driver software.

The conclusion could be that the ANSI Standards Committee must take on the design, specification and testing of i/o architecture, controllers and devices. This standard shows that it's prepared to take on only a part of IBM's.

c. Even the Japanese believe it to be useless. A recent ISO communication (IAC/77-16: ISO TC 97N Feb. 77) proposes that a serial protocol be the standard. This document concludes that 8 years of standardization effort have been wasted due to a poor standard.

3. <u>Adherence to this specification may, quite possibly, cause several mid- and high-end vendors to withdraw products or to withdraw from the market</u>.

The net effect of such an action would be to increase system prices for equipment in this price range...no matter who supplies the disks. Fundamentally, these businesses are <u>dictated by</u> the IBM high support cost style of doing business and only differ by the architectures and being able to position products that differ from IBM's. This standard would force more cost, and nearly total compatibility with the 360/370 and hence the competitive prices would either move up to IBM's or a vendor would be forced out. For example, RCA tried this strategy. Amdahl is a counter example that has existed for one year; Amdahl has stated that IBM believes it doesn't make adequate profit in the high end part of its business. Also, Amdahl now has the capability to track and modify IBM's software.

Thus, to be compatible with IBM as this standard dictates, means we should all build 360's and 370's. While this might appear to save money for some buyers, it wouldn't permit the minicomputer or microcomputer industries to exist. While it is too early to tell, I believe the substantial behemoth computers that exist in the bureaucratic, IBM trained, computation centers in industry, universities, and possibly Government have limited life. <u>This standard perpetuates inaccessible, centrally controlled computing as we know it, and brings all other computing down to this level. Even IBM is beginning to supply small systems for distributed computing...further rendering the standard useless</u>.

<u>No IBM System, except 360/370, including Series 1 use the standard</u>. If there was economy of scale, goodness, or it was usable, then surely IBM would use it somewhere else (e.g., Series 1, Systems 3...15 32/34).

a. <u>IBM only benefits</u>. Among mainframe manufacturers, the standard is only beneficial to IBM and the IBM plug-compatible mainframe vendors who are already there now. To other vendors, it is a make-work activity that will only cause a diversion of resources and hasten their demise.

Because of "learning curves" other vendors will be forced to produce the same goods as IBM, but without the value of the learning in manufacturing or in maintenance IBM has experienced; hence, our cost can easily be a factor of 4 or more higher. The exact numbers would have to be based on say a 10% cost decline associated with each cumulative doubling of units produced!

b. <u>The Japanese could (most likely) benefit</u>. The Japanese, who also copied the 370 architecture and provided some superset capabilities to permit the one-way flow of programs, may also ultimately benefit in the various world markets. Now they don't support standardizing this I/O Channel precisely because they believe it's bad.

c. <u>DECsystem 10/20 would be jeopardized as a marketable computer</u>. In the case of the DECsystem 20, where we have a price edge (with comparable or better performance) of a factor of two, the alternatives are really poor for us. They, at first glance, appear to consist of: withdrawings from the market entirely; not marketing to users who require conformance to the standard; making a simple adapter to meet the spec; and going completely to the IBM Channel design. Since the DECsystem 10/20 group is small, meeting the standard entirely would rob it of future (sustaining) development.

A simple adapter to convert between the Massbus and the standard would risk our competitive position and provide poor performance through an interface we would have to evolve. There clearly isn't adequate time to do this before the effective date for the standard.

For the DECsystem 10/20 we would anticipate a price for a simple adapter to be $45,000. The number of systems containing the IBM Channel we forecast to sell is so low that poor reliability and poor performance might result.

We estimate our development cost including support, for 1 device class, to be about 1.36 million with about .3 million per extra device class for capital equipment and special micro-programming/programming. From a development viewpoint, these costs could bring development to a standstill. In fact, it would probably be better not to market to the Government. (If the DECsystem 20 maintains its current market position, we estimate the price to the Government by buying alternative systems will cost the Government an additional $30M in 1979.)

We use the

PDP-11 for low speed peripherals on DECsystem 10/20 since minicomputer peripheral costs are much lower. Thus, these peripherals are significantly cheaper than those for the 360/370! If low speed peripherals were forced to a Multiplexor bus, it would take virtually all the development resources to build the necessary communications, unit record, tape, disk and other controllers. If we put adequate development resources into meeting the specification, then we will have higher manufacturing cost for peripherals (than IBM). Because of software support costs and the semantic compatibility problem discussed herein there would be no way for us to market products that could be placed on IBM's computers. (Nor is this DEC's strategy.)

(Note that IBM clearly has the manufacturing cost advantage through learning curves in the large systems area and since it sets the support levels (costs), there is virtually no market.)

d. <u>Government use will be at expense of other users</u>. In addition to inequities forced on computer system vendors, consider the effects on other users. Since the collective influence of the Government purchaser is so much larger than any other single user, it can effectively cause vendors to be more responsive to it. Unless there is widespread support among the user community for the interface standard (little has surfaced since the standard was first proposed), then the Government representatives are clearly trying to benefit themselves at the expense of all other users. The damage to the users, as well as to most system vendors, will certainly outweigh any possible benefits. This move must certainly add to the problem of credibility in Government. So far the information processing standards have been quite positive, yet this one appears to be totally destructive (at least to us). The recent comments by Tom Pyke in Data Communications are in total disharmony with the proposed standard.

In fact, it would seem that the expected benefits are suspect. If other users (most of them IBM users) cannot find a reason to support the standard, it is unlikely that a benefit exists for any user.

4. <u>Although a standard might save the Government 100 million according to rumors, we seriously doubt that these savings would take place, and it is quite likely to cost more</u>.

a. <u>The savings have already occurred via IBM/add-ons</u>. Any savings by competition has already occurred in 360/370 via independent peripheral vendor competition. For other systems suppliers, we already have arrays of 3rd party competitors! Engaging in this make-work standard will only add to our costs (prices) and delay introduction of more significant products.

b. Unique software is still required for each system. Because each system is fundamentally incompatible (due to semantics) each third party supplier will still have to supply unique software for each different operating system and its releases for a given hardware system. In the case of the smaller system vendors, the competitive base won't be any larger than it is now because the cost to generate the software won't be worth the return to the third party supplier, nor will the system's vendors be able to supply to each other. This will also result in: poor performance when added-on to; inadequate reliability; maintenance by the user, as low volume designs persist.

c. Controller compatibility is not guaranteed among mainframes even with standard. The standard does not guarantee that a controller which has been designed for one system (e.g., IBM) can be connected to another system (e.g., DEC) since the standard doesn't define all bits in all controllers for all possible priced systems. Hence, the proposed standard does not provide a scheme whereby a disk sub-system can be moved among computers of different vendors.

d. <u>IBM total systems prices haven't decreased as rapidly as disk prices</u>. Although we don't have the data, it seems that the prices for IBM systems have not decreased as rapidly as disk prices since the competitive disk vendors have appeared. The prices of disks have decreased rapidly, but apparently have been offset by varying the prices on other components (including the software). Quite possibly the markup is more even now across components, or it is artificially high in the processor where there is less competition.

e. <u>The cost of ownership most likely will increase</u>. Although the purchase price of a system might possibly decline over what it is now, the cost of ownership (by having the user become the system designer, integrator and maintainer) will probably increase. Again, this results from having only a few systems (and poor learning curves) hence higher prices due to inexperience. If this standard is enforced, there must be records to measure the total costs and compare costs for various ownership/maintenance strategies--especially in Government!

f. <u>Increased component count would increase minicomputer prices</u>. If this standard were to be applied in the smaller systems (e.g., the large minicomputers) the costs would be substantially greater because of the additional components. The net effect on minis would be to constrain them to the larger computer prices. This would impede the trend of rapidly decreasing minicomputer prices.

g. <u>The standard is poorer for low cost peripherals</u>. While it appears that the intent of this standard is to use the channel interface for only disks and tapes, it was designed by IBM to interface everything. If extended here, this would be a fundamentally bad move. As described above, it is cheaper for us to make peripheral interfaces for minis only and to connect the mini to the DECsystem 10.

h. _Mainframe development costs would rise, therefore system prices_. A manufacturer adhering to the standard would spend resources (thereby increasing his costs and prices) resulting in fewer systems sales (e.g., to the Government) because of the increased price. Fewer add-ons would result, due to problems mentioned above and the lower volume.

i. _Semantics and devices must be specified to have full compatibility_. A manufacturer can adhere to the standard and still not provide an add-on port, due to software as mentioned in (4 b, c) above. The semantics are as important as the syntax.

j. Software copyright protection is inadequate to protect supplier investments. If a standards-based marketplace could be effected, then software protection would have to be enforced to a more significant degree than it now is. (This would cause a redistribution of costs that might not so clearly benefit anyone.) An operating system is never totally unbundled or bundled, nor is it clear how the cost of a component (e.g., a disk driver) can be fully unbundled. This is especially prevalent as other suppliers provide higher performance (e.g., seek optimization) and these are quite tied into the operating system.

k. Prices will be rebundled and increase. The concern with standards and interfaces at this level, especially when this one is fully sorted out as to semantics and the internal software interfaces, will be more costly to everyone concerned, simply because we will all be working on the specification of what appears to be rather arbitrary interfaces (i.e., the operating system, handlers, diagnostics, file systems, etc.). If a manufacturer were to fully adhere to the standard, it would be reasonable for him to bundle the file system with the disk system, and the supplier of the disk would then be fully responsible for the design and implementation of the file system. It should also be mandatory to provide a disk pack standard for interchange and for the diagnostics to be used interchangeably. These aren't part of the standard.

l. Much "make-work" will delay any true technology and cost gains. Any slight delay in computer evolution will easily produce a net loss in performance benefit which would more than offset any savings!

5. The current defacto standards are adequate to motivate competition.

a. For the IBM

add-on, there are vendors. Each device has a source of alternative suppliers that are appropriate to the device.

b. The minicomputer suppliers have adequately defined interfaces (e.g., the Unibus) with lots of competitive suppliers. For organizations who want to use the IBM standard, there are alternative supply sources who meet the standard (e.g., System's Concept and who supply to our PDP-10 and PDP-11 computers).

6. The computer industry is a complex one and this clear, direct form of Government regulation will quite likely affect the performance adversely. This standard totally constrains a design (if it is to be as effective as desired by its supporters...even though it is not adequately specified to accomplish this goal now.)

The computer industry has evolved rapidly over its short 30 year life providing an increase in performance (memory-size x data-rate) of over 10 billion. This has been accomplished, in part, because the Government has nurtured it by being an extraordinarily wise user and funder of R and D.

With this standard, the ANSI Committee is taking over a key portion of the design of systems of computers and it's unclear it has the experience and understanding of computers or the computer industry to do so. The industry taken as a whole seems quite complex to me, and it's doubtful there is a good econometric model of it. Even if there were a model, the prospect that the ANSI Committee would be using it in this instance to predict future development trends and then, advisedly, choosing a standard interface technology, would be of concern.

7. <u>Although the proposed standard has been in the computing environment for some time, it's underlying goals have not been adequately stated and analyzed</u>. For example, we have never seen a document stating: (a) the goals, (b) the underlying assumptions (e.g., more competition, save $100 million), (c) how to accomplish the goals, and (d) answers to some of the basic questions (e.g., semantics versus syntax, technology, cost, effect on non-IBM mainframe suppliers).

Sincerely,

Gordon Bell

Dear Mr. Jescke:

Thank you for allowing me to address your users in Berlin on 17 May. It was an honor to help you celebrate the Tenth Anniversary of PSI.

Under separate cover, I'm sending you a copy of the book, Computer Engineering which three of us at Digital compiled to commemorate our Twentieth Anniversary.

Sincerely,

Gordon Bell
Vice President,
Engineering

PSI
Katharinenstr 19/20
1000 Berlin 31
Berlin, GERMANY

Dear Dr. Jaeschke:

The stein is a lovely reminder of our stay in Berlin.

May your next ten years be as successful and rewarding as the first.

Sincerely,

Gordon Bell
Vice President,
Engineering

I really question whether we want to assist the wide-scale education of the Japanese engineering community as TAC might do. This will ultimately come back to haunt us when their products are improved. They build nets and terminals, and further tune their notion of distributed processing as we know it. TAC tells "how to" and is therefore not germaine to selling.

Please don't even consider publishing <u>Computer Engineering</u> in Japanese, assuming there may be a demand. Also, I would minimize the distribution there.

SUBJECT: WE MUST GET A PUBLICATION POLICY

Craig and I had a good discussion last nite on this, but I am quite
confused as to what the policy is. Craig is operating under the policy
that all his CAD work is pretty open and can be discussed. I.e. he can
publish and lecture on the problems and techniques the group
have developed for coping with 80K transistors, etc. This is
not the policy that I outlined which restricts discussion of the
product (that's clear), design process , or manufacturing

process, or circuit technology until a product has been announced. Given that in VLSI, the major impediment to the design is the CAD tools, Craig's policy doesn't feel very good to me because it helps our competitors like Intel, and I'm not sure how they are helping us in our areas like better process technology.
Also, we have restricted Ivan Dobes from publishing about gate arrays, even
though the work is quite non-product specific because it applies to MCA and
we are so far away from FCS. Similarly we are not open on the analysis necessaryr
to parallel power supplies, which is the theoretical underpinning of Modular
Power supplies. Also, here I am reluctant to talk very much after publication
because Power Supplies represent an area where I believe we now have a
technology lead, and I don't want to help our competitors catch up. In the
Research group, there might be some issues, although I don't think they do
that much publishing.

One thing is becoming clear and clearer: we have a problem here because various
groups are operating according to different policies. Would you please arrange
a meeting with some of us to input to the policy and then get someone to write
a trial balloon one that can be reviewed? I would also like to inform the maMarket-
eting Committee too and get their input.

To refresh our memories, the 12/16/79 EMS message was: We are not going
to publish papers on product or process that are product related until the
product in question is announced. Note this really squelches just about
everything, including the VLSI VAX, assuming CAD is a process and related

or targeted at a product. I would like to get the right policy here ASAP,
and as I indicated before, I have no pre-disposition to it. If I don't get
a policy forming soon from you guys, I intend to move to further restrict p
publication and outflow of information. Your help is needed.

SUBJECT: PERMISSION TO PUBLISH ON TINY

I think we should go ahead with it, provided that the announce
is somewhere around the time of Tiny. At any rate, I don't see
any harm of saying that we have it and it will be used for
internal products. We could almost say this now! (Who cares?)

Since there isn't a product surrounding it per se, and it as
an internal part, then can we just announce it in this rather
interesting way?

Dick, I'm for it, but if there's an issue that will upset the
marketing folks, I'd like you to get the clearance.

I'll give you strong support on this.

Subject: **FY 80 Planning**

To: OOD

CC: Paul Bauer, ML3-3/B91 Operations
Mitch Kur, ML12-2/A16

Date: 22 NOV 78
From: Bob Puffer
Dept: Engineering
Loc: ML12-2/E38 Ext: 223-2863

Last week's OC Woods established a tentative NOR plan for FY '80. Overall, we can start planning based on an average central engineering growth (including contingency and reserve) of 25-28% over FY '79. This should translate into a 10-12% people growth.

The balance of FY '79 looks good and the corporation is planning on and committed to meet its BOD budget. Engineering is also expected to meet its original BOD budget. The bottom line is that the plan has not changed and still looks good.

Attached is a sheet qualitatively describing the budget growth by engineering area, which Gordon initiated and I edited. It is a talking point from which we will begin discussion of the budget for your areas. Obviously the goal is an allocation supportive of the engineering strategy statement. I would like to see us agree, up front, on this sheet (after appropriate ECO's) so that we don't get expectations and detailed planning out of touch with reality.

I will schedule this for discussion at our next OOD meeting.

In walking through the mill, and other facilities, I think I see a couple of solutions to our space problems:

1. Clean out the unused equipment; especially VT05's, LA30's, and some VT52's.

2.give terminals (e.g. the public room 3-5 and R + D) to TPL to sell, or to individuals. I've yet to see anyone use this equipment.

This should get us space, cut the capital equipment, get some $'s back in and make the place much neater.

What do you say?

Yes, I support a strong VAX-11 Basic (alas new Basic + 2) at DECUS. It has to include demos with full screen at the sessions.

A really good product is essential in order to get RSTS users to switch to VAX, because the AME approaches will never (can never) offer enough incentive.

The theme should stress:

1. Performance
2. Big address
3. Cleaner language + interfaces
4. Ability to mix languages (including) in a single program.
5. Ease of conversion from RSTS (talk about the conversion program).

We should have documents there too that show this, especially the conversion.

Also, we should have some demos that show conversions. Could we have a customer(s) give testimonials?

SUBJECT: THANKS FOR THE LONG AWAITED Q VS BI REPORT

Fantastic to finally get this information at last. We've been
speculating about BI and Q based systems for quite sometime with
no data! Although the distribution list was relatively long, it
didn't include several key people who are trying to sort out and
understand this space including: moffa, bj, kalb and teicher.
We lost valuable time in getting some understanding. I like
Ken's saying: Open distribution of information, formal decision
making.

It seems like all the data's there to make decisions on the
use of BI vs Q bus. A hasty reading says to me:

Get a semiconductor company to embrace the BI, get the cost
down and go for it as a high quality, competitive bus to
outdo VME and Mulitbus. We must have the chips to compete!

We want our first systems to use Qbus for cost reasons, but
a major factor (not mentioned) was the earlier time to market
of a system based on Qbus boards and boxes. I want a system
out based on uVAX ASAP... otherwise kiss the TVG business
goodbye.

Note, we now need some formal plans and this is possible now
that we have less noise about the goodness (versus time) of
the BI. My two observations above are just that, no commits.

Thanks
g

GB3.S8.69
I'm happy to give this Q1 report after a 6 month lapse in the Yellow Book publication. Lot's of changes should be observed (see the contrasting product charts).

The big changes: the low end is moving in terms of computer and terminal systems (e.g., Krypton, the new CRT, and the printing terminals). The market thrust is increasing too with LSI-11 sales picking up at the board level where we have a unique, great product that has the highest performance of all the microcomputers. The DCG Engineering Group has been doing enhancements to provide significant market-oriented and mid-life kickers to these products. It's nice to get the various disk (especially RK06) shipping...it's clearly the largest most complex hardware system we've built. PDQ seems, at last, to be on a course to ship at a predictable time. It looks like quite an interesting machine although a year earlier ship would have been better.

Although we have been updating the development plan (the Red Book), there's been significant product development activity. (Our fear of planning is that it will consume us and no development will occur). Since there was a plan in place, this Red Book has been used extensively to:

1. Work on about 10 product problem issues...many of which have been solved, the rest will be reported on at PL Manager meetings until they are solved.

2. Start "systems planning" as viewed by customers...not a collection of memories, disks, power supplies, software as we've been doing. The Spring Red Book will be the first full-fledged plan this way.

We (about 100 mostly hardware-oriented engineers from Central and PL Engineering) attended a 2 day LSI seminar that really covered plans and activites in all hardware. It was the most intense, interactive, interesting meeting I've been to...and I look forward to next year's session. (We have to figure out how to include software, systems, and other engineering...200 people in a group probably isn't the answer.)

The M/E Committee is soul-searching its charter to move to a more policy- vs police- orientation. We need a similar (M/E+?) group oriented to service (FS/Software/Software Support/Development). Bob Swarz has been here for a few months as the Corporate Manager of the RAMP (Reliability Availability Maintainability Program). He reports both to Field Service and to OOD, and is beginning to work with our engineering groups to understand, educate, analyze, and make standards and policies in this area. We'll clarify this soon.

There's been a small group defining the Commercial Instruction Set architectural addition to our computers. The one we have defined is quite extensive, but I believe necessary if we're going to have a range (low to high) of high performance, competitive, commercial machines (which I feel we must). The process was somewhat frustrating, but we've learned quite a lot from it (which I've tried to state in a memo).

Various standards are beginning to consume more resources...the price of being in nearly every marketplace. The responsiveness is impressive as we often need quick commitments to make product/business decisions. A related activity, standard systems, or systems that can be configured is being attached by Jim Barclay. It looks as if it may someday be possible for nearly any of our customers to order predictable systems that are buyable, buildable, billable, and useable in a deterministic way.

Gordon Bell
10 NOV 76

STRATEGY Q & A

Q1 IS THERE "BUY IN"?

. THE OPERATIONS COMMITTEE, B.O.D. AND OOD HAVE APPROVED IT.

. NEARLY ALL PLM's SAY THEY SUPPORT IT.

. THERE ARE INTERACTIVE PRESENTATIONS PLANNED WITH P/L GROUPS.

Q2 DOES BUDGET SUPPORT THE STRATEGY?

. DON'T KNOW YET.

. AM USING STRATEGY FOR ALLOCATING RESOURCES...MUST REMIND OTHERS TOO

. THERE IS PROBABLY NOT ENOUGH MONEY TO SUPPORT <u>ALL</u> OF THE STRATEGY.

Q3 WHO'S MANAGING THE STRATEGY?

. ALL OF US. A FULL TIME PERSON IS NEEDED.

Q4 WHAT'S DIFFERENT FROM WHERE WE WERE HEADED?

. DECISION ON VAX MADE IN SPRING '75.

. MUCH EMPHASIS ON COMPATIBILITY...ESPECIALLY IN 11's.

Q5 WHAT ARE THE "HARD" PROBLEMS IN DOING IT?

. CONCENTRATION AND MANAGEMENT.

. IT HAS STRONGER STANDARDS AND MORE PRODUCT INTERACTION (THIS

COULD BE CHEAPER AND EASIER TO MANAGE THAN BEFORE).

. MUCH SOFTWARE.

. INTERCONNECT NEEDED QUICKLY TO "GLUE" IT TOGETHER.

. GETTING TERMINALS EXPERIENCE.

. GOING TO APPLICATIONS.

SUBJECT: USING THE Q BUS FOR BUILDING COMM SYSTEMS

Sam informed me that we are about to get 12 Qbus Ethernet interfaced from Bob Metcalfe's company. Maybe we could license his design instead of building our own here.

I've asked Bernie and Dick Davies (who is doing comm hardware and software in the UK) to look at building our gateways out of lsi 11 based systems. We are not using our own 11's enough hopefully because we don't know about them. Is there a way you guys could get with Bernie so that we could start to build these systems this way?

What happened to the Shoebox? It is really important to have a cost-effective way to build these point products. The world is going to demand a plethora of them to convert among the various protocols, terminals, etc.

USING THE VT103 AS THE BASIS FOR BUILDING COMM SYSTEMS
What really looks good for the point products is the VT103 since it offers a box, power supply, crt console, and computer. With it, we would make special dual board options for interfacing to all the protocols. We and CSS could build these boards and systems very quickly. Also, it would make an ideal box for the concentrator, tcp, that the commercial group needs that is to concentrate 4 lines. In looking through the Yellow Book, I can't find the option I think we need, namely an 11/23 with 128Kbytes (using 64Kbyte chips), and 2 serial lines. Are we building such a board? (It would be the basis for the concentrator.) Where is the plans for all the Qbus options that

would be appropriate?

The kinds of products then that I see would be:
a 4 line concentrator - using the board + serial line board
a gateway - using the board and special boards for the
  various brands of X25 and SNA
a concentrator for Ethernet using the Metcalfe interface
  until we get ours
a front end for concetrating line printers on large
systems...
  in essence, the print server.

Note the cost per line has to be low cause the box won't cost over a 1000.

Can we look at this approach for really cost-effective systems?

SUBJECT: QUALITY AND PRODUCTIVITY: WHAT'S THE ANSWER?

Let's talk a little about this issue. I want to learn what you know about quality and how to get it.

We (Engineering Staff) had a discussion at a recent Jungle Meeting on measuring these as they relate to Win's request. I
am still depressed from the discussion. BJ has operated a quality organization for three years and things are improving.
This is the only encouragement.

You guys apparently tried some sort of top down organization approach and gave up. I don't see how Engineering can hire the
same folks and have them do any better, as Dick Amann suggests.
Our product quality is really too low, and we engineers don't have the understanding of quality. Our productivity measures
are non-existent... and we are being asked to improve both parameters, neither of which we understand.

Let's discuss in one of our joint meetings, but in the context
of some teacher and readings.

It should be able to be proven that given our current understanding
and behavior about quality, we are clearly doomed.

What is the answer?

SUBJECT: QUALITY, RELIABILITY

THIS EMS IS ACTUALLY FROM DICK AMANN

On a recent article you wrote "without some total (quality) program
across the company"..."we're (not) going to make it."

The possibilities of getting a total program going are diminishing.
The groups who have tried to provide cross company quality focuses
in specific areas are being decimated and decentralized.

Central Manufacturing's Corporate Q.A. group is being decentralized.

The Manufacturing Process Quality group is already gone.

Corporate Component Engineering, who help assure quality components,
will be next on Manufacturing's hit list for decentralization.

Corporate Product Safety, who look at the quality of our products'
safety design, is being decentralized.

My fear is that by the time this company's management wakes up to

the need for a cross company quality focus, the very people, operations
and groups who could have been a nucleus for this focus won't be
around.

If you feel strongly about this, why not stop all future decentralization
of quality oriented groups and, instead, look at transferring them
into engineering?

MESSAGE ID: 5199269688

SUBJECT: RE: QUALITY

Am strongly supportive of a central quality focus. Would even
go so far as a special appointment as suggested by Lou Cohen as a VP of Quality. Am happy to hear that for the time being until we improve, yo're the VP of Quality! Lou is a resource with in engineering who could help enormously in terms of spreading out into various hardware groups, based on his software work.

I have long felt we need strong guidance because I don't think
I see the talent, concern and understanding of the relationship
of engineering quality to product quality AND schedules. That's
why I'm ve tried to push the thingprogram called Quality Design
Methodolgy.

BJ's the only one pushing this inby an explicit porgram arogram and
assignment of people. He had a Process workshop a month ago and John Manzo's working it full-time. SEG's already been there and I don't workry about them either because you can't build chips without such a commitment to quality design.

Am concerned about mass storage and the low end where there's non-trivial engineering of connecting complex vlsi parts... a typical eco rate is one wire/ic! We should have some results soon too on Venus to see if all this pays off. So far, there were 300 wirewires on the one board that wasn't simulated, whereas
the first two boards that had extensive simulation had 5 wires.

We need a revolution in our design thinking in the short run. In the long run, I'm convinced that automatic design (i.e. compilation of hardware) is the right way and what we must target.

Get us quality.

Gordon

SUBJECT: A QUALITY PROGRAM

I'm pretty sure we (engineering) should propose that
we focus on quality as a sole goal, even though it is more difficult than productivity. This should also really get after the predictability issue as variance is a great indicator of poor quality. I still maintain that productivity
will be very much higher doing than this than if we
go for the two measures.

In your first memo, you said: "WE have chosen to not have a corporate czar...". When was this decision? Who made it? What
is the rationale?

The discussion with Engineering Staff was alarming. We don't understand either issue very well. We need teachers and a corporate wide program as a major theme.

I'd like us to reconsider a single, directed, company-wide quality program and include campaigns, prizes, school, and metrics. Suggest WE tune the program slightly as stated.

SUBJECT: QUALITY PROGRAM AND INSPECTORS VERSUS INSPECTIONS

Hopefully I've not set the quality program back by my apparent
misunderstanding of inspections versus inspectors.
What I objected to was having some full time people who do nothing but inspecting. This is similar to the design review process in hardware where people review how a design is done and try to verify whether it will work, NOT review the design in terms of whether there's a better way. My concern was that
full time inspectors would soon become obsolete and useless. It's necessary to have some formal walk-through and if you have to call it inspections, then fine.

Yes, I think code walk throughs are really necessary. This is sure a process I support. I also think it is vital that the process be started in hardware. There it should be easy because diagnostic engineers should be providing this function automatically. This would let us formalize the process. Software appears to be about 5 years ahead of hardware in terms of understanding quality. Can we get a similar program going in hardware?

As you know I strongly support the quality program including the teaching and believe we have to go significantly farther in understanding errors in the classical way that Demming has taught the Japanese. Here, we have no effort. If we take this
approach, then it's possible to build some tools that will assist in checking for the errors and eliminating them.

I really support the quality program and my only complaint is that it isn't quantative or widespread enough yet! Finally, it doesn't exist in hardware engineering, but it must!

GB3.S5.28
In the finale when you actually delivered a spec and commitment to a timely schedule, I hope it was clear that I was and am truely thankful. (Rejoicing with you may have been diminished since the same work is starting for printers and then communication servers.)

Although I started on the project to get a decent personal VAX in January, Ken urged me to work on it seriously while I was in the hospital. Now, I finally feel we have an approach to getting this first, and then I hope for the follow on products.

REDUCING THE PERFORMANCE RISK FOR 19" WITH MICROCODE, NOT HARDWARE
Although we're all confident the scheme is going to work, given LISA. There may be a problem in performance for the 19" monitor and the larger number of pixels. It's pretty clear what the bitblt (area move instruction) is, and if this can be kept as a macro in the software, then when we do

performance monitoring, we can see if it makes sense to make this a VAX instruction.

I now believe that ALL future micros that are microcoded, as opposed to RISC-type, should have some form of the bitblt operations when they are to be used in the PC market. This is akin to why we put decimal instructions in machines that process Cobol. With this capability, we get the necessary speed and direct control without the highly special, inflexible hardware that's hard to communicate with. Past micros have taken the approach of co-processors chips (a misnomer because there's not a seperate Instruction-set).

The microcode option should be kept in mind, although at this time we clearly can't undertake it because of the work for DECwest. We ought to think what the format would be (eg. several simple instructions versus one, general complex one).

MAKING IT A PRODUCT WITH SEAHORSE in Q384
We can get the product out very, very quickly by proceeding directly into the test process by coupling directly with Seahorse when it enters its test (DMT, etc.) In fact, we save enormous $ and time by not having to do two tests. Reid estimates that the market doubles for Seahorse, and I estimate that it goes up by a factor of 4.

The product should be co-ordinated with Dave Cutler and Reid Brown.

SUBJECT: RE: RE: COST-SHARING AND THE NEW RESEARCH TAX CREDIT
REGULATIONS -

GB4.S1.21

This R & D Tax stuff is absolute bull-shit and just what I
predicted
when I gave my very luke-warm support to NSF, DOD, etc. who
pushed to
get this as a means of increasing R & D spending to compete
with the
Japanese. I was skeptical because I felt U.S. managers would
merely
use this to save money so that they'd look better. Your memo

says we
save $75M/5 years --- confirm this !

I wanted (hoped for) an entirely different behavior that addressed the fundamental problem . . . we do no research. Your memo merely confirms my correct observation about human nature. I would like to meet with you folks about getting me the $15M back you think you saved so I can do the critical work needed to beat Japan.

SUBJECT: COST-SHARING AND THE NEW RESEARCH TAX CREDIT REGULATIONS -

DIGITAL WINS A ROUND

The 25% tax credit for increased research spending is of considerable value to us. Under the law as adopted in 1981, it appeared that we could not claim credit on research spending reimbursed to us by our

foreign subsidiaries under our cost sharing agreement. (In a recent year, this amount was over half of total Digital research spending).

We thought this was inconsistent with the intent to create the incentive, and sought to resolve this in our favor during the 1981 legislative process. Treasury then opposed it, and we were un-successful.

Refusing to give up, we met several times last year with the Treasury officials drafting regulations for the new tax credit in an effort to get our point of view accepted. Few other companies in our industry have our sophisticated approach to sharing the costs of research, and we were alone in seeking this modification.

The new
regulations, as proposed in the Federal Registerfor January
21, 1983
allow the credit for all research spending regardless of cost
sharing
chargeouts.

The result will be to approximately double the effect of the
credit
on our reported earnings.

Subject: **R and D Organizational Change/Charter**

To: Consulting Engineers
Engineering Committee
Engineering Managers
Operations Committee
Product Line Managers

Date: 8 DEC 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

Effective now, Jim Bell, head of the Research and Development Group, will report to me. This change recognizes the somewhat wider activity scope for the R and D Group.

It should be noted that much of DEC's R and (advanced) D will reside in development groups in central engineering, Product Lines, and outside of DEC.

CHARTER

The charter of the Research and Development Group is to provide Research, Advanced Development, Information Services, Consulting, Technical Education, and Technical Staff Services to the Corporation, with particular emphasis on meeting the needs of the Office of Development.

1. Research - To conduct an internal research program and to interface with external researchers.

2. Advanced Development - To turn ideas into working prototypes for further evaluation.

3. Information Services - To provide comprehensive library services to the Corporation's employees, regardless of where they are located.

4.   Consulting - To provide consulting, utilizing both internal and external resources.

5.   Technical Education - To supply, influence, and coordinate technical education activities.

6.   Technical Staff Services - To provide other technical staff functions as designated, with emphasis on those services which are future oriented, are leveraged by a broad payoff, or serve to bind together the activities of diverse groups.

SUBJECT: YOUR NOTE ON THE R80

All of us have been actively working on this. The cluprit in terms of stop was the head redesign. We had used Alum instead of steel, and it had an exceedingly high creep (hence got unspringy) after 3000 hours (still undetected in dmt). We have/had many project in parallel to clear this up. There were many other issues like bad boards and the clean room that heaved a sigh when the head problem came up cause everything had used up its slack. This will be cheaper and better in long run... given we get the capacity elsewhere.

LIGNOS

cc: GRANT SAVIERS   DEPT: STORAGE SYSTEMS
EXT: 522-3242
LOC/MAIL STOP: CX

SUBJECT: R80/RM80 PROJECT STATUS

GORDON, PER YOUR REQUEST, I SENT YOU COPIES OF THE CX PROGRAM REVIEW PRESENTATION MATERIAL (GRANT SAVIERS IS BRINGING THE MATERIAL TO YOU).

THE R80/RM80 PROGRAM IS PROGRESSING IN PARALLEL WITH THE HEAD REDESIGN EFFORT IN MAYNARD. RIGHT NOW IN COLORADO WE ARE BEGINNING HDA PRODUCTION ONCE MORE, FOLLOWING THE CLEAN ROOM CONTAMINATION PROBLEMS. AS YOU PROBABLY HAVE HEARD, THE CLEAN ROOM WAS VERY POORLY CONSTRUCTED AND IT IS POSSIBLE THAT MOST OF THE HDA CONTAMINATION (ERASURE) PROBLEMS WERE CAUSED BY THE CLEAN ROOM LEAKAGE. THE REPAIR WILL TAKE SOME TIME, BUT WE CAN
WORK AROUND IT ON A LIMITED PRODUCTION BASIS.

THE MODULES ARE COMING ALONG VERY WELL. WE HAVE ALL NEW ETCH BOARDS BUILT AND WORKING ON DRIVES. AS A RESULT OF ETCH PROBLEMS, WE HAVE A TOTAL OF EIGHT WIRES ON ALL THE BOARDS INSTEAD OF 280 WIRES AND ETCH CUTS.

DIAGNOSTICS, MICROCODE, SOFTWARE, TECH PUBS, ALL IS PROCEEDING WELL IN PARALLEL. DMT IS DOING VERY WELL (THREE DRIVES) AND WE HAVE SURPASSED THE 30 PERCENT CONFIDENCE LEVEL ON THE RM80 MTBF. WE ARE USING, HOWEVER, THE EXISTING HEAD DESIGN AND THE 280 WIRE/ETCH CUT REV. CONSEQUENTLY, THE DMT RESULTS DON'T COUNT FOR PRODUCT SHIP, BUT GIVE US THE

CONFIDENCE WE NEED ON THIS PRODUCT.

MANUFACTURING IS PREPARING THE NECESSARY PLANS TO BE ABLE TO SHIP FIVE TO TEN UNITS A DAY WHICH IS THE VOLUME MATRIC THAT THE READINESS REVIEW TEAM SUGGESTED.

WE HAVE STILL A LOT OF WORK TO DO. THE PROGRAM IS, WE BELIEVE, UNDER CONTROL VIA THE PERT BUILDING PROCESS. THE R80 HEAD REDESIGN EFFORT IS GOING WELL SO FAR (A FEW ALTERNATIVES EXIST), BUT THERE IS STILL RISK IN TERMS OF TIMING. WE ARE WORKING VERY CLOSELY WITH MAYNARD (ROTTMAYER, RIGGLE) AND NATICK (B. PETRARCA) VIA TELECONFERENCES AND MEETINGS TO MONITOR THE DAY TO DAY ACTIVITIES IN THE HEAD AREA.

I HOPE I HAVE GIVEN YOU ENOUGH INFORMATION ON THE PROJECT AS WE STAND TODAY. WE ARE LOOKING FORWARD TO SEEING YOU SOON.

Lon Beaupre, Bill Hanson,

John Leng, Julius Marcus,
Mike Riggle, Jack Smith

Please convey my congratulations to the developers of the R80 and RL02.

I'm especially relieved in the case of the R80 -- to see a breadboard -- and I look forward to hearing about the engineering prototypes when they get up in mid July. The R80 is perhaps the single most important product we have under development.

It was especially gratifying to see the close co-operation and teamwork between manufacturing and engineering -- and I look forward to the R80 continuing on schedule. At one of the fall milestones I'd like to get Ken to visit Colorado Springs Engineering and Manufacturing.

SPECIFIC ACCOMPLISHMENTS:
Tony has been the key organizer of computer science information for scientists and engineers. This is evident in his Encylopedia and the Taxonomy effort resulting in the AFIPS Taxonomy. In addition to the work listed by Sammet, he compiled a two volume numerical analysis on the approximations of various functions for computers.

These are all massive efforts involving nearly 100 volunteers.

RELATIONSHIP TO RECOGNIZED LEADERS:
I believe he is number one in this effort of structuring knowledge.

IMPACTS OUTSIDE OF ENGINEERING:

TEAM EFFORT:
Fundamentally his work on the taxonomy and encylopedia is a team effort. His role was as the leader.

Subject: **Goals and Constraints for RAME (RAM + Expandable) Non-Stop Computers**

To: Roger Cady, Bill Demmer, Pete vanRoekens

Date: 2 MAY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

<u>Constraints</u>

1. Provide a system so that non-stop configurations can be built (non-stop requires no single hardware or software point of failure).

1A. A secondary goal would permit high availability, spatially independent systems to be built using the same components, tools and programming techniques.

2. Use the COMET modules.

3. Use the VMS program interface such that no change is required on languages, utilities and other non-operating system programs.

4. Use the same names, mnemonics, and general mechanisms, etc. for system primitives that do the same thing (e.g., pass messages) as DECnet and VMS.

5. VMS designers are tied up till August. Minimize consultation x hours/week of these resources.

6. Prototype will operate on 11/780 mP system.

7. Provide significant intelligence in all PMS level components of the system so that each can be independently self diagnosed, including: controllers (e.g., KMC-11 like), drives (RP06 and TS04), terminals (e.g., VT100), and bus interfaces interconnecting the computer. (We may assume that primary memory is checked using the Pc.) The Pc can be microdiagnosed.

8. Any component can be disconnected and taken out of the system using the proper powering procedures. Similarly, the system can be expanded or contacted without taking the system down. (A reboot might be allowed?)

Goals

1. Minimize time to market.

2. Design a structure that is at least as expandable as the Tandem, but without the Tandem limitations requiring both C's for inter-C data transmission.

3. Eventually make all our computers using the modular, expandable approach.

4. Cover Tandem in all dimensions of cost, performance, R, A, M, E while not increasing component count significantly. Add some functionality dimension to segment us in the marketplace.

5. Permit all three forms of: tightly coupled computers, duplexed network computers (i.e., Tandem) and physically separated computer networks to be built (at O/S build time and/or by the hardware configuration) by users:

a. the 2 or 4 Pc multiprocessor, in a single cabinet to form the basic computer module (a cluster); by sufficient private primary memory, and no shared memory the system can be alternatively configured as a multicomputer structure.

b. the mP, cabinet clusters used as either 2-4 Pc single C's or 2-4 separate C's will be interconnected to form the basic, tightly coupled C network; and

c. the same basic mC network can be distributed in a duplex or quadruplex fashion over long distances to get operational independence for very reliable operations.

<u>Why Change the Current Strategy</u>?

We have arrived at the current strategy by integrating our past customer needs, with the result that nearly every past system we have ever built is being evolved. This evolution creates too many systems with converging functionality. By prolonging the phaseover to VAX, we're unable to invest enough in VAX due to continuing and evolutionary support costs. Also, we're unable to provide applications, or have any slack resources to respond to competitive threats (eg. large micros or focused products such as the 8100).

We are just beginning to get a feel for the expense of putting new software systems in the field, and there are other systems still to come. Since we provide many choices, we find our sales and customers have difficulty deciding what to sell and buy. This makes us difficult to understand and to do business with. Lots of low volume products mean we don't have adequate volume to amortize the start-up manufacturing, sparing and training expenses.

Why Not Aggressively Evolve All Four Base Hardware Architectures?

In reality, our past strategy has been almost a divisional product structure. Customers can choose among the 4 basic hardware computer systems with 2+3+7+1 models and then select the appropriate software system, among 2+2+7+1 software systems for 8, 10/20, 11 and VAX respectively. This gives us several hundred systems. The number of alternatives is too large, resulting in small and decreasing volumes of each of the systems as all architectures are extended to cover a full range that we believe our customers require. We can not afford all the necessary enhancements to support four architectures over the range of size and use that our customers demand.

While any of the architectures can be implemented at any size down to and including LSI chips, there is no significant differential cost of the processor between the 10/20, VAX and an 11 with commercial and scientific instruction-sets. An evolved 8 to handle the strategic range would even be the same cost. The main differentials are: the cost of the memory to hold the tasks and the size of the operating system software. The 10/20 operating systems have been oriented to generality, and while VMS and TOPS 20 have roughly the same functionality, the 10/20 requires 512K bytes of resident memory, whereas VMS require 256K bytes. This occurs because TOPS 20 has evolved and because of the efficiency of VAX architecture. VMS also has real time capability. Similarly, it is now inappropriate to consider 10/20 based architecture for terminals and personal computers, when compared with VAX, because small problems cannot be encoded to be competitive with modern 8- and 16-bit microprocessors. Furtheremore, extensions to the 10/20 architecture would require basic work in the operating system and languages to build a VAX competitive product.

Why Not Segment Products By Market?

Since the 10/20 has significant commercial software and since it is believed that our customers are insensitive to architecture, we might simply have a market segmented approach and use 11's at the low end and 10/20's in the high end. Lower priced 10/20's would be implemented over time as appropriate.

Our technical users (EDU, ESG and even LDP) do not segment computer purchases into commercial vs scientific. A "control" customer such as DuPont doesn't segment its applications either. Even NASA wants COBOL to off-load their mainframe and to do administrative EDP. Universities likewise want a single machine, and hence the software will be "pulled" into existence. Version 4 of VAX COBOL executes faster than the 20's already.

Since there is basic incompatibility between the 11 and 10 architectures, the migration problem is enormous. Now our large commercial customer base is with 11's. Our users perceive VAX and 11 are of the same family.

The 10/20 still requires basic changes (CIS, 30-bit addressing) to bring it up to VAX performance and capability together with compilers and some basic software (eg. multi-keyed ISAM). TRAX-36 and RSTS 36 will also have to build off our 11 base. In short, while it might be feasible to build 10/20 software so that our 11 users could meet our strategic goals for distributed processing, we would still fall short of the distributed system one can build with a single architecture as described in a subsequent rationale.

How Do Customers Preceive The Situation?

In mid October, a group at Bell Laboratories, building PBX systems visited us and made the comments:

> "Only you have the basic architecture in VAX to cover the range of products we need for distributed processing. This includes: terminals, offices and large offices.

Give us a truly compatible range of VAX machines, starting with a VAX-on-a-chip and extending through the IBM 3033. (Don't corrupt VAX, since as in the 11, we must preserve our software base, given that the processor is only 4% of the cost.)

The machines must have a reliability and security orientation.

Why don't you do it?

We will help fund the development."

Recent discussions with Stanford, ITT, CERN, NASA (Ames) indicate concurrence even though they are large 10/20 and 360/370 users. MIT is proposing to build a homogeneous VAX-based network. DuPont wants a similar structure, but is less rigid on the need for a homogenous architecture even though they've standardized on the RSTS machine internally for many of their systems. (There's a videotape describing their needs and ideas.) CERN, and NASA (Ames), for example, feel that the large mainframe may be on the way out as we offer small group-level computing with VAX. There are probably 10/20 customers who feel strongly that we should base our future on 10/20's. The main reason to focus on the single architecture is that it is part of the 11 family.

Why Have A Single Architecture?

There are technical, marketing and economic reasons for choosing a single architecture at this time on which to base a major part of our future. However, this does not mean that we must neglect our 12- and 36-bit user base.

While computer networks can and have been built with heterogenous computers and IBM is betting that it can build distributed computing systems with only similar machines, a single architecture is the most effective for distributed computing systems. The homogeneous (identical) architecture approach insures that software will give the same results no matter where executed and therefore programs may be run anywhere in the network, data stored anywhere and programs moved about in their object form without the overhead of recompiling or translation as data is transferred. This also insures that the human interface to the system remains constant, because identical software is executed in different machines instead of relying on software that is specificed to have identical interfaces (e.g. languages, command languages, file systems, utilities).

From a user viewpoint, the homogeneity is ideal, and the success can be verified by reviewing the history of IBM's decision to build the 360 (and not continue with the 1401, 1410, 7070 and 7090 series machines), even though there was an incredible base of these machines. This was also the time that Honeywell established itself with the 200-series and RCA with the 301. The homogeneity provides a simpicity for the entire DEC organization and its customers, and lets us all focus on end use applications rather than choosing a particular operating system and language. Currently, we have too many low level, incomplete choices and the software efforts of us and our users are not focused. An applications base can only be built effectively on a good, stable architecture.

Economically, a homogeneous architecture is essential because it allows us to concentrate and become a focused, high volume manufacturer and take advantage of learning curves. While 10% learning curves mean a doubling of manufactured quantity causes a 10% decrease in cost, they also imply that having two very similar products at one-half volume causes 10% higher costs in each. There are similar effects of learning in hardware, software and sales training costs, although the learning costs are small in comparison with the logistics and start-up costs associated with our many, different though functionally equivalent, products. We become difficult to do business with in the process.

Why Base The Architecture on VAX?

Although we went through the arguments in the spring of 1975 when we decided to build VAX instead of building lower cost versions of the 36-bit architecture, we now have a real machine that met its development goals and has user acceptance on which to base future products in a natural, evolutionary fashion.

Mostly, the choice of VAX in 1975 was based on having a large, PDP-11 user base. Furthermore, the choice to stay with the 8-bit byte was of convenience because of the IBM and communications worlds.

The VAX architecture was designed to permit the building of a range of machines with sizes that are important to us. Our targeted range of implementation was 1000:1 and this is attainable with an LSI implementation for terminal applications in January 1982. This is why a small page size and simple paging system was chosen, versus a larger page size and more complex scheme that would have been particularly oriented at large systems. However, it would not be wise to build the machine 1000 times as large in 1982, because it would take the system size beyond the suggested $250 K selling price limit and into mainframe price and customer expectations territory. Thus, in January 1982 the LSI VAX could sell for several hundred dollars at a board level. An ECL technology machine might be configured to sell for $ 500 K, giving the 1000:1 in price and a range of 64 Kbytes of RAM and ROM for VMS in the terminal to as much as 32 Mbytes in the large configuration (4000 64 K chips, costing $60K and occupying 20 PC Boards).

VAX was also designed to address the high cost of programming. Already VAX has been acclaimed (by a customer in our ads) as the best machine for implementing software. The large address space eliminates the need for much of the effort we spend encoding large programs into overlays. The architecture has instructions for the important data-types, the addressing is independent of the data-types and the important language constants are built into the hardware. There is clear separation among program and data. The procedure call instruction allows more sub-program sharing than with architectures that are dependent on conventions (e.g. 360 and 10/20) and it eliminates a class of systems programming errors resulting from the multiple assignment of general registers among different programs.

The 32-bit address space of VAX appears adequate for the computing needs in the foreseeable future and there is extension capability given that any special needs arise. The address space and protection modes also give us a capability to run sub-programs written in different languages as a single program. This capability is unique and may turn out to be the single most important attribute of the machine. Since only one other computer has the capability, we don't understand it or how valuable it will be.

Another technical reason is based on the encoding efficiency of the VAX instruction-set. The VAX architecture can encode a Fortran program in about 1/2 to 2/3 the space of a comparable large computer such as a 360 or our 36-bit computer, while providing 32-bit addresses versus 24 or 20 bits of addressing for the 360 or 10/20. Benchmarks in BLISS and FORTRAN show this now, and the Common Family Architecture studies also indicate similar results. While memory cost is decreasing, memory is still a significant fraction of system cost. Three years of cost decline at the historical rate of 20%, is required to get factor of 2 the cost difference back. That is, from a memory cost viewpoint, we have a 3-year cost edge on the market. More importantly, there is a similar effect on performance. By having only 1/2 the bits to move between primary and secondary memories, the performance is higher due to disk-MOS memory swapping bottlenecks.

Finally, we have an 11 user base on which to build that is approximately 7 and 50 times as large as our 36-bit base in terms of installed equipment dollars and installed units.

<u>Why Not Use The 10/20 As The Base</u>?

The software and user base on the 10/20 is the major reason to not arbitrarily reject the architecture. On the other hand, since the 11 user base is larger and has grown more rapidly, its software base is larger and we have to protect and build on it as a higher priority.

Right now, the 10/20 requires incremental investment to make it competitive with VAX and the rest of the mainframe market. Extension to provide a large address space, to extend the floating point range to fulfil customer commitments, and to give a competitive commercial instruction set for COBOL are needed. Making these hardware investments requires comparable software investments and we must again wait to compete because there is a new machine and software to support.

Subsequent implementations for small systems will be expensive both in terms of new software and start-up because TOPS 20 has been oriented toward large mainframe generality.

Smaller systems will require contractions. Also it stands to only cloud the market more as alternatives for mid-range systems will include 2 VAX and 1 or 2 11-based systems. As small systems are implemented there is a need for compatibility with the even larger 11 base.

Why Distributed Computing?

Distributed computing keys off our strength in interactive computing through timesharing, small systems, real time computation, terminals, and networks. Furthermore, we believe this is what our customers want. The issue is not distributed computing, but solving the problems that it creates.

Now that I've seen the IBM 8100 (and System 38) I understand the recession in your marketplace! This may cause subsequent recessions in other marketplaces too. You might invite Don Alusic and Ted Webber to talk about these -- also the Marketing Committee might listen.

We have to get a market message to counteract and sell current products against these early paper announcements for August '79 - February '80 FCS's. We have products here, now.

<u>We</u> have to get (and plan to get) better applications terminals, and distributed processing links quick! We can now do all right, and must plan to be much better.

SUBJECT: RE: TURNER'S ARTICLE ON IBM AWARDS PROGRAM

IBM seemed to put it together right. I had several students at CMU that swore by the company and the way they were treated... and who remain there. WE HAVE A STRONG COMPETITOR AND ROLE MODEL TO FOLLOW... THEREFORE, WE SHOULD BE ABLE TO DO BETTER WHEN WE PUT A PROGRAM TOGETHER.

John and Don.
Can you lead us to put together a really strong recognition program?

As Bruce indicated, the basic problem we have very often is simply neglect. Dave Cane may have not left if we had shown more concern about how important he was to building Digital and its computers. Therefore, I think it is important for each of us not to wait for a comprehensive, automatic program that makes up for direct attention and thanks.

As you do various recognition programs, can I urge you to share them with each of us. Also, maybe we ought to think of something special this year at the 10-20 year award dinner to brighten an otherwise sterile affair.

Subject: **Red Book Data**

To: PMC (Mike Gutman, Per Hjerppe, Bernie Lacroute, Jack Mileski, Stan Pearson) OOD

Date: 3/12/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-

With our going to a two-year plan this time (ie. 80-81) wouldn't it be worthwhile going all the way in providing financial data on the projects and programs? This would include: FY79 and/or Money spent up to and including FY79; Cost to complete; and Total cost of program outside of engineering. This would give us 3 or 4 extra columns, but much insight.

As indicated in a previous memo, we need to have uniform presentation of systems. Let's use the MSD format, which plots log price versus log mass memory size, arranged on paper that has some overlap among the ranges (1K-16K, 16K-250K, > 250K).

1. Here, though small is 1-16K, it might go up to 25K, as suggested at EBOD, and possibly to 40 K to show the overlap with the low MSD range. This would give a 40:1 range.

2. MSD is clearly from 16 to 250K, but perhaps needing the extra low High range (250K-625K) to cover the 11/70 multiprocessor. This would give a range of about 40 also.

3. The 36-bit systems presumably cover from the high part of low Medium (i.e., 25K) with Minnow, and go up to mid High (1.6M) with multiprocessors, for a range of 64, or if Minnow gets down to 16K, then a range 100.

In plotting the configurations, please show all the diskless and disk and tape offerings and how multiple disks of a given kind represent different points in this space. Here, the point (superficially hidden agenda item), is that we seem to be offering too many overlapping systems. E.g., Nebula is in Comet space, and Comet offers every disk and tape system (RL, RK, RM, 2-3 RP, RA and RM 80). Certainly multiple RK's equal an RM, or offer no RK. Nebula does about the same thing, even though there is little to be saved by its cheap processor/memory pair at the high end. (Did we screw up by not having Nebula be an 11/04-like relative to Comet (the 11/34 analogy), instead of a separate system? Other overlaps between MSD and T/SS should also be apparent.

Given these plots, we must <u>also</u> make the other plot of # of users versus system size (in $), plotted as areas (performance group calls them "plates"). Here, a plate border is outlined by a set of configurations and a range of users with varying use (arranged from light to heavy use). Note, a couple are attached, but let's show all the configurations using log price and log # of users.

In this pass we must add cost-of-ownership as a metric, versus just the purchase price we're used to.

Carlo H. Sequin
Associate Chairperson
Computer Science Division
University of California, Berkeley
Dept. of Electrical Engineering and Computer Science
Berkeley, CA 94720

Dear Prof. Sequin:

David Patterson is personable, enjoyable, and verbal. He seems to interact well with his industrial peers. His papers are well written, contain insight and are generally useful. A recent paper for Computer Architecture News is one such paper, but contains only conjecture. Given that two very capable architects, Strecker and Clark, strongly disagree with the paper - based on data, then I'm somewhat concerned about his thoroughness.

Although I don't fully understand Berkeley's professorship requirements, I believe he would be just on the borderline of meeting tenure at Carnegie-Mellon.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Dean Riordon
Carleton University
C.J. Mackenzie Building
Ottawa, Canada K1S 5B6

Dear Dean Riordon:

I've known Dr. Morris through the year he spent on sabbatical at Digital. During that year he was a mature, respected, effective and energetic contributer. He advised and made architectural proposals. He also made suggestions for improved performance in our scientific processing software that we used.

Since I have not been active in the signal processing area, I don't know where he ranks in this field.

I believe he meets the external criteria for promotion to full professor.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

ORGANIZATION

Board of Directors: Meets once a year in May.

Executive Committee: Gwen Bell, 3 DEC people, 2 external people
Meets monthly to discuss policies, budget, money spent.

Director: Gwen Bell Fundraising, memberships, business

plan, Fiscal Year
(June)

Exhibits Coordinator: Jamie Parker
Collecting, archiving, displaying, letting, borrowing, in charge of audio-visual for talks in cafeteria. Need to know procedures for assigning numbers to artifacts, thanking people for gifts, what lists are used.

Librarian-Archivist: Gregor Trinkaus-Randall
Reports to Jamie, leaving Jan., been here 3 months, works in 4th floor storage area. Need to know what he has accomplished while here.

Program Coordinator: Chris Rudomin
Events, talks, Sunday afternoons, Bits and Bytes (5 or 6 times Spring and Fall), plays, tours, tour guides (DEC and elsewhere?) Need to know routine for events.

Office Manager: Geri Rogers
Responsible for David and Debbie. Goal is to send out 100 leters per month asking for money. Manager of Cost Center number which is 20E--from DEC-budget is $60,000 per year.

Secretary: Debbie Sterling
Reports to Geri?

Business Manager: David Bromfield
Accounting, money, leaving in August, MIT. Need total job description.

Store Manager: Carole Strecker
Buying inventory, shipping, mail order catalog. Hours are Sunday through Friday 1-6. Office is downstairs.

Store: Linda Davidson
Merle Insigna

Handyman: Bill Meany
Works part-time, reports to Jamie, leaves before dark

Other: Laurie Burroughs

Lives at Bells, transcribes notes of talks (?), works with Chris on special dinners, takes care of food for Sunday Bits and Bytes.

Meredith Stelling
Works for Chris and Jamie; also helps in store. Working on blurbs for tours. Other jobs?

a)
Dr. Reddy was the leader of a DARPA Speech Research Project for approximately 10 years that resulted in producing the highest performance speech recognizer. The Harpy System has been a model for subsequent commercial systems and for the training of researchers and engineers who have continued in speech research.

He has played a similar, but less dominating role in the understanding of vision.

Finally, he has been a key member in the Artificial Intelligence community.

Most recently, Raj has originated and headed the Robotics Laboratory at CMU. This effort has resulted in several practical results in robotics.

b)
I believe he is in the top 5 speech and top 20 Robotics researchers.

c)
The areas of Raj's interests are quite broad. Most recently, Raj has been a member of the Paris Group. This research group has a goal of providing significant computing to people in both underdeveloped and developed countries through various techniques.

d)
Dr. Reddy has lead the teams. His leadership has included direct work, indirect motivation and the supply of ideas.
7 April 1983

Moira Roth
Visual Arts Department
University of California, San Diego
La Jolla, California 92093

Dear Moira Roth:

From looking at Cohen's vita, it would seem he easily qualifies for someone who's attained national and international recognition. I'm not in the art world. I don't know how he's regarded except that he seems to have an excellent reputation.

As a computer scientist, I think he's built and continues to build pioneering, rule-based programs. His engineering ability is quite good too, as he's also built various drawing equipment.

From a personal standpoint, I've enjoyed the interaction with Harold since 1977. I've tried to be supportive of his work by sponsoring equipment grants through Digital Equipment Corporation and recently a VAX-11/750.

It would seem there's a strong case to be made for the promotion of Harold Cohen to Professor VI.

Sincerely,

Gordon Bell
Vice President, Engineering

1 June 1983

Ms. Linda Mihalko
Executive Assistant
Marconi International Fellowship
333 Jay Street
Brooklyn, New York 11201

Dear Ms. Mihalko:

I would like to recommend Dr. John McCarthy for the Tenth Marconi International Fellowship Award.

I have known and worked with Dr. McCarthy since the early 60's.

In 1961 while a consultant to Bolt, Beranek and Newman he was instrumental in defining and implementing the first timesharing on the PDP-1. Later, at Stanford, he built a timesharing, Zuse, on a much more advanced PDP-1. He was a consultant to me and Digital in defining the PDP-6 -- a machine which was designed for timesharing and to be able to execute the LISP Language effectively. His invention of LISP is well known, and for the last 25 years has been the basis for implementing Artificial Intelligence Programs. John continues to have innovative ideas in computing, including forming the LOTS (Low Overhead Timesharing) at Stanford so that students could have access to computing.

As head of the AI Lab at Stanford, John provided an environment where much of the early ideas in AI were formed, including: computer music and art, robotics, television based CRTs, computer aided design, etc. all of which are basically interfacing people with machines.

Sincerely,

C. Gordon Bell
Vice President, Engineering
Professor, on leave, CMU

Pat Sullivan put the priorities of Dolphin at RAMP, Performance, Cost while Venus was Cost, Performance, RAMP.

I just came from CMU and the perception is that VAX's are reliable and 10's are big and not so reliable. We must not/cannot change this with the new machines!

Let me suggest there are even other metrics: time to market, development cost, simplicity cost-includes monthly service cost. My priorities feel like:

1. Cost-including monthly service cost (that'll get the RAMP goal).

2. Time to market, development cost and simplicity (also address RAMP).

3. Performance -

MCA scares me because of the high development cost, the need to make an ECL breadboard for checkout and modifications and the long turn around time and high cost for modifications. Let's go for a really straight forward circuit family, simple packaging scheme and be satisfied (hopefully) with the resulting performance. If this is not the case, then get the power via vectors added to the ISP or by multiprocessors, or something that is very straight forward. Let's be creative with simplicity.

Gordon Bell
V.P. Engineering

No, No, No. Such a report by Larry and I flies in the face of our trying to build a set of responsible, independent engineering managers. If we want responsibility, we don't build a reporting/tracking system to watch 4000 people...requiring at least 10 people just to keep it up to date. We have two people just barely reporting on the projects! I don't want any more centralization. This might be part of project accounting, so we can get a report on projects and people on them. If we want to audit the groups this way, then let's put it in Win's Operations Review! I want more designers not people and thing counters!

Subject: **Request for Data by February 1**

To: George Plowman, ML5-5/E97

Date: 10 JAN 79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 1/22/79

I'm giving a talk and need some standard data about your area that I presume you have.

If you don't have it or can't find it, let me know by January 22.

Generally, I've seen these curves somewhere.

Specifically, I need:

1. Cost of various kinds of phone lines and switching systems versus time.

2. Cost per bit/sec. of various lines and switching systems versus time.

3. Cable TV cost versus time.

4. a. modem speed, b. cost, c. cost/byte/sec., versus time.

I'm giving a talk and need some standard data about your area that I presume you have.

If you don't have it or can't find it, let me know by January 22.

Generally, I've seen these curves somewhere.

Specifically, I need:

1. CCD and Bubbles cost/byte (for various sized memories) versus time.

2. Tape cost/byte/sec. of drive and media cost/byte versus time.

3. Same for disks.

Roger Cady, Dick Pascal

follow up 10/24/78

Should we OEM modems?

It seems to me our customers really have a painful time installing total systems as there's a free-for-all with many services and options available from the operating companies. Smart users buy their own modems. Furthermore, we could provide a better, more cost-effective solution, get more system control, ease the cabling problems and minimize space, if we sold a complete system with modems.

We get the pain, why not get the profit?

Does anyone in sales have an opinion (or understanding) here?

I still see the communication area (P/L? Product? Field Skills? CSS?) as a major strength/thrust that marketing and sales should deal with. Can we get it on the agenda for resolution?

Vince, have you ever heard of Gandoff Modems? Dave Lilie of NOAA (303-499-1000, ext. 4171) has the poop.

SUBJECT: BUILDING A FIRST CLASS RESEARCH GROUP

The WCRL really looks good. What concerns me now is overall research at DEC, and what your role is in it. The group here looks a lot weaker and even more decoupled to the rest of the company. Eg., we want Forest to be involved in the product review, but no one knows who is doing what here. I've tried to get a rise from them, but got none.

You could get someone overall, or you could strengthen this part... because you are fragmented, as technical director, into a strongly co-ordinating role in architecture. Also, there's all the needs we have to do external research (eg. CMU). There's also an opportunity to assist in this external research by building experimental machines for universities... like I believe IBM has decided to do. This would help us intellectually and with research, as well as the universities.

As part of the research charter, I would like you to take on the CFM program, or get rid of it. Alpha Omega is really flourishing, and needs a leader too to co-ordinate the flow of ideas from it into DEC.
Again, I see this as your responsiblility.

We have Ken's encouragement to go out and get funds for research. I think we need to do this! We haven't moved, and I am going to continue to push you to do it. Right now, I'm frustrated

because we
can't get the Dataflow compiler work done, along with the GaAs work.
ARPA should fund them. Nothing's moving!

There's a lot to do!

GB0003/72

Note some criticisms got answered later on. I've left the comments as I read the paper in order to see when I thought of it.

1. Definitely want it de-thesized w/photos, figures added. Remove parenthetical footnotes. The work should maybe use or at least reference the difference in the invention paradigm presented by Eric von Hippel of the Sloan School. There are other people there that might be interesting to reference - Ed Roberts,? Paradigm of person-type: scientist entrepeneur, manager, gate keeper, mentor, etc. as it relates to motivation of each worker! This

characterization of roles is really important and missing!

2.Referees: von Hippel, Brian Randal, Willis Ware (Rand)?, Harry Huskey, Fred Gruenberger, Phister (good reference) - also would be a great co-author to redo this if possible.

3.There's probably some ties that he may not know about that I wrote in Bell + Newell. Eg. Wilkes at Penn, Huskey at NPL, that made for information exchange. B+N time line has many of ideas leading up to C. Also the COSERS report has (will have if it ever comes out) the key hardware ideas in machines. I'll have to re-arrange them.

4.Lack of understanding of evolution see COSERS + (B+N), learing curves, limits of technology, especially scientists vs. mathematicians vs. engineers.

5.Need the paradigm of individual motivation versus team work and funding. Calculators were done by individuals. Babbage got funds, advanced test but failed on a C. There seemed to be minimal awareness of others work.

6.He must have a paradigm of innovation consistent with other work...see! Also a taxonomy of paradigms would help in a separate chapter.

7.Observe that all calculators were individual efforts and the C was a group effort. The people who might have built the calculator would have had to get together. The time to do this is approximately 10 - 15 years!

. Should really mention Ludgate too. Bletchley's work is too light.
. Defense is underplayed as a market-motivation - source of funds. Note on cost - benefit, annihilation allows for high costs.
. Would like to identify + label forever generations. Try:

5 VLSI
4 LSI

3   MSI
2   Transistor

A.P.C. 1 "Reliable" Vacuum Tubes <-----> coincident with <---- Information
the computer strange is electronic

B.C. or B.P.C. (Before Programmable Computers)

1 Relays (Electro-Mechanical)
-- <Begin use of electron-flow to control
information processing

2 Motor driven mechanisms (important)

3 Mechanical (gears, levers, etc.)
<Begin possibility for Automaton

4 Manual movement of beads, rods,

5 Stones, tables, paper.

p2 - It is clear that the C is an epochal invention.

Time is wrong measure! It's technical time (in units) see measures by Fusfeld. Fusfeld is right, this work using time feels wrong!

C is significant because it is embodiment of "process". It supplements or supplants other information processors (eg. humans, special control mechanims, systems of flow) by its ability to process (compute), store, switch, transmit, transform/transduce information!! (This is very pervasire and includes telephony for example.)

The computer is as significant as the idea of mechanical mechanisms (wheels, motion conversion,...)

The key inventions are probably only four so far:

1. Mechanisms - formation of matter to permit organized motion of mass.
2.Mechanisms to make other mechanisms.
3. Energy and chemical conversion -
3A. Possibly there is electronic mechanisms - where matter is formed to permit motion of electrons!
4. Computers -

Interviews: Forrester? Wilkes? Kilburn? <---- no references!

5. B.S. a computer is well-defined mechanism! Poorly written - needs algorithm and leave of interpreters. The discussion with computer scientists doesn't help.

p12 - no choice. Look at speed, reliability, and size (also design technology)

Shannon's thesis was important here...he references it, but used later.

p19-20 - why sci/dp distinction under Babbage? earlier or late in writing?

The argument here on sci may say that it pushed harder than business for the stored program computer.

Note age of people, eg. Babbage is interesting (important?) - should there be a table with significant factors (characteristics) of people involved.

p28 - Note Buyer-Seller paradigm |
| in Hollerth Story vs. Nasa, TVA,
| NSF paradigms
Note Breakaway paradigm |

p30 - Eccles Jordan flip flop was essential.

Requirement for a C.
- gates +
- memories for processor and program
- I/O - Teletype?

von Neuman ----> blind alley by long word

Note Aiken's failures: Little effort to "engineer" and understand technology. Non-engineering environment!

He was always sub state-of-the-art, machine weren't interesting. and 1 generation behind:

MK I Mechanical (motor driven) - the best; IBM built it (could have been relays ----> see Stibitz Bell Labs)

MK II Relay 48 ----> should have been v. tubes

MK III Electronic 51 -----> ok, but not a decent<?> memory! (You should look at crude engineering.)

MK IV Drum 52 ----> vs. Whirlwind

Bush treatment is neat (should cite SNOW's book on the two cultures and Lindaman - Tizzard Feud.

Interesting role: there are organization + people who become inhibitors -

e.g. <u>Bush</u> who was pushing DDA's + Analog
e.g. Government by standards. Note also a concept of negative work to   inhibit.

Whirlwind - Number of tubes, -- reliability
- Real Time really important (read Redmond + Smith manuscript)
- Scopes
- Parallel
- Core greatly under estimated

(Note importance of Gov't Buying of working machines.

p81 transistors weren't incremental & were significant (probably pivotal) to evolution as we now know it. See the figure.

Performance levels approximately Machines Ability approximately TECHNOLOGY

. simple 4 functions
. complex pre-programmed functions
1st generation ----> . universability
. real time
. higher level languages (compilers)
How are we now ---->
. interpretted lanuages such that non machine language interface is possible.
Machine understanding
-----
to C . human speech input-output

Chapter 3

No. WW II created a whole theory of reliability analysis that did NOT exist in 25-30! The early radios in WWII didn't work. Do the research on this important theoretic underpinning. A C was out of the question. Agree C would have been invented without a war Here Shannon's work ('38) was important - should do research to see what understanding was in automatic switching which Bell had.

I still see no memory available. Thus how a C?...
Teletype ASR was important - necessary for memory. Note the concepts (Architecture) have always just barely streched reality. Beyond this is called Science Fiction.

Supply Constraints = conventionally call Technical Push

conceptual (Architecture)	physical technical
. Turing paper	. Memory technology
. Boolean algebra applied no design	. Tube reliability
	. Relay

p85 - I don't believe it's fair to say Babbage did all those things - We've "read into" history more than is there.

Alternatively once a basic idea is given, just like a theorem in mathematics, it's easy and straightforward to invent the rest (i.e. come up with all the useful corollaries)! Then a technology which determines what to do:

for mechanical - Base 10 is natural because large #'s can be
represented for electronic, it's harder (un-economical to
represent >2, hence base 2.

p89 - Am unconvinced about statement that I could have been built in late 20's (versus mid - late 40's)!! There's work to do to prove it. I'd read the MIT R + D Lab work for state-of-the-art Radar did much to make pulses & counters. See also above. Is there an issue of management of projects? (This was a very large one) (I'd certainly list project scale of management as a supply limiter.

p89 - Demand

Didn't it simply take the war to get a fundor that would put up enough $'s? Read Whirlwind article and book by Redmond and Smith. I claim Whirlwind was the first, properly funded C proejct - look at it vs IAS (look at results too). IAS was a junky non-functional machine. The great thing about the mathematicians (e.g. vonNeumann) is that they wouldn't help the gov't bureaucrats kill Whirlwind.

Talking about firms is so limiting. Most early invention of C and calculators were by individuals, not firms. Occasionally, the individuals had to form a firm to build it. Some wanted to for the wrong reason ($).

Revolutioning invention are not firm based
Evolution invention are not firm based in neo-classical way. This has been proved many times.

Read the von Hippel stuff. Later C-based inventions come from user or University - based machine. Unlike many inventions, the user -- designer and hence, the more than rapid evolution. Note try these extensions:

Floating point
Compilers

Time-Sharing
Interactive computing
One-level store + memory segmentation
Data bases -
ALL the applications languages
Real time computing

Neo-classic vs. behaviorist theory is not true. The computer has been largely outside the classical firm. Use this model to show why firms like GE, RCA, etc. were unsuccessful. I submit that for a variety of reasons (double learning curves occur for transistors in both computer and consumer industry, user pull, new developments) C's evolved much more rapidly than anything else and those who operated firms as neo-classical to maximum profit got creamed because the time constants were different. The model has to reflect the incredible evolutioning time constants and the constant implied obsolescence.

p112 - Be careful. The Hollerith work is probably based on something mechanically fundamental (eg. 4-bar linkage), or 7ms. electromagnetic or a magnetic material. Note Babbage failed due to Manufacturing technology in about the same way you predicate a more complex device at about the same time.

p114 - Note the irony of all the adding machines Company's that weren't out of business where electronics came in. This should be included (Friden, Monroe, Marchant). Rarely does a company who has no research ever do it. Rarely does a company switch base technologies.

p114 - Ugh. The groupings are poor and probably wrong.

Might read Turing's Biography (by his mother)

p124 - Also physicists usually aren't concerned with reliability...hence, ENIAC has built because they didn't know better. Contrast with MIT (who did pre-product breadboards) and IAS or IAS ala ILLIAC I (and copies).

I see Aiken operating exactly like the Moore School except 1 generation delayed. Most likely because he operated with a more closed mind. (The others were experimental physicists?) He <u>eventually</u> got there. Was he too head strong to listen to anyone else? to conservative?) <u>Ultimately</u> there was competition when MIT went after the Moore School (but by there E-M left for their own business).

p134 - I have trouble with economic view as stimulating invention in machines. To market them ultimately yes. Mostly CS is in search of the ultimate - building a machine that rivals man. This has been true for a 1000? years... and probably shickard too. Certainly Babbage and the other machines; market is incidental.

A machine is an embodiment of scientific knowledge - unlike pure science of mathematics which is just the finding of it without application. Hence, CS is both engineering and science the way it's played. Read Perlis, Newell, + Simon "on CS" in <u>Science</u>.

<u>Chapter 4</u>

Is too in. Can it be re-written, because the triva-like talk are not apparent to non-economist.

Labor saving isn't necessarily where it's at. We do things that weren't ever possible - eg. no organization could be built so large without C's, e.g. Airline scheduling, space shuttle.

Chapter 5

Note NO PATENTS spur invention. What about Los Almos + Livermore<?> effort.

Move Chapter 5 back and cut B.S. Stuff needed for Ph D that has no imperial data for backup, and is typical of the verbage needed by Yale and symbolic of Yale's graduates. The sophomric diagrams here about economics is really in bad taste! Nothing backs up this B.S. This is a non-analytic, B.S. thesis, but possibly an interesting story when made complete. Don't clutter it with the social non-science (a paradox) needed to get a degree.

Chapter 6

Too much B.S. why not put specific stuff on Chapter 5 there too. Show % of government C buying vs. time. Can it be argued that government was the only buyer, hence, it evolved C's rapidly (i.e. clear market target). This certainly holds for super computer development (i.e. CDC 1604, 6600, 7600, STAR, Cray 1).

Note single buyer-seller paradigm...plus Cray!

Chapter 7

There is more than one way to do a task. Programs or algorithms aren't patented (and that's what C's are). Also rapid evolution is to side-step patent. Many significant works e.g. COBOL is works of the standards group.

p234 - Sorry MIT + Forrestor got $13M or core patent.

I like time line diagrams.

April 13, 1981

Robert J. Robinson
22 Locust Lane
Clifton Park, NY 12065

Dear Robert Robinson:

The draft report looks fine. I concur with the theme of the

80s: Transitions.

If you're in the area and want to chat, fine. Alternatively, why don't you give me a call some evening and we'll do it by phone?

Since you might be interested in industry, I'm taking the liberty of sending your vitae to several people here.

Glad to hear from you.

Sincerely yours,

Gordon Bell

LARRY PORTNER EXT: 223-2236
JACK SMITH LOC/MAIL STOP: ML12-1/A51

SUBJECT: RE: MARCH ENGINEERING REVIEW. LET'S REVIEW THOSE WHO NEED IT!

Basically I agree, but we have to be able to have a review of the critical product piece of engineering that is not working on the low end. This critical part produces products that pays for the low end hobbies.

Since nearly every group has its own processes for designing and introducing products, we MUST review them. THIS IS NOT THE CENTRAL GROUPS... WHICH WE DON'T HAVE. This would take away from development time, but since these areas are generally poor and have relatively poor interfaces with manufacturing, a review here might make sense. The money is spent within the development group and is the other 50%!

Some of the products that you (as low end engineer) might be interested in are: distributed systems which is building the Ethernet (and we don't have the low end connected to it yet), modems, the File/Print/Computation Server for Personal Computers that we need to make that will run on all our systems (especially the 23 for the stores), what we should do with UNIX (that's being proposed now and we want to get the decision made soon), what software is going to be available to use the VT200 (do you understand that the MAJOR contribution of the 200 is to have a computer in it that has to work with the operating systems and we don't yet have these functions defined yet, and probably the biggest one of them all is whether we can get a DECENT engine for the Personal Computers/Terminals you want in may. I'm skeptical that the world is going to be very happy very long with the 11.

The products you might want to know about as a low end engineer, because the rest of the company is paying for the sand in your sandbox are: chips that will let us have competitive chip and board products (which we don't now have), getting competitive

low end systems (a pricing, manufacturing and disk problem!), asking whether our VAX products are competitive in the next few years (I'm worried and would have used the March meeting to make sure that this gets fixed!!!!), reviewing the comm plan
(which seems to be coming around nicely because they have had to do their homework and because they have to SHIP Ethernet for the 36-bit folks, how to have a compatible and competitive
36/32 bit product set that will get us the most business with Jupiter.

There's a real biggie that could save about $100 Million in development by NOT introducing the BI. I want to get this settled by then and use that date to make the decision.

In short, I applaud having a whole bunch of people go ahead and work on products for May. Let's excuse them from the meetings. Let's decide who we are going to excuse, then let's demand that these other loose ends get tied up. We can not flounder on these critical issues.

I think it's possible to have one group walking and another group chewing gum at the same time. Are we capable of watching the walkers and listening to the gum chewers concurrently?

Basically, there are many areas that have to shape up. They all need the rigor of a review to clear their heads.

HOW CAN WE GET THIS REVIEW AND CHANGE OF DIRECTION?

TO: ENG STAFF: DATE: SUN 24 JAN 1982 6:36 PM EST
JACK SMITH FROM: GORDON BELL

DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-
1/A51

SUBJECT: REAL REVIEW OF NON-PRODUCT ENGINEERING GROUPS

I think we got a basic understanding of what a real review might look like. What youse think of the following?

Our review meeting was productive in that it showed we had several project areas which have just evolved to be there, and
there's an inadequate feedback mechanism for control of the direction and output of work. This situation has evolved because
we all direct our management in engineering at the product output, and the project part that feeds this output is left up to
the manager. I see these mechanisms:

1. givem the money, trust em
2. givem a base budget, trust em, and then let them sell services

   This is where we are in many of the areas. Given that the customers need some specific work, there's always adequate $'s
   to match the growth and aspiration of the manager cause he can
   always "hold-up" his customers for the real work, while he does what he wants.
3. givem a base budget, review the base work by the customers and let them sell the rest.
4. put all the budget in the systems' groups.
5. have me or some other autocrat review and decide their budget
   according to what I think are the needs, in conjunction with
   any kind of input.

NOW
We have operated at 2 for some years, continuing to squeeze the

base budget. The resulting growth while sometimes less than the
product groups, appears to be significant. At our next review,
this total growth has to be reviewed, INDEPENDENT OF THE FUNDING
SOURCE! (DEC is an ideal environment for both the entrepeneurial
and ransom-type manager). The sources of funds abound: product
lines, many manufacturing plants, manufacturing overhead and
flow, various seed money, etc. All in all, I think we may manage
this better informally than say TI which has an incredibly
complex system and the decisions seem to be made at a very high
level (expensive and unimformed folks).

WHAT WE SHOULD DO TO REVIEW THE NON-PRODUCT GROUPS
There appears to be no alternative than to have an extensive
review of the projects by the customers in order to set the
priorities and budget. Rather than involving all the Engineering
Staff or even all the Product Engineering Managers, I believe we
must have small reviews, chaired by the lead customer of an area.
The review includes BOTH the part that's allocated and the part
they sell to various customers. Here's a starting point:
Physical Interconnect/Packaging Power-Thompson
Technology aimed at high end and mid range and fast turn-aroung.
Fagerquist (chairman), Demmer (or surrogate), Saviers, and Avery
(here, I'd like to get Gonzales to be the representative, plus
someone to represnt the manufacturing sites. (5 persons)

Components-Metzger
Same group

Semiconductors-Teicher
Gutman (chairman), Demmer, Fagerquist, Saviers, plus someone from
mfg.

TOPS-Holman
Could be either group or whole hardware PEG group

Fuller, and Bell Portner/Staff
BJ (chairman), Demmer, Saviers, ?

If such a review could be successful, then we might ask that a similar technique be used for the non-product part of each of the engineering groups... together with some outside audit.
For now, I hope we are all committed to a thorough review of what we do.

SUBJECT: MORE ON WHAT NOT TO DO

I believe the terminals area is ripe to cut.

There's also a printer that we are cycling up to do that is budgeted at 4M that could be done in 1/2 the time and less than 1/2 the budget in Japan. The parts are all there. Why cart them over here?

Of course there's the whole monitor, video, workstations morass with long projects requiring much money.

Note Walt's suggestions for some places to look.

I see several big areas for projects to cut in software:

1. The whole Office effort, given that we're evolving to a reasonable set of software based on buyouts and make dos. This is especially necessary in light of the lack of output there.

2. There are many 4th generation languages that we ran across in the A/D review. These would all kill us if they came in.

3. Based on my interaction with the group that's bringing us DECalc, I would like to see that whole group abolished. They almost copied Visicalc. This is basically immoral and I would believe we should be sued over this sort of behavior! No way do I consider this the mark of an ethical company to do this kind of software plagurizing!!

EXT: 223-6788
LOC/MAIL STOP: ML5-3/E12

SUBJECT: PROJECTS/PROGRAMS WE SHOULDN'T BE DOING

Some projects/programs that I view as questionable are:

1. Marlboro & Tewksbury are purchasing CAD systems from two(2) different vendors. The groups are in agreement that only

one(1)
of these vendors will win. This redundant approach has been
justified on a "cover your bets" basis. My feeling is that we
can't really afford the luxury of multiple approaches except
in rare cases. I believe that these efforts are costing in the
area of $.5M each.

2. The Marlboro & Hudson chip CAD projects seem to be on a collision
course. The fact that these groups can't even get together & have
a rational meeting on the two(2) approaches speaks for itself.

3. We've got lots of human factors efforts that seem to be totally
decoupled from any real product development(CRG, Industrial De-
sign, Small Systems Software,...) These effort should be merged
totally into the product groups & I'm sure that we'ed save a lot
of redundant effort.

4. We're spending close to $1M to have a group hype the Unigraphics
CAD/CAM system. The basic function is needed & useful but should
be done for a small fraction of what we're spending.

5. The External Commercial Development has seemed to be totally in-
effective as a catalyst for external buyouts. I don't know of a
single significant product buyout that has been sparked by this
group & we seem to be spending a lot of $s to do it.

SUBJECT: REVIEW OF PRODUCTS AND PROJECTS WE SHOULDN'T BE DOING

EMC is going to do a full scale review of the projects we are doing and have to do a forced ranking of the projects in order
to reduce the engineering budget.

I'd like to solicit a listing of the non-critical things from within engineering, especially our senior consulting engineers
who know about both the quality and timeliness of them.

Some of the things that come to mind to be reviewed critically
in the area of software revolve around make versus buy. Here,
I am tremendously impressed with the CT program to get software
such as NPL running on CT. Also, Personal Software is going to put their software on CT. These are major efforts and we need them, yet could not possibly have staffed up to get them done.

Some of the programs that I definitely do not think we should be doing are: DECSET (buy both TEX and SCRIBE); ANY manufacturing
programs... we should buy all them ala ESG and test them; ADE (NPL and Visicalc are alternatives); DAWN; VISICALC (buy it!);
PASCAL (we have one and ours is late and doesn't use the common
compiler). APL... is it going to come out? I hesitate to mention it, but then there are the 4000 incompatible mail systems... any idea of how to deal with this one?

Conversely, there are languages such as RPG that should have been finished when we have the alternative to do it based on COBOL. I want to understand the function of the Commercial Systems Hardware group too.

Ken has raised concern about the plethora of experts running around, with tin cups that every group feels obliged to have. Of particular concern to me in this regard is ID and human factors and performance folks. The experts seem to take the need to design away from the designers who don't have to worry now about estetics, form or its usability.

These were just a few things that came to mind in the middle of the nite. Could I get a list of the projects and efforts that you think are unnecessary, redundant, going nowhere and that could be eliminated?

Dear Dave:

It was nice to get the paper on RISC. I passed a copy along to several people here who might have a better feel as to what's novel.

The architecture looks clean, and resembles a NOVA or a 6600 at first glance; the register idea is novel. At first glance it seems like the BTL machine architecture. It's unclear there is anything that's counter-intuitive; at least I don't see it.

It's awfully hard to comment on the next logical step since I don't know what the project goals are. It sounds like building the chip is next, which would give some insight into building chips and their use.

Thanks for the paper. Please keep me informed on the progress and give my regards to Lloyd Dickman.

Sincerely yours,

Gordon Bell

SUBJECT: REWARD/PENALTY SYSTEM IN ENGINEERING/MANUFACTURING

I think you have a responsiblity to make it visible that you took a risk in putting the 780 out without the usual testing and that this saved a year on the schedule. Furthermore, this
risk wouldn't have been possible without your counterparts in manufacturing.

You state that the people who took this risk have been penalized
within manufacturing, yet we (engineering) have tried to reward the persons who were part of the 780 team. Clearly the 1
year bought us the market!!! It clearly shows up as an anomonly
because it got on the market quicker than any other product.

Recently, we have had longer product gestation times,

resulting
in less than competitive products, and part of these are probably this added time. Others, I might argue, are just a result of problems in engineering, manufacturing or the coupling.

Let's get this understanding out in the open, and also, let's get these manufacturing folks out of the penalty boxes, if they are still around. We need careful, risk takers
like your 780 manufacturing counterparts. I, for one, believe
they are the key to our future... not the paint by the numbers
folks.

SUBJECT: RE: RISC

We are all vitally interested in RISC and have been following it with great interest. The code density is more of a problem than people think because our programs have been growing so much, especially programs that are written in LISP which are a lot more like data structures than programs. VAX gets a major boost over the 370 because the code density is about 2 x better and there are fewer tables and data to swap. Programs have gotten bigger at a faster rate than disks have increased in speed.

I don't think RISC will be understood very well for awhile until it gets in a real work versus simple benchmark environment. Somehow having all the registers will mean they have to be loaded and stored during context switching and in certain cases of procedure calls and clearly when there's calls between programs written in different languages where the single compiler is really several compilers and several conventions (unless one thinks they can live with a single language at a time environment).

The other part of RISC that's really not understood is the need for special data types, especially floating point to speed things up. Clearly the RISC chip isn't made for that, but requires support there.

Forrest, Jud, Bill, Sam, Doug and I are all vitally interested and want to understand, particularly in light of the fact that making VAX's is a tough design job with lots of Fortran, Pascal, and Cobol and the operating system built into the architecture. The alternative of a faster but dumb cpu (with no microcode) and a big cache is a different approach using about the same amount of hardware.

The code density and protection in procedure calls from mixed languges etc was a major goal of VAX... so we all want to understand.

Joe Smith, ML8-3/T13
Grant Saviers, ML3-6/E94

I made the decision to stop the work on putting th R80 in the corporate cabinet versus having cabinet compatibility with the RM03. We don't currently manufacture the cabinet in CX. There's much work to do to it and it increases risk in the schedule. There's real progress on the R80 and now's not the time to open this or divert manufacturing and engineering resources for what only gets us increased cost! The empty corporate cabinet was broken on arrival.

We have a real winner in the RA80 and the UDA attachment if we can get people in CX interested in doing it. It gets rid of the MASSBUS baggage. Furthermore, getting volume is essential to getting us the RA81...where we can have the leadership we all want at all parts of the system. Let's get the UDA for the RA80 and the software for RSX, RSTS, and VMS so it can quickly get on the 11/44, and COMET, 11/780. This also gets us the RA81 when it's ready.

Roadrunner looks great, even though I had to read a 100+ pages to get what could have been in a two page project summary, with perhaps 30 pages of appendix. It did prompt some questions:

Why aren't the CPU groups signing up?

Why don't they use it for their interface chips?

Who intends to use it and for what specifically?

Where is the go/no go decision scheduled?

What is the decision process?

Could you get some user to use it concurrent with the design?

Why don't we build the T interface chip this way?

SUBJECT: RE: RE: 3 WEEK CAT SCHEDULE IS GREAT, BUT LET'S FINISH ROBIN FIRST

Please re-read the title: Get Robin First!

I think we need to close on a plan to get the TRIAD built. I thought, apparently erroneously (cause I just got through talking to Ken) that Cat=Triad. If Cat is just a cost reduced Robin, then who cares. We've lost a bundle in all the corporation's cost reduction efforts.

I say the 6 months is too long, by 5 months to get 2 processors
added to the existing Robin structure. Why can't we get the work done by no latter than Nov. 1?

For starters, let's get our product definitions down in writing, with no more than one page. If you note the orginal worry about Robin that started this dialog, it was
What is the software that is going to run on Robin?

If I look at the continuous, unbroken string of about 30 products in this space that have lost the corporation money, it is that the hardware has no software or software support. Now is the time to get this settled on Robin before we add another loser! Also, let's talk about Cat only in terms
of what is from Hw/Sw ... starting now!

First, get Robin straightened out, then CAT!
(Or fly before we walk).

SUBJECT: 3 WEEK CAT SCHEDULE IS GREAT, BUT LET'S FINISH ROBIN FIRST

Right now I hope there is NO effort going into CAT except some
A/D somewhere as to how you get the extra processors into the system. Aaron Boxer was doing this and I hope he and Bob and Don are moving ahead on it.

Mostly I'm worried about the software now on Robin. I have yet to see any sort of plan as to what it is and who's doing it.
To make the market believe we have a serious personal computer
(it's unclear that Xerox did with their small computer), the components appear to be:
.A decent word processor ... apparently this is the Wordstar
.VISICALC
.some sort of Operating System with file system
.BASIC and preferrably in addition,
.Pascal
.Terminal emulation and file transfers to a host... in this case
this is essential cause we are billing it as a part of a DEC system cause our users have VT100's already.

Where are we on these? Could I see the manuals?
When can I spend an hour or so at a system and test it?
(In addition to having Mary Jane and I test the product, I hope
there is some formal testing taking place too.)

It is truly wonderful to see the speed at which this product hardware is being done. Let's make sure it is a Quick and Quality
product and not a Quick and Dirty product.

SUBJECT: COMPUTER SCIENCE BOARD REVIEW OF US ROBOTICS

The Computer Science Research Board of the Nat. Res. Council
reviewed the situation in Robotics on Friday. Pat Winston,
MIT
AI Lab. and someone from the Schlumberger Robotics lab
(formerly
of IBM Research) gave position papers. I was impressed with
the
work and the level of Robotics. The direct use and indirect
effects to real time control, vision, image processing,
languages, inspection, and various transducers may be more
important than the products built in the short term. (For
example, much of the processing is on arrays and they need
both
special purpose and general purpose instructions. Most
likely
lots of the functions will be built into special chips such
as a
vision chip that does a 2 dimensional cross correlation with
a

filter to do blurring so as to find surface lines on an image.)

Pat Winston presented a depressing picture regarding Japan. They are absolutely committed and are working very hard. They are building a really advanced LISP machine, are assimilating our most advanced language (Stanford's AIL), and they are structured to form an engineering discipline based on software. In the past they have systematically seeded every US research lab to train their PhD's, while using their own universities to train Master's students. The PhD's then head the teams that do the work. (I've observed this too!) Hitachi has a machine for wire coating inspection and lead bonding control. They are about to release a machine to work in their factories for solder blob and PWB inspection (something we've been after for years!). In general, their work follows an engineering, versus science approach. They do little to advance the overall state of knowledge, but they take the current ideas and apply them in a systematic fashion. (Sort of like DEC in this regard.) I enjoyed the discussion with Pat and got an invitation to spend a day there... despite the fact he complained about the number of visitors in their labs.

The Board's position was:
We believe that Robotics Research is a vital part of computer science and we are particularly concerned about recent advances of Japanese robotics research and products. Furthermore, we would like to sponsor a review to assess the state of the art here versus Japan at the National Academy of Engineering meeting

next October. It appears that there is better coupling between
American robotics research laboratories and Japanese companies
than to American companies. The level of American products
versus the Japanese is lagging and we believe that both research
and coupling to research is the key to competitive robots.

The work going on at the universities and our work is important
in order to ultimately develop and apply robotics. The direct-
and side-effects will be quite large.

To: Al Crawford   Date: 28 APRIL 78
From: Gordon Bell
CC: Al Bertocchi   Dept: OOD
Loc.: ML12-1 Ext.: 2236

I heard a presentation of the above. They are getting out of the AT&T system and building their own. Rockwell has about 100K people, 80K phones, 400 locations and several hundred teleprinters. They spend about $40M and project going to $55-80M. Their traffic is 85% voice, 6% data, 9% teletype and FAX.

Overall their productivity has improved greatly over the last 3 years.

For a communications company their thinking is as backward as ours, although they don't have a centrex to write off.

GB:ljp

December 19, 1978

Mr. William A. Rodgers, Executive
Director of University Computing
Eastern Michigan University
Ypsilanti, Michigan 48197

Dear Dr. Rodgers:

Thank you for the proposal. I've sent it to Jerry Witmore, the Product Line Manager for our Educational Product Group. Since I'm just an engineer, I often don't see the value (market) for ideas, but nevertheless, I'll comment.

We have some microprocessor development systems, and may not be interested. At any rate, the large expense of the package is their support. The mobile computer is interesting, but I don't see why one wants it. The Scope Edit/Sort program didn't come through in the directions you sent. It clearly must be good since your users give it such high marks.

Since Jerry will have a better feel and is responsible for marketing I hope you can work something out with him.

Sincerely,

Gordon Bell
Vice President,
Engineering

SUBJECT: MORE ON THE ROI ISSUE. I'M CONCERNED TOO.

What I think we might do is to take the vt100 study and show how by our conventional measures it is great and that it has been shown to be profitable. Then we pose the question do you want to continue our simplistic pc measures or do you want to consider roi? I haven't read the memos on the woods that ko is proposing where he has invited his group vp's to expound in lectures, but believe we have more insight to this mathematical function via burp.

I'd like one of us to give the lecture.

Meanwhile go ahead and get someone to make a memo that shows the vt100 is great as viewed via our simplistic pl measures.

Gary Cole wrote a memo like this on how well the wps 78 did versus the plan (as measured simplistically). Let's take his simplistic memo and give it the treatment ala vt100 for our lecture. Also, I believe you are doing the 780 as a study too.

SUBJECT: JAPANESE DISCUSSION AND MORE THOUGHTS ON UNDERSTANDING WHAT TO BUILD

Can you write up your version of this and possibly send it to me by Friday by EMS? Want to try to get the problem formulated and segmented as I raft down the Snake River on 8/5.

Also, appreciate any notes on the OC Woods on organization. Hope you build your version of a product/organizational model.

Am enormously frustrated by not having a good feeling about where we are investing big $'s in plants (and inventory) versus
where the revenue is. For example, we are going balls out to build MOS capacity and design capability. Our management

heads, talent and thoughts are all there. The revenue is all coming from Comet and Venus I believe. We are violating the principle that if we don't sell it, then we should buy it (Have you read the policies on Make/Buy that I try to use in our M/E decison making?). Am really scared when you factor in Intel (who'll clobber us in MOS because they sell it) and Japanese who have key hi end bipolar, magnetic storage
and video and speech processing technologies.

Can I get one of your people to help us address this issue across M/E about segmenting and trying to understand TOTAL investment picture?

Similarly, I think we probably should look at selling disks simply to get the cost and volume and quality... but need a way to look at it. It may/may not make sense, but need to understand!

Note that Ken's model of Briggs and Stratton or Tecumseh as being competitive is probably falactious. Both are probably low growth, but both, no doubt are really backward integrated and automated to the foundry and would believe they are highly automated. Both supply a component to a relatively difuse, market (lawn mowers, garden tractors; air conditioners
dehumidifiers, refrigerators) hence they can dominate. The specials like Harley Davidson or Japanese make their own no doubt. In our case, we are not like Briggs and Stratton because we have only a small foundry (Hudson) which supplies most of the work. Silicon Valley has always been our foundry and we have been an assebly shop supplying to our OEMs in iron and base software. Note that the % labor is significantly
decreasing as we buy more and more out (like the expensive 16K rams). With bigger parts and more performance in the micros cpus, our oems are going to Si valley for boards or chips. Alternatively, the cost is going into the magnetics and if we have volume there and are good, it may be our salvation. It feels like we are merely an assembler and when you consider we are 80% materials and 1/2 our added on manufacture is FAT that shouldn't be there in the first

place, we may be heading toward big trouble in the mid-80's.

The use of ROM for software distribution and/or protection has been studiously avoided by the SDC, Software Groups and Basic Systems Group. A recent article in Computer by Shepard of TI states that this is clearly the way to distribute much software. Can you examine how we can get there?

Can we use the TI calculator form factor?

SUBJECT: A BIG ROM FOR 1 FLOPPY? (<1 PAGE) FOLLOW UP: 2/29/80

Why can't we substitute a big rom for 1 floppy? (Does it do much, given that the expense is in the controller?)

What about a big rom, extra ram, and TU58? (This takes extra software in WPS. What would be the cost - especially if we can cram it in the VT100?

We need someway to get the cost down...the packaging and the RX is clearly the culprit. Could we let Dick Gonzales loose for a week on the problem (show him the IBM 5120)? I'm not proposing to hold up the intro into manufacturing, but I'd sure like a less homely, cheaper product.

I am delighted we agreed to only have RL02's as an option to a 278 versus the RLX78 shared disk, much software, long cables, etc.

Overall the plan and spec looks impressive and aggressive. Let's make it happen.

SUBJECT: BOD PRESENTATION OF ENGINEERING FACILITIES PLANS

At our next Board of Directors meeting, which is right after the Annual Meeting, we will have no presentations except the normal red tape. However, I would like to have you make a short presentation showing where you think we will have engineering facilities in the next twenty years.

Can you make a chart that lists for 1980, 1985, 1990, 1995 and 2000, the percentage of space that today we guess will be in each of the following locations: Northeast, Southeast, North Midwest, South Midwest, Northwest, Southwest, England, France, Germany, Italy, other European countries, Canada, Australia, Japan and other countries.

I know we have not thought much beyond the next five years, but I think it would be very worthwhile for the Board, and for us, to present your thoughts as they are today, so that we have something upon which we can work and for which they can make a contribution.

SUBJECT: WHY ROSING WENT TO APPLE ... AND US

In debriefing:

1. Challenge of job: build the best, total office computing environment including computer (with no restriction as to what microprocessor to use (I suspect it will be the 68000), copier, Network Interconnect (his preference and belief is to use Ethernet...but this may change), a File Server and a Printer Server. The group is a newly formed division headed by John Couch, former head of software. He has responsibility for the engineering of this, including the introduction into manufacturing. All their software is in Pascal and this is quite significant. Ironically, Apple has a prototype 1 megabit Ethernet running which they could probably get to market quickly. Hopefully, they won't cause it will wreck havoc in the standards world and put another incompatible thing for us all to interface to ultimately.

2. Reward: 40K shares of stock over 4 years, enough to make him a millionare a couple of times over, given that Apple blossoms. Also, better salary with profit sharing and perks to get a better house.

3. He views the fact that he is entering a whole new start-up division as fun, aside from the potential reward. Is certainly looking forward to small company and small group within a small company. He came from DG and certainly has enjoyed and contributed to DEC. His concerns: we have the depth, but we aren't fundamentally preditory and mean like DG, because we are always growth limited and there are too many people with good ideas around. Somehow, he still believes we have too many products cause there is too much history in 11's. We should be supporting VAX more.

4. Is worried about our getting the Personal VAX (though not enough to stay and get it), especially given the rumblings that Andy wants to KILL Nebula. His view is that this would be a tragedy of short sightedness, given all the emerging personal computers and the disdain our customers are beginning to show for the 11's especially in the low end. [Here, we must protect the people we have from migrating to him at APPLE,

cause they have the knowledge to build high resolution scopes.
There are other people he feels are not being rewarded adequately and he, no doubt, will somehow go after them.]

5. Generally, he believes that Apple has and will have no trouble in staying the leader because they are not vertically integrated and because of their organzational philosophies. They only do a task if they can be the best at it (hence, no PCB work or module assembly). Their recent addition of peripherals seems to violate this, but then they may either mean to dominate this area, or are scared by the lack of quality suppliers. They have a very small, very high quality organization and they revel in hiring the fewest number of people they can, and this is reinforced with profit sharing. Hence the more persons, the less profit per person. The stock and rewards are distributed widely in order to motivate, versus the large company where the rewards are mostly to the top few persons who have tenure. DG wasn't especially oriented to motivate the doers, versus the managers of the doers.

Frankly, I think we have a serious competitor on our hands. He has all the technology we have, and very few constraints. The people are both good and extremely motivated.

I quite agree to sponsor the royalties for Digital Press at the Operations Committee. Could you get the package together so that it could be there for the January 29 meeting? I'm sorry for this urgency, but since several people within engineering are working on books now, with no real plans in this area, I feel you must drive to get it resolved.

I've had a change in attitude toward a point of view that we have professionals that do not work all their hours for DEC, but merely put in a 40+ hour week, and they are going to write books on the side. The purpose of the plan should be to encourage them to write for us (versus others). Certainly, given that they are going to write, we should support and encourage them to do it for Digital Press.

It's your move, but I would like you to come with a plan in the next few days and I would like to have someone from personnel and legal there to get their respective blessings. Let's get this resolved since it has taken too long and there are implicit agreements being made.

The message is very clear in Australia. The users who have RSTS would like some way of upgrading their current systems to VAX. This could be as weak as a link (DECnet) for current 11/40 - 11/70 systems, but there has to be a plausible, attractive product.

Could we explore what such a product might look like?

What's the possibility of running 8 SW on microcoded 11s?

How fast will an 8 running on the LSI-11 run?

How about on the FONZ?

Isn't this the way to migrate 8 users and software?

GB:ljp
I thoroughly enjoyed your paper on MOS design styles. I think it should be extended to cover the issue of designing dense circuits and the time penalty they cause... the message, make it bigger and lay it out QUICK! Also something on the design time versus time for various size (# transistors) chips would be nice.

LOC/MAIL STOP: ML12-1/A51

SUBJECT: SACRED COWS AND GOLDEN CALVES

Aren't they the same, only just different religions?

We make strong statements from time to time about products and methodologies. Most of the time, I believe we're right. The problem is that if we ever give ambiguous or conflicting statements, the people believe they have to be scholars and interpret the statements. I stamp them out whenever I find them because the problem can be solved by asking or simply doing the right thing (if there's been strong statements to the contrary).
In no cases do we want these kind of scholar/politicians around.

TABOOS... Let's list these too
There is another category too, called taboos, which are things that people aren't supposed to do because we've told them they can't, like 10 commandments, serving liquor, having wife/girl friend work for you, etc. These include: programming in assembly language (came out of desire to get us to higher

level languages) such that now Bliss is all that's permitted
...
here, I wanted even higher level and more available
languages;
using 15 or 17 inch monitors; color; graphics; I'd like to
make
modem-less terminals and PC's a taboo (here I thought you had turned everyone around. but alas Kirk and Folsom produced products which don't deal with the modem problem). If any of
us
have these things that we don't want people to do then let's make sure they get listed too so as to save time.

Sacred Cows Within Engineering
Industrial Design got to this status and we can now change the situation with Schneider gone. (We have an identical view of what they should do I suspect. Clearly we needn't have so much work so early. This requires engineers to
take
the reponsiblity they now delegate, hoping that someone will create for them. A similar category of people are growing up within ID and elsewhere, Human Factors people. I've asked to review every additonal hire of these people. They are
priests.

Base technology people have been in this category because we obviously need them. Unfortunately they've been
decoupled.
I believe Metzger is going to solve this and get us
product programs.

Non-Research, mustn't be a cow
I don't think we encourage this enough. Both of us have made strong, non-supportive statements. Here, we need something very good and very directed to get the work in place to make competitive products. Over the last few years, I've
concentrated
on getting the various product groups to do their own A/D because I used to find managers all saying that the 20 guys
in
research were doing all the advanced work for the company.

Right now, the research group is doing work that we think must be done that the product groups don't yet recognize as being essential (eg. Security, robotics with MFG., helping build the inhouse Local Area Networks... really operational, Charle' Rupp on a Silicon Compiler is not recognized as vital).
Also, the myth that rewards only come from products doesn't encourage longer term basic thinking that will lead to a product. For example, there are several very good ideas about
pipeling that won't be in products until late 80's, but we have to have them NOW so as to be ready when the next design starts. They are getting into the Nautilus though.

SUBJECT: RE: PRODUCT LINE SUPPORT OF SALES DEPARTMENT

Based on a very tiny sample, supporting our salespeople has to
be about the number one corporate product, and probably at

the
root of the lack of orders. As one sales veteran stated:

"We've had high backlogs (and high sales) and had to spend our time
chasing people internally about shipments.
We've had no backlogs (and low sales) and we had to spend our time
chasing orders.
But this is the first time when we've had no backlogs (and low
sales) and we have to spend our time chasing shipment problems.

We want to spend our time selling and not on internal shipment problems!""

The comment is that going back to training on products was great.

The field diagnosis, was lack of clear responsibility in TND. In TOD (The Old Digital), the system was crappy, but the P/L people made it work because it was the only way to make the P/L numbers. Now, it's difficult to find out if and when something has or will ship. They are having the most trouble with new products where there are allocation or engineering hold problems.

Also, compounding this problem is the new Point of Manufacture
system, which will save much when it's operating.

Bottom Line
TND is somewhat like Reagonomics. Some good ideas and much needed changes and belt tightening. The implementation puts the whole idea and system at risk. Many parts are working, but much is needed to make it work. Let's make TND work!

Subject: **About a Score of Impressions and Recommendations from Visiting Three Sales Offices**

To: Marketing Committee

CC: Dick Clayton, Bruce Delagi,
Bruno Durr, John Leng,
Julius Marcus, Gerry Moore,
Larry Portner, Jack Shields

Date: 10 MAY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

Introduction

I think we have a massive sales effectiveness problem. It starts with a complete inability to know anything about what we are going to sell, transcends into a labyrinth of finger pointing about products and sales support and goes finally into general office procedures. The most condemning aspect of the situation is that there is no visibility that we have a problem...in this case a hierarchy of problems, and then a setting out to solve the problems.

The purpose of this memo is not to define the problem (this can be done by McKenzie and Company) but to give symptoms based on my impression from recently visiting sales offices and talking to customers and salesmen -- and to urge us to get McKenzie in now! The impressions should not be taken to be universal about offices or salespeople. The salespersons are open about these problems and anxious to get the problems resolved; they are anxious to discuss them with other officers too -- the only hopeful sign.

Summary (* Action possible)

1* We have inward focus. No output is caused by intra-sales and sales-P/L talking.

2* DEC salespeople have no identity. We got them everywhere else, and with our unstructuredness they're ineffective. Also, we have no way to build DEC salespeople.

3. There is a dichotomy of product-oriented and customer-oriented sales. Can this be managed centrally?

4. There's little method of account control (selling, service, software versus time).

5. The three organizations are both ineffecient and cause less team behavior.

6* One office at least, looked amateurish and are there adequate office procedures, etc.?

7. The order processing system is pretty questionable, but then there was no plan with performance and costs.

8* The pink sheets are a joke and as officers, we may be liable for incompetence. Let's change sales measures to ships -- not books.

9* A complete sales plan for the product (e.g., VAX) is either nonexistent or incompetent. Sales should object. This has to be done at a group marketing level.

10* WP could be a calling card. All salesmen would like to use it -- since it's something everyone understands, can appreciate, and sell.

11* There is a complaint sales doesn't have time to plan or to report correct bookings. I don't think they know how anyway. These might go through a different organization (e.g., F/S or the Controller).

12. Sales has to be approached as a training and logistics problem, not the management of artists!

13. There are too many products for anyone to know, yet too few because every P/L Sales group needs more.

14* Left alone salespeople try to sell the largest systems. There is no focus, discipline, or goals (quotes) by size.

15* The DEC 100 doesn't recognize the team work necessary for account management or encourage a second salesperson. Segmentation is encouraged.

16* The P/L literature is a collection of garbage! I defy a customer to understand our products from what we distribute as literature. I propose every product line put together a single catalog that explains its products to a prospective marketplace/use. I'll help put the first one for ESG together.

17* There's lots of informative transmission within P/L -- sales by paper, word of mouth, and meetings and essentially no reception. Low quality information (by documents like Sales Update) requires continuous rebroadcasting, etc. We require every salesperson to be a file clerk.

18. We're totally naive that we can have lower costs and compete with the equally large mainframes (e.g., IBM) that force much service. Our manufacturing base isn't that big -- especially as we continue to cut orders back!

19. The VAX-2020 hassle is a field conjured situation by competition in the sales force. There is a relatively well segmented market.

20. The lack of sales is transient as we try to move from OEM to End User -- is a perception.

Details

1. We're fundamentally inwardly focused. I believe, based on sampling of calls to salespeople, that the sales organization spends too much of its time communicating with itself and with product lines. There is essentially no time or people left for customers. It recently took <u>2 salesmen</u> to call on me to tell me what they wanted me to say at a presentation to a customer seminar. (This could be a phone conversation, TWX or memo -- those 2 salesmen were not making their quotas this year!) In many cases there is emphasis on trips to Maynard or elsewhere and <u>meetings</u> to discuss the situation versus written statements and action-oriented conference calls.

2. There is no identity now as a DEC salesman. I personally identify with the older, technical salesperson who speaks bits, instructions/sec, operating systems capabilities and detailed applications...so I am significantly less critical of the technical salespeople. We now have a mix! We have the truly professional salesman, who, as all the salesbooks say must have first and foremost the ability to sell themselves. We hear all the time how professional (recall Kaufman's comments on the professional) they are, but they are simply not results-oriented. They all came from another company because we do not believe in training programs or growing them from the ground up. Since we are at a reasonable size, it is getting somewhat more difficult to get them and since Burroughs is the only company relatively screwed up and not growing, it's the only source of trained people. The sales associate program is a joke in the field...as one salesman said we are spending our time creating Rolls Royces and we need a factory to produce Chevrolets. Our fear to hire college graduates, for example, is typical of the problem. (Note, if Manufacturing had not put schools in PR to train

electronic people, we would not have been able to get the rapid growth...we couldn't steal these people from all the other companies.)

Since the newer less product oriented, less DEC oriented salespeople are better personal salespeople they may occupy the senior sales management staffs and cause a downward bootstrapping of product knowledge without the attendant improvements in sales performance.

3. There is a distinct dichotomy between the commercial and more scientific salespeople and I don't doubt if there is effective management because of this.

The problem of having no identity as DEC salespeople is that older more established companies totally run by procedures and when we have such a lax procedural base, a lot is left to the individual initiative; structured people will blame the company for every thing (e.g., yield setting, literature, sales training, product segmentation, no time to plan, no team selling, OEM versus end user, selling by size, etc. etc.)

4. There is not a very good concept of an account that lasts over time. With a high growth and lots of people movement even before they are ever tested or qualified, this tends to get in the way of a stable relationship with a customer or with a team of people in an account. There is a muddy pecking order within sales, software support and field service; the notion of a team really doesn't pervade the group in most cases.

5. The three organizations require independent top-down structure which seems redundant and probably enforce segmentation.

6. My impression of the NY office was that it looked amateurish and a place I wouldn't want to take a customer. Their computer room had cables laying about and skins off the equipment which was in a state of repair and upgrade (do the repair off hours). Only 50% of the proposals were done on word processing systems and it is unclear for such a large office why there were only two WP terminals (in a very large disorganized looking room). One of the midwestern offices had only 10% utilization and knowledge of WP. In talking with the head of the office I couldn't get sales bookings and sales costs figures for the last two and projected years.

Although there was a literature room, and area of the office held an assorted overflow. Surely there was no one responsible for literature.

The very pleasant work area was where the top level management had their offices, walled off from the troops.

7. The salespeople wonder about the effectiveness of the order processing system. It seems like we have decentralized one small part of the

operation, while leaving the rest in tact, and now we have a more cumbersome operation with only additive costs and delays. There is no measurement of this performance or its costs, nor did it have a plan!

8. The system of measuring and reporting backlogs, especially in the OEM marketplace is at best incompetent and it may even be illegal. As an officer I would like to know the extent of our collective liability in this area (Al Bertocchi, I believe you should formally access this). There is no way that the backlog and order rate we have had has any basis on reality. Supposedly the sales offices fingers, memos and meetings point back to the product lines to make them aware of the situation. There is nothing written on the subject. The pink sheets, which we watch religiously are clearly only random data and I submit that taking some appropriate temperatures in .01 degree increments of every salesman at 2:30 every Friday would yield better data about our backlog. For starters, the backlogs are cumulative numbers and can not be represented or even approximated with the single number we

use. Secondly there is no way that the companies who order from us can go through the growths that are attendant with the backlogs we project.

I would like to propose we throw out the pink sheets and go to the measurement of ships in the OEM area as an aside, each sales office has a Field Service planner who must plan spares and the training of field service people...they know what the order rate really is and don't go through the euphoric ritual that we do to get the high backlogs. We continue to joke about the oscillations superimposed on our exponential growth, but in this case it may just be the last time we oscillate.

9. There is little or no training and/or focus on new product programs (e.g., VAX) together with a sales strategy as to how to go about selling it. Each of the product lines are doing different things and there is not strategy or deep understanding across the groups. The selling is essentially contained within Win's product lines, and there should be sales, promotion, customer identification, sales support program at this level. In this way, the training can take place across ESP, EPG, LDP, OEM for real time users, IPG plus the few in GIS. A central support group would get the training fast, get the advertising co-ordinated, provide a backup sales group, give field seminars which at this time have to be on a product basis (note Brookhaven has not had a presentation yet on VAX). The manager of the NY office, a commercial type, hasn't the foggiest notion of what the machine is or how to prospect for it. The salespeople don't either! (They only know that it is a hot machine.) We must get organized on VAX!

10. With the big inventory of VT78s and the universal interest in Word Processing, I believe we get these systems into the offices for quick delivery. These also provide a good calling card for all customers. Salespeople agree but don't know how. Also, there is the usual reluctance to sell anything they don't get credit for.

11. Sales managers believe they are flat out working on today's problems and don't have any time for planning or for account management because they are driven to get orders (which they are clearly not getting). I don't think it is in the nature of salespeople to plan, and I would propose that this aspect of understanding go through field service or financial organizations on a separated reporting basis. I believe the controllers organization should be solely responsible for the assessment of order rate and the recording of shipped nor, etc.

12. In a quick perusal of our sales training, I don't see how the training is set up to take people who have fundamentally been salesmen working on short term goals and turn them into people capable of managing offices. The logistics, planning and field service management has better training for managing sales offices where the goal is to get, and equip trained salespeople, plus interface with the suppliers (i.e., P/Ls) to insure there is a message. In this regard the concept of sales being anything more

than a congeries of artists seems foreign to sales management. The problem is that the company is locked into the output of water and oil color painters, house painters (with a few barn painters thrown in) together with a collection of musicians and finger painters all trying to get us some sort of artistic extravaganza.

It seems like we need effective co-ordinated, plans on how we are going to get the orders in the various products/marketplaces. I have never seen a single sales plan, for example, giving: the number of salesmen, the areas, how they are to be trained, how the training fits in with promotions and how prospects are gotten, what the gestation period of a sale should look like, what the competitive posture is, how the P/L supports the field, etc. etc. Such a plan would be the basis for effective product line support and the management of sales. From the plan, we can assess deviations and measure results. Alas -- nothing but the artists.

13. Although we have too many products for the multi-priced, multiapplications markets based on our ability to mobilize salespeople effectively, we are still in a runaway situation requiring more products because there are still lost sales in every possible area because we go after orders anywhere we can instead of having a targeted, organized measured and controlled approach.

Business products is the best example of this now, where when it was successful, had only a limited set of products and a targeted approach to selling.

14. Business products used to be segmented by size and hence had a clear product focus, and with reorganization into end user and OEM, lost this and lost control so that all groups went for the biggest ticket items, and ignored the small products we were initially successful with and where we had a clear niche. Now we compete with every competitor and our OEMs compete with us in the small, medium and high end marketplaces.

15. The DEC 100 somehow destroys any notion of team work that is necessary for account management and selling the right product.

I would propose there is no credit for bookings, but only ships and that reference account selling where a second salesperson is brought in be accounted credit toward quotas in some sort of shared fashion that could even be negotiated by the two salespeople. I believe we would rather lose an order to a competitor than to give the business to a fellow DED salesperson.

16. The plethora of product line products and collection of what we kindly call promotional literature and can be more accurately called garbage is disheartening to customers and to salespeople too. I believe that each product line must build a product catalog of what they're selling including hardware, software, services for their particular marketplace. This, relatively large catalog, would be aimed at the customer (and we wouldn't have to produce some of the horrendous marketing guides that I doubt our sales

people read (nor are many of them capable of reading). The catalog would establish who the customers are and what the products are for the particular customer base. Let the customers decide our sales costs are out of sight because no one knows about a product. (I will personally volunteer to help with the catalog for ESG in order to get this focus. Here, we want something like the Tektronix or HP catalog!)

17. The P/L - Sales; and Sales-Customer interface is an inefficient, mouth-mouth resuscitation process. (Note, no ears are involved.) The transmission process needs to be clarified, and our messages simplified and cut down with less irretrievable (i.e., unless we want every salesperson to be a file clerk) garbage in Sales Update and flash TWXs!

18. Our marketing vis a vis large competitors (IBM) is naive. A salesperson will, within seconds state we sell because we have lower prices and better products, yet we aren't selling because we need much more sales support and service that cause higher prices. I can't identify any uniqueness now in the commercial market (a few years ago we had OEMs and low prices). The EDP Manager/IBM salesman controls what the Fortune 1000 computes on! There is perhaps a strategy to get a foothold, but we have to only sell completely unique products (i.e., VAX to scientific, TRAX, 2020, DECnet, WP, RT Factory Data, or unique small systems). Forget all else!

19. See summary.

20. There are probably more but this is all I could recall from a few days in the field and a feeble memory.

Ted has complemented you as a clear product/technology presentor. He asks for more of your time for field presentation. Let's decide how much.

Ted would also like to get a list of presentors that could make these presentations. Could you collect such a list from the rest of OOD and within R&D together with their presentation titles?

As an immediate problem, could you figure out how we can pull together a "canned" presentation that attends to the following (attached) problem?

SUBJECT: SANDIA AND LASL: VAX, LAN, OFFICE AND VT18X

Some comments regarding a recent visit:

Environments (VAX... and 2080 support).

They each have about 25 780's and really love VMS. The only complaint
was a need for a larger exponent. LASL has four Crays and a

large
network of supercomputers. VAX is used for: switching, processing
for print service, CAD, Central computing and distributed computing to
a small collection of users. They compute, do pre- and post-
processing and check out for the super computers. A 780 supports
about 18 users. Sandi's going out for a replacement for a 6600 which
supports about 60 users. THEY NEED A MORE POWERFUL VAX!!!

We must provide a really clean way to make the 2080 an upgrade from a
VAX. Given their FORTRAN orientation, this should be relatively easy.

Their supercomputers have dial in and fixed terminals, file server
(>1000 gigabytes in a disk form, 3850 and automatic tape library),
LANS a print/COM server, concentrators, authentication/securing
servers. They're both building LAN's over their large areas. LASL is
using and going to wideband for remote connection. Sandia has a
Hyperbus in their center with gateway machines for 9 VAX's and fiber
optic links to the remote VAX's.

Their fiber optic back bone is built with Western Electric, 144
strand cables, $20/ft. A receiver or transmitter costs $100., and
operates at 32 Mb/s, but could run at 90 Mbs.

Neither intend to use Ethernet as their primary LAN, but each would
use EN within a building. (The geographical areas and security issues
preclude this use... although the main part of Sandia is only

1.5 km.)
They are worried about security on EN.

Sandia envisions both a single EN across buildings, interconnected via
fiber optic repeaters AND separate EN's for various buildings that go
through gateways to other ENs.

Thus, there are three options needed for their EN:

a. Repeaters using fiber optics as an intermediate link.
b. Gateways using fiber optics among EN's.
c. Gateways using CATV among EN's.

It would be nice to map EN into several channels of wideband.

I think we want to sponsor and encourage the development of these
gateways and repeaters to be done by the 3rd party LAN Industry!
Liddle is going to discuss with us at the DEC-Intel-Xerox PR seminar.
The technical user communicates and publishes.

There was a problem of not being able to sell word processors
directly, but requiring a commercial salesperson. I don't understand
why?

We just have to start to attend to our technical users! Their
requirements for office processing:

1. Run with dumb terminal VAX or

2. Run standalone to off load the VAX on a WPS

3. Scientific character set.

4. Mail

5. Typesetting, (with typesetter support). They want us to offer the typesetter. They use TEX. Should we support it too?

6. One terminal for: dumb terminal, including graphics, and upgradeable as standalone.

Where are we on being able to do this on the 278? On the CT?

GETTNG MORE PERFORMANCE FROM VAX

1. They need Venus.

2. We must have a really clean connection between the 780 and the 2080. Given the VAX installed base, a cluster upgrade using the 2080 looks like a much better market than just upgrading the current 10/20 base.

3. Atlas is expected and being discussed.

4. Is there any way to get a 4 processor Atlas? Los Alamos is building a 9 processor 8086 to study single task, multi processing. Good Luck.

5. Better communications hardware would get some cpu cycles? What is the effect of combo? What else is needed?

6. Personal computers for word processing and intelligent terminal functions for editing would also get may machine cycles. Here an electronic 278 provides the best performance.

7. Can HSC and clusters help? Can the clusters be used

to get
more users on a single system because of separation between
control files and processing?

VT18X

Basically confusion. Can they buy it? Can they get a demo? How does
it work with VAX? How do they get their hands on all the third party
SW? How much will we offer?

GENERAL

Interface to Product Lines is tough LDP, GSG, TPG, ESG, (and commercial for WPS).

GB3.S2.37

Two Lieutenants: A Parable on A Parable

In the early days of the year 1979 there was a famous parable
about two lieutenants who came back from a meeting with their

commanding generals. One transmitted the message to attack a particular hill at 0700. Two got the message that there was dissension among the generals and that there was likely to be bloodshed if said hill were attacked. Two met with his group to plan a way to convince the generals not to attack the hill. The alternative plan would be delivered at 0700.

Here, endeth the first parable

Like any good parable, it is simple and has a message. The following tactical probabilities make other, interesting parables:

1. taking more than one hill, given both groups;
2. taking the hill, given both groups;
3. taking the hill or hills with only one group;
4. annihilation of the groups for the given attack forces;
5. annihilation of the generals' camp.

Furthermore, there are various situational rewards:

1. medals;
2. promotion for results at the hill or hills;
3. getting killed.

And one might believe that Two's troops included sergeants, and possibly women, who would:

1. actually go for the hill, as apparently directed;
2. go back to the generals at 0700;
3. retreat.

The final result of the attack turned out to be:

Lieutenant One's Group was annihilated and he was given a post humous dishonorable discharge.

Lieutenant Two's Group scattered. Some of the professional soldiers sold out as mercenaries, two sergeants were killed (possibly by their own troops) and got big medals, and the rest were captured, soon traded back and went home.

The camp containing the generals was captured while the generals were discussing Number One's bad luck. The general with the most stars escaped and went back from the fighting as chief of staff, bringing with him his promoted assistant, Two.

Moral, aside from being careful about getting involved with people who fight and about knowing when to run, because parables are as complex as taking hills:
  Given a few people and a simple situation, things never turn out to be as simple as one would think beforehand... or, complexity sure can kill a lot of people.

Given our interest and affinity to want Pascal, I fail to see why we're not using one of the many versions for the LA124. It's available on the 8080 and 11, and permits movement of programs (eg. LA124) to Tiny.

Why aren't we using it?

The strategy looks good, but:

1. Why don't we buy the new OMSI-11 Pascal instead of doing Micro Pascal?

2. Why staff so much on Pascal+ on VAX?

3. How are we going to keep compatibility among the products?

4. How's # 3 doing so far?

5. Will we be able to have Pascal+ be the base for the ADA run time system?

6. Why can't we bring in the current Pascal 11 now from OMSI for use internally (e.g. special LA's, new terminals)?

Who's responsible for watching/co-ordinating Pascal on VAX?

How's the project coming?

Can we get them here for a design review?

GB:ljp

October 10, 1978

Mr. Stuart Patterson
National Center for Atmospheric Research
Atmospheric Technology Division
P.O. Box 3000
Boulder, Colorado 80307

Dear Mr. Patterson:

Let me take this opportunity to thank you and your staff at NCAR for the fine hospitality and interaction on the 3rd. It was truly an honor to talk about VAX with such an outstanding group. The trip through the computation center and seeing the Cray 1 was a high point.

It was intriguing to speculate how we might use smaller computers (such as VAX), located within an individual scientific group, to provide similar levels of service (for over 90% of the users) to that obtained with the Cray 1. I hope Dawn can get some benchmarks and understanding of the NCAR user profile from you. Such a system will, of course, exacerbate the need for networking. Here, I hope you might avail yourself of some of the understanding we have of networking within the Denver office and also visit our network group.

In order to really get a better understanding of your future needs, I'd like to get you to write down and present us with various scenarios of how you see the NCAR computation needs developing with time. We could then understand and respond to your needs. Could I ask you to come and present this view some time when you're in the area? This would also be the basis of seeing whether we could help in the network area.

Again, thanks for the hospitality.

Sincerely,

Gordon Bell
Vice President,
Engineering

November 26, 1984

Mr. John Payne
National Semiconductor Corporation
2900 Semiconductor Drive
Santa Clara, CA 95051

Dear John:

I'm glad that there is increasing concern about National's future microprocessors. I'll be in the Valley during the week of the 10th of December and hope we can discuss the progress and direction then. I see three critical issues:

1. Get the 332 done and out by May
2. Establish the overall goals and constraints for the 532 project now. Follow this up within a month with a review of the functional specification and high level design. My target, is described below, but may not be aggressive enough.
3. Deciding on a longer term, hardwired architecture, which has 32000 data-type, operating system and language compatiblity to compete with the so called, reduced instruction sets, including MIPS Co.

The 532 described below is needed within two years, in order to be only a year late!

Here's some background data that we might start from:

Machine	Implm.	Clock (ns.)	(Mhz)	Ticks/ instr.	Speed*	Mips
VAX						
750	u	250	4	11	.75	.375
780	up	200	5	10	1.0	.5
8600	u4p	80	12.5	6**	4.2	2.1
32000						
32032	userial	100?	10	27	.75	.375
32332					1.9	
32532	u	30	33	15	4.4	2.2
Risc II	hardwire		83	12	8	2.0 1.0
(1.5)						
MIPS Co."	250	4	4	2.0	1.0 (1.5)	

* Note the 780 is commonly rated at 1 Mips, but actually runs less than 0.5 Mip when averaged over a long period. The rating comes from doubling the number which roughly corresponds to the number of 370 instructions which would have to be executed to do the same work.

** The 8600 (Venus) has a multiple stage pipeline, each of which is very complex to fetch (Ibox), Execute and do floating point. In addition, there's a special interface (Mbox) to interface the cache and memory.

Note the large number of ticks required to interpret the average instructions in the 032. Some recent benchmarks show that the 032 is probably able to keep up to a VAX 750 if you ignore the slow floating point in the 032 and use the same, poor UNIX compilers. I'd like to see the Whetstone numbers you have here.

The 532 above would use a package that would let you get all the 32 bit or possibly 64 bit data and 32 bit addresse lines in and out rapidly. The design should be incredibly simple and brute forced, not piplelined. Note most of the performance comes from the technology (3.3), the other performance gain should come from a 32-bit organization (2) and a wider microprogram control. The MMU should be on chip, like the Microvax chip, in order to avoid the package and handshake delays. I assume this can be done with double level metal, 2 micron CMOS, and most certainly 1.25 micron CMOS. I think it is also crucial to utilize Weitek in your planning to reduce the internal work.

I believe it is possible to build an ECL Risc that's 10-20 times faster than a 780 for programs (but may require 1.5 times the number of instructions) using a 25 mhz clock. This would have about 3-4 ticks per instruction, and could be implemented in CMOS. An article by Jean Yates is enclosed which describes the opportunity of Riscs.

While it is crucial to persue all three paths in parallel I would like to concentrate mostly on the first two on this visit to insure they are on the right track. Then we should explore ways to get a faster architecture.

Sincerely,

Gordon Bell
Chief Technical Officer

CMU SPICE ADVANTAGES

1. LARGE, CYCLE-INTENSIVE PROGRAMS CAN BE RUN EFFICIENTLY (NO SWAPPING OF N USERS)

2. MICROCODE TO EACH TASK

3. HIGH RESOLUTION GRAPHICS (PERMITS WORK ON VLSI LAYOUT)

4. NATURAL COMMUNICATION

VOICE AND VIDEO

5. EACH USER HAS A BIG COMPUTER TO SELF

6. RELIABILITY

7. EXTENDABILITY IS REALLY MODULAR

<u>CMU ASSUMES</u>

TIMESHARING IS ENDING

SMALL, HIGH VOLUME SYSTEMS WILL EVOLVE TO BE EMBEDDED IN TERMINAL

NO EVOLUTION OF CENTRAL SYSTEMS TO

SOLVE RESPONSE TIME; PROVIDE MORE; BEST SHARING

PROVIDE DIGITIZED AND RECOGNIZED AUDIO (AT + T FUNCTION?) -

STORE, TRANSMIT AND PROCESS VIDEO

(BECAUSE LOCAL TRANSDUCTION/PROCESSING IS NECESSARY)

CMU SPICE SCENARIOS

1. DOCUMENTATION PRODUCTION INCLUDING ALL FIGURES COMPLETE PAGE LAYOUT

2. PROGRAM DEVELOPMENT USING COLOR, EMACS-LIKE, CO-ORDINATION WITH TEAM/MANAGEMENT

3. PROGRAM DEBUGGING

4. VLSI DESIGN

5. MULTI-MEDIA COMMUNICATION (TEXT, FIGURES, SPEECH)

6. NON-INTRUSIVE COMMUNICATION

7. TELEPHONE ANSWERING SYSTEM

8. INFORMATION DISTRIBUTION

WHAT IS CMU CSD SAYING?

WANT / NEED? MANY MORE CYCLES/SEC; Mp; Ms (CURRENTLY 200 USERS SHARE
2 KA, KL, 3-780'S) TO:

DRIVE MUCH BETTER SCOPES AT FULL DATA RATE (Pc)

EMACS TYPE EDITING (Pc, Mp, Ms)

ABILITY TO MANAGE A TELEPHONE AND VOICE (Pc)

PICTURES (AND GRAPH) STORAGE, TRANSMISSION AND PROCESSING.
(Pc, Mp, Ms)

WANT A CENTRAL FACILITY FOR FILES, PRINTING

DON'T SEE A NEED FOR A HIERARCHY OF CAPABILITIES OF PROCESSING

HOW DOES A PERSONAL SYSTEM DIFFER FROM A SHARED ONE?

. TO A USER, NO DIFFERENCE EXCEPT:
CONSTANT RESPONSE TIME
LOTS OF RESOURCES (Pc, Mp, AND Ms) TO THROW AT TERMINAL,
SPEECH, VIDEO

. IS ECONOMY OF SCALE OF WHAT MATTERS DISAPPEARING?
Pc -> 0
Mp -> 0
Ms = CONSTANT; SIZE INCREASES
.ECONOMY OF SCALE
.PERFORMANCE LIMITED BY MECHANISM
T.CRT -> 0
= CONSTANT; SIZE INCREASES
T.COMM = CONSTANT;
= INCREASING; UNAVAILIBILITY
T.LOCAL AREA NETS = ?

. LOTS OF RESEARCH QUESTIONS
MAKES EXPLICIT PROBLEM OF MULTIPLE, NEED TO CO-OPERATE/INTER-COMMUNICATE
DIST. DATA BASES
DIST. PROGRAMS AND PROGRAMMING
INTERFACING OTHER SYSTEMS

. IN SUMMARY
WE ARE TAKING LARGE SYSTEMS PROGRAMS THAT WERE EXECUTABLE ON CENTRAL SYSTEM AND BRINGING THEM DOWN TO OPERATE ON THE MANY INDIVIDUAL- AND GROUP-LEVEL COMPUTERS.

THE DEDICATED PROCESSING WILL PERMIT SYSTEMS TO BE BUILT WE NOW DON'T UNDERSTAND.

SUBJECT: FOCUS ON A MICROVAX PC

GB4.S1.42

We're driving like crazy to get 1 or 2 significant PC's based on
MicroVAX and the Qbus. The first implementation is with Cutler's
2-board MicroVAX.

The options are:

. the disks, including floppy (for loading)

. the connection to an Ethernet and some other net (if necessary)

. Cutler's MicroVAX, followed by MicroVAX chip & board

. Two or Three Crt options:

  . low resolution - probably 15" monitor or CT-compatible screen
  . hi resolution - 19" monitor

. color (simple)

. Board to interface a laser printer to make a print server

We need to go back and address our technical market who are buying HP,
Apollo, the IBM 9000, Sunworkstation, and are looking forward to the
Apple Lisa.

Will you provide the box?

At this time we're trying to get 3 MicroVAX-based PC's.

1. Rainbow III - Barry will get CP/M to be transportable and move to
   a 32-bit micro. They'll probably do this for a 68020, which will
   be in the same time frame. This will be a portable operating
   system.

2. Pro 750 -

3. The Qbus-based PC's using your box.

If we play our cards right, the situation will be:

1. CP/M - It will evolve to be multi-user, and ultimately
   transportable to 68K - and MicroVAX.

2. UNIX - on 68K, Intel, 11's, VAX, IBM 370.

3. Vanity systems (eg. Apple, Atari)

4. One language, no O/S (eg. TRS).

5. DEC-VMS compatible - permitting dynamic movement of files and programs. Let's continue this and keep our compatibility, quality and coherence.

JACK SMITH		

WPS USERS - Leave HP mode and type <CR>

These 5 slides (definitions) may be of interest to you. They try to segment what and how computing is (and may be) done.

A TIMESHARING COMPUTER consists of:
.processor and primary memory,
.secondary memory for programs and data,
.communications links to other computers and to
.human interface terminals (eg. CRT and keyboard).

A timesharing computer is used interactively by several persons in a shared fashion. The computer belongs to a group, while the terminal ususally belongs to an individual.

A PERSONAL COMPUTER consists of:
.processor and primary memory,
.secondary memory for programs and data,
.communications link to other computers, and
.human interface components (eg. CRT and keyboard).

A personal computer is used interactively by one person at a time. The computer usually belongs to an individual. (LINC is the first to satisfy this defintion, if you ignore the addtional constraint that says a PC must be portable!)

A CENTRAL FACILITY (mainframe) provides:
.network communications among computing nodes, with conventions for exchanging data,
.archival storage for group and personal facilities,
.large, shared, central data bases,
.large, special facilities beyond group or person (eg. printing, plotting, high performance processing, electronic mail),
.general computation on a service bureau basis.

A GROUP LEVEL FACILITY (timeshared minicomputer) provides:
.ability to be part of communicating network,
.intra-group communications via the facility,
.shared programs and data for a single group,
.special facilities for the group (eg. microprocessor debug, simulation, printing, plotting, processing),
.shared, general computation for members of the group.

A PERSONAL FACILITY (personal computer) provides:
.ability to be part of communicating network,
.private programs and data for an individual,
.fast response for simple human interactive (eg. editing) tasks.

SUBJECT: MAKING COST-EFFECTIVE PC'S. LIKE SONY?

The SEG proposal to get a chip of the month out is vital to our success. The recent Sony announcement very likely is a result of intensive custom LSI. Note that they use VAX's and 4 years ago when I visited were already doing much custom work for consumer electronics. Their president, Iwama, was proud of the fact he had worked with Leo Esaki and that Sony was the first to pick up the Western Electric patents.

If you look at their recent, portable stuff, it is really VLSI intensive and probably CMOS to boot. It would not be a surprise if this is what it's all about.

Recently Avram showed that we have 2 x the chips as the IBM PC. We do more, but the issue may come to cost, reliablity and uniqueness or not. In this case, IBM probably had no customs. Clearly guys like Apple don't use customs, or if they do it's joint with another vendor.

Right now we are in an abyss that the chip a month program has to get us out of:

1. We believe we can do our own chips, yet we don't
2. We've cut ourselves off with working with the outside to any great degree

3. We don't use standard chips because of our uniqueness needs
4. We've stopped outside customs that gave us uniquenss in the vt100 and la120

SEG is going to need help and every product group is resposnible
for its own competitive destiny, without having the right skills, attitudes and sufficent targets.

Now that we have the PWB and cabinet turnaround times down, using the QTA, we have to have a CQTA!

Avram, What's your guess here vis a vis looking at their Typecorder and Word Processor? Is the Sony PC another breakthrough in cost and functionality?

SUBJECT: PDP-11 PROGRAM ENVIRONMENT ON VMS

Several events have prompted the following proposal:

1. Wondering what a 370 in a terminal would be and do, vis a vis use with a large 370 mainframe.

2. Speculating significantly better software support systems for our microprocessor systems. (Also noting that Intel is supporting their 8086's on VMS...smart people.)

3. Terrified at building the KO Jr. (65Kbyte + 2 - 200 Kbyte disks) and KO Sr. (256Kbyte + disks + 5 Mbyte disks) software on them.

4. Thinking about how we might get rid of 7000 PDT 150's.

5. Wondering how to build and debug software for intelligent terminals (especially the new ones for the commercial group).

6. Thinking how vax on a chip and in a terminal would work with a centrally supported type vax. Wishing that 11's were vax's, but remembering that vax does execute 11 programs damn fast.

Fundamentally, I'm proposing a bare, full function, virtual 11 environment for building 11 programs on vms. In addition, it might be sufficiently good so as to be useful for executing particular programs in production mode...though not a goal.

It would look like a simulator that was used at one time on the 10 to do 11 development before there was 11 software, and have:

1. The mass storage, terminals, and communications to vax with processor, including interrupts. It would run at faster than 11 speed for the small processors. Most likely it would have a terminal to control it and a terminal simulating the real one.

2. Software environment to load, run and debug programs in the simulated environment. It would allow monitoring of the whole state including the files and comm lines.

3. Ability to load and monitor a real 11 when ready.

4. Fallback of a really good monitoring and support capability enabling control of a real, local 11 such as the KO or PDT or computer on a board (a harder case). This is double, but still tricky cause it requires vms to have a monitor to access all the state of the system and to be able to have breakpoints, etc.

It would be aimed at applications 2-5 above, especially 3 & 5.

What's the chance of getting something like this together out of the SSC effort in order to support the effort on getting lots of software quickly for the PDT 150, and the KO?

What would it have precisely?

Would it really make things a lot more productive...not

waiting for
disks, assemblies, etc. or having to have the software development
environment anywhere near the thing being developed?

What youse think?

follow up 3/9/79

I hear that we have all but announced this. What's the story? Why was this announced without Marketing Committee approval?

What are our options now?

Can we delay announcement and get the PAX in it (especially since there's a problem in semiconductor capacity)?

Certainly we don't need the 11/24 early...and, can we save some engineering money? We do need Fonz to be built in to other products. Could we give them high priority?

SUBJECT: KEN'S COMMERCIAL 11/23 PACKAGE

I hope you'll keep abreast of this. It looks interesting (provided we can remove the contact paper). If we do it, it should offer a significant payoff in terms of cost. The big saving I see is making the long box in a high volume plant
and then shipping the manuals, software (on disks) and frame from FAT. The disk drives would come directly from high volume.

The site merge of the parts would cut the inventory and wip down considerably. (It's too bad we simply don't simply assign an inventory carrying charge to PL's to encourage them to do the right thing.)

The package should be able to handle a 23B 9 slot backplane. We also might consider taking the DF03 modems out of their boxes and use a single PS (if the 23 one will do it), to further clean up and cost reduce the whole system.

Am anxious to see what the costs and a working system would look like.
gordon

Subject: **Post Mortem on 11/70 CIS**

To: Bill Demmer, TW/D19 Date: 3/12/79

Dave Rodgers, TW/C04 From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

I hope in putting the 11/70 with CIS away, you will write-up a history as you understand it. As I go back many years on this project, I find us always pushing against doing the extensions. This is understandable. However, some of the marketing people occasionally say this has been the problem on the project. My analysis is somewhat different, I believe any machine or architecture can be extended once. In this case, the extension was the second/third one beyond the original 11/45 and well beyond the range of the design options due to nature of the two extensions. Alternatively, was it because of two design options for mP and CIS?

We (I especially) learn from history. Is it too painful or too useless to try to make an internal history of the project that we can all learn from in the future?

Bill Strecker, TW/A08
Mike Titelbaum, ML1-2/E65
Roy Moffa, ML1-2/H26

Although there are many arguments why we have to carry out this expensive chip development effort, the following summarizes my thoughts:

1. It's a classic follow-on, constant cost product for our module (DCG) business. Here, we have a large base built on the 03 ('75), and 23/24 ('79). Jaws (the proposed 11/70 on a chip), available in '82 would support this large, user base.

2. It would be used in many places as a major cost reduction. As an 11/70, the cost reduction at just the box (no memory) would be in the order of 9K! No other cost reduction project could get anywhere near this leverage.

3. There will be some obvious uses for it as it becomes available, based on the fact that the Fonz chips will create markets internally. These include use in the mass storage controllers, Hydra front end (Mercury), as special speech and signal processors, and the terminals (e.g., graphics) evolve to need this kind of power by then.

4. There will be many uses for standard 11 systems at the lower cost put in highly integrated systems. These would run RSTS, SCS, RSX, and TRAX.

5. It is the way to build our systems in this time frame using one engine. In retrospect, we could have probably avoided the 11/44 and covered the space with an 11/24 if the memory

space were extended to >128KW. The speed of the Fonz is adequate, but the memory space is not. A similar situation will no doubt exist as the need for the 11/44 follow-on (called 11/XX) is identified. This is the way to do it.

6. Just as the 8 is the really low end now, so too will be the 11 until we get the price of VAX systems down. I don't see this happening until '85 or so.

7. By identifying it, hopefully we can avoid doing enhancements to the Fonz.

8. It is getting to be clear that we can't get a VLSI-VAX in this time frame. The specific details will be forthcoming on VAX as we learn how difficult the project is. This is both a hardware and a software base maturity issue.

SUBJECT: WHAT IF THE 780 WERE REALIZED USING MCA'S OR NEW TTL/FAST LOGIC?

Let's talk tomorrow. Bob has been off doing a quick study as to how fast an MCA translitteration of the 780 would run. His rough answer: 2.5 x a 780. If we had done this, it would have shipped 2 years before venus, at a small fraction of the development and start-up costs. I am concerned that we don't understand how to compute time/cost/performance (that's why I wrote the little essay in Computer Engineering whichh apparently no one read). Anyway, the bottom line is that a 780/mca would have roughly a price/performance ratio of 250K/2.5 or 100K, where the 780 is the standard base. Venus will have price/perf. of 320K/4 or 80K. Since this ratio should get better at .8 per year, then a 2 year delay should be .8 x .8 or .64 either lower cost or higher performance.

The point of this is: We seemed to have screwed up in not making this product. Now, with some faster TTL coming out, maybe we could do a direct substitution of FAST ttl and get a speedup of say 2, with virtually no redesign, but by using the new parts.

Could you look at this one?

I think we ought to spend a little more time on the mca version too and see if the Stewart numbers can be improved any. I think these should be kept alive until there is some better feeling about Venus.

GB2.S6.50

Mr. Alec Peltier 15 August 1980
Special Assistant to Counsel General
Operations Branch
American Embassy
London
England

Dear Mr. Peltier:

Reference your conversation with Richard Goldstein on August 15 regarding Dr. Maurice Wilkes. I wish to extend my personal appreciation for your efforts on this matter.

I am writing to explain our situation regarding Professor Maurice V. Wilkes with whom we have made arrangements to join the staff of our Corporate Research Group.

Professor Wilkes has been a towering figure in computer engineering and computer science from the invention of computers until the present day. He is one of the small handful of men who originated the modern computer; he was personally responsible for the construction of EDSAC 1 which was working in May 1949. Some of the concepts first proposed by him, such as "microprogramming," have continued to grow in importance until today virtually all computers manufactured in the world are designed using this technique which he created.

For the last decade Professor Wilkes has been Head of the Computer Laboratory at the University of Cambridge (England), where he was previously Director of the Mathematical Laboratory for a quarter of a century. I will not attempt to list all of the honors and awards which he has received over the years; this information is available from standard reference works such as <u>Who's Who</u>. Suffice it to say that he has been one of the intellectual leaders and respected senior statesman in computing for the last three decades. He is a Fellow of the Royal Society, a Fellow of the Institute of

Electrical and Electronics Engineers, a Fellow of the British Computer Society, of which he was the first President, and a foreign associate of the U.S. National Academy of Engineering. He received the Turing Award and the Harry Goode Memorial Award, two of the highest honors in American computing. He has received honorary Doctorates from five universities in three countries, together with other honors from around the world, including recently being named as a foreign associate of the U. S. Academy of Sciences. In summary, he is a distinguished scientist and engineer of world reputation, possessing unique background and qualifications not available elsewhere.

Dr. Wilkes is urgently needed to run our research program on techniques for making computer systems more secure. This program is not only important for us as a major computer manufacturer, but also may have a significant impact on U.S. leadership in computer technology throughout the world. Dr. Wilkes' presence is necessary to move this work forward. Also, we need his interaction and leadership across all our research.

Dr. Wilkes is scheduled to leave England the last week of August and will start to work here September 2. He has made all personal arrangements including letting his house in London and renting a house here in Massachusetts. We were lead to believe several months ago that his visa was in order but he was told by your office a few days ago that it would be 1 to 3 months before he could get his permanent visa. This is totally unacceptable. Please check into this urgent matter, expedite, and return TWX the status of this situation. Your help is most urgently requested in this matter.

I have known and interacted with Dr. Wilkes for many years. We need him here. Won't you please, please help us? What other information do you need? I will be calling you and Dr. Brewster after you have received this.

Sincerely,

Gordon Bell

SUBJ: People to Place

TO: John Meyer Date: 7/10/78
From: Gordon Bell
CC: OOD Dept: Office of Development
MS: ML12/A51 Ext: 2236

There are a number of people casting about for jobs either within OOD or in other parts of the organization. These are the ones I'm aware of:

1. Bruce--try Stan or Larry's (commercial organization). We discussed a job with systems (hardware and software responsibility). Also a job with customer/end use would be preferable. He needs to know how to motivate a set of unrelated projects...as distinct from a highly focused program which I believe he could successfully manage.

2. Stan Pearson--I don't know. Somehow we aren't giving him the strokes here. I've been awfully impressed with what he is doing in the RAD committee for example, but we've signalled that he has to go to line management. I believe we desperately need him in the planning role and we have to make this rewarding.

3. Peter Jessel--I can't tell what he wants to do. I believe he is good in focussed Advanced Development and might be good in R and D. Ulf should talk to him, as Jim has been unable to do anything. Whatever Dick is going to do the small systems areas might create a need. I said talk to both Dick and Bill regarding the systems job. (Here my reasoning is that if Dick's only customer is Bill,

maybe he should turn the function over to Bill.) Also, Peter might like to get more involved in end use (DCG, Stan, Commercial) as he believes the realignment will be more useful to product definition. He is also talking to Telco.

There are undoubtedly more. Please make a list of other people...the unhappy or the groping. Assign them to various people. I am tired of losing people who get in this mode and that we make find themselves. I expect them to be settled in or out of their current jobs by the first of September.

Subject: **Doing Business With The People's Republic of China**

To: Carl Janzen, AK
Ted Johnson, PK3-2/A55

Date: 26 JAN 79
From: Jean Bow
Loc: PK1/E33

As a DEC employee, I would like to support DEC and help you in deciding about, and hopefully doing business in China. I'm going to China April 11 for one month and could present DEC products and meet people.

I understand from Gordon Bell that you are formulating our trade policy and that you will meet with me in regard to a possible assignment.

Should DEC Try to do Business with China?

Yes. China's desire to modernize her industry, agriculture, science and medicine via western technology has opened up a vast potential market for DEC. I believe DEC has the unique know-how and adaptability in building special systems (hardware and software) to solve difficult problems. Indeed, China has many difficult problems at present that could be solved by the innovative use of computers. Therefore, China should be given a chance to listen to what DEC has to offer prior to her commitment to our competitors, both U.S. and Japanese.

Making Contact

The purpose of my forthcoming trip to China is to visit my family, whom I have not seen for 30 years. I also intend to visit government research centers, universities, laboratories, hospitals and manufacturers. I am prepared to take courses here, if necessary, and give informal lectures on the practical aspects of our computers and how to use them. I do have a technical background as you can see (attached). For example, how to organize and manage computer data centers, how to teach practical mini courses on using computer software, and the difference between university and business data centers, etc. I will have opportunities to establish contacts and personal rapport with various key Chinese personnel. In addition, I will be able to plan and establish contacts in advance from Boston as soon as you can give me some guidance. Please take advantage of my enthusiasm. I want to help.

DOCNO8/21

Digital **Interoffice Memo**

Subject: **Peripheral Buy Out/Getting Co-operative Vendors:Versetec Case Study**

To: Distribution

Date: 20 SEP 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

F/U 9/28

Given our limited resources, particularly in PL Engineering, F.S. and Software Support, I'd like to suggest we limit our product offering higher volume, supported products. This would have precluded our offering the Versetec printer, for example.

0. We don't make much on it, and it adversely affects PLC.
1. It's expensive for the graphics user.
2. Customers don't buy it because it's too expensive.
3. We don't support it well because we don't have good margins (i.e., both poor hardware and software).
4. Versetec has a good product with hardware and software support.
5. We offer the obsolete (100 pt) version.

Therefore:

LET'S NOT DISTRIBUTE THE VERSETEC PRINTER BUT LET'S HELP THEM SUPPLY PRINTERS TO OUR COMPUTERS!

Everybody wins! Also we could offer Calcomp plotters in this same way.

Instead of adding a new printer to the VS60, let's co-operate to get a good product that we do not make. What other

products should be bought/attached out?
Why not just offer this and not process it through our books?

SUBJECT: GEORGE IS PROBABLY RIGHT

Somehow we have to get the personal VAX project going quickly in order to deal with this problem of one-ness and the built-in complexity that it might imply. The intent of the single VMS is to be able to run a program at any level so as to preserve programs, and more importantly data across the various systems. The thing that can vary is the user interface and the packaging of the system and the documentation to reflect the specific uses of the variations.

George is absolutely right on the evolution of a complex system.
It implies tons of manuals, and expensive system programmer experts, high support and massive overheads that only the CS depts can afford because the people are free and can deal with the complexity. Also, large organizations want them
to keep their staffs challenged.

Personally, I have had waged and lost all the battles in this regard by trying to get a manual written for a user (here, I have wanted to try the simple experiment of putting all you need to know if all you know is APL, BASIC, PASCAL, or Fortan,
and simply want to login, create, run (with a library), and debug your program in a single manual). This would have made VAX simple for all who touch it in 95% of the cases. Alas, it
doesn't cover all the intricies of the file system, loader, debugging, writing macro programs, user defined commands, and administering the system. Not only have I lost the battle, but
I found out that we can't even get manuals like this written because the typesetting system and writers are not enough in control of their words that it is a 2+ year project...instead of simply moving a few files from previous manuals around. We
are somewhere in the early 1970's in our manual writing and typesetting capability it feels like.

Yes...we need some work here, and a plan. The systems organizations
as we have them now will never deal with this cause there are hundreds of other issues like Dock Merge that have to be dealt
with. Somehow it is in the domain of the Technical Director of
SW, and we need real leadership here to keep us from going down the current path that will inevitably mean a set of new systems to cope with the complexity.

PS
The IBM approach ain't right...cause it means no movement of computing styles, files, programs, and a mess in the complexity due to the fact that SNA won't be that good in solving the Interconnect problem. I still believe in the concept of where we could go, but it takes a belief and design to do it. The personal VAX is a start.
... assuming it starts someday. (The test is how big the manuals
are.)

George, I'm delighted you have bought some programs from the outside and potentially have saved us t to mkt and precious development resources. Given that we share a common problem/
vision here, how can you in addition help guide us?

Anybody worried about this besides George and I?

SUBJECT: RE. DEC UNIQUENESS

Read your note and will throw out a couple of comments-

Think we're striving for ease of use for our large customers by
expanding on the generality of the Operating System so as to minimize their training,networking, interchange, etc, problems.
Unfortunately a by-product of generality is to give up some

of
the "approachable,friendly, and easy to use" characteristics
that the single function user can have in 11 Land (single
user
is RT-11, T/S is RSTS, multi programmed real time is RSX...)I
suspect that a large part of this ease of use is in the
manuals
which are describing a smaller functionality and are therefor
easier to read....

It's worrisome in terms of the single function prospect that
we're putting so many eggs into the one Operating System
approach
which by definition is more complex than a system dedicated
to a
subset of the universe. The system your data base prospect
gets
will not only be able to run DBMS-32 but also Transaction
Processing, Real Time, Time Sharing, etc which is great for
the
General Motors Programming Shop but complicates life for the
single function guy. Maybe what's needed most is really good
Tech
Writers who produce sets of single function system manuals?

It's even more worrisome that IBM seems to be trying to get
where
we came from: the image of the S38 is Data Base; the 8100 is
Real
Time; the 4300 is GP; etc. And they seem to feel that SNA
will solve
all their compatibility problems? At any rate it seems
intuitively
clear to me that whatever DB system you may develop on VMS
just
has to be more complicated than say the S38 with its more
narrow focus.Better manuals and prebuilt systems can help,
but....

Maybe you've guessed by now that I question the one Operating
System approach; you're right I do! On the other hand I don't
advocate the chaos of the 11 Land where Operating Systems

continue to proliferate, but rather a rigidly planned set of compatible, functional subsets of VMS. I would think this would
return "ease of use" to the single function user while VMS would
continue to be the GP system needed by the GM's of the world.

I'll also question the notion that 1 OS is easier to maintain than
several(when blaspheming why not go all the way). I'll argue that
there's a powerful synergism of complexity that more than makes up
for the extra drivers and manuals. In five years we're going to
need some pretty smart people to maintain VMS (Remember when OS370
went critical; ie fixing 1 bug was introducing 1.x bugs? or when
the TOPS-10 solution was to throw away 1000 SPR reports?)

In sum then I'm suggesting that the multi function capability required by the one Operating System approach promotes ease of
use for our large customers at the corporate levels but has to
cost the single function user in terms of complexity. We can mitigate this to an extent with prebuilding systems and more precisely focusing our manuals but nothing's free;controlled additions to the O/S lineup could help on the ease of use axis.

Regards

SUBJ: NOMINATION: BILL JOHNSON, VICE PRESIDENT OF SOFTWARE ENGINEERING

TO: OPERATIONS COMMITTEE

Date: 2/16/82 Tue 9:46
From: Gordon Bell & Jack Smith
MS: ML12-1/A51 Ext: 223-2236

We would like to recommend that Bill Johnson be appointed Vice President of Software Engineering. BJ fulfils the agreed upon criteria*.

BJ has the largest engineering group, and due to the complexity of the interconnection of the components has the most difficult management job. In this regard, we are known for quality and creatively compatible systems. He is an excellent manager, managing by inspection, and knows what goes on in the products and within the projects.

The recent announcements of the 782, VAX Information Architecture, and Office are indicative of the performance of our creative and productive software engineering group.

BJ is pivotal to our product future.

Due to BJ's wide experience in both hardware and software engineering, he is a widely sought after person. He can handle a wide variety of future assignments.

*   "<u>Officer Criteria</u>

Past (a) sustained, excellent performance in key positions

(b) major contributions to DEC

Future

(c) <u>strong belief that person will make contributions in future</u>

<u>Future factor is the most critical</u>."

CANDIDATE: Bill (B.J.) Johnson Sponsor: Gordon Bell

Jack Smith

CURRENT POSITION: Manager of Software Engineering

ACCOMPLISHMENTS: B.J. has been our fast track performer; in rapid succession he has been Manager of Diagnostic Programming, Technology Director for Central Engineering, and Manager of software Engineering. In all of these roles he has demonstrated leadership and strong technical and organizational skills. His role in software is to manage the largest, most complex (organizationally) Engineering group. He has increased focus in quality and advanced development, and software methodology.

He has put into effective operation Reading and DECwest. We believe that all groups are operating very effectively.

FUTURE: B.J. will continue to be a fast track performer. He is rapidly acquiring a broad perspective of DEC's business which when allied with his hardware and software technical skills makes him extremely valuable.

SUBJECT: HIRING FROM WITHIN AND WITHOUT, AND OUT-PLACEMENT

Bill Thompson really probed at me on the issue of approving many hires. I've been doing it, assuming that you folks are doing this within budget! At the same time, I know that we are going to have to let some people go, if things continue to deteriorate bookings-wise. Jack is dealing with his group and I'm approving the Nautilus expansion. I also approved a very strong technical person (and manager) for Sam, along with the 6 people for the California startup.

I had a request for a former general manager and VP which I think both Jack and I should look at, cause it looks like there will be good managers available with similar experience within DEC. It's unclear as to the quality because the person had been running their videodisc effort and hence I'd question his technical judgement and esthetics. The OC is asking members to identify high quality people for reassignment. They are also asking for the budget to be made 2 ways for FY83: one as is; one if some of the marginal people can be identified and put in a holding place for reassignment. This should also be done for engineering too.

In short, we gotta really put on the brakes. There are many people that are going to be identified for reassignment that we might have and that we want transferred. We do have to keep our commitment to the colleges and strong technical contributors because they are what really make the products.

Any managers are going to have to be screened thoroughly, and unless they possess very strong technical skills, I don't intend to approve them.

LARRY PORTNER

FROM: GORDON BELL
DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: A PROPOSAL FOR EVALUATION OF DIRECT REPORTS IN JUNE

We recently evaluated the direct reports within engineering using the salary, proposed salary, and proposed stock. In addition, Don Ames provided the stock value available in 1982 on an if sold basis, treating all past stock grants as compensation. The data was suprising and useful! In addition, I believe we should have the total value of all remaining stock to be used as a guide.

We asked each person to rank order their candidates together with the justification of the stock shares. The criteria used were:

1 exceptional performance
2 criticality to continued success and who were not proportionally compensated or recognized
3 position in the organization and who might receive stock assuming they were doing an adequate job

The method we used for the evaluation was to:

1 have each person present their candidates in order of importance (what amounts to the LAST person that one would throw out of a lifeboat)
2 have the whole group comment on the candidates and collectively decide on the shares for the candidate. This of course required additional stock shares.
3 these new requirements were then merged back into the initial list so that we could compare across organizations, and
4 finally we made a single pass of the complete list from the largest number to the smallest number. At this time, the total number was reduced, as we found there were persons within each group that were reduced (this amounts to finding persons we didn't need in the boat at all).

We found that the past data was useful in a several cases: there were critical persons we always want in the boat with us and who are neither compensated very well nor who have many shares. Also, there were a bunch of harmless folks with us who are doing little to move the boat, and who would probably not be missed if they fell overboard. In fact, we found that we were paying some riders $120K, while our key people were only getting $60K. Since the initial recommendations were to add some more to the riders, in proportion to their position in the organization, the final recommendations came out nothing like this.

Therefore, I propose that in the June meeting, we come with the

personnel list which includes: name, salary, proposed salary, percent increase, rating, stock compensation this coming year,
remaining stock compensation for all following years, and the proposed stock grants, together with the justification as to why
each person occupies the critical position in the boat.

I recommend that we use a similar procedure in June.

Gordon

In addition, we observed that stock value to a person varies by a
factor of 20 to 40. If a person is really committed to DEC, then
the value is at least the spread x 10 x (2 - 4), or 15K to 30K
per 100 shares! If the person isn't committed, the value is only
the spread he can sell next year, or about $750. When we
ultimately grant the stock, we should accompany it with a sales
pitch!

SUBJECT: 16-BIT PROGRAM OFFICE MANAGER

We are very pleased to announce the appointment of Mike Gutman as
Manager of the PDP-11 Program Office reporting directly to Gordon
Bell and Larry Portner.

The Program Office covers the development of all PDP-11 based products from microprocessors to large systems for technical, real time and commercial systems.

The PDP-11 Program Office will be responsible for determining the
strategies for PDP-11 products, the line management of QBus and
Ubus hardware development and support, and the resource allocation of all hardware and software projects.

There will be a transition period as Mike works out of his current job in Storage Systems and he will take over the Program
Office on a full-time basis by the start of the 1982 fiscal year.
Mike will be announcing the PDP-11 Program Office organization at
a later date.

Mike came to Digital 7 years ago to help found the Components Group. For 3 years, he was Product Manager and then Engineering
Manager of the Memory Systems Group. For the last 3 years, he
has been Storage Group Product Manager.

He received both his Bachelors and Masters degrees in Electrical
Engineering from Worcester Poly Tech. He and his wife Lois have
4 daughters and reside in Framingham.

We look forward to seeing Mike in this challenging and demanding role and hope he can count on your support.

ALAN KOTOK
BILL STRECKER

SUBJECT: RE: PROMOTING CRAIG MUDGE TO SENIOR CONSULTANT

The criteria in my head is two, significant technical accomplishments. Strecker (11/70, memory hierarchies modelling
general case, and vax architecture), Kotok(10 architecture guidance, our telephone system, many 10 implementations, and the ecl gate array push), Cutler (11/M, VMS and now a new compiler technology that promises to be backbone of much of future compilers). I would like to meet with the senior consultants on this and maybe go over names of all the people we have that fit this highest category. Believe he has done very solid work on the 60 FP and WCS, and Nebula advanced development, and in Managing the cal tech inteface including the idea of formal ports. Although I don't believe we have to wait for Scorpio, I do believe the transfer of the MOS work into production this year could constitute a second major accomplishment. Certainly the book was useful too.

This issue is so hot that I want you to keep pushing but I think it is essential to get with the Senior Consulting Engineers to get a bit more formality. I'll get this set up quick!

Senior Consultants how do you feel on this?
Who are we missing?
What do you think the criteria should be?
(Note, I'm putting some pretty strenuous criteria that goes beyond promotion of full professor with tenure in the academic
world.)

I also consider both Riggle and Fred Hertrich to be fitting of the title, although Mike has a manager's title and Fred isn't in the company.

PLEASE LET'S JUST KEEP THESE MEMOS VERY, VERY CLOSE TO OUR BODIES AND POSSIBLY NOT MAKE COPIES OF THEM!

Can we try exploring this a bit more this way and then get together? Also, how about a telephone conference tomorrow?

GB1.S2.11

THE BASIS OF SUPERCOMPUTERS:
SEMICONDUCTOR AND PACKAGING TECHNOLOGY

RELATIONSHIP OF SEMICONDUCTOR AND PACKAGING TECHNOLOGY TO PERFORMANCE

Semiconductor logic circuits and memory chips and the ability to interconnect them densely is the basis for today's pipelined supercomputers. For the last 20 years, Cray has taken "off the shelf" transistors and integrated circuits and packaged them creatively, forming a very dense structure to achieve the fastest speed clocks and therefore, the fastest computers. In addition, Cray has also organized his computers from a number of computers, processors and functional units to operate in parallel, giving greater performance.

For machines just being characterized, the Cray X-MP (a quad, multiprocessor) and the Fujitsu V-200, the clocks are 9.5 ns. and 7.5 ns respectively. The peak performance of the V-200 is about twice the Cray uniprocessor for the Livermore loops. The speed difference is probably attributable to a better vectorizing compiler for the V-200. The clock difference is due to Fujitsu's impressive semiconductor technology and the packaging capablity evolved from Amdahl. The X-MP is simply an evolution of the low density semiconductors used in the Cray 1. Virtually all computers today use Japanese high speed MOS and CMOS memories.

A Cray 2 uniprocessor, appears to be a breadboard for the Cray 3, and will be delivered soon to Livermore. It uses the fluorocarbon cooling bath and has a 4 ns. clock. The commercial version, the Cray 3 might be ready by '86. NEC's machine which will be introduced next year has a 6 ns. clock. Cray is currently exploring GaAs for increased speed and lower power.

Since the V-200 is IBM compatible, with a large virtual memory, Fujitsu is likely to create a new market, and begin a major erosion of the U.S. dominated supercomputer market unless the X-MP can be parallel processed, or new, faster models introduced quickly. Because the V-200 and corresponding Hitachi machines are IBM compatible, they will make an impact on supercomputers as we have known them.

THE JAPANESE POSITION IN SEMICONDUCTORS

Japan's semiconductor technology lead is increasing. All major manufacturers have operated submicron facilities for up to three years. Since these facilities represent a discontinuity in equipment for cleanliness, lithography, handling, etc., semiconductors are likely to be our technological blindside unless a major discontinuity is introduced to offset their effort. Today, the Japanese have closed the gap in manufacturing equipment by introducing their own, non-exportable equipment. The tight coupling between producer and consumer of semiconductors within a single company in Japan is also another interesting facet.

Note the situation in these directly critical semiconductor areas:

1. CMOS for RAM and gate arrays; Japan is several years ahead because U. S. suppliers were slow to make the transition from NMOS to CMOS. The best U. S. gate array supplier, LSI Logic, uses Toshiba chips. Toshiba has the most advanced CMOS facilities today in both manufacturing and research.

   While today's supercomputers are not CMOS based, one company, ETL is basing its future on a large, CMOS gate array.

2. evolution of ECL; Current and projected ECL gate arrays have continued to outperform U.S. produced devices. While efforts in this area are decreasing, evolutionary devices could enable the current Japanese supercomputers to be "evolved" again with relative ease.

3. revolutionary HEMT and revolutionary GaAs devices; The Japanese continue to build and describe high speed circuits at various conferences. Cray is working with GaAs; however, chip manufacturers are required to make the technology viable.

4. packaging; Trilogy's ECL circuits and packaging represented the most advanced design, but is currently "on hold" because of the company developed a design

that went beyond their ability to manage and process the complex design. Only a few efforts exist outside of IBM and are aimed at the necessary interconnect and packaging densities.

While not directly relevant, these areas are of similar importance:

5. <u>conventional microprocessors;</u> These are dominated by U. S. "Semicomputer" manufacturers quite likely because the Japanese are unwilling to make the architectural and software investments when the return is so low. It is much easier to copy the architectures and produce compatible chips.

<u>Microprocessor Opportunity and Potential Blindside</u>

Because of the low cost, reasonable speed (compared with minis and mainframes) and rapid rate of progress compared to conventional computers, the microprocessor represents two technological opportunities that could impact supercomputers and represents a unique opportunity for the U.S.:

5a. The PC provides about the same number of floating point operations per dollar as a Cray for a number of scientific problems, whereas a mainframe is an order of magnitude more expensive. High performance, scientifically oriented micros, would provide cost-effective computation for a much wider class of users, and it could reduce the dependence of some supercomputer users by offering an order of magnitude better performance/price.

5b. A substantial number of multiprocessors have been built which provide substantially better performance/price than large computers. Also, several multiprocessor computers have been built which provide performance that deliver power in the same range as supercomputers, but at substantially lower prices.

6. <u>microprocessor peripherals;</u> While not directly relevant to supercomputers, peripherals indicate the state of the art in design complexity. Many of the

major chips are designed in Japan such as the NEC graphics and disk controllers for the IBM PC.

7. Computer Aided Design: CAD has been developed by U. S. Universities. The programs move almost instantaneously across all borders, creating an even more powerful industry in Japan.

Today's CAD systems are aimed at chips or small, board-level systems. CAD for large systems appear to grow exponentially in complexity and size. An opportunity exists in this area, if simpler methods can be found to deal with the large system size without increasing the CAD or designer complexity. In this way a larger number of ideas could be explored without requiring the massive engineering resources of the large, Japanese companies.

8. electro-optical technology; Some effort should be made to access the likelihood that this technology offers for both computation and for interconnections.

RECOMMENDATIONS TO MOVE TO TECHNOLOGICAL PARITY

Several alternatives have been suggested to establish submicron facilities, beyond those at AT&T and IBM. The Semiconductor Industry Association, SIA, has recently focused on long term research through its research company, SRC which is supporting basic research in universities (and supplying additional engineers).

If the technology for future supercomputers will come from the SIA member companies following an evolutionary path based on CMOS, then the current direction must be acclerated. If the technology requires evolutionary materials and circuits, then an additional effort is required because of the commodity focus of the semiconductor industry.

We recommend following as many of the following alternatives as possible:

1. Startups. An entrepreneurial energy driven, industrial/venture capital financed company, such as Picotech, proposed by Integrated Circuit Engineering Corp., ICE, a market research firm in Phoenix. This would be located in the New Jersey and New York area and presumbably "pull" technical people from AT&T, IBM, RCA Labs, etc. to produced 0.5 and 0.25 micron chips. With the right leaders, this would could be the "best" solution. A facility in Silicon Valley would lack people with submicron experience.

1a.Picotech, Japan would be an interesting alternative. A company would be formed in Japan which would draw on the experienced semiconductor leaders and utilize Japanese process equipment.

2. An SRC or national effort.

a. Form an effort as part of, but in addition to, Microelectronics Center of North Carolina, MCNC done in conjunction with Semiconductor Research Company, SRC.

b. Some other SRC initiative directed at an aggressive submicron chip facility.

c. A National Laboratory for Submicron Device Circuits.

3. Synergy with VHSIC Phase 2. Use VHSIC's second stage results which are targetted at producing the first 0.5 micron chips beginning in two years. The first VHSIC phase obtained 1.25 micron chips within a 3 year timeframe because this was simply a transfer of technology from commercial advanced development to an expensive military line where the government can pay an order of magnitude more for chips. Since current facilities are not in place for submicron fabrication, the effort is unlikely to be successful in time for making competitive supercomputers.

4. Industry. An incentive program which would establish submicron facilities in ALL current semiconductor vendors who are working on high speed circuitry. A special effort should be directed at sorting out the viability and timing of GaAs. If VHSIC is involved in GaAs, the experience gained in this effort should be made available to the commercial industry in order to have cost-effective chips.

5. CAD aimed at small systems could be extended for sets of chips which are necessary for supercomputers.

6. Revolutionary, But Trivial Microprocessors for PCs and Multis. Providing substantially better microprocessors than currently exist or are likely to evolve. The evolution of microprocessors from Intel, Motorola and National has been slow. The key parameters for building effective computers are address size and floating point performance have improved much slower than the semiconductor parameters would predict. The architecture for micros has followed the time worn evolutionary paths of minis and mainframes, and this is not appropriate now because the memory speed and internal clock times for micros are almost identical, given a poor mismatch between processor and memory.

Today's micros need to be abandoned and a simpler load/store architecture that is characteristic of the Cray designs is needed, but with floating point arithmetic and large virtual address. Both Stanford and Berkeley have built the MIPS and RISC chi

Dear Ms. Pickett:

Ken handed me your letter. Bob Puffer, of our organization, has responsibility for the mill and I'm sure would be delighted to walk around the mill pond and mill with you. In particular, to see the restoration we've done. It's been the subject of several architectural studies.

We're delighted that you're interested in solving our parking problem and want to get your ideas.

You may be interested in the history. Enclosed are two pamphlets our project printed.

Sincerely,

Gordon Bell
Vice President,
Engineering

Follow-Up: 7/9/79

Several of us visited ATT's Picturephone Meeting room in Boston. It is one of a dozen (Atl, Bos, Chi, Det, La, Ny, Phl, Pgh, Sf, Wdc) or so linked together by full duplex color video channels. Apparently up to 4 of the rooms can be connected for an even larger conference. The cost per hour varies from about $150 to $390 (NY to LA).

The rooms hold 6 at a table, plus about 10 in a row behind, and another row of chairs can be installed. Apparently 24 have made it in a room, assuming the air conditioning is on better than when we visited. It has the following:

. 3 cameras that are voice actuated that cover pairs of the 6 at the table
. 1 camera to give a panorama of the room, when no one is speaking
. 1 camera with tilt and zoom to cover a presentor at a

whiteboard area
. 1 camera with zoom to cover back or top lighted viewgraphs or opaque stuff
. 1 camera on a slide projector
. 1 camera can be brought into the room for special use
. a tv videorecorder for input or recording the proceedings of a channel
. a Tektronix hardcopy output of the incoming channel
. several consoles where the camera channels can be selected
. 2 tv screens for viewing incoming and outgoing video

Each of the participants wears a neck mike, hence there is great audio. The numerous cameras make for lots of action to hold attention of the conferees. The person who manages a transmission has little to do, and in fact can do nothing and the voice actuation and presentor can do it all. This means there's not another person in the room to manage the conferencing.

I talked to people at BTL Friday and discussed the changes to subsequent rooms. Hitachi is building a digital encoder to get the color tv down to 5 MBS so it can use the regular network. There was some notion of a large (60") screen, which seems essential because the 2 TV screens were only 25" or so. Also, it would be worthwhile having some automatic or easy to use videomixing so that static material such as slides or viewgraphs can be mixed with the conferees.

What I would like to see:

. Let's make a concerted attempt to use the existing videoconference facility of AT&T's...and log our reactions, find out its use and limitations.

. Put in place these rooms as per what BTL will provide and a network among the NE sites assuming it pays on the basis of transportation costs (the worst case).

. Work with BTL to see just whether we can get down to a cheap, 50 bps link so that it can also be used among widely separated domestic facilities (eg. ML-CX).

AT&T hypes it for: product introduction and sales, especially to multiple sites; personnel interviews...it looks very good for this in certain cases where the interviewee has a hard time coming to visit; design reviews and technical problem solving between two groups; staff meetings such as regional sales or service (note with 4 sites, the travel time could be significantly reduced in our case). It has even been used for depositions.

Why can't these be identical in terms of power supply, electronics, and overall package? I assume they differ by a rom for the different positioners. I don't see why the form factors aren't identical such that either could be put in a cabinet slot.

What you say?

Certainly we must abide with PPC decision to not announce PL/1 or make a product commitment at DECUS.

Since we often describe R+D efforts, it seems totally appropriate to discuss your work as such and get feedback you might want.

I believe a talk on "The Structure of a PL/1 Compiler for VAX" or "PL/1 Code Generators for VAX" or "An Experimental PL/1 for VAX" would be good and should get on the program. Let's describe the work.

SUBJECT: HOW CAN WE GET A REALISTIC GEMINI/SCORPIO/NAUTILUS PLAN?

Having just looked at the potential competitors, it's clear that
they are based on the emerging 32-bit micros (Motorola and its
Japanes licensees, Intel, Zilog and its partner) which will
permit the construction of systems that are competitive with all
systems we build up to and including the 780 and multi-780's!
Also, these machines will be available BEFORE Gemini, Scorpio and
Nautiuls!

I'm not confident that we're going to get the competitive

machines of Gemini/Scorpio/Nautilus, even within the normal 6 quarter slip times. Is there a meaningful basis for producing
schedules since there are many undefined and very high risk parts? Is the management overcommitted too? We ought to not overlook these signs:

HUDSON

1. Tiny has had 5 passes and will require a complete redesign... it is also several years late.
2. J is behind schedule.
3. We were just surprised to have to design our own very complex rom/ram for the microcode. This a very advanced design.
4. BI looks like an even more risky and complex chip than the now 3 chips of Scorpio.
5. DECSIM has slipped and parts are one year late. It's needed.
6. We are behind in hiring and we are constantly adding people to maintain the schedule. A/D resources have to be used.
7. Plans and commitments are made independent of the doer because hiring is behind the commits (I.e. he who plans does not do).
8. A complex organization with lack of project role clarity.
9. All effort is on MOS, little involvement in the gate array.
10. Scorpio is the FIRST state of the art design we've tried.

PACKAGING, POWER AND PHYSICAL INTERCONNECT

1. Management is only by level of effort with no measureable programs.
2. No reporting of direction or progress outside the organization
3. No evidence as to doability of technology cause there's no communication or project.

MID RANGE SYSTEMS

1. Large FCC workload

2. A non-zero work backlog for CI, the 750 and other projects.
3. Lack of systems manufacturing interface and rapport (not critical until there is something to build)
4. Lack of recognition of the incredible work load ahead implied by the Gemini/Scorpio/Nautilus Program (too many CPU designers and no systems, and option module designers)
5. A PP/PI plan (wish) without a manufacturing engineer
6. A requirement for a sophisticated engineering process and no CAD gurus or managers
7. A basically arcane engineering process with process responsiblity buried 2-3 levels below Demmer
8. Lengthening project gestation times, giving less competitive products without the accompanying understanding
9. A Nautilus plan requiring the use of chips at the limit of their capability AND well beyond the needs that all other users will put them to. This was same problem with the MCA!
10.A Nautilus plan requiring a sophisticated CAD CHAS-like system for: drawing, communication, much checking (due to chip use), q/c, project scheduling, testing, etc.
11.A Nautilus plan of sufficient length to burn out people

WE HAVE MANY POSITIVES
The Hudson folks are working hard and are very good. Also, CHAS was just released on schedule and may be a breakthrough in tools that even MOS designers may use.

We have very talented designers, and they can do very good work if we don't overcommit and frustrate them. They can be frustrated by:
1. changes, false starts and lack of resources at the beginning,

2. a long project caused by poor planning and poor processes,
3. a long project because we can't get it manufactured.

The managers are very good with fine records of accomplishment both on technology and to schedule.

The architecture and the software are ready, and we have: VAX, VMS, BI, CI, NI and SI products. We have a SUVAX prototype. It is clear what components we must have. These are our real aces!

The system possiblities are quite clear, even though our planning is yet to catch up with this. (I don't advocate building a planning staff as it's too late.)

Bill,
I do not have an answer, but certainly have a concern about the enormous work load ahead and the underlap and overlap of organizations, products and projects... amounting to lack of clarity. None of the negatives taken alone are a problem, but the collection of them is frightening.

The project set is larger than the original VAX Project!!

We need to be calm. We need to understand. And, we need a believable plan!

SUBJECT: PLUTO'S GREAT. LET'S SELL IT WIDELY AS THE COMM.
COMPUTER!

It was great to see Pluto in operation yesterday. It looks
like
we finally have a Corporate communications server product
after
10 years of trying to get one. The mechanics too are a
landmark
and the ability to stack and have 96 lines in a small space
is
really great. We have a basis for future communications
system
products using the packaging to eliminate the intermediate
cables.

It's the first unpack and stack system.

It's clear to me we ought to consider selling it as a communications
computer in other than NI contexts without the UNA. In this regard
we'll clearly want the J in there as line speeds increase.
Also there'll be a demand for higher speed lines and doing
interfaces to high speed common carriers to couple LANs.
Similarly, you're planning the multidrop hdlc to get the cost
per terminal interfaced down even further.

I think it's time to take the cover off it and start talking to
people like the phone company and OEMs who need good communications
hardware. Clearly we ought to be able to clobber the 8100 and
the other IBM kludges that do comm! Let's do it. There clearly
has to be a market for it as our customers have been building
communications systems for years with our relatively crude
hardware. Now they ought to be able to do much better! Let's
figure out how we can sell it. Clearly there'll be a demand for
other components that can stack on it like a disk. It's by far
the neatest package I've seen from Digital. Congratulations.

SUBJECT: GETTING A REAL START ON PLUTO, GATEWAYS, ETC.

Pluto scares me. I see lots of paper and little real content on its
REAL (future vs. past) competitiveness, or what it is, or most
importantly, how it's going to be built. Now I see a second Product
Manager: US Paper!

For starters, I'd approach it as an evolutionary design by building it
now using current hardware (DMC lar serial line interfaces),
then evolve to support UNA and the Protocol Assist Module/line units.
In this way, you have an automatic backup to a standard 11 with a UNA,
cause all that PAM, etc. hardware will demand very large diagnostics
and a big handler change.

Also, the folks building the CATS and the old 10/20 DN may know
something that could be used to design this.

The sequence:

1. Get a host (10/20/VAX or whatever)/Pluto environment using today's hardware that supports PLUTO SW development, down line loading and debugging. (Decide on how to handle the multiple host development/down line loading and debugging environment).

2. Get a PLUTO environment that works with 1.

2A. Buld a PAM SW interface

3. Develop and TEST as concentrator while

3A. developing and testing a separate, parallel RJE (line printer part).

4. Replace the standard D(L,H,...Z) with the PAM.

5. Replace the DMR with UNA

We're doing the review soon. At that time, please give me a demo of 1 and 2. Note that this base software 1 and 2 has to be done and has to be completely general before you can build any gateways, servers, repeaters, etc.

CC: Ulf Fagerquist, MR1-2/E78
Mike Gutman, ML3-6/E94
Bill Johnson, ML21-3/E87
John Kevill, ML3-6/E94
Pat White, ML12-3/E51

I'm appalled at the lack of any PMS Architecture of VAX. (I saw Bernie's input to Mass Store.)

Surely there are more ways than SBI, CMI, ICCS (only 1 version?), Unibus, and New I/O Bus to interconnect the range of VAX systems to disks? What about Massbus and the inevitable Nebula Backplane?

This will be a good lesson (case study) in losing money. There are now no standards!

Ulf and Bill, please get together to help, not sink, John (and Bill).

As an aside, Bernie suggests no CCD in HSC or no optimization. This, I believe is only because there is no performance data on VAX, our customers are in honeymoon period and not yet complaining.

Founder and VP of R&D, Prime Computer 1972-1979
Under Bill's technical leadership, a significant minicomputer company was formed that grew from 0 to about one-half billon dollars revenue. The Prime minicomputer had the FIRST computer implementation of a 32-bit, virtual address with Multics style computing at a fraction of the cost. The entire product line which Bill managed, before leaving consisted of wide range of compatible minicomputers which were used for a wide range of applications (general purpose to office automation).

In 1978, VAX was introduced as a 32-bit minicomputer; today all minis and micros have been extended to 32-bits, but Prime was the first to extend the addressing of small computers and provide a virtual memory program environment.

Commercial development, in 1975, of first token-passing, local area network. (The first implementation of IEEE 802.5 will occur in 1984.)

Citation

For technical vision and leadership in computing that established the first minicomputers with large virtual addresses and the first company of a new industry of distributed, co-operating workstations.

6a

Founder, Chairman and CEO, Apollo Computer, 1980 - present

Under Bill's entrepreneurial and technical leadership, a new industry has been formed based on powerful, fully distributed workstations. The Apollo environment typifies distributed computing of the future.

The Apollo Domain environment provides computing directly at the user's Workstation, thus avoiding the response-time bottleneck of timesharing for what is highly interactive work. In addition to the workstation, the environment consists of a token passing ring (similar to IEEE 802.5, but at least 4 years earlier) to interconnect the stations. A 48-bit name space permits all workstations to communicate and share resources (especially files) with one another.

Apollo was the FIRST company to provide this environment. Now 150 new workstation companies have been formed to compete with some segment of Apollo. In addition, traditional companies such as IBM and DEC are attempting to provide similar products. Apollo still maintains the leadership position.

6 explanation

The Apollo environment is the FIRST commercial implementation of the fully distributed cluster outside of a laboratory environment (Xerox Palo Alto Reseach Center; Ethernet interconnecting Alto workstations). This kind of environment will be the main style of computing of the 90's. Only two companies appear to be providing products which are similar, but less extensive than the Apollo environment (eg. SUN Microsystems, Silicon Graphics). A proposal in 1979, at Carnegie Mellon University, SPICE, offered such an environment, but only now is it partially operational. The Apollo product(s) constitute a system formed from hardware (various workstations), a local area network, and distributed operating system-- any one of which are a significant.

The above examples illustrate the engineering difficulty necessary to make the Apollo Domain Environment and set of products, i.e. the work is well beyond what can be done by 100's of startups or capable research groups. Bill lead this effort!

Apollo started in '80, and introduced their first product within the first year. The company has just reached $100M annual sales, and should reach the billion dollar level by 1988.

7

1980-Apollo Domain, Distributed Computing Workstation Environment

Demonstrated vision and technical leadership to found a company to develop a computer system that is generally viewed as the successor to time sharing. See "Architecture of Apollo Domain."

1975-Prime Token-passing local area network

Delivered first, commercial high speed, token passing ring local area network. See Reference Manual for Primos.

1974-Prime Virtual Memory Minicomputer

Delivered first implementation of large, virtual memory on a minicomputer. One of first companies to do systems programming in a high level language (subset of PL/1). See Reference Manual for Prime 400.

7 additonal

1973-Prime
First product with demand paging on a 16-bit minicomputer. See Reference Manual for Prime 300.

1968-Honeywell
Consulted on the 16-bit computer that ultimately became the Series 16 minicomputer.

1968-NASA
Demonstrated demand paging on a minicomputer.

1968-NASA
Pioneered in the use of higher level languages for implementing operating systems by using Fortran as the implementation language for a NASA system.

1966-MIT
Pioneered a first course in systems programming with text.

7 next page

Bill has demonstrated exceptional technical vision, followed by leadership to implement the vision resulting in two key 'firsts" in computing which others have followed.

In the case of Prime, a recent study (which will be published shortly by me in Computer), showed that of 100 companies that began making minicomputers in the early 70's, only the startups Prime and DG remained autonomous. 75% of the companies failed. Only 8 companies succeed to any degree: Prime, DG, DEC, IBM, HP, Interdata, Harris, and SEL.

In the case of Apollo, they were clearly first and everyone is following. In this case, I expect a much more brutal fallout of companies. Of the 150, I expect only Apollo and perhaps 2 others will win. I expect DEC, IBM and perhaps 2 of today's computer companies to produce products that will compete with Apollo.

Bill's leadership as an engeering entrpreneur should weigh heavily in favor of his becoming and IEEE Fellow, because I believe this combination of superb engineer/leader/entrpreneur is who we want as leaders and role fellows in engineering.

Enclosed is a set of notes I took from a lecture Bill gave to the IEEE Engineering Management Chapter (12/83). It shows why Apollo is no. 1, and why Bill would be an asset as a Fellow of the IEEE.

Lecture to IEEE Eng. Mgmt. Chapter, 12/13/83
slides, (comments), [GB comments]

THE APOLLO BUSINESS PLAN

Business Plan
$100M by 1985. (Will achieve 4 Q run rate by early '84. Poised to be running at $1B by 1988.)
Marketplace
Computing Professionals, especially engineers. Productivity based, and the natural successor to timesharing. (3.5M engineers who potentially could be

twice as productive is the market goal. This amounts to 100B market. Trick is to convince public to part with money. This was easy because the buying decision is initially under 100K and is incremental. Model was positied by various universities including CMU. Take advantage of micro and evolving, poor performance of timesharing.)

Product

Network of dedicated Computers. The technology of the '80's. (MIT taxonomy: It's a NEW product to an OLD marketplace. It's a Workstation with 16 Mby VA, 4 Mby Mp, 154 Mby Ms, 1000x1000 x 1 to 8 planes x 2 for image backup. Operating system allows paging over a 12 Mbit/s LAN with 48-bit address in full transparent mode. pages: 1 Kby, average of 4 pages transferred. Apollo's own LAN has 280 nodes. Is busy 10%. Price: $40K monochrome.)

(Product strategy: [straight from computer engineering. Introduce a product, go up in performance, go down in price and form a wedge of **compatible, LAN'd** products.] '81 monochrome 40K; '82, color, flt pt, 100K; '83 desktop mainfram at 10K to 20K; Oct 83 fully compatible TTL version of 68K giving more Whetstones than a VAX 780. Soon a 100-150K product. Easy to add a node. They are predicated on NO BACKWARD INTEGRATION. THEY ARE A SYSTEMS COMPANY...). [RECALL WE MAKE WHAT WE SELL, NOT WHAT WE CAN BUY.]

[They simply exploit mini lethurgy and inability to move on micros. Apollo is clearly working on an ECL version!]

People

Used seasoned Professionals and entrepreneurs. Now 1.3Kp. (Company started in 5/80 with FCS 3/81 to Harvard. The Operating Committee has 8p with 3 Prime, 2 DG, 2 DEC, 1 outside Computer industry. Six had been founders before. The average age at startup time was 42! The average age for all startups is 32! Bill is now 45. Apollo ONLY hired quality people... most of whom had done it before.)

[Apollo is simply going to pick off the cream from DEC, Prime, etc. (I believe DG has its act together and is not vulnerable now.) in much the same way that the mini folks (DEC, DG, Prime) used Honeywell as the basis to start to build their companies. The issue of the average age of a company, particularly the top management is quite interesting.]

Money

Venture financing to be a public, profitable company. (The company is now selling at $32 with 22 Msh, giving a 700M market value. 80% of the people in the company are shareholders. 60 are Millionaires via the stock.)

MANAGEMENT PRINCIPLES

Risk

Use time line management; have plan A, B and A+. (Tradeoff cost, functionality NOT schedule. Be able to work with a slower part, but if a faster one comes along, also be able to exploit it. Not all breaks are bad. Whenever people work hard, they end up getting lots of good breaks too.)

Organizational focus

Functional based

Products look like organizations [Conway's famous law.] (Take lots of time for organizational design.)

Management is a contact sport (Air hostilities, but get the hate out in 24 hours.)

People Principles

Justice and share the rewards

Fun (Don't think that it's the end goal that's it. Achieving the goal is ALL the fun.)

Excellence!

TOOLS AND MEASURES (PREDICTION VS FACT... have a plan)

Money

P&L and Balance Sheets (are your friends. Understand and use them.)

People

Oranization Chart with names and dates (Put responsiblities here.)

Time

Schedule (has names and resources on it)

Time Line Management for resources
Bad Tools
Marathon Staff meetings that are problem solving sessions. (Charlie Spector taught them to have short, 2 hour, meetings that have problem identification and reporting. No problem solving on line. People are to do this.)
Committee design reviews

THE ENTREPRENEURIAL STEP

New ideas
Market driven, technology driven, Opportunity (exploit some pathological phenomena such as lack of parts, or high prices)
The Business Plan (note the first slide)
Business
Marketplace
Product
People
$
(Poduska as VC: business plans must be less than 10 pages. Have never read or known anyone who has read a business plan over 10 pages long. Go for Grade A people only. Grade B people with a grade A plan loses. Grade A people have fire in the belly and steel in the eyes.)
Selling the Plan
Value of the investor. (The VC system works!)
Seperate investors and management. (Keep the investors independent of the management! VCs know nothing about management. A business without management is useless, and VCs are now beginning to realize this more and more.)
Everyone must win
Pace and timing (Be in it for the long race.)

RISK AND REWARDS

Rewards
Ego- achievement
$- capital gains (Watch for $'s not for the % of the company. Control always rests with the management, NOT with votes.)

Risks
Ego- failure
$- no way (People may be out of a job 3 months.)

ELEMENTS OF SUCCESS AND FAILURE

Success
Ego drive
Faith in the idea
Trust in the people
Humility and humanity

Failure
Misjudgement (technical and people)
Mismangement
Unrecognized success (giving up too soon
Lack of courage

People
More important than the idea
More interesting than bits, bytes, nanos

Q&A
lots, eg.
Q: How will you keep Apollo from becoming large and lithurgic?
A: The key is to use some form of entrepreneurism. People like the personal challenge of proposing something and the freedom to carry it out with the corresponding risks and rewards.

Other thoughts (by GB)
My simple model of computer generations has to be extended to include people (leadership) and new organizations as I see incredible new highs and lows of performance.

Apollo is an archetype of the phenomenon that creates a new generation and industry... even though it is simply a replacement (New product to old market) designed to eat a large segment of the mini market. It is clear that old organizations rarely make it from generation to generation (eg. BUNCH to build minis). This can be seen by looking at every level of integration and systems including: logic technology, computer, software and various peripheral vendors. The notable exception is IBM who has moved out by significantly stronger leadership at the top.

Gordon Bell, Decmember 17, 1983

June 1, 1978

Mr. Bill Pohlman
INTEL
3065 Bowers Avenue
Santa Clara, California 95051

Dear Bill:

It was good to talk with you again on Tuesday regarding your kind offer to write a chapter for the update of Computer Structures by Professor Dan Siewiorek. You will of course be free to publish the chapter elsewhere and to get any other co-authors involved in the writing. We would encourage and urge the publication in the regular technical literature. I'm enclosing a copy of Computer Structures and a copy of the recent PDP-10 paper which may be useful as models.

I believe the article should cover the interaction of technology, architecture and use surrounding Intel's 8008...8086. The peripherals chips and bus are of interest too. I don't believe the 8086 should be more than 1/2 the chapter and the article should cover all the Intel machines back to the 8008 and any other machines that are relevant to the evolution of the microprocessor. The 8080 should be emphasized, particularly because it became a standard.

We need a first draft by September 1. Although the size is up to you, I believe that it would take 10-15 book pages or up to 45 typewritten pages to do justice to the subject.

If there are any questions, please contact me or Dan Siewiorek.

Sincerely,

Gordon Bell
Vice President,
Engineering

follow up 3/8/79 (OOD Mtg.)

Given the strategy, we need the above. Can you get someone to deal with this and give us a report at OOD in early March. Both Al Crawford and Bob Grimes have made commitments and have policies with respect to VAX (see the attached). I think we need a similar set of statements and we need to know who should make them...and implement them.

I don't have any detailed thoughts, but would like to get a general direction such as:

0. Probably plan to minimize the buying of more 10's. Buy VAX's instead.

1. Let's look at applications which we say will always run on 10's unchanged! Let's not rewrite them, but use them till we don't need them or they're obsolete (e.g., PC Layout).

2. Establish a network so that as work builds up on a given 10, we can off load it on VAXs and place new work there rather than having any kind of massive migration program. For example, the new PC Layout program should be moved to VAX because we're out of 10 address space. This will free up a lot of 10 capacity.

3. No programming anywhere in anything other than VAX languages (common Bliss, Fortran, Cobol, APL--betting on the cum of a good, compatible APL, etc.)...but specify!

Whoever is going to manage this would have the whole thing planned, and all I want you to do is to identify the person or persons within engineering.

OBSERVATIONS ON GENERATING COMPUTER GENERATIONS

ABSTRACT

We've implemented thousands of species of the computer in a few, basically evolutionary technologies. These technologies mark the generations. The evolutionary process is cyclic and includes the technology, the architecture and implementation of species, followed by use which in turn generates increased demand for better technology, permitting evolutionary new computer structures.

Since new generations spring from new technologies and often different people, a new generation most likely follows the time-worn path of early pioneers. New generation builders tend to relearn the same lessons about technology limits,

architecture, its evolution including the "wheel of reincarnation" for specialized functions, multiprocessors, etc.

Subject: **Portability and Waterloo's Widget, Watfor, Watfiv and Watbal on Series 1**

To: Bell Heffner, Bill Keating, John Leng, Jerry Witmore

Date: 31 MAY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

CC: OOD, Gus Ashton, Denny Doyle, Ed Fauvre, Win Hindle, Ted Johnson, Andy Knowles, Gordon McConnell, George Plowman, Ron Smart, Bob Trocchi,

follow up 6/14/78

I just talked with Professor Wes Graham at the University of Waterloo. He believes we're not too responsive in selling these products when compared to the system he put on (ported over to) the Series 1. Still, he wants this software on VAX.

His people have made 4 trips to IBM to train 100+ salesmen/trip and IBM has sold 100 Series 1 systems as a result of his products (we've sold less than 100). He would like us to get interested in pushing the products on 11's. (He'll also send us data as to the number of systems that run his software--even though he believes three times this number should with some reasonable selling and promotion!) Is there any way we could do this and at least give the customer the option of an 11 over IBM? IBM is also mounting a major sales effort to push this product.

As an aside, he said there is a faction within IBM that was pushing a 32-bit architecture for Series 1 that is now saying "I told you so" when we announced VAX! We apparently sucked IBM into a small, low end, 16-bit architecture -- when others within IBM think its too little, too late.

Portability and DEC

These systems were written in a portable way and moved over to Series 1 in a rather straight-forward fashion! Portability is being used more and more (e.g., UC/San Diego with PASCAL, Bell Labs with Unix and C). (Note much 10 and 11 software has been "ported" from other machines too!) Somehow, not only are we not developing portable software internally, but we often have multiple redundant efforts for software (e.g., many 11 Cobols and a new non-ported Cobols on VAX+ 10). Although Cobol may be the wrong example, there have to be good examples (e.g., the new Editor).

This year (FY79) I, again, want from Software Engineering:

1. Clear statement on where we (numerically) are vis a vis the language used to implement systems together with a policy!

2. Portability considered on each piece of software (i.e., what systems it is for and when will it move.

3. In DECnet, especially, there could be a complete overhaul of software, tools and policies considering high level languages and testing.

SUBJ: POST OFFICE AND MAIL COLLECTOR

Date: 2/28/79 Wed
From: Gordon Bell
Dept: Office of Development

TO: Don Alusic

Al Crawford MS: ML12-1/a51 ext: 223-2236

George Plowman

Follow up: 3/16/79

I hope that your Post Office program will deal with the problem that is now bugging me: I have two places to look for mail since the ARPAnet isn't connected to our systems.

Is it possible to have some background jobs in Post Office that will go out to specific computers like CMU10A and pick up my mail on a periodic basis?

Also, I would like mail delivered to the user community there, but the Post Office does that, I gather.

GB:mjf

Post v N Computing: A 10 YEAR, DIRECTED RESEARCH PROGRAM AND NATIONAL FACILITIES AIMED AT PARALLEL PROCESSING

A Draft Outline*

Proposal(s)**

Gordon Bell, DEC

George Clark, Harris

Bruce Delagi, DEC

Sid Fernbach, Consultant to CDC

Bob Lillestrand, CDC

Red Phillips, Univac

13 August 1982

ntive references to previous and ongoing work and bibliographic references have been omitted. While we believe the general is correct, specific tactics such as the applications to focus on, will be subject to change with the final proposal(s). We now th conceptual and detailed critiques.

The final proposal must come from the program group dedicated to produce the results. Thus we solicit:

- sites
- individual researchers and a program director
- applications and other research projects

ng Summary

x

1. Some Critical Global Questions
2. Why use CDC's Advanced Flexible Processor?
3. Rough Budget

OVERVIEW

egan as an exercise by positing a computing environment we believe is attainable in 10 years based on parallelism c of the single, von Neumann machine and then asking ourselves:

Are we doing anything significant to understand and build this environment?

overwhelming:

most industrial research appears to be aimed at incrementally improving today's products and processes; while

academic research is aimed at basic research and the mechanism of getting grants, producing papers and Ph.D's.

f this program is to develop the technology and build next generation computers by establishing several National Laboratories cience and engineering research within the U.S. military, academic and industrial community. This technology is essential:

1. for defense;

to improve the declining computer and semicomputer part of the U.S. Information Processing Industry which now constitutes d supports much of our economy directly and via exports; and

3. as a basis for uch of the 21st Century Industries.

echnology position in the computers and semicomputer industry is a national crisis. As such, this necessitates these unique program:

1. collaboration nong national science, defense, university and industrial applied research, often called technology, in a fashion not unlike the ISIC program;

2. National

oratories so that limited machine and people resources can be shared, unlike the VHSIC program;

3. a large, fast

twork including access both for experimentation and to extend the program to other research sites;

4. construction of

ototypes by industry for evaluation within the research community;

5. technology

nsfer by industrial residents at the laboratories;

6. tighter

upling of application (need), architecture, construction and use by co-location in order to rapidly engineer, build and test ideas. is speeds up migration of ideas to use by applying engineering resources earlier.

will be the hub of a goal directed research program aimed at new VLSI-based, highly parallel computing structures. Parallel ems, including: specialized processors and hardware algorithms, multiprocessors, multicomputers, dataflow and high speed ork based meshes will be built and evaluated. Evolutionary projections show a performance increase in processing of only a 1) to 11 (Fig. 2) over the next 10 years. In contrast, the Japanese Fifth Generation Research Project, is aimed at producing high llel computers with a factor of 100 to 1000 more computing power for conventional and Knowledge Based computing systems .

goal of the program is VLSIzation, the ability to transfer an algorithm, simulated within the computing environment, to VLSI the foundry time in much the way programs are currently compiled. By it's nature, this structure adds inherent parallelism to e national facilities would also support the goal that computers would do a substantial part of the VLSI design. Research in the ting structures we target will rely on accomplishment of these goals.

er generation is marked by concurrence of technology and needs causing a new computing structure and resulting in new use. driving need is for the ability to transmit, store, and process (understand) the same information as people, including voice, es and images. Images are a major data type of this research program because of the links with people. The research need is hardware and technology and by the potential of Knowledge Based Systems requiring much higher performance. These must be gnal processing to assimilate voice and images.

ould be organized in 3 phases, covering roughly a decade, in order to focus the work in a timely fashion. Generations have en 7-10 years and consist of two periods: specification and construction; followed by use and evaluation. The immediate he most powerful, high speed network of general purpose computers would start the program in the use and evaluation phase. n application of this facility would then be applied to produce new VLSIzed computing structures by the end of this first phase. se would apply these newer structures, forming the basis for new designs in the final program phase.

MOTIVATION FOR THE PROGRAM

the combined Information Processing Industries is now declining relative to Japan. While there are many reasons for the re noteworthy and represent the motivation for this program:

1. The U.S. (and rld) funding for basic and applied research is large. This mechanism produces far more results than can be applied.

2. There is NO S. effort or policy aimed at systematically examining the basic research results and refining them so they can be applied to oducts. The cost to do applied research on even a small fraction of the basic research is usually far greater than the original work d is well beyond the scope of a single company or a laboratory. Furthermore, most laboratories doing research can only carry eas to the paper stage because of the engineering nature of the final stages to build and test the idea. Thus, overfunding search relative to applied research means a "spilling" of knowledge that forms the basis of a significant industry.

3. U.S. companies ve not worked collaboratively to develop these technologies because of legal and cultural reasons.

4. U.S. industry s been especially short sighted in its funding of this phase of research. Now, many short term, mundane product opportunities g. another Z80 + CP/M based personal computer) exist to attract resources resulting in further decline. This is further fueled by e venture capital market and increased R&D tax credits which in turn produce even more mundane products.

5. An inadequate pply of people and equipment exist to carry out the work in industry and the research organizations.

6. A research ogram aimed at parallelism requires interaction and co-location with a user community.

e effectiveness of the Japanese collaborative research programs and believe we must emulate them. Both France and the U.K. d programs aimed at the next computer generation. Note the past and present programs in the Information Processing area:

1. Pattern ormation Processing- voice and vision

2. VLSI- improved
ocessing characteristics (eg. 64K and 256K rams resulted in a 2 year lead over U.S. industry)

3. Supercomputers- high speed technology

4. Optoelectronics- just established

5. Standard
nicomputer for NTT- Fujitsu, NEC and Hitachi

6. Fifth

eneration Computer- Fujitsu, NEC, Hitachi, Mitsubishi, Matsushita, Oki, Sharp. ICOT Lab and 10 year program were established.
e first phase builds Relational Database and Prolog machines.

7. Local Area

etwork standards as part of the Fifth Generation.

8. Next

neration research and technology program.

THE RESEARCH PROGRAM CONTENT

ECTIVES

dertaken with the expectation that the confluence of the disciplines of parallel processing applied to image processing, and ineering, and implemented using VLSI will prove fertile. It, and the resulting VLSIzation process, that of first understanding am and tasks and then VLSI'ing them, may well be a major characteristic of the next generation computing systems, which the e Fifth Computer Generation.* The establishment of a quasi-competitive, but coordinated program of research using common es is intended to stimulate a national understanding of such systems and their potential application.

ed at a fundamental understanding of parallelism and its application to a class of problems critical both to the growth of the stry in this country and to the maintenance of a preeminant US position in intelligence based military systems.

AND USING THE FACILITIES: PHASE ONE

focus will be on installing and applying parallel approaches to image procesing and logic/circuit/process simulation problems, flow. We think it is vital to understand the range of dataflow from theory to practice across a wide range of applications. In its dataflow can be viewed as a formalized, generalization of pipelining that is conventionally used for graphics and image process. eral form, dataflow looks appealing for logic simulation, signal routing, and conventional array processing type tasks where a rallelism exists, but cannot be exploited due to the difficulty of expressing algorithms in conventional languages. It is indeed ataflow-specific machines <u>will not</u> exist, instead dataflow languages will enable programs to be written for large, multiprocessors. l be based on a high performance local area network to interconnect the central machines, including:

. supercomputers,

. experimental achines (dataflow and conventional multiprocessors and multicomputers), and

. the CDC AFP.*

erate with <u>fixed microprograms</u> to simulate several computer structures including dataflow computers. This will enable begin now and to understand the limits and use of dataflow architecture, for example. These efforts must be put to the test of applications in order that the tradeoffs discovered be relevant to solve.

), believes that the current generation, number 5, is based on powerful personal computers interconnected via local area
Japanese are working on the sixth generation, beginning in the late '80's.

have real applications on which to "benchmark" various designs. The following applications cover some of the possible ary and industrial problems: scanning electron microscopic image enhancement, automated assembly inspection, target ligital system design and construction (eg. logic simulation, routing and IC signature analysis). The actual applications should be final proposal.

l results have focused on using a dataflow architecture to examine its limits, the network and facilities we envision are much and will be used as alternative ways of computing.

ELOPMENT OF THE CENTRAL FACILITIES

hat the central research facilities will be enriched further over time by including, as additional research tools, the fruits of the program particularly focussed on realizing more powerful forms of processor interconnect and process (or operator based) ation. It is expectd, further, that several realizations of parallel solutions to specific application image processing problems will d (in VLSI) and included in the central research environment.

NG PARALLELISM: PHASE TWO

hase of the program here proposed, the principle results will include a deep understanding of the dimensions and metrics that ace of parallel computing - costs, performance, programming expense, and reliability. The proposed facilities provide a rich set ealizations for parallel computing - ranging from tightly coupled multiprocessors to conventional Local Area Networks. We do t the kind of interconnect for switching is a particularly fruitful area of study because it is really an economic issue that shifts with ulation, market demand, and supply. Thus, the goal is to provide various structures for evaluation and use very rapidly, but not interconnect possibilities!

and knowledge engineering efforts are expected to yield their most important results in the last phase of the program. stones are established throughout the research effort: discerning the computational (and data management) primitives rrent rules-based expert systems languages, establishing an effective integration of image and symbolic information into a e (consistent with the data management primitives noted above), realizing a VLSI implementation of a highly parallel, post von uter structure for expert systems, trying it out on (say) a SEM analysis problem, a fully automated VLSI design, and finally on an or (semiconductor) process/crisis management (or threat evaluation and reconnaissance mission). These will, in turn, provide ing needed for a second VLSI implementation of the expert system engine above.

ingredient of effective VLSI implementations supporting the research goals of this program we need the 1990's VLSI equivalent he Guttenberg Press but of the linotype machine and the automatic typesetter. The process would be completely controlled by small group. The most important element of this program then is the development of the capability for (fully) automated VLSI om representations of parallel algorithms simulated on the parallel computing facilities proposed. At first, this will likely be by conventional supercomputers and the dataflow machine simulators running at the central facility.

design capabilities will be made to stand the test of real use in VLSI implementatins of (at least one) dataflow machine. The achine will be based on the measurement and analysis of simulated dataflow machines running applications as noted earlier. pabilities will be also tested in VLSI realizations of IC signature analysis dataflow algorithms and the mobile object identification ojects implemented previously. The culmination of efforts in image encoding and compressions will be a special purpose VLSI that provides full motion video-conferencing within the bounds of a 56 Kbps phone line, for example.

A FACILITY TO UNDERSTAND AND EXPLOIT PARALLELISM

applications usually result from having new, higher performance computers allowing solution of problems that previously were y intractable. Performance increases in computing come from two sources: technology improvements and increased is program is aimed at understanding and exploiting parallelism to gain performance.

s to parallelism in two ways.

nmodity processors allow the low cost construction of the most cost effective systems. That is the Mips/chip of microprocessors rips the densest, high performance ECL gate arrays.

Second, VLSIzation is an inherently parallel process - standard algorithms are off loaded.

ots to improve performance through highly parallel structures has been relatively disappointing. We believe the major reason progress is the high real and personal cost to build and evaluate parallel structures. This program supports systematic research nt on the following alternatives. In this regard, we posit this fundamental hypothesis: <u>in order for a new computer structure to a user, and hence ultimately developed and exist, it must offer an order of magnitude improvent in performance over his l of computation.</u>

OCESSING (AND VLSIZATION)

order of magnitude or more speed improvement has resulted from looking at the execution times of particular work and then are to carry out the function. VLSIzation is a realization that this evolutionary process exists and is an attempt to formalize the

s of "off-loading" using special function hardware:

1. Floating point rdware versus a software interpreter

2. Channels, I/O ocessors and I/O Computers versus interrupt and hardwired I/O

3. Display

ocessors

4. Array Signal

ocessors

5. Front end

ommunications) and back end (disk, file and database) computers

g from a computation on a particular kind of data occurs.

n a requirement for a new computing structure. The function is then "off-loaded" in specialized hardware that operates in
e general purpose computer.

eral purpose, very high speed system, the resulting, specialized structures can be totally simulated before they are committed to
n this way the designer can interact with the structure in a quickly iteractive fashion instead of waiting at each iteration for
system (re) integration.

ORS

w computer class is formed, there are strong arguments to build multiprocessors for performance reasons. Invariably, others
rformance Uniprocessors at the same time and deliver more power via the strictly sequential approach. Multiprocessors were
e early 60's, with Burroughs probably delivering the first one (B5000). By the early 70's Burrough's, CDC, DEC, GE, IBM and
uilt 2 - 4 processor multiprocessors. Unfortunately, these were either used in an asymmetrical fashion, or at most they were
nary multiprogramming environment. In no cases was parallel processing of a single task provided.

n investigated parallel processing of a single task with a 16 procesor multiprocessor and showed that for various tasks speed-ups
By 1975 two 16 processor systems were built by BTL and at CMU. The CMU system was predicted on the 11/40 minicomputer,
ord the construction, and speed-ups of up to 10 were observed in various algorithms.

d Flexible Processor is an ideal machine to investigate the use of multiprocessors and multicomputers since the interconnection puters is via very high speed local links (ultra LAN) and shared memory. It can be used in many ways, including:

1. a 16 computer ultiprocessor;

2. a 16 processor ultiprocessor;

3. a fixed, rpreter for particular structures (eg. dataflow); or

4. a particular, dicated pipeline processing configuration (eg. image processing).

ories are building systems with up to several hundred microprocessors.

multiprocessor, the successor to the S1, with 16 supercomputer class processors. As soon as the processor's available, it should the multiprocessor case for evaluation, since the processors are both tightly coupled and have very fast inter processor mechanisms. This should be within the next three years.

ffering a 64 processor multiprocessor which requires investigation. We strongly recommend the installation of this machine in rder to work on the multiprocessor problem.

artz, et al at NYU has proposed the Ultra-Computer, a multiprocessor with up to 16,000 VLSI microprocessors. Just as soon as we easonable number of processors together, construction should begin on this very large multiprocessor.

hat one can produce conventional parallel processors which should be able to deliver up to a factor of four, for specially coded ctor of 10 is possible, but there has to be a significant amount of research to make this automatically possible. Studies continue amounts of parallelism in algorithms that we have no way of exploiting.

t the optimistic (Fifth Generation) projection for computing power speed-up over the next decade could be accomplished simply parallel processing using multiprocessors and not by semiconductor and packaging technology if a significant effort were ubtedly the dataflow language is an important part of this effort to represent, control and thereby exploit this form of

TERS

een done formally with arrays of tightly coupled multicomputers where independent computers (Pc-Mp pairs) operate and communicate with one another by sending messages. By 1980, CM*, a multicomputer system based on the LSI-11 with 5 clusters of 10 computers was constructed, and speedups of up to 30 were observed for particular problems, including tion. Because there is less interconnection among the computers, it is more difficult to predict the performance: the algorithm ully partitioned across computers rather than distributed in memory.

FP, we believe that other multicomputers should be constructed and used, particularly those with several hundred computers. l support the construction of several, (say 6) different multicomputer alternatives.

CHITECTURES

dataflow computers have been proposed, only a half dozen computers have been built. The performance of dataflow ot understood, although the use of dataflow graphs and languages to express parallelism is promising. In particular, dataflow most useful in expressing signal processing operations. For example, the AFP is programmed using a dataflow-like representation essing tasks. Individual computer modules can be assigned to various processing stages of say a digital filtering task. The AFP also deal to simulate static dataflow architectures and their application. It would be microprogrammed to be a general purpose ne using separate computer modules in a functional fashion: matching store, switching, processing, and i/o.

AND CONVENTIONAL LOCAL AREA NETWORKS

works, LANs, are systems which normally allow the physical distribution of functional, server components to cover a local ea (eg. a building, or campus). The functional servers roughly correspond to various parts of a shared system: person servers rkstations/terminals), file servers, print servers, and communicatins servers. The communications is via message passing le the curent 10 Mbit/sec LANs are relatively slow, they are well matched to today's, slow terminals, personal computers and for networking.

ve also posited that LANs can be used to provide high performance, parallel processing. We too believe higher speed LANs are nterconect architecture for new computer structures. The higher speed, 100 Mbit/s LANs will be the basis for interconnecting puters in a hierarchy as shown in the facilities section (Fig. 3).

tra-LAN as a major architectural component and standard for truly fast, highly parallel structures of this next generation. Note at interconnects the AFP provides transmission at about 2 Gbits/sec for each computer node connected for the tightly connected us, the AFP would be used for some studies of this type of LAN-based architecture.

the hierarchy of three LANs is summarized:

AFP's processor intercommunication; as first basis for an ultra-LAN architecture	Ultra-LAN	2 Gbits x p
Facility computer intercommunication and center to remote sites, forming a single cluster	Fast-LAN	100 Mbits
Individual workstations to form centers	LAN	10 Mbits

CESSING FOR KNOWLEDGE BASED SYSTEMS

widely agreed that Knowledge based Systems can exploit parallelism. For Rule Based Systems, it is believed that many rules can parallel. The research will be aimed at first answering the question, and then simulating and evaluating the resulting structure. sed to simulate such a structure, provided this approach looks worthwhile.

THE RESEARCH PROGRAM FORM

, DIRECTION AND RELATIONSHIP TO ONGOING RESEARCH

e, together with a board of directors would contract the research in a fairly structured fashion. While research of this type is not e today in computer science, we believe it can and must be done effectively by a joint industry and computer science research t. Industry can be effective at providing facilities and systems that have been traditionally absent from the research laboratories. the major motivation for the proposal.

the research project is to provide a large infusion of computing systems to support existing, more basic and unstructured work, ics.

ould not be to change the nature of the existing unstructured research to be highly focused and goal directd, but rather to nal resources so that both the structured project and unstructued work could co-exist and complement one another.

uld be aimed at very similar research targets in order to get the benefit of "friendly competition". Similarly, several approaches ined within a center. This approach was successful in the mid-70's in speech research and should be the "model" direction. peech research resulted in few, commercialized industrial or military applications, because the research coupling between ndustrial research was poor. Unfortunately, the final transfer phase of research was terminated before the program ended.* It een basic research and applications research that the program is fundamentally addressing. It is interesting to note that NEC ed development operating separately, but concurrently with the ARPA program. The result is that NEC provides recognition

e that a better model to follow is VHSIC. It is crucial that the participants be able to exploit the technology for commercial and tions propitiously. Unlike VHSIC, we believe that the work should be done at a few sites with movement of personnel.

OFFICE

is research is a fairly close weave. The environments are, indeed, established anticipating that unexpected leverage and will yeild significant results not included in the program plan. However, it is precisely the existance of a structured program and n of its several work flows that will enable this to occur. The program office is responsible for the successive development of the ources as it can find them and coordinating efforts so work can easily build upon what came before.

munication with Allen Newell and Raj Reddy at CMM.

ffice will set adequate standards so that ideas meet no unnecessary boundaries between the workers and the worksites in this , stable agreement on the common rules, language, workstation, the network and the general computational support structure he most important contributions of the program office, the goal is to use this commonality of interface to allow pyramiding of reful not to pyramid risk.

ses applications to test ideas, and uses realizations of those ideas to build the next generation applications. It even uses these emselves to acomplish future generation realizations fueling the next cycle. The central facilities are the place that application ng ideas, the realizations themselves, and the applications for testing ideas all come together. This must all flow forward rather k into a deadlocking interdependencies. The opportunity and expectation for people to build on each others work as it becomes key. In the natural uncertainties inherent in this ambitious program of research, there must be enough alternative paths so an use their wits to find a critically helpful piece of another's work or another's facility wherever it may turn up.

ffice must have the ability to facilitate the construction of important engineering breadboards so that systems can be rapidly built We envision utilizing the industrial sponsors for this breadboarding.

ffice is deliberately kept small to force most standards to be developed collaboratively with the groups doing the work. The g for the parallel computing facilities is very light in the expectation that site personnel will be provided by the host institution. le, Appendix 3, provides a more detailed breakdown.

EFICIARIES

as conceived in order to improve this flow of basic and applied research into industrial research and eventually into products. ficiaries are those who use these ideas to <u>eventually</u> build products. Products will not come directly from this program.

and, virtually everyone will benefit by the program:

1. the U.S.

chnology will be drastically improved - thereby improving defense and the economy;

2. the

searchers will be more effective and productive by having more meaningful work;

3. certain

search will be published; and

4. researchers

ll still migrate from the coupled programs, being attracted by venture capital, and build higher technology products.

ANSFERING THE TECHNOLOGY

tive means of technology transfer is through the transfer of people. Program sponsors will each have the right to place people in the program. It is expected that assignments be for a three year interval and that the assigned person return to the sponsoring epared to produce the competitive products of the late 80's.

operative working environment among the members of a project team, intellectual property rights for the work done as a team ies of the host institution will be controlled by the policies of the host institution. However, each program sponsor will have the xclusive license at reasonable terms.

the transfer will occur when the sites and industry collaborate on fabricating a design that a site has specified.

, chips produced as part of a research project would be licensed to the sponsors. The "rights" to chips and software produced as ch program are indeed not clear at this time and vary among the institutions. This area would have to be worked out between and the program.

sms for technology transfer include sponsor access to prototypes, distribution of published technical reports and invitations to ars.

e held quarterly for program sponsors with invited speakers from universities, government and industry.

kers the organizers of the seminars will have the freedom to draw on the wide range of topics encompassed by the program,

. Pattern and

age processing applications

. A. I. algorithm

search

. Multi-

ocessor architectural developments

. CAD/CAM

ftware systems

. VLSI design

ocess advancements

FACILITIES

ERARCHIES OF AREA NETWORKS

ould be organized around at least central research computation centers containing a variety of production and experimental ems (nodes) interconnected via 100 Mb/s links and forming the central facility for a hierarchical set of closely coupled, high ocal area networks. The centers will be linked to several campuses via the highest available links so that they could be used in a on "as if local" computation centers.

contain supercomputers, AFP's and experimental computers.

proposing ARPA-net II. This must come into operation relatively soon, to be used to interconnect the more remote research to gh bandwidth, such as several video channels would be needed to avoid limiting the interaction between sites. Here, the goal ovide only millisecond delays between processes operating on separated machines.

CILITY

cts would be designing many VLSI chips, the facility would need a way to build state of the art VLSI chips from mask design. this plished by a multi-year committment of appropriate existing capacity to the needs of the program.

ould start immediately and be coupled to existing computer science and computer engineering research facilities and programs. n is strictly on the basis of the intensity and quality of work in VLSI, image processing, parallel computing and AI. Either more or Berkeley Laboratories would be ideal sites for the computation center which would link to Stanford, SRI, and MIT, MITRE or Lincoln Laboratory could be the basis of an East Coast facility. Los Alamos has the largest network of s and support computers including storage and image production. If a central site were Los Alamos, this would force the nd installation of high speed links to other sites.

ENTERS

ery imcomplete list of application centers is included as an example of how work would be contracted by the program office to rs throughout the country.

DELIVERABLES

mpassed is broken into three classes shown in the Deliverables Table. Within each class there are families of projects and finally emselves. The program runs about ten years broken into rough phase transitions at the end of 1985 and 1989. The work in the the research environment and work standards in place and develops the first generation tools and applications. The second several machine realizations that use the tools and runs the test bed applications. In this phase, the research facilities are he machines realized by program efforts. These are in turn, the base of the second generation tools and applications. Finally, provides refinements and solves the hard problems that depended on the new understandings generated in the first two phases .

MOTIVATING SUMMARY

e motivation for this approach is timeliness and effectiveness:

1. THE RESEARCH
OGRAM SHOULD START NOW

2. WE NEED
OUPLING OF INDUSTRIAL R&D AND APPLICATIONS WITH COMPUTER SCIENCE RESEARCH

3. WE CAN BUILD
N EXISTING RESEARCH PROGRAMS AND COMPUTERS

at we start now on the research program, as our computer science research has been drifting these last few years as both mputer science research have both gotten large, diffused, and independent of one another. Significant industrial research Bell Labs and Japanese companies is non-existent and there is no coupling of basic and industrial research. For example, we better coupling of Bell Labs work to the Japanese computer industry via NTT's, ECL, than between Bell Labs and the U.S. dustry. Furthermore, both the academic and industrial research communities are now poorly coupled to real applications. We ogram focus of some of the existing research efforts into a goal directed system will enhance their productivity and enable the a vital Information Industry for the 21st Century.

APPENDIX 1

SOME CRITICAL GLOBAL QUESTIONS (AND ANASWERS)

1. Why is the tablishment of national facilities the correct way to attach the parallel problem?

. No single lab now has critical mass or focus in anyone area - currently all resources are difused.

. The lab(s) and programs operate together to do the work.

. Users, architects, and builders must couple.

2. What impact ll this proposed program have on existing research facilities? Programs?

. The intent is to build on, and extend current facilities by additionla resouces. We believe that this program is close enough to some of the existing.

2a. What about the extra space required for these facilities?

. We don't ow.

3. How will this effort help the basic problem of a shortage of qualified researchers?

. It is hoped that a "program" will stimulate the demand to produce more researches over the long term.

. Short term, the focus should increase everyone's effectiveness.

. We hope to apply industrial researchers to the problem that are now difused and often operate as a sub-critical mass.

4. Who is supposed to benefit from this proposal and in what specific ways?

(See Section on Program Beneficiaries)

5. Is there a nationla crisis and exactly what is it?

(See section on Motivation for the Program)

6.What evidence do you have to support the level of funding which is projected as being adequate to achieve the goals?

This is really a draft outline for concrete proposals. From this we expect specific sites to be established and operated in very rgetted areas: such as parallel knowledge based systems, high performance parallel processing and parallel image processing.

7. What, exactly is the overall objection of the program?

(See the first sentence of this document)

APPENDIX 2

WHY USE CDC'S ADVANCED FLEXIBLE PROCESSOR?

e AFP has demonstrated high performance in digital image and signal -

s. For example, a processor system can transform the every co-ordinate of a million point picture in 1/30 second. Several
operation today. It includes various support software including simulators.

e design, build and then use. A machine as fast and general as AFP would require at least 5 years to build. By using the current
l purpose research tool, we can gain at least 5 years on starting such a program from scratch. To illustrate, consider the several
cts that could use AFP today to simulate architectures. Since we need to evaluate these architectures by using them, we could
benefits and drawbacks of these machines five years (or so) sooner by adopting the AFP as a hardware simulation base.

ovides a very fast, flexible, microprogrammed set of up to 16 computer modules for experimenting in various parallel computing
rious type. A single, AFP microprogrammed processor provides the following capability:

. 20 to 800
ops in 16 parallel, 16-bit arithmetic and logic units

. Microprogrammed control

. Access to 32
egaword (256 Megabyte block oriented memory)

. 2 X 1 Gbits/sec
mmunication with neighbors in ring

processor and multicomputer structure are both provided since, the sixteen processors can be interconnected both to a common
emory and to adjacent processors.

us be used as a tool to study several different computer structures that we believe are much of the basis of the next generation.

so highly parallel, including having functional units with side effects, we believe it will not be imcroporgrammed to any great nvision is that it would operate in several configurations, with fixed microprograms to behave as:

1. Set of

croprogrammed pipelined, functional units within each processor. Four units can be initiated every 20 nanoseconds, although average of seven units operate in parallel for most problems. Because of the difficulty of programming this highly parallel ucture, the most important benefit, or side-effect will be understanding in how to do it effectively. Because the croprogramming so heavily pipelined, we believe a better understanding of dataflow techniques for expressing algorithms will sult from the use. Nearly all high performance machines are pipelined; hence, we believe AFP is a good vehicle to get a better derstanding of pipelining.

2. 16 processor

ultiprocessor with shared memory and very fast interprocessor intercommunication. Here, the processors will be programmed be particular ISP, such C. If C could become the basis of the machine, then UNIX could be run.

3. Set of 16

mputer Modules microprogrammed for particular functions. AFP was designed to be operated in this mode for image ocessing.

4. A dataflow

mputer. This is a special case of item 3 whereby particular computers are programmed to behave as the various functionla units a dataflow computer.

5. A set of

ecial, parallel processing architectures using individual, microprogrammed processors as the functional units of the particular uctures. In this mode, AFP turns out to be a very good emulator of relatively complex VLSI chips.

6. An

perimental Ultra-LAN based architecture. To examine how computers can be coupled effectively and work together on a task, e AFP looks like an ideal for study.

APENDIX 3

ROUGH BUDGET

xpenses are estimated at approximately $18M/year running from 1982 through 1989. Equipment is expensed as delivered. In three "competitive but collaborative" groups are charged with each project family.

SUBJECT: 784/PPA AT STANFORD

GB5.48

I think we made some progress getting Stanford to get their act together so it can be used. It's clear to me that CMU is 10 years
ahead in thinking about parallelism, especially applied to multiprocessors (ala C.mmp and Cm*).

The vision is pretty much along the strategy (dream) I outlined for
PPA: get a 784 in now so that the ultimate software writing and
testing can be started instead of waiting two years till PPA arrives.
The 784 should "simulate" the ultimate machine with n processors and
be able to output what the actual running time would be.

The users there would include:

1. Heuristic Program Project's Machine Architecture Research. This 3 year program, with Bruce as one of the team members, is aimed at examining the performance and parallelism of AI applications as the basis of the next generation architectures. This work is badly needed because I view we have NO understanding about LISP performance, the desireability of special P's for LISP, whether or how LISP can be extended for mP's, etc. This work would also include running on PPA to verify conjectures.

2. John Hennesy's Single Assignment Language for Multiprocessors.

   VAX is currently the host; having PPA would let them accelerate their research by several years. I believe this will turn out to be the way to get performance from mP's. This is also probably the path to build a "parallel LISP" -- not by starting from each of the baroque dialects.

3. Dave Cheriton's distributed processing is quite different, but PPA could be the best vehicle for experimentation because it can provide the most rapid communication.

4. Many applications: Tom Binford - Pixel and image processing; Hennesy - circuit and logic simulation; plus many others in computer science, electrical engineering and the center for integrated systems.

5. Jeff Ullman - experimentations in parallel algorithms.

Bruce is coordinating the 784/PPA procurement and our part of the
program both within Stanford and DEC.

SUBJECT: STRATEGY (OR BETTER CALL IT DREAM) FOR A HOT MACHINE

We appear to be making excellent progress in the design of
PPA (the 32
processor MicroVAX) which would have the power of roughly a
CRAY 1.
The performance picture doesn't appear to be appreciably
different
than what is given in the attached EMS.

It is becoming increasingly clear that the real limit to PPA
is the
problem of either modifying existing programs or re-
programming to
take advantage of parallelism. Therefore, we must have a
strong
program which puts 4 processor machines in the hands of users
so that
the programming can start. Otherwise, the acceptance in the

market
will be delayed two years until the real machine is in the market.

THE DREAM FOR PPA
Would like to see the following timetable:
Q184 Ship several 784 (quad mP's) to the test sites so they can be used for parallel program development during the next 1.5 years:
CMU-Joint development. CMU to use in their Supercomputer workbench, and to test the parallel processor AI machine.
LLL-Debug phyics programs for the Cray mP, and the S1 (16Pc).
LASL-Physics applications.
LBL-Physics applications, but move the techniques they've learned on their Midas system over to VAX/VMS... help us.
Illinois-Get them started on our system versus doing their own. Kuck knows more about compiling for these machines than anyone around.
NYU-Some bright folks. Save them from trying to build their ultracomputer and get them to work on the hard problem of software. Currently they plan an 8 Pc in 3 years on their way to 16000 Pc's.
Cornell-Ken Wilson, Nobel Prize winner, has been advocating.
Stanford-Might get them to want one for AI.

MIT-Might get them to want one for AI, etc. We really need
someone to work on parallel processing for AI languages.
Concurrent Prolog and Scheme (a LISP) dialect are candidate
languages which permit expressing parallelism.
PURDUE, YALE-Has work in this area.
Q384 Ship really good software so that applications can be
developed on PPA. This would include the ability to "simulate"
PPA such that a user can run at 4 x 780 speed and measure the
performance as if it were on an n processor machine.
Q185 Ship first MicroVAX PPA to a test site.
Q385 Ship PPAs to test sites. Verify that PPA matches the results
that were obtained by the 784 and that their software really
runs as predicted.
Q186 Begin shipping PPAs at a volume (eg. 780) rate, thus creating
a new level of price/performance, and performance (for this
price band) that has been heretofore unattainable.

What you think?
Are there other places? (eg. Schlumberger)

SUBJECT: BETTER COST, PERFORMANCE AND PERFORMANCE/$

GB4.S1.24

Cycles for the Masses is beginning to look up. The following table indicates we have some very interesting possibilities for competitive machines everywhere. It also shows we are in a new computer generation, the Fifth, as the cost decreases by a factor of 10 or performance increases by a factor of 10. This gives a factor of 5-50 in performance/cost over where we are today. Note the following table of machines.

	Time	Price($M)	Perf.	Mflops	flops/$	# Users
Microvax W/S	85	0.01	0.9	0.45	45.0	1

Scorpio	85	.04	0.9	.45	11.0	5- 500
780	78	0.4	1.0	0.5	1.25	5- 500
790	6/84	0.5	5.0	2.5	5.0	5- 500
Nautilus	4/85	0.25	4.0	2.0	8.0	5- 500
dual proc.		0.4	8.0	4.0	10.0	
PPA	6/85	0.25	40.0	20.0	80.0	5- 500
Titan (proto)	12/83	0.1	10.0	5.0	50.0	1- ?
KL	74	0.75	1.3	0.66	0.9	10- 500
Jupiter	+30(mos)	0.75	6.0	3.0	4.0	10- 500
Cray 1	76	10.0	40.0	20.0	2.0	50-1000
with vectors			100.0	200.0	10.0	
Cray 2/XMP	85	10.0	120.0	60.0	6.0	
with vectors			300.0	600.0	30.0	

Notice there are several ways to get a performance:

1. Supercomputers (eg. Cray) operate in batch mode. At LLNL, a large user gets a maximum of 1 hr/day. Therefore, if one of our systems can deliver only 1/8 to 1/24 the performance, the price performance is likely to be better with a Supermini depending on the problem. In a real environment, most users would rather have something else so they can escape from the center.

2. Supermini, operated as a personal or with a small number of users.

3. The new, powerful microprocessor based personal computer with 750-780 performance. This gives a user the most power. I believe our technical marketplace wants this.

4. The new, shared, Supermicro such as Scorpio - These computers have the best cost/user, but will the added sharing be worth it versus the low cost PC's? This is quite attractive.

5. New, specialized facilities such as PPA, a 32 processor based on MicroVAX, FPS-164, XYCAD for high performance batch. All are quite interesting.

Performance/price depends on the fraction of a system that can be dedicated to a user. With MicroVAX PC - the price may be in the don't care range 10K-20K (or 10% of a professional's salary) but the performance is at 780 level. Therefore, work will migrate both from supers and superminis.

We have some incredible opportunities. It would seem desireable that
we first simply consider Titan and PPA as purely computational
processors, although Titan would eventually be a PC when it has
software. They would be operated as servers running, say Fortran, to
off-load KL's or VAXen via CI.

This VLSI generation is going to generate many more kinds of computers
than ever. Supers, Mainframes, and Superminis are all going to feel
the impact of Supermicros, PC's and interesting specials.

Bottom Line

We've entered an era (the Fifth Generation) driven by the powerful
microprocessor and this drastically changes the price,
price/performance and maximum performance of the systems we can build.

The numbers should reinforce the gut feel that the Fifth Generation is
going to be exciting.

SUBJECT: DISCUSSION WITH RAJ RE PPA AND DEC/CMU RELATIONSHIP

GB5.26

Just talked with Raj an hour or so He says that Kahn and Adams
say the money's in the bank and they are going ahead with CMU part.

I had pushed Allen re the notion that they would go someplace
else with our ideas. Raj said no. They only discussions they
are having are with Fairchild building a proprietary chip with
th new Fairchild 1 micron CMOS technolgy. CMU would do the
architecture and Fairchild the implementation. It would be
based around the Forgie/Newell ideas.

He also talked about Intel's interest in supplying a 432
redesign which Intel ispnding a 100M on, courtesy of Siemens.
apparently it has caches everywhere to make it perform.

He discussed the PPA concerns:
want more bus bandwidth so that on next go around 256 Pc's

are
possible.
Want to have a 10-100 x Cray on the 3rd version, by 1992. He wants us to think about evolving the design several times and to try and plan for it.
Wants 1 Gigabyte or so.
Worried about cache size too small

He needs a letter from one of us (It should be from BJ/Demmer/Strecker)
describing our intent and how we want to work with CMU. Raj will
send a template via Siewiorek this week.

He now buys into the 784, provided we can get a big, shared memory. I concur. We somehow have to get a memory of reasonable
size. Is there any work here? What's the limiting factor? Here, they would take it with the small one, provided we can get
an upgrade soon Tom, can you help here? This has to be a problem
that can be solved, and really must be solved to have a good running system (suitable for either production or simulation of PPA).

Preliminary Draft for Commment by Digital Engineering Community

HEURISTICS AND COMMENTS FOR BUILDING GREAT PRODUCTS

Gordon Bell, Vice President, Engineering

Product goodness is somewhat like pornography, it can't fully be described, but we're told people know it when they see it. If we can agree on heuristics about product goodness and how to achieve it - then we're clearly ahead. Five sets of dimensions for building great products need be attended to (roughly in order of importance):

. a responsible, productive and creative engineering group;
. product and design metrics (competitiveness);
. design goals and constraints;
. product evolution, revolution and death; and
. the ability to get the product built and sold.

ENGINEERING GROUP

As a company managed primarily by engineers, groups are encouraged to form and design products. With this right, are responsibilities.

The Team must have:

. a_chief_designer/chief_programmer_to_formulate_and_lead the resolution of the problems encountered in the design; No matter how large the project, it must be lead from a "single head". We often make two errors in leadership: having no clear technical leader/problem resolver, and abdicating to a committee.

Committees do not do design! They are never held responsible, nor are they rewarded or punished. Committees can review.

. management who understand_the_product_space_and_who_has engineered_successful_products; The two most important jobs are:
. making sure that everyone knows their job; and
. setting and reviewing work on a timely basis, ie. MBO.

. team skills and resources to implement the proposal so that we adhere to the cardinal rule of Digital, "He Who Proposes, Does"; A plan must include the chief designer, team, project organization and resources (eg. computers). Supporting skills and disciplines are essential in the respective product areas, eg. ergonometrics, acoustics, radiation, microprogramming, data bases, security, reliability.

. an_understanding_of_the_design,_design_production_(eg. CAD) processes,_and_manufacturing__processes; Learning curves apply to all processes! The organization must be staffed with people who understand the product, the design process (CAD and management discipline) and the production introduction process. One or two out of three isn't enough.

Behaviorally, the team must:

. do_it_right_the_first_time; Being correct has the highest payoff everywhere: timeliness, quality, lack of rework, and mfg. cost.

. execute_the_project_in_a_timely_fashion; Virtually ALL of our projects are late because we start too late, don't get it done on time because some critical invention is required, take too long to get it introduced, etc. For the very long, very late projects, the failure is lack of planning, tools and organization. Finally, people burn out. This suggests we:
. limit_projects_to_two_years_by_a_small_team. We often make an aggressive business plan, then hire the team. They then find out they have neither tools nor technology to do the project.
. not_predicate_a_project_on_scheduling_inventions_in_the_design, process_and_CAD_areas. If we can't see how to do the work in 2 years, then let's not start the project! This means the product must be cut down to fit the tools, people and process. Advanced developement is to insure that we can do development.

. have a_written_design_methodology that includes: all design processes in the form of manuals, design conventions, conflict resolution, criteria for task completion, PERT structure, etc.;

. be_open_and_have_external_reviews,_and_clearly_written_product descriptions_for_inspection; For new product areas, we require breadboards in addition to the above heuristics. When the product gestation time equals the generation time, a full advanced development effort is the only way to be successful.

- start_small,_be_reviewed_and_grow_on_its_demonstrated_success;
- learn, in order to handle the increase in complexity that comes with technology. Until there's a formal sabbatical program, individuals would do well to consider taking the equivalent of a semester of technical courses each 10 years.

PRODUCT METRICS KNOWLEDGE includes:

- products_for_which_there'll_be_no_competitor;
- all_product_cost_metrics (cost, cost of ownership, cost to operate and use);
- all_product_performance_and_cost/performance_metrics; These are the goodness measures of a product and tell how easily it will be to sell, and if we have improved. Cost and performance is measured against a state-of-the-art line represented by the first shipment of a more advanced product. Alternatively, when there's no direct comparison, the time goodness is determined from the day the product could have shipped. For example, because of parts availability, Nebula and CT could have shipped two and three years ago based on component availability.
- reasons_why_the_product_will_succeed against present and likely future competition; sure success in the market is to introduce a needed function (eg. 32-bit address) by which all other products have to be measured.
- major_competitor_products by cost, performance and functionality; This should cover the past and future five years.
- leading_edge, innovative, small_company_products;
- productivity, quality and design_process metrics for projects.

DESIGN GOALS AND CONSTRAINTS

Design constraints are generally set as various kinds of standards. These are useful because they limit the choice of often trivial design decisions, and let us deal with important free choices, the goals.

Goals are vitally important because they target our uniqueness.

Poor "mind-set" standards can create poor products, even though they may have made sense at one time. The historical English measures is a good case in point. Currently, the 19" rack and the metal boxes Digital makes to fit in them, and then ship on pallets to customers, act as constraints on building cost-effective PDP-11 Systems. This historical "mind set" standard often impedes the ability to produce products that meet the 20% per year cost decline curve.

- . Goals_and_constraints must be_written_down_and_updated_from_the day_the_project_starts. Virtually every product failure and period of product floundering is a result of no clear goals and constraints since everyone has a different idea of the product.
- . A_product_can_only_have_a_few_goals_and_constraints. The ranking is usually: it must work and have improved cost of ownership, be the shortest time to market, highest performance and lowest cost.

We must adhere to standards which we either follow or set!

- . If_a_standard_exists,_follow_it_or_change_it_for_all! We lost the IEEE Floating Point format. It is likely we will eventually have to support it.
- . If_a_standard_is_forming_go_all_out_to_set_it. When formed, then follow it. We didn't make DDCMP a standard. When HDLC came, we didn't use it. The result: expensive, low performance products.

Standards can be grouped into four distinct sets:

- . DEC Engineering Standards; These cover most physical structures and design practice for producibility, and assimilate critical external standards, such as UL, VDE, and FCC.
- . professional society, industry and area information processing standards, from EIA, CBEMA, ECMA, ANSI, ISO etc. such as Cobol '74, Codasyl, IEEE 488;
- . defacto industry wide information processing and communication standards such as IBM SNA, Visicalc;
- . standards implied by the architecture of existing DEC products to insure our customer software investments are preserved include:
    - . architecture of computers, terminals, mass store and communications links; Our current ISP's include 8, 11's, 10/20, VAX, 8048, 8080, 8086, 68000; VT52, VT100, keyboards, Regis; MCP; HDLC, CI, NI, SI.
    - . physical interconnect busses for computers and for interconnecting them CT, Q, U, NI, CI, etc. These insure that future system products can evolve from component and computer options between generations.
    - . operating system interface file commands, command language, human interface, calling sequence, screen/form management, keyboard, etc.

- . Products_must_be_designed_for_easy_translation_into_in_any natural_language_since_we_are_an_international_company.
- . All_products_must_have_be_customer_installable_and_maintainable.
- . Portability_is_an_important_goal. Personal computers must be portable! We must achieve this for all systems ASAP!

WHEN TO CREATE, WHEN TO EVOLVE AND WHEN TO STOP PRODUCTS
Engineering is responsible for designing evolutionary products in our markets AND for producing products that are natural to our tradition of supplying the most interactive, cost-effective computing. If a new product such as personal computing emerges and we do not have a product, engineering has failed, independent of being asked for it!

Given all the constraints, can we ever create a new product, or is everything just an evolutionary extension of the past? If revolutionary do we know or care where product ideas come from? The important aspect about product ideas is:

. Ideas_must_exist_to_have_products! If we don't have ideas to redefine or extend a market, then we should not build a product.

It is hard to determine whether something is an evolution or just an extension. The critically successful products are likely to occur the second time around. Some examples: PDP 6,KA10,KI10,KL10,2080; Tops 10,Tenex,TOPS20; PDP5,8,8S,8I/L,8E/F/M; OS8-RT11; 11/20,40,34,44; RSX-A... M, M+; TSS-8,RSTS; various versions of Fortran, Cobol and Basic follow this; LA30,36,120; VT05,50/52,100, 101 etc.; RK05,RL01/2.

. A_product_tree_MUST_be_maintained_by_each_engineering_group showing roots, gestation time and life.

Goodness_and_Greatness = NO CRAPPY PRODUCTS!
All products whether they be revolutionary, creating a new base, or evolutionary, should:

. be elegant and high quality; Russ Doane's working definition is: "every feature contributes two benefits", like a double pun. Quality means no excess. Elegant, high quality designs, do double duty with a minimum use of resources. Quality is also the absence of errors, by being right the first time so that it doesn't have to be inspected or redone.
. offer_at_least_a_factor_of_two_in_terms_of_cost-effectiveness over_a_current_product; We have classic failures because a CPU cost has been minimized, only to find the total system cost has barely changed 10% and the total cost to the customer is only 5% lower! If each product is unique then we will have funds to build good products.
. be_based_on_an_idea_which_will_offer_an_attribute_or_set_of attributes_that_no_existing_products_have; For example, the goals and constraints for VAX included factor of two algorithm encoding and also offering ability to write a single program in multiple languages. VT100 got distinction by offering 132 columns and smooth scrolling.
. build_in_generality,_and_extensibility; Historically we have not been sufficiently able to predict how applications will evolve, hence generality and extensibility allow us and our customers to deal with changing needs. Extendable products also permit mid-life kickers to products. We have built several dead end products with the intent of lower product cost, only to find that

no one wants the particular collection of options. In reality, even the $200 calculators offer a family of modular printer and mass storage options. For example, our 1-bit PDP-14 had no arithmetic ability, nor could it be a general purpose computer.

As customers used it, ad hoc extensions were needed to count, compare, etc. and it finally evolved into a really poor, general purpose digital computer.

. be_a_complete_system,_not_piece_parts; The total system is what the user sees. A word processing system for example includes: memory, keyboard, tube, modems, cpu, documentation including how to unpack it, the programs, table (if there is one, if not then the method of using at the customer table), and shipping boxes.

. be_a_great_system_because_the_components_are_great; We should not depend on system markups and software functionality to cover poor components and high overhead.

. if_we_don't_make_it,_buy_it; We must carefully decide what components to make versus buy. It is very hard for an organization to be competitive without competing in the marketplace, hence unless we sell it, we should buy it.

Product_Evolution

A product family evolution is described on page 10 of Computer Engineering along the paths of lower cost, and relatively constant performance; constant cost and higher performance; and higher cost and performance. In looking at our successful evolutions:

. lower_cost_products_require_additional functionality_too; A lower cost product, with constant performance or constant function is risky because a new customer base and new way of marketing may be required. Some other company may, however, be successful with the concept. The PDP-8, based on new technology, was radically more successful than its higher priced predecessor, the PDP-5, because it was 2/3 the price and 6 times more performance. The PDP-8/S was a failure at 2/3 the price and 15 less performance than the PDP-8. There are similar stories about the LA 34, VT50/52 and PDT as replacement products.

. constant_cost,_higher_performance_products_are_likely_to_be_the most_useful; Economics of use, the marketing channel and customer base are already established and a more powerful system such as the LA120 will allow higher productivity (see Computer Engineering for the understanding and economics). In the 11's there was a successful evolution: 20, 40, 34 anChied 44. Not the 60. The 11/70 was probably our greatest success; it was billed as a mid-life kicker to the 11/45-55.

Revolutionary_New_Product_Bases

. A new product base, such as a new ISP, physical interconnection, Operating System, approach to building Office Products, must start_a_family_tree_from_which_significant_evolution_can_occur. The investment for a point product is so high that the product is very likely not to payoff. In every case where we have successful evolutionary products, the successors are more successful than the first member of the family. Point products with no follow-on will probably fail all roi tests.

Product_Termination

. A_product_evolution_is_likely_to_need_termination_after successive_implementations,_because_new_concepts_in_use_have obsoleted_its_underlying_structure. All structures decay with

evolution, and the trick is to identify the last member of a family, such as the 132 column card, and then not build it. This holds for physical components, processors, terminals, mass storage, operating systems, languages and applications. Some of the signs of product obsolescence:

- . It has been extended at least once, and future extensions render it virtually unintelligible.
- . Better products using other bases are available.

SELLING AND BUILDING THE PRODUCT

"Buy in" of the product can come at any time. However, if all the other rules are adhered to, there is no guarantee that it will be promoted, or that customers will find out about it and buy it. Some rules about selling it:

. it_has_to_be_producible_and_work, AND be useful to software; This, although seemingly trivial rule, is often overlooked when explaining why a product is good or not. If it is a piece of hardware that requires software to support it, the hardware must be available to the programmers who must support it. Software engineers approach new hardware with much caution! The often ask: is it significant? is it needed? why isn't it compatible with the past? If a hardware is viewed with distrust by software engineers it may be met with the same distrust by customers!

. a_business_plan_with_orders_and_marketing_plans_from_several marketing_persons_and_groups_needs_to_be_in_place; Just as it is unwise to depend on a single opinion in engineering for design and review, it is even more important that several different groups are intending to sell the product. Individual marketers are just as fallible as unchecked engineers. This rule can and must be violated for revolutionary products!

- never_build_a_product_for_a_single_customer, although a particular customer may be used as an archetype user; predicating a product on one sale is the one sure way to fail! Paraphrasing a remark by former GM executive Charles Wilson: if it's good for General Motors, it may only be good for GM.
- it_must_be_done_in_a_timely_fashion according to the committed schedule, price and functions as previously described;
- it_must_be_understandable_and_easy_to_use. The small size, complete hardware books were the DEC trademark that established the minicomputer. We must revive these such that a particular user never need access more than one. Simplicity must be the rule for our documentation.

What heuristics are missing? What heuristics do you disagree with?

What heuristics could be removed? reordered?

Could I please have your feedback before this becomes a final draft?

3/13/82 Sat 19:47:01 GB3.S2.5

OTHER PREMISES AND CONSIDERATIONS

1. OUR BASE PRODUCTS ARE OK, EXCEPT THERE ARE TOO MANY. GO FOR BETTER

LONG TERM STRATEGY. SKIP HOLE FILLING WHICH INCREASES CLUTTER.

2. WE'RE SUPPORTING TOO MANY SYSTEMS.

3. NATURAL PRESSURE THROUGH SALES, DECUS, MARKETING AND DEVELOPERS

REQUIRES ALL SYSTEMS TO BE SUPPORTED AND ENHANCED FOREVER.

4. NATURAL MARKET PRESSURE FORCES MORE GENERALITY INTO EXISTING

PRODUCTS. THIS DETRACTS FROM MOVING TO APPLICATIONG.

5. A "GREAT SYSTEM" WILL ATTRACT LANGUAGES (COMMON, EXOTIC AND

SPECIAL APPLICATIONS) AND APPLICATIONS BY EXTERNAL USERS AND THIRD

PARTY COMPANIES. TOO MANY SYSTEMS BY A MANUFACTURER WILL DETRACT FROM

THIS NATURAL MAGNET.

6. ALTHOUGH WE DON'T HAVE A PRECISE UNDERSTANDING OF VAX ACCEPTANCE,

IT FEELS LIKE "A GREAT SYSTEM" (LOVED BY KNOWLEDGEABLE USERS,

INSTALLS EASILY, WORKS AND IS EASY TO USE). IT'S EXCITING

ARCHITECTURALLY AND FITS WITH 11'S. THERE'S PRESSURE TO EXTEND IT

WITH MORE PERFORMANCE AND AT LOWER (11/34) COST.

7. EVEN WITH TOPS 20, THE 2020 HASN'T FOUND ITS NICHE YET.

draft press release

DIGITAL ACCELLERATES 32-BIT STRATEGY

ST. LOUIS, MO -- 23 MAY 83 -- Digital Equipment Corporation announced today that it is accelerating its program for moving users of its 36-bit products over to its more broadly-based 32-bit architecture.

Speaking at the Spring symposium of DECUS (Digital Equipment Computer Users) held at the (name of hotel) here, Winston Hindle, Vice President Corporate Operations, told 00000 members of Digital's users group that the company has decided to" divert its development resourcEs away from a follow-on 36-bit machine and into accellerated development of hardware, software and communications capabilities to enhance our already-formidable offering of 32-bit products.

"It has taken longer than originally planned to develop a follow-on to our existing DECsystem 10/20 family and it looks like we're still three years away," Hindle told the users. "So, we have decided instead to shift some resources and speed up the development of software and communications tools that will allow DECsystem 10s and 20s to be more easily integrated into our corporate architecture.

"We think the needs of our customers would be better served by concentrating our high-end development efforts around our more broadly-based VAX architecture," Hindle said.

...hype VAX, clusters, LANs....

SUBJECT: PRICE VS. FUNCTUALITY FACTS

We (you) could add much insight to BOD (us) by taking a number of the products which change in price or function (you have a metric) and plot log (price) vs. log (volume) for a given functionality (e.g. LA30, LA36, LA34), and (DS210, VT78, VT278 [projected]). This should begin to answer some arguments and might give us great business insight re predicting volumes in turn of coefficients of elasticity (e.g. 20% lower cost doubles volumes). Then, we might also use price not cost to set operating points for factories rather than redesigning every product for 20% lower cost. These kinds of things are probably only done in only in business schools, but since I'm only an engineer it probably doesn't have any application to us...or does it? At least the data shouldn't hurt anyone and would make me feel better about affects if price, functionality on volume.

SUBJECT: WHEN DO WE MEET ON THIS?

I got the Celi/Lomicka report.

Please get us (and your users) together to settle on the goals.

My priority is: quality (i.e. works), time to market, performance, range (print-no buffering to graphics server)... cost. Please select type 3 using an F (J's an upgrade) for the base work, with the option to go to type 2 if a limited product is possible -- but wait till it runs to decide. We'll use the MicroVAX board when it arrives. I don't see why we have to use Seahorse I since the processor isn't doing anything except routing. I assume the main controller is a 68K.

We need a product . . . yesterday !.

SUBJECT: REDUNDANT PRINT SERVER EFFORTS FROM NOD

GB5.20

The only 4-8 laser print controllers / print servers I know of are:

1. Craig James, John Celi, Roy Lomicka, Mickey Smith -- Printer group

2. Baum, Conroy, Feinberg, Friday, Fultyn, Laurune, Lint, Samberg --
Consortia of people who have a working prototype .

3. Brian Reid, Forest Baskett - Western Research Lab A/D project

4. Ron Criss's Server Group under Bernie (wait>2 years!)

5. Barry Folsom -- Omninet Shared Printer (get it soon)

6. CT clusters -- has/had a print server project?

7. MicroVAX / Seahorse I -- Server

8. Office ? Old typesetting group on LN01

9. A VAX based print/plot server that Marlboro uses for its

computation network.

I really don't expect to ever see a modern DEC print server that can print graphics, multifont as a product given our perfect record of producing nothing in this area, (including the LN01) there are undoubtedly more internal efforts at each site to serve comp centers and CAD groups.

Is there anyway to get a product? Or more engineering budget to support these redundant, folks?

SUBJ: PRINT STATION WE MUST REDIRECT IT

TO: JIM CUDMORE
SAM FULLER
BILL JOHNSON
JACK SMITH

Date: 6/13/83 Mon
From: Gordon Bell
Dept: Eng. Staff
MS: ML12-1/A51 Ext: 223-2236
EMS: @CORE

The attached memo fairly accurately reflects our meeting.

At the meeting, I felt we should continue on our present course to build the current print server interface, while having a simpler controller built in parallel for software development.

Today, I feel we should DROP the design because the product and project are so far beyond our capabilities. We would go on some kind of buyout or to a much simpler plan. One of our software groups has an operational breadboard of a printer, and this might be the basis of a product, too.

A MUCH SIMPLER PRODUCT AND PLAN

We might change the project, reflecting a much simpler product structure on which the group has a chance, to implement. There is no way that the current group, with this set of specifications, abilities and processes could ever come close to building an operational design in anything under 3 years, not ONE. In general, the approach is similar to the recent redirection to get a Personal VAX based on the Qbus, and that approach we should have used for the PRO, Pluto and VS100... all of which are roughly 2-3 years late, and uncompetitive using better tools and a more experienced staff.

In making the change, we should in parallel train people in hierarchical design for complex systems, and provide them with the managment and process tools to be successful. I see a problem not unlike Jupiter. (I suspect this may be the reason why the LA200 has taken many years and will never ship.)

The approach:

. Clarify the distributed organization, and make sure there is adequate management to undertake this complex projectt.

. The print server should be renamed to be an Ethernet-based Print Station to more properly reflect its function and structure. The product functions have to be drastically cut.

. The server will NOT queue print jobs, but operates as a printer attached to Ethernet. It doesn't have a disk or console. Seasoftware permits very nice debugging from remote VAXen. Fonts, and station programs are nicely stored on a remote VAX.

. The station will be based on Seahorse I (followed automatically by II). Seahorse I operates in prototype mode TODAY with a VAX, Seasoftware, an NI, and a Unibus to Qbus adapter.

. The hardware for this first product should be greatly simplified so that we can get a completely debugged system up asap. This would correspond to the current products on the market. Fundamentally, the design approach is several stages:

1. get the product built as quickly as possible in software, while using rigorous design methods with

specs. We will ship this unless it's too slow. If it is too slow, then microcode Seahorse to have the bitblt function. This will get the text-only print mode to be clearly acceptable.
2. when we understand the functions well enough and the amount of processing they require, selectively move the functions into hardware.
3. replace Seahorse I with Seahorse II (for cost reasons). A bounded version with MicroVAX, NI, etc. may be considered when we understand the current design space AFTER building a product.
4. VLSIzation of a function such as line drawing or bitblt might be considered when we understand performance.

. acquire and use the Adobe system for graphics description and font generation. It may be run partially in the station.

TODAY, USING THE LN01

C-T.printer-

PROPOSED STRUCTURE

```
C...C
!___!__ (Ethernet)
 !
 T.print_station
```

Where T.print_station :=

```
------- (Ethernet)
!
K.qna Pc Mp K.laser-T.print_engine-    (Pc :=
Pc.Seahorse!Pc.Microvax)
!_____!__!__!___(Qbus)
```

and K.laser is a double buffer memory which alternates between printing and being loaded by the processor. Pc accesses the Mp.

The current design has two gp processors and their associated busses, neither of which do very much except talk to each other and prepare work for a third, microprogrammed processor, which also controls a complex chip for line drawing. This design is based on one MicroVAX, and no special hardware in the first, potentially slow implementation. There are several ways to speed the design up:

- doing more operations in the hosts in preparing documents
- microcoded pixel operations
- some form of the current microprogrammed machine, or one special hardware operator to do a time consuming operation

WHY I THINK THE PROJECT HAS TO BE REDIRECTED

The reasons for this are not whimsical, but based on several previous projects, including Venus, Jupiter, VS100, Pluto, HSC and PRO.

- There's no definition or spec on what the system is supposed to do. Likewise, functional specs are non-existent for each hardware and software sub-component.

  The sketchy hardware specs are non-hierarchical, incomplete (memory sizes or locations aren't given, busses and links to busses are missing, etc.), conflicting, informal, etc. There isn't a manual for the various microcode machines or the hardware. I've seen nothing on software!

- There's no analytic data backing up any of the design, nor is there any data showing how each of the subsystems must perform.

- The design I see is incomplete (as reflected by the lack of specs), even though there's hardware coming. Flaky, incomplete hardware is a giant millstone! As such, it is precisely in the state of Jupiter when it was cancelled, even though much hardware was built and some of it running for 2 years.

. The design is far too complex to ever operate with this level of rigor in the organization, specifications and tools to carry out the design.

. The printer group is evolving to take on this major software effort, while lacking software engineering personnel and practices.

. We should have done PRO this way. Put on the Qbus, get the software operating, ship, and then cost reduce if necessary with a new bus, accelerators, etc.

. The VS100 and Pluto have similar structures: seperate 68000's, accelerator hardware with microcode and specialized software. ALL have taken more than 3 years, NONE perform acceptably, nor do we know why. On VS100, two of the processors are now acknowledged to be redundant.

I'm not advocating a large organization. This one is already larger than DECwest, and the project is of similar size. The quality of the project is over an order of magnitude poorer in every respect. As such, it is unlikely to ever reach completion.

Jim,
I think you have to lead us through this one. We badly need this printer. If it's available outside, and the project can be entirely software, then that's the easiest way out. Alternatively, we can go the painful route of training the people rather than giving up on them and never being competitive or able to build complex systems. Frankly, I think there are enough bright engineers among the intellectually bankrupt management structure that it's worth what will be a very difficult project and process. Success is probably some combination of the two.

Since the distribution of function and the need to print what our workstations produce is such a key part of the product structure, I have no choice but to help. What do you want from me?

ATTACHMENT
The attached memo fairly accurately reflects our meeting.

At the meeting, I felt we should continue on our present course to build the current print server interface, while having a simpler controller built in parallel for software development.

Today, I feel we should DROP the design because the product and project are so far beyond our capabilities. We would go on some kind of buyout or to a much simpler plan. One of our software groups has an operational breadboard of a printer, and this might be the basis of a product, too.

A MUCH SIMPLER PRODUCT AND PLAN

We might change the project, reflecting a much simpler product structure on which the group has a chance, to implement. There is no way that the current group, with this set of specifications, abilities and processes could ever come close to building an operational design in anything under 3 years, not ONE. SUBJECT: SOMEHOW FINDING $'S TO BREADBOARD THE LQP/SHEET FEEDER

I really liked what I saw. Somehow we have to move post haste
to get a breadboard to see if there are any flaws in it and

how hard it will be as a project. The intriguing thing is that
we could take the WHOLE Spinwriter lqp market away from Diabolo,
NEC, Qume and C Itoh. This ought to be a major incentive to go balls out and get it. Also the add on ribbon/belt market would be enormous.

Let's get to working breadboards immediately. What will we NOT
do in order to get this one?

SUBJ: The Centronics Quietwriter--Is it for us?

Date: 8/21/79
From: Gordon Bell
MS: ML12-1/A51 Ext: 223-2236

TO: Jim Bell, Dick Clayton, Henry Crouse, Bob Glorioso, Gene Jones, Walt Tetschner, Art Williams, Bill Zimmer, OOD

Although I'm enthusiastic that the Quietwriter could be a major alternative to the Selectric or daisy wheel impact printers, it is important that we do a thorough evaluation. Right now it looks good, but then at this stage of engineering, many things always look good. It seems like the alternatives can be ranked:

	Selectric Dot Matrix	Daisy Wheel		Quietwriter
quality	1	2	1?,2?	3...but rapidly improving
noise	4	3	1	2
font variability	4	3	2	1
graphics ability	3	3	2?	1
reliability	3	4	1?	2
best cost	?	?	?	?

So the issues are: the cost differences may not be significant, the Quietwriter's quality is unknown, but unless it gets to Selectric level, it is probably not worth pursuing, and it feels like Dot Matrix will come up rapidly because everyone is working on it in one form or another. I resent the fact that we have to really evaluate the Quietwriter because life would have been soo simple proceeding along the matrix path.

I hope this adds some balance to my position. Let's go flat out to evaluate the Quietwriter, cause it could be significant for the short (5 years?) time frame. We do need the quality most likely for mail and for personal communications. In the long run I believe dot matrix will win.

SUBJECT: SHEET FEED VS. ROLL OR FOLDED FORM FEED: AN OPPORTUNITY!

If we could go to ALL sheet feed it seems it would offer incredible opportunity for us.

Having only sheets, permits:

0. Handling all kinds of paper including envelopes, thereby allowing us to get rid of the lingering typewriters in the office.

1. Any paper can be used.

2. It's right. It avoids the cruddy roll paper where it's impossible to get to be 11" long. It avoids the messy bursting and stripping required in the folded/form feed.

3. It's unique and represents a competition knock-off.

4. By using cartridges, paper types can be switched early.

5. Eliminates the "box" or "roll" and is easy to place anywhere.

6. A different style/shape of printer can be made!

What do you think?

ps which are small in transistor count, but these need to be available for widescale use. A program to make this transition within 2-3 years, providing 10 - 20 million instructions per second would have far greater impact on supercomputers than any other factor as described above for use in PC's and multiprocessor structures.

It should be noted that these multiprocessor computers do not provide a lasting uniqueness, but rather, lower the barrier of building supercomputers. Furthermore, any country can make a substantially better micro than those on the market (and in development) today, and with known interconnection techniques achieve substantial parallelism. This represents another technological blindsiding giving a 2 - 3 year lead.

7. <u>Packaging.</u> This crucial area needs to be examined seperately and an action plan formulated.

Subject: **About a Score of Impressions and Recommendations from Visiting Three Sales Offices**

To: Marketing Committee

CC: Dick Clayton, Bruce Delagi,
Bruno Durr, John Leng,
Julius Marcus, Gerry Moore,
Larry Portner, Jack Shields

Date: 10 MAY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

Introduction

I think we have a massive sales effectiveness problem. It starts with a complete inability to know anything about what we are going to sell, transcends into a labyrinth of finger pointing about products and sales support and goes finally into general office procedures. The most condemning aspect of the situation is that there is no visibility that we have a problem...in this case a hierarchy of problems, and then a setting out to solve the problems.

The purpose of this memo is not to define the problem (this can be done by McKenzie and Company) but to give symptoms based on my impression from recently visiting sales offices and talking to customers and salesmen -- and to urge us to get McKenzie in now! The impressions should not be taken to be universal about offices or salespeople. The salespersons are open about these problems and anxious to get the problems resolved; they are anxious to discuss them with other officers too -- the only hopeful sign.

Summary (* Action possible)

1* We have inward focus. No output is caused by intra-sales and sales-P/L talking.

2* DEC salespeople have no identity. We got them everywhere else, and with our unstructuredness they're ineffective. Also, we have no way to build DEC salespeople.

3. There is a dichotomy of product-oriented and customer-oriented sales. Can this be managed centrally?

4. There's little method of account control (selling, service, software versus time).

5. The three organizations are both ineffecient and cause less team behavior.

6* One office at least, looked amateurish and are there adequate office procedures, etc.?

7. The order processing system is pretty questionable, but then there was no plan with performance and costs.

8* The pink sheets are a joke and as officers, we may be liable for incompetence. Let's change sales measures to ships -- not books.

9* A complete sales plan for the product (e.g., VAX) is either nonexistent or incompetent. Sales should object. This has to be done at a group marketing level.

10* WP could be a calling card. All salesmen would like to use it -- since it's something everyone understands, can appreciate, and sell.

11* There is a complaint sales doesn't have time to plan or to report correct bookings. I don't think they know how anyway. These might go through a different organization (e.g., F/S or the Controller).

12. Sales has to be approached as a training and logistics problem, not the management of artists!

13. There are too many products for anyone to know, yet too few because every P/L Sales group needs more.

14* Left alone salespeople try to sell the largest systems. There is no focus, discipline, or goals (quotes) by size.

15* The DEC 100 doesn't recognize the team work necessary for account management or encourage a second salesperson. Segmentation is encouraged.

16* The P/L literature is a collection of garbage! I defy a customer to understand our products from what we distribute as literature. I propose every product line put together a single catalog that explains its products to a prospective marketplace/use. I'll help put the first one for ESG together.

17* There's lots of informative transmission within P/L -- sales by paper, word of mouth, and meetings and essentially no reception. Low quality information (by documents like Sales Update) requires continuous rebroadcasting, etc. We require every salesperson to be a file clerk.

18. We're totally naive that we can have lower costs and compete with the equally large mainframes (e.g., IBM) that force much service. Our manufacturing base isn't that big -- especially as we continue to cut orders back!

19. The VAX-2020 hassle is a field conjured situation by competition in the sales force. There is a relatively well segmented market.

20. The lack of sales is transient as we try to move from OEM to End User -- is a perception.

Details

1. We're fundamentally inwardly focused. I believe, based on sampling of calls to salespeople, that the sales organization spends too much of its time communicating with itself and with product lines. There is essentially no time or people left for customers. It recently took 2 salesmen to call on me to tell me what they wanted me to say at a presentation to a customer seminar. (This could be a phone conversation, TWX or memo -- those 2 salesmen were not making their quotas this year!) In many cases there is emphasis on trips to Maynard or elsewhere and meetings to discuss the situation versus written statements and action-oriented conference calls.

2. There is no identity now as a DEC salesman. I personally identify with the older, technical salesperson who speaks bits, instructions/sec, operating systems capabilities and detailed applications...so I am significantly less critical of the technical salespeople. We now have a mix! We have the truly professional salesman, who, as all the salesbooks say must have first and foremost the ability to sell themselves. We hear all the time how professional (recall Kaufman's comments on the professional) they are, but they are simply not results-oriented. They all came from another company because we do not believe in training programs or growing them from the ground up. Since we are at a reasonable size, it is getting somewhat more difficult to get them and since Burroughs is the only company relatively screwed up and not growing, it's the only source of trained people. The sales associate program is a joke in the field...as one salesman said we are spending our time creating Rolls Royces and we need a factory to produce Chevrolets. Our fear to hire college graduates, for example, is typical of the problem. (Note, if Manufacturing had not put schools in PR to train

electronic people, we would not have been able to get the rapid growth...we couldn't steal these people from all the other companies.)

Since the newer less product oriented, less DEC oriented salespeople are better personal salespeople they may occupy the senior sales management staffs and cause a downward bootstrapping of product knowledge without the attendant improvements in sales performance.

3. There is a distinct dichotomy between the commercial and more scientific salespeople and I don't doubt if there is effective management because of this.

The problem of having no identity as DEC salespeople is that older more established companies totally run by procedures and when we have such a lax procedural base, a lot is left to the individual initiative; structured people will blame the company for every thing (e.g., yield setting, literature, sales training, product segmentation, no time to plan, no team selling, OEM versus end user, selling by size, etc. etc.)

4. There is not a very good concept of an account that lasts over time. With a high growth and lots of people movement even before they are ever tested or qualified, this tends to get in the way of a stable relationship with a customer or with a team of people in an account. There is a muddy pecking order within sales, software support and field service; the notion of a team really doesn't pervade the group in most cases.

5. The three organizations require independent top-down structure which seems redundant and probably enforce segmentation.

6. My impression of the NY office was that it looked amateurish and a place I wouldn't want to take a customer. Their computer room had cables laying about and skins off the equipment which was in a state of repair and upgrade (do the repair off hours). Only 50% of the proposals were done on word processing systems and it is unclear for such a large office why there were only two WP terminals (in a very large disorganized looking room). One of the midwestern offices had only 10% utilization and knowledge of WP. In talking with the head of the office I couldn't get sales bookings and sales costs figures for the last two and projected years.

Although there was a literature room, and area of the office held an assorted overflow. Surely there was no one responsible for literature.

The very pleasant work area was where the top level management had their offices, walled off from the troops.

7. The salespeople wonder about the effectiveness of the order processing system. It seems like we have decentralized one small part of the

operation, while leaving the rest in tact, and now we have a more cumbersome operation with only additive costs and delays. There is no measurement of this performance or its costs, nor did it have a plan!

8. The system of measuring and reporting backlogs, especially in the OEM marketplace is at best incompetent and it may even be illegal. As an officer I would like to know the extent of our collective liability in this area (Al Bertocchi, I believe you should formally access this). There is no way that the backlog and order rate we have had has any basis on reality. Supposedly the sales offices fingers, memos and meetings point back to the product lines to make them aware of the situation. There is nothing written on the subject. The pink sheets, which we watch religiously are clearly only random data and I submit that taking some appropriate temperatures in .01 degree increments of every salesman at 2:30 every Friday would yield better data about our backlog. For starters, the backlogs are cumulative numbers and can not be represented or even approximated with the single number we

use. Secondly there is no way that the companies who order from us can go through the growths that are attendant with the backlogs we project.

I would like to propose we throw out the pink sheets and go to the measurement of ships in the OEM area as an aside, each sales office has a Field Service planner who must plan spares and the training of field service people...they know what the order rate really is and don't go through the euphoric ritual that we do to get the high backlogs. We continue to joke about the oscillations superimposed on our exponential growth, but in this case it may just be the last time we oscillate.

9. There is little or no training and/or focus on new product programs (e.g., VAX) together with a sales strategy as to how to go about selling it. Each of the product lines are doing different things and there is not strategy or deep understanding across the groups. The selling is essentially contained within Win's product lines, and there should be sales, promotion, customer identification, sales support program at this level. In this way, the training can take place across ESP, EPG, LDP, OEM for real time users, IPG plus the few in GIS. A central support group would get the training fast, get the advertising co-ordinated, provide a backup sales group, give field seminars which at this time have to be on a product basis (note Brookhaven has not had a presentation yet on VAX). The manager of the NY office, a commercial type, hasn't the foggiest notion of what the machine is or how to prospect for it. The salespeople don't either! (They only know that it is a hot machine.) We must get organized on VAX!

10. With the big inventory of VT78s and the universal interest in Word Processing, I believe we get these systems into the offices for quick delivery. These also provide a good calling card for all customers. Salespeople agree but don't know how. Also, there is the usual reluctance to sell anything they don't get credit for.

11. Sales managers believe they are flat out working on today's problems and don't have any time for planning or for account management because they are driven to get orders (which they are clearly not getting). I don't think it is in the nature of salespeople to plan, and I would propose that this aspect of understanding go through field service or financial organizations on a separated reporting basis. I believe the controllers organization should be solely responsible for the assessment of order rate and the recording of shipped nor, etc.

12. In a quick perusal of our sales training, I don't see how the training is set up to take people who have fundamentally been salesmen working on short term goals and turn them into people capable of managing offices. The logistics, planning and field service management has better training for managing sales offices where the goal is to get, and equip trained salespeople, plus interface with the suppliers (i.e., P/Ls) to insure there is a message. In this regard the concept of sales being anything more

than a congeries of artists seems foreign to sales management. The problem is that the company is locked into the output of water and oil color painters, house painters (with a few barn painters thrown in) together with a collection of musicians and finger painters all trying to get us some sort of artistic extravaganza.

It seems like we need effective co-ordinated, plans on how we are going to get the orders in the various products/marketplaces. I have never seen a single sales plan, for example, giving: the number of salesmen, the areas, how they are to be trained, how the training fits in with promotions and how prospects are gotten, what the gestation period of a sale should look like, what the competitive posture is, how the P/L supports the field, etc. etc. Such a plan would be the basis for effective product line support and the management of sales. From the plan, we can assess deviations and measure results. Alas -- nothing but the artists.

13. Although we have too many products for the multi-priced, multiapplications markets based on our ability to mobilize salespeople effectively, we are still in a runaway situation requiring more products because there are still lost sales in every possible area because we go after orders anywhere we can instead of having a targeted, organized measured and controlled approach.

Business products is the best example of this now, where when it was successful, had only a limited set of products and a targeted approach to selling.

14. Business products used to be segmented by size and hence had a clear product focus, and with reorganization into end user and OEM, lost this and lost control so that all groups went for the biggest ticket items, and ignored the small products we were initially successful with and where we had a clear niche. Now we compete with every competitor and our OEMs compete with us in the small, medium and high end marketplaces.

15. The DEC 100 somehow destroys any notion of team work that is necessary for account management and selling the right product.

I would propose there is no credit for bookings, but only ships and that reference account selling where a second salesperson is brought in be accounted credit toward quotas in some sort of shared fashion that could even be negotiated by the two salespeople. I believe we would rather lose an order to a competitor than to give the business to a fellow DED salesperson.

16. The plethora of product line products and collection of what we kindly call promotional literature and can be more accurately called garbage is disheartening to customers and to salespeople too. I believe that each product line must build a product catalog of what they're selling including hardware, software, services for their particular marketplace. This, relatively large catalog, would be aimed at the customer (and we wouldn't have to produce some of the horrendous marketing guides that I doubt our sales

people read (nor are many of them capable of reading). The catalog would establish who the customers are and what the products are for the particular customer base. Let the customers decide our sales costs are out of sight because no one knows about a product. (I will personally volunteer to help with the catalog for ESG in order to get this focus. Here, we want something like the Tektronix or HP catalog!)

17. The P/L - Sales; and Sales-Customer interface is an inefficient, mouth-mouth resuscitation process. (Note, no ears are involved.) The transmission process needs to be clarified, and our messages simplified <u>and cut</u> down with less irretrievable (i.e., unless we want every salesperson to be a file clerk) garbage in Sales Update and flash TWXs!

18. Our marketing vis a vis large competitors (IBM) is naive. A salesperson will, within seconds state we sell because we have lower prices and better products, yet we aren't selling because we need much more sales support and service that cause higher prices. I can't identify any uniqueness now in the commercial market (a few years ago we had OEMs and low prices). The EDP Manager/IBM salesman controls what the Fortune 1000 computes on! There is perhaps a strategy to get a foothold, but we have to only sell completely unique products (i.e., VAX to scientific, TRAX, 2020, DECnet, WP, RT Factory Data, or unique small systems). Forget all else!

19. See summary.

20. There are probably more but this is all I could recall from a few days in the field and a feeble memory.

Ted has complemented you as a clear product/technology presentor. He asks for more of your time for field presentation. Let's decide how much.

Ted would also like to get a list of presentors that could make these presentations. Could you collect such a list from the rest of OOD and within R&D together with their presentation titles?

As an immediate problem, could you figure out how we can pull together a "canned" presentation that attends to the following (attached) problem?

SUBJECT: SANDIA AND LASL: VAX, LAN, OFFICE AND VT18X

Some comments regarding a recent visit:

Environments (VAX... and 2080 support).

They each have about 25 780's and really love VMS. The only complaint was a need for a larger exponent. LASL has four Crays and a

large
network of supercomputers. VAX is used for: switching, processing
for print service, CAD, Central computing and distributed computing to
a small collection of users. They compute, do pre- and post-
processing and check out for the super computers. A 780 supports
about 18 users. Sandi's going out for a replacement for a 6600 which
supports about 60 users. THEY NEED A MORE POWERFUL VAX!!!

We must provide a really clean way to make the 2080 an upgrade from a
VAX. Given their FORTRAN orientation, this should be relatively easy.

Their supercomputers have dial in and fixed terminals, file server
(>1000 gigabytes in a disk form, 3850 and automatic tape library),
LANS a print/COM server, concentrators, authentication/securing
servers. They're both building LAN's over their large areas. LASL is
using and going to wideband for remote connection. Sandia has a
Hyperbus in their center with gateway machines for 9 VAX's and fiber
optic links to the remote VAX's.

Their fiber optic back bone is built with Western Electric, 144
strand cables, $20/ft. A receiver or transmitter costs $100., and
operates at 32 Mb/s, but could run at 90 Mbs.

Neither intend to use Ethernet as their primary LAN, but each would
use EN within a building. (The geographical areas and security issues
preclude this use... although the main part of Sandia is only

1.5 km.)
They are worried about security on EN.

Sandia envisions both a single EN across buildings, interconnected via
fiber optic repeaters AND separate EN's for various buildings that go
through gateways to other ENs.

Thus, there are three options needed for their EN:

a. Repeaters using fiber optics as an intermediate link.
b. Gateways using fiber optics among EN's.
c. Gateways using CATV among EN's.

It would be nice to map EN into several channels of wideband.

I think we want to sponsor and encourage the development of these
gateways and repeaters to be done by the 3rd party LAN Industry!
Liddle is going to discuss with us at the DEC-Intel-Xerox PR seminar.
The technical user communicates and publishes.

There was a problem of not being able to sell word processors directly, but requiring a commercial salesperson. I don't understand
why?

We just have to start to attend to our technical users! Their
requirements for office processing:

1. Run with dumb terminal VAX or

2. Run standalone to off load the VAX on a WPS

3. Scientific character set.

4. Mail

5. Typesetting, (with typesetter support). They want us to offer the typesetter. They use TEX. Should we support it too?

6. One terminal for: dumb terminal, including graphics, and upgradeable as standalone.

Where are we on being able to do this on the 278? On the CT?

GETTNG MORE PERFORMANCE FROM VAX

1. They need Venus.

2. We must have a really clean connection between the 780 and the 2080. Given the VAX installed base, a cluster upgrade using the 2080 looks like a much better market than just upgrading the current 10/20 base.

3. Atlas is expected and being discussed.

4. Is there any way to get a 4 processor Atlas? Los Alamos is building a 9 processor 8086 to study single task, multi processing. Good Luck.

5. Better communications hardware would get some cpu cycles? What is the effect of combo? What else is needed?

6. Personal computers for word processing and intelligent terminal functions for editing would also get may machine cycles. Here an electronic 278 provides the best performance.

7. Can HSC and clusters help? Can the clusters be used

to get
more users on a single system because of separation between
control files and processing?

VT18X

Basically confusion. Can they buy it? Can they get a demo? How does it work with VAX? How do they get their hands on all the third party SW? How much will we offer?

GENERAL

Interface to Product Lines is tough LDP, GSG, TPG, ESG, (and commercial for WPS).

Mr. Raymond C. Sangster,
Senior Scientist, Workshop Organizer
U.S. Department of Commerce
National Bureau of Standards
Boulder, Colorado 80302

Dear Mr. Sangster:

Thanks for your pro forma letter of October 27, arriving October 31, inviting me to a workshop on November 8 and 9, 1978.

Of course, I can't come so why bother sending it. As usual this is another ineffective transaction by the Department of Commerce. The conference looks useless too.

Sincerely,

Gordon Bell
Vice President,
Engineering

SUBJECT: RE: SCHLUMBERGER

I'm reluctant to let them have this.

They complained to me that they weren't tuned in enough. This will take engineering resources, and I'm reluctant to promise these unless we have a very firm understanding in writing. I'd let them have protocols but only on a very restrictive basis (eg. they cannot use them on non-DEC equipment).

Overall, I think they're crazy to be pushing so far beyond our releases. This will be both expensive and painful for both parties.

Why can't you produce a plan that is constrained so they operate as a test site?

If we want them to be a research group, then that's another story.
BJ + Heff, what you say? Your decision.

SUBJECT: SCHLUMBERGER

Gordon,

The meeting with Schlumberger, Friday Feb. 4th was very good and I want to thank you for your help.

In summary we could supply them with what they need although we will not be ready to support it as a product for at least 18 months.

They need the cluster support we are developing for CI to be implemented on the N.I. We are not in a position to do this. We could give them the preliminary code developed by Kerby Altmann, but we would also have to give them some protocols that we might not want in the public domain. We could also open up our VMS development people to a level of support that could disrupt our cluster effort on the CI.

On the other hand we could gain some valuable information on how Kerby's cluster software works on Ethernet.

My personal opinion is that Schlumberger will not be successful if we do not give them the code. Schlumberger has told me they desperately need this draft to protect our protocols. They are also willing to take the code without any support. This however is unrealisitic. The best thing we accomplished out of this whole exercise was that we identified a group of people who could answer questions regarding our plans for networks. We need to develop this capability further because there will be more "system engineering questions" asked as our customers become more knowledgeable. Local software CANNOT answer these questions.

My recommendation is to supply the code to Schlumberger if we can protect the protocols and not disrupt current VMS development on CI clusters. I would be willing to take responsibility to coordinate all the necessary meetings and act as a buffer between Schlumberger and our development people.

I think the risk is high but I think it's worth it! Schlumberger will hack out a solution with or without our help. I would rather have them hacking wiuth out software. Also I can't think of a more technically competent client to gable with.

I look forward to your comments.

Philip Abelson
Editor, Science
1515 Massachusetts Avenue NW
Washington, D.C. 20005

Dear Mr. Abelson:

When I met Arthur Robinson last year at the Submicron Research Conference and presented a statement of technology management in Japan, he noted an interest in my paper for Science. Since then, I presented the paper at a Conference on Innovation at Dartmouth, and as such it might constitute prior publication and not be appropriate for Science. If you are interested in reading it, because it has some views not yet published, I'd be delighted to send it.

Since that time I have used a similiar approach based on a recent trip to Brazil and deliberation on how the Chinese might start to produce computers. Also, virtually all countries have made erroneous policy decisions about establishing a computer industry because their experience doesn't fit and because their decision making cycle is too long. As a result I have put together a paper on "Establishing National High Technology Industries: The Computer, A Case Study" and am enclosing it for consideration for publication in Science.

At present, the material is in what I consider a "final draft" for review and being sent to several people for their comments. My plan is to pull together some appropriate references at the point that it is in an acceptable form for publication.

Cordially,

Gordon Bell

5183917657

SUBJECT: SCORPIO: ORGANIZATION REVIEW AND INSTALLING TND/EQDM

At the recent Scorpio Design Review, several issues came up:
.Who's in charge of the system architecture and various
modules?
.Do you specify and characterize the components and
processes?
.What is the design methodology? Who's in charge of it

.Will you use quality walk-throughs? how much simulation?
.How are you doing the training? since engineers will run programs
.Do you have the machine resources?
.How do you manage across all the sites?

While I don't think you are near VENUS/Jupiter disease because I see much more involved and knowledgeable top managment, I would like to see how the detailed design is organized, managed and what the designers know regarding handling a design of this complexity. Also, we simply can not afford any slips in Scorpio or the BI options... and I would like to accelerate them, as well as get more modules for the same effort. Note that quality design increases productivity.

PROPOSAL: LET'S USE THE QUALITIY DESIGN METHODOLOGY...

While this has not been flushed out very well, I'd like to use Scorpio to define and use it. John Manzo and Sharon Keilor would come in and help in the definition, and then go on to work on training.

The following slides were given at the State of the Corporation last week, and what I think we need to have in order to get the job done.

THE NEW DIGITAL (TND): ENGINEERING

THE EDGE IS THE ENGINEERING ENVIRONMENT

where we use our Fifth Generation products based on a homogeneous VAX environment, to learn, bootstrap and build the Sixth Generation

WHERE ENGINEERS, ENGINEER!
products, tools and processes to build products, and
components for building products in ALL parts of the World

AND USE THE QUALITY DESIGN METHODOLGY
to drive and exploit engineering learning curves so that
as engineers, we do lots of designs in our lifetime!

(The ROI on designs that have a shorter gestation time will be very
high because the designs will be much more competitive...)

A PROJECT EXPERIENCE (in the old Digital)

Specify the scehdule: 9...27 months to FCS
Establish a program office to co-ordinate and trade-off:
Service, Manufacturing, Marketing, Design Processes, Scheduling,etc.
Establish a design group and leave them alone to oranize, argue and
try to write some sketchy specifications about the product
Occasionally review but concentrate on the periphery, not the product
Predicate design on QUICK DESIGN, BUILD, SEE IF IT WORKS METHODOLOGY
where a poor, half-done breadboard is somehow built to learn from,
followed by a redesign (or two) that will be manufactured,
Avoid: understanding, conflict that comes from design trade-offs,
timing analysis, formal (computer checkable) interfaces,
verification, design inspections, simulation, etc.
Manufacture and wait for the ECOs

VENUS EXPERIENCE
(an example, of the Quality Design Methodology)
Copy and install the ideas from complex VLSI design and software:
Organize in a hierarchy of chief designer, project leader and box
projects (each with chief designer and project leader)...

in a team!
Establish clear goals: eg. quality, shipment, performance and cost
Characterize the processes and components (eg. gate arrays, modules)
Be able to understand the "state of the design" automatically
Predicate the design based on the QUALITY DESIGN METHODOLOGY:
  where at each step, there are no errors...
  design it correctly, verify and model it, inspect it, test it via
  simulation, and then build it (and expect it to operate at power on)
Use the physical hierarchy as a "friend" to segment the design and
  establish formal contractual boundries among the team
Use the logical hierarchy as a "friend" to segment the design in time
  and make sure that there is always a "running" (simulated) design!
Repeat on the next design!

TND: ENGINEERING FOR THE FIFTH AND SIXTH GENERATIONS

Highly trained, engineers and managers who understand the competition
  by being with customers, at school and technical seminars,
  competing with the Japanese, IBM, AT&T (et al), and start-ups
Install and use much improved design tools based on our own
  Fifth Generation...the VAX, homogeneous computing environment
  (with direct links to all engineering and manufacturing sites)
Tools for technology scaling to allow re-use of designs at least once,
  and learned from. Also, tools for automatic, low level design which
  will allow creative, higher performance and higher reliable designs
Underlying semiconductor and interconnect technology for designing (by

SCORPIO GOALS AND CONSTRAINTS (ROUGH DRAFT...I mean rough)

Scorpio covers the products eminating from the Scorpio chip set. Products such as the Suvax workstation and database processor will be described elsewhere in detail, but they must be included within the Scorpio goals and constraints.

Because of the power and low cost of the processor, memory and emerging specialized processors, we must think radically about designing new systems! (Note, Amdahl's rules about computation in conventional environments imply that we have indeed reached the point of a ZERO cost Pc, when balanced with Mp and peripherals!) Others will be using Semicomputer Company processors and special chips to make a wide range of systems. This has to be our mindset.

Gemini, Scorpio and Nautilus are the first processors of the non-Unibus, BI form factor. The processors and combinations of mass storage and other peripherals permit a wider range of systems to be built than in the past. G&S also are sufficiently small, yet powerful to be the basis of a revolutionary way in which we must build this next generation. At the same time we can use G&S to build drastically lower cost per terminal shared systems, there is an identical need to provide ALL the power of a Scorpio (750 power) to a single user in order to make that user more effective by voice, image and other complex processing required of Fifth Generation Applications.

THE ZEROTH GOAL is to use a very small set of Scorpio (Gemini now) modules to build the widest possible range of current and future oriented computing environments, including:

- ONE module set for oems and building our systems!!
- Group Servers -conventional shared systems as cost-effective follow-on to current 730-780 systems and delivered in the Unpack & Stack form factor allowing customer installation in an office, laboratory, computer room or rack environment
- Group Servers built into Mass storage with NO customer integration except to PLUG (on the NI) and GO
- Clustered systems using the CI and Cluster technology to provide increased availability and power by replication
- Multiprocessor-based Group Servers as an alternative to somewhat larger uniprocessors
- a homogenous, clustered environment, with process location transparency, interconnected via NI, and containing:
    - Group Servers operating conventionally (as above)
    - Personal Workstations of CT150 class (Person Servers)
    - File and Database Servers, storing voice and pictures
    - Printing/Plotter/Picture Servers
    - Communication Servers to terminals and gateways to other computing environments
    - Real Time Servers to various external processes (eg. power plants, industrial processes)

PRODUCT UNIQUENESS GOALS
Understanding and maintaining, useful uniqueness is a goal. VAX has attained this by: the basic architecture, evolution from the 11, the high quality VMS environment including

coupling of multiple programs in various languages, datamanagement, and the applications that it has attracted.

Some possible uniqueness goals:

- . smallest number of components for maximum range of use
- . ability to incrementally upgrade without throwing out
- . ability to design and trade-off for high availability (We must take our CI based work and cost reduce it!)
- . ability to design and operate in a distributed system environment in a transparent fashion, i.e. interprocess communication is independent of physical locality of the process (We must take our NI based work as the base!)
- . having computers above Scorpio that can be used for computational and data base work
- . having PDP-11 computers below Scorpio that can operate in a compatible, upgradeable fashion
- . ability to start now in building Fifth Generation, Homogeneous Computer systems
- . the "best" real time design, build and run environment, including: simulation of both controller and controllee on the development system, remote checkout of controller with a simulated controllee, remote checkout of controller operating controllee, and monitoring via the development system of the total system via the controller
- . user microprogrammability to help us get out of the various competitive holes, and to work on the various image and vector ops for speech and pictures we'll be in

PMS STRUCTURES
The ideal set of hardware and software might let us build every type of multiprocessor or multicomputer network that's ever been invented. There is a need for both mP and nC structures.

Single BI Multiprocessors Are the Basis
Conventional multiprocessors are not yet effective for

greater than a few processors (about 4) when multiprogrammmed or on a single task. Multi-Pc's on a single BI is for incremental performance and to interface special processes. It is also desirable to support systems with computers on the BI, operating with its private Mp.pvt (Cs = Ps + Mp.pvt). For multiprocessor systems on a single bus (a single computer), we have these goals:

- . multiple Pc's on 1 BI up to BI bandwidth (C= constraint)
- . all processors, including special processors (Ps) and computers (Cs) which can (must??) access all memory on a BI system (C)
- . reduction of BI bandwidth and isolation of programs by private memories which are accessed by Pc's or Ps's, thus forming local Computers on a BI (This option could come later, as it is fundamentally a way to reduce bandwidth. Depending on the globality of the M's, this becomes a physical protection mechanism.) I think I favor having global accessing so that all M is in one address space.

Multiple BI Multiprocessor, Single Computers
Given that we have so many ways to address the issue of performance and reliability, these multiport memory structures will probably just cloud the issue and introduce more complexity into our software and testing. Furthermore, given the limits on the BI, and cabling in general, they are difficult to build.

Since we are building multiprocessor and multicomputer systems already, rather than proclude them, we should make sure they are possible to build, although it will not be our intent to build and offer them.

Special multiport memory systems are inevitable as we begin to process raw video. Access of a video channel will be direct to a memory card, and a memory may be accessed by several BI or other special busses for transmission to some other part of a system.

Multicomputers for RAMP Using the CI
We have two unique pieces of technology with the CI that

should be exploited as part of Scorpio: the basic fast, interprocess communication that will result in high performance; and RAMP! We must have a Goal to cost reduce and offer CI or CI-type communication.

Distributed Processing on the NI
We must tune the interface of NI such that the overhead to communicate among processes on seperate computers is NO higher than the communication of among processes on the same computer!

SOFTWARE ENVIRONMENT
rooted on vax dist. systems and PCC's
gets into PCC's
Note, the systems should be transparent to whether there's a disk

RAMP
every card is capable of self diagnosis and reporting, (If this is made as a constraint, then there is an implication about Mp partitioning

every card can diagnose the bus, and go a long way toward diagnosing co-residents of the BI

UNPACK AND STACK SYSTEMS (U&S); AND INTEGRATED SYSTEMS
Environments: office and lab, C room, oem equipment in a rack (we haven't addressed this yet)

With Unpack and Stack (U&S) systems all components are shippable in 50# increments via UPS and can be installed by the user! There is no rack. This is the goal of all G&S, U&S Systems. For Scorio in or with large peripherals, the user can do all but move the drives into place. He can still build his Rackless system and connect it.

MODULE SET
what they are (can we get a set of specs for each of them asap?):

Pc, includes the various serial line diagnostics, etc.

Mp (hopefully solving this ability to have either global or private access) for a given Pc,

C.comm boards such as the combo ... alternatively, a protocol assist module would be used to access the vast array of line cards,

C.voice ability to do voice i/o for both personal and shared use

C.display such as Suvax, would also drive an imager for printing and plotting

NI,

SI,

CI,

K.Aztec, or shouldn't it be C.Aztec to be SI compatible?

K.Wini or C.Wini for small systems

eurocard: cost and benefit and will we not have Amerocards?

backplane interconnect and standardization. Must be able to handle multi-module options and to get cables off. How's CT?

longevity vis a vis U and not Q (Let's get the poop on why the Q bus has been so poorly executed ... Q16quad, Q16double, Q18quad and double, and now Q22quad and double... with need for Q22mP

escape to other busses ... why?? Which ones??

video and video bandwidth is not quite 1 BI ??

CHIP SET
The biggest constraint here is that we must predicate our designs on using industry standard microperipherals and special microprocessors for cost (eg Wini) and possibly performance

How close is the Scorpio Chip set to the II?

Can we sell the chip set? ie. is it easy to apply?

FORCE '83; THE MODULE/SYSTEM BUILDING PROCESS
What if we really made a very effective design process such

that we could do high volume specials reliably and cheaply?

If you folks would have a look at this, send me comments and then I'll try to get it in a better format.

Hope this will give us a couple of things to talk about this week.

.

PROPOSAL: LET'S USE THE QUALITIY DESIGN METHODOLOGY...

While this has not been flushed out very well, I'd like to use Scorpio
to define and use it. John Manzo and Sharon Keilor would come in and
help in the definition, and then go on to work on training.

The following slides were given at the State of the Corporation last
week, and what I think we need to have in order to get the job done.

THE NEW DIGITAL (TND): ENGINEERING

THE EDGE IS THE ENGINEERING ENVIRONMENT

where we use our Fifth Generation products based on a homogeneous VAX environment, to learn, bootstrap and build the Sixth Generation

WHERE ENGINEERS, ENGINEER!

products, tools and processes to build products, and components for building products in ALL parts of the World

AND USE THE QUALITY DESIGN METHODOLGY

to drive and exploit engineering learning curves so that as engineers, we do lots of designs in our lifetime!

(The ROI on designs that have a shorter gestation time will be very high because the designs will be much more competitive...)

A PROJECT EXPERIENCE (in the old Digital)

Specify the scehdule: 9...27 months to FCS
Establish a program office to co-ordinate and trade-off:
  Service, Manufacturing, Marketing, Design Processes, Scheduling,etc.
Establish a design group and leave them alone to oranize, argue and
  try to write some sketchy specifications about the product
Occasionally review but concentrate on the periphery, not the product
Predicate design on QUICK DESIGN, BUILD, SEE IF IT WORKS METHODOLOGY
  where a poor, half-done breadboard is somehow built to learn from,
  followed by a redesign (or two) that will be manufactured,
Avoid: understanding, conflict that comes from design trade-offs,
  timing analysis, formal (computer checkable) interfaces,
  verification, design inspections, simulation, etc.
Manufacture and wait for the ECOs

VENUS EXPERIENCE

(an example, of the Quality Design Methodology)

Copy and install the ideas from complex VLSI design and software:

Organize in a hierarchy of chief designer, project leader and box projects (each with chief designer and project leader)... in a team!

Establish clear goals: eg. quality, shipment, performance and cost

Characterize the processes and components (eg. gate arrays, modules)

Be able to understand the "state of the design" automatically

Predicate the design based on the QUALITY DESIGN METHODOLOGY:
where at each step, there are no errors...
design it correctly, verify and model it, inspect it, test it via simulation, and then build it (and expect it to operate at power on)

Use the physical hierarchy as a "friend" to segment the design and establish formal contractual boundries among the team

Use the logical hierarchy as a "friend" to segment the design in time and make sure that there is always a "running" (simulated) design!

Repeat on the next design!

TND: ENGINEERING FOR THE FIFTH AND SIXTH GENERATIONS
Highly trained, engineers and managers who understand the competition

SUBJECT: SCORPIO REVIEW: IT AND TEAM LOOK VERY GOOD. THANKS.

In the April Engineering Review, Scorpio turned out to be the cornerstone of our future and of the greatest concern throughout
the company. Therefore, I wanted to look at it closely as we enter the May Woods.

I asked the Scorpio team to review Scorpio with me, Craig Mudge
and Bob Supnik this morning in order to get more understanding
about the status and the team. The issues of concern:

.how tight is the design in terms of density? (25% area margin... more than we have had in the past. The FP chip
is 90K sq mils)

.what issues are pending that could stop em? (DECsim)

.what about the system? (they're concerned... there are several possibilities. This has to be addressed.)

.when will we see chips? (Sept. 83 and variance -10% +20%)

.what is the time between passes? (8 wks.)

.what if we change to the IEEE floating point format? (3 qrts)... basically, we can not change to the format!

.what other standards could affect the design? (the new,
IEEE bus interface that though similar to BI is NOT BI!)
Architecure must get involved, we can not afford to have
another "IEEE floating point standard" that we will
ultimately have to comply with and that is different from
what we are doing!" HELP! (Fuller/Strecker)

.what other VAX architecture changes could alter the design?
(there are some)

.what is the regularity factor? (as much as it can be...
that's the basis of the design)

.will the speed be adequate, given it is only a 5 mhz clock
and others are at 10 and are going to 20? (the VAX

architecture is complex and won't fit on current chips, we
are using parallelism to get speed versus raw parallelism.
Nevertheless, there has to be work in determining the
competitiveness of the chip vis a vis architecture and
implementation. This is the domain of Fuller/Strecker and
Supnik; we need to hear from them.)

.who is taking their methodology and applying it elsewhere?
(up to Supnik and Williams)

.what is the design methodology and how is it managed? (This
is a major part of the project. It is formal and
documented. It is virtually under spec. control.)

I am very happy about the project at this stage, and the high likelihood that Scorpio can be produced as planned.

Thanks for the review. I look forward to the phase transition in September. My congratulations to the fine team.

Gordon

SUBJECT: DISCUSSION OF SCORPIO AT GVPC MONDAY... URGENT!

I just received the following memo, entitled SCORPIO, from Andy:

"Already we are facing another monumental disaster in terms of this project, its goals its time frame, it management, its lack of market sensitivity, etc. etc. etc. Eight chips for greater than $1000 in 1986 ain't going to make it. Can we have a review of at least the goal set before we spend the 20 million plus in capital next year to put a technology process in place which runs counter to the industry.

Please help us. SUVAX, etc. is at stake here. Help - we'll miss the 32-bit window if we continue on the current plan."

I believe that Andy may be exactly 100% right here. Rather than wait around till after Thanksgiving to get this review, I would like it to receive top priority at the GVPC on Monday, where we ask Bill and Jim to give us an update, plus how we are going to set a full review in motion. The Zilog possibilities should also be presented.

This is a topic we do not want to muddle and wait to discuss. The project is at the heart of our 1980's business. We must

have
it very soon and it has to be good; otherwise, we might as well
stop making VAXes.

(Will be at MR and would attend via conference call if possible.)

SUBJECT: IS SCORPIO SOON ENOUGH TO COMPETE WITH NEW 32-BIT MICROS

Several machine announcements arrived in today's mail, they are:
1. Bell Lab's 3B-5 32-bit microprocessor board using a MAC80 chip

working fall 81, production fall 82 at about comet speed. A
3B-20
at greater than 780 speed. Apparently ATT is headed into
computer
business for their internal use.
2. Meanwhile BTL, Indian Hill is using the Intel 432 to build
an ADA compiler.
3. HP is announcing a 5 chip, 32 bit set at the International
Solid
State Circuits Conference (when we discuss Tiny). Each chip
has
about 100K transistors, our target for Scorpio. The CPU chip
contains 450K transistors! Clearly the record for a non-ram
chip.
The performance looks like possibly 780 speed, and it has a
29-bit address. Clearly an outgrowth of the HP3000. Given
that
the chip has to work before it can be described at the
conference,
then they could be awfully far along at a system product.
(I make it, that they are 5 years ahead of us, by
comparison.)

We should also recall that there exists many micros on the
market
today that have 20-22 bit virtual addresses, all of which
will
be adequate for market already, and all which beat the 11 in
cases where the address is a limit. Also, they are all
getting
UNIX.

I believe we have a significant technical threat here in
several
dimensions. Furthermore, I don't believe the plans we have
in
place are adequate to meet HP, assuming they just move their
3000 software over and they go out and aggressively market.
Worse yet, if they can do it, so will IBM, the Japanese, and
we know about the big micros.

We must get together a small task force and begin this

assessment
and ask various groups what they can do.
Can I ask for a leader for it?

SUBJECT: SCORPIO MANAGEMENT

I really believe that conventional engineering managment and promotion principles should not apply within semiconductors and Scorpio. We push really great project engineers into the next level where they oversee lots of projects. Some are effective at this level, but we end up losing some really talented persons because of this reward structure. My own personal frustration is that I don't know enough to be a great
project engineer. The engineers that I most admire here are those that build great products as chief designers.

It feels like Scorpio is being managed by a person who has not previously managed a product, furthermore, our most talented
leader, Duane Dickhut is being wasted on supervising multiple projects... among them Scorpio. Scorpio is our highest priority project, and I'd like to see the project leader(s) report directly to you. Here, I say possibly two leaders, cause I have as the model, something like the chief surgeon model for programming. His second, will handle a number of the tasks, or there may be an adminstrator who deals with all the outside environment (budget, resources, product managment,
users of the chip, etc.) and possibly some of the project administration in a two-in-the-box fashion... while the leader
really leads the design team.

Within semiconductors, it is important to not follow the regular
path of promotion, since each design is much greater than the previous one, and hence the task is expanding exponentially already.

Can I really implore you to restructure the Scorpio project so that it reports higher, and is lead by the best that you have? (I had this discussion with Roy. Why don't you guys kick it around and then let's talk about it?)

SUBJECT: PLANNING, ARCHITECTURE, IMPLEMENTER GROUP FOR SCORPIO

Demetrios, as Scorpio leader, has proposed that a very small task force plan what we are going to do with Scorpio chips and boards, as there is such wide useage. The opportunities are that it gets us in the high performance board business, as well as being the basis of the personal vax, as a file server, as a database accelerator when coupled to an HSC50, and then as a really red hot multi- terminal computer to replace comet, the 780 and nebula as it has equal performance to all these at essentially zero processor cost. Also, as a high performance board set, it would also be used to move to a really hot front end, real time machine for lab and industrial use. Therefore, the range of use is enormous. Also, I'm pushing having multiprocessor capabilities, as all the micro busses now have this.

The team Demetrios had in mind to outline the plan, and then to go off and implement the various parts (whether they be hardware or software) are You, Dave Rodgers, Bill Avery, and Duane Dickhut (the chip builder). He wanted me to be a part of the early definition task force.

The approach sounds right as it is based on the planners=doers.
He should get it going in the next week, or two at the latest.

SUBJECT: RE: REVIEWS OF SCORPIO AND OF METHODOLOGY

I would like to get the understanding of when I am wrong. I want
to be told ... it bothers me that you either think my ego
is a problem or that I'm incapable of learning. It feels
like you are building an incredible defense mechanism here by
putting the blame back on me for something.

I have levelled several concerns at the semiconductor group recently:
1. I don't sense a good enough understanding of the
technology space. The gate array fiasco was an indicator where
I watched us listen to bean counters shoot beans at each other
and the war was totally in another contintent. I
didn't see the relevant metrics, competitive comparisons,
or understanding of the industry scenarios.
2. The products coming out don't look competitive. Supnik
was able to defend the FPA in terms of Intel. While
I bought this, I have a gut feel that someone else will
have something better (eg. note the 68000 in the EDN article).
3. Apparently you learned something about the process in
my queries. I still don't feel good enough about your
understanding of it.

Somehow, we are arguing that I am another dumb manager, like Ken that is harassing you. (By the way, I am making similar arguments to and about Ken.) Admittedly I do not understand the semiconductor space, but I haven't been given the education.

The point is: the enemy is not me. While you are succeeding in intimidating me and chasing me out of the space, I wonder if others like Fujitsu, etc. aren't the real invaders?

You might talk to Grant, we had similar discussions and you might ask him how he won? or who won? or what happened?

We do have to get together on this. Maybe it will take some personnel folks too.

I really am not the enemy, and I can learn and I am wrong... let's deal with all of these.
gordon

Mr. Ed Niederhofer
Vice President, Marketing
Scott Instruments
815 North Elm
Denton, TX 76201

Dear Mr. Niederhofer:

Thank you for your proposal. We have reviewed your offer of R&D services to develop voice recognition technology and have decided not to accept at this time.

We are currently evaluating the role of voice recognition in our products. Until we have a clear picture of our requirements, we are disinclined to enter into cooperative development arrangements or to draw premature conclusions about appropriate technologies or implementation approaches.

Your proposal and the enclosures have been directed to the appropriate development engineering groups. At a later date, when needs are better defined, there may be an opportunity for further discussion.

Sincerely yours,

Gordon Bell

From: Gordon Bell
Date: THU 14-JUN-79 08:41:01 EDT
Subject: SCS-11

Please forward to Daley, Heffner, and Keating.

I am not very happy about the scs decision, because it runs counter to what I
think gives us the long term best software position. For some reasons it may
not be possible to get to where this can happen. Certainly the position that
SCS is a new operating system will probably get us one and get us going down
the wrong path. Hopefully it might be as simple as having the work for the

human interface done in the m group. In no way do I understand how doing the
same interface to both RSTS and RT is going to get us an overall lower
support unless we make the assumption that these users will demand the same
interface and hence we will have to do everything on all operating systems.

Although I thought all the avenues had been persued, I would like to have some
more time to explore this. Bill Johnson should drive how we might look at it,
but I want to get into some of the implementation questio s. Cutler should be
invaluable here because he has been doing some work on the small system for
the micros group.

Overall, I would like to get to a single system that is compatible with VAX at
the M level such that it would run down to and including a single user. This
is the only way we are gooing to get the growth and compatibility I think our
users need and that we must be able to sell. This will require a lot of
discipline in the marketing domain that I'm not sure we have because the
users will come after us on the transition and the pressure will be fierce to
do everything. On the other hand, it may be the only way to get the
capabilities that are inevitably required for communications, data management,
human interface, reliability, foreground/background that will continue to
plague us to be done on m, rsts, and rt. ... I wanna go to m and get it down
in size too and get everyone over to it.

Having attended Fall DECUS let me congratulate you and your co-workers on their performance. It was one of the most intensely technical user-developer conferences I've seen and it was impressive to see the respect our customers have for our products and people. (It was also much larger than the first FJCC I attended in 1960.) We want to keep up this communications channel.

The exhibits and talks were extremely professional and very stimulating. The VAX sessions, were crowded and the customers very happy.

I was truly proud to be an engineer at DEC.

The Secretary reports to the Coordinator of Administration and spends most of the time in tasks related to the calendar, telephone, memberships and correspondence.

Calendar

- o Daily updates the calendar which includes staff meetings, appointments, events, store personnel schedule, etc.

- o One copy is posted, one copy each to Director and Store, and one copy is kept by the Secretary.

- o Staff makes additions, deletions, corrections each day to posted calendar.

- o Current calendar is kept on floppy SUESYS, document 0.5 and archive is on 0.10.

Telephone

- o Museum's main numbers are

answered by the Secretary

o Most calls are requests for information, for literature, or to schedule tours.

o A listing of all literature sent out is kept.

o Tour Information Sheet is filled out for tours and this information is added to the calendar.

Memberships

o All memberships are processed by the Secretary.

o A monthly running total of members and money is kept. (See Secretary's Office Procedures Manual for details.)

o Floppy MBR001 contains information about memberships.

o Rolodex cards for all members contains work and home addresses, telephone numbers, and effective date of membership.

o Book called "Membership Lists" includes alphabetical and zip code lists, Founders and Corporate Founders.

Correspondence

o Processes most outgoing correspondence

o Kept on floppies CM001, CM002, CM003 in chronological order and a copy if also kept in correspondence file.

o See Secretary's Manual for

detailed procedures.

Secretary's Office Procedures Manual

o New Members Procedures

o How To run labels, Rolodex cards, pull a founders list, do a member list, and procedures for correspondence file headings.

o Disk Index of floppies used by Secretary

Floppies

o SUESYS -- DECMATE System disk

o DEBBIE

o SYSMBR -- System disk for memberships

o MBR001 -- Membership List

o C001, C002, C003 -- Chronological correspondence

SUBJECT: 4 SEGMENTATION DIMENSIONS FOR OUR PRODUCTS AND WORK

I spend a lot of time trying to structure what we do. For the
last few years, I've been using this 4 dimensional space of:
Level of integration (the what), the size (scale) of what we
build; where we are in the life of what it is we are building;
and the activity (or what it is we do).

SEGMENTATION DIMENSIONS
Note the 4 dimensions, which we need to continually refine and
hold as our segmentation for engineering and manufacturing
organizations:

Level of integration:
H/S-chips, chip carrier, module, backplane, box, cabinet, hardware system/ operating system (including files and communications), language, generic tools, application;

Hardware price of the things (components or systems) we sell:
(hand held .4-1, Terminal based 2.5-6.25, stackable 6.25-16, cabinet(s) 16-40, 40-100, interconnected cabinet 100-250-625, multiple computers using CI 250-625-1.6M);

Phase (life-time):
Basic research, Research, Advanced development, Development, Support, Enhance, and Obsolescence;

Activity:
.Component design, sometimes we call it the technology (the thing- whether it be a chip or a word processing system. We must stick with the notion that one person's system is another person's component... hence we only

make components.),
.Engineering Process (how can designers use it as a component in the next highest level a design),
.Manufacturing Process (how do you make it?),
.Manufacturing test process (how do you know it works?),
.Maintainence Process (How can it be made to work over its lifetimea?),
.Market process (How do we define it during its various phases and sell it?),
.Management processes (how do we organize, manage and interface to one another to get the work done?)

TOP-DOWN APPROACH (MFG./ENG./MKT. SEGMENTS)

The taxonomy is only useful if it allows us to segment our activities. We are extremely lucky in having growth, because it is comparatively trivial to manage charters. On the other hand, left alone, there will be overlaps and underlaps in an area where the new product opportunities abound (eg. WPS, voice on packet switching networks, small systems growing into terminals). I think we ought to use the remainder of the summer to sort this out. Let me suggest two approaches: top down- we look at a cleaner manufacturing/engineering divisional structure; bottom-up, we look at overlap, underlap, and new opportunities.

Significant manufacturing-engineering (and occasionally marketing coupling). I don't want to muck in the divisional space, all I want is to STREAMLINE each group's charter and to have a clear relationship with all other groups as a buyer or seller.

This is the background thinking that led to the organizational
proposal today.

What you think?

GB1.S5.52
process record

GB3.S1.?

We've made great progress in building an organization, but I'm really concerned with whether we're on a successful course. The dismantling of the Burroughs Semiconductor operation brings this home.

It seems that the part aimed at VLSI has this quad-whammy:

0. It's just plain expensive. Maybe there's better use for the $100 million/year.

1. Being cut off from the merchant market by not participating in their designs.

2. Late, hence obsolete, proprietary parts. Parts such as the video controller, and BI chip take so long that we don't have timely, hence competitive systems.

3. Our low factory loading means expensive parts, but this is a minor problem.

Furthermore, the semiconductor use based on gate arrays that brings in the revenue is outside the mainline VLSI support.

It's unclear what the answer is, but it might be helpful to look at various reasons:

1.

Our architectures simply can't be implemented in VLSI! It took too long to get the 11 on a chip, and VAX seems more difficult.

2.

We only do the very difficult designs, hence they're all long and expensive.

3.

At the one or two chips designed per year level, we have virtually no learning curve since the technology and people changes erode transfer of useful relevant skills and knowledge.

4.

We have an organization that's staffed by "old DEC", not semiconductor engineers. The top three levels haven't designed a chip or semiconductor process from scratch.

5.

The projects may be mismanaged with too much emphasis on circuits versus chips. There may be the wrong mix of chips.

6.

We may have too much money and also misallocating funds, given that we can afford to start our own unique CAD system and our own unique MOS process. These will both be expensive to maintain, while also robbing us of potential chip development. There are other signs of this too.

7.

The semiconductor organization mirrors the rest of DEC and has simply gotten fat, very wide and defocussed on its mission.

There appear to be two future scenarios for getting semi-conductors, with reality in between:

1.

Only a few makers of chips because they're so expensive.

2\.

Everyone designs chips, only a few make them on standard processes just like color photograpy/processing.

I don't see us getting closer to either scenario.

What are your thoughts? I think we really need to discuss, perhaps after the Scorpio review next monday.

SUBJECT: YOUR (FAULTY) PERCEPTION ABOUT SELLING TINY

I believe you and Peter are all wet. Whoever thinks we can get
50-200 for Tiny chips doesn't know the market! The PDP-11 is becoming about as interesting to the informed engineer or TOEM as
a PDP-8 (6120 chip), where there were an unmeasureable quantity
sold.

There is no risk of the Tiny being especially useful to an OEM
just as there is little use of it for our own products. With the 64K RAM chip it is hard to build a system that uses less than 128K (64K more than the Tiny addresses). Nor is there system software.

I do agree with trying to make the Qbus a commodity bus and selling peripherals. We must go significantly farther:

1. Get a semicomputer company to license and build and sell ALL 11 Chips very aggressively! In this regard, I have asked Philips (and Signetics) to come here and discuss this with us.

2. Publish our internal interconnect specs so as to get the semicomputer folks building in a more organized way.

3. Publish how to build really cost effective board based systems built on the Tiny, Fonz and Jaws.

4. Keep a strong license position on our software! This is the control, not the hardware.

5. Forget about competition from anyone taking the chips and making systems that will compete with us! The micros business is selling boards and anyone who would want to do that is free to now. Selling chips versus boards only means a differential of a 100 or so dollars anyway.

6. Push to try to stave off the onslaught of the scenario we have been looking at within engineering we call Doomsday. (Doomsday, is that time when the processor is free and an established commodity standard. There are commodity peripherals, commodity software (like say UNIX), the world has standardized on card busses (say like the IEEE 488 and Intel Multibus, an IEEE bus).

Please help to get the 11 out there in this form as we have a chance of convincing the market that the 11 is the best, 16-bit processor, and they needn't go to Z8000, the 68000, or the 8086. Already, these folks have shipped more chips than we ever did 11's. Recall that we were forced into using the

Z80
for Robin. Note also, that there is REALLY ONLY the 370 as the
standard mainframe (recall what happened to Honeywell, Burroughs, Univac). There are many vendors of the 370 ... and
IBM is successful!

If we wait, we are going to have a system in the 11 that is about
as exciting as the PDP-8 was in 1971-75. In fact, as we avoid
making this decision, we are on a clear course to kill the 11.
The demise, I think will be faster than with the 8 cause there
are exciting alternatives in the market.

How about pushing to help make this crucial decision to be an aggressive supplier of 16-bit chips, board, boxes and systems?

The bulls make money and the bears make money, but the pigs get
slaughtered.

SUBJECT: PRESENTATION OF SEMICONDUCTOR STRATEGY TO THE BOARD

Let's get this scheduled asap. It is important and we all have to understand and agree to it pretty much the same way. There are two developments this coming month that I hope will be useful to this: visit to Japan in regard to acquisition of MOS and bipolar gatearrays; and deciding to sell the 11 at the chip level (which is about to be proposed and has strong support from the Marketing folks).

A part of the presentation should be directed at the glue parts and how they are turned around quickly.
We ought to get into the whole issue of education, turn-around, learning curves and how we are going to get learning when we only do 1 MOS chip/year.

Our current position / strategy is simply:
.Hudson supports Bill, Ulf and Grant, wishing them well
.Hudson may propose to have a fast turn around for gate arrays
.Ulf buys gate arrays outside for hi end
.Bill buys gate arrays outside for mid range and glue
(Meanwhile the mid range is possible to be built from good MOS parts if you don't mind using someone else's architecture.)
.Hudson builds 1 MOS processor every few years (or 1 MOS chip/year) to feed our micros business and now the 11. In 84, their chip will feed the whole VAX base up to 100K systems ... whch is VERY important for us!)

.We set a standard for building MOS parts in the II and then buyout as many standard chips as possible for CRT controllers, comm., disks, voice i/o, etc.

They might not want the sublety of the question of when or if bipolar is replaced by MOS (because it eliminated the whole concept of the mid range), but I sure want this in our version of the dry run. This is the question I asked about last Thursday that we must answer!

Let's get on with the presentation first at PEG, probably waiting for the other Japan folks to return and also after the task force I want to schedule reports on how we can use standard micros parts to build mid range performance systems. (Bill, I'd like you to lead this one!)

SUBJECT: SEMI-CONDUCTOR STRATEGY TO THE BOARD OF DIRECTORS

Some of the Board of Directors are concerned when they read about the goals and huge investments of the Japanese in order to dominate the world of high density semi-conductors. They worry about us and IBM being wiped out eventually. I think we owe them a comment on this subject.

At one of the next meetings, will you present our strategy as it pertains to semi-conductors.

The strategy I would suggest is that we decide how much we can afford, and decide the best way to invest it, then state this to the Board. This, of course, will not be enough to compete with the Japanese in all areas. On the other hand, we've never had the most of everything, and we've always faced that same situation with IBM who, in any one area, could invest many, many times what we could invest.

I then suggest that we say that in addition to that large, but not overwhelming investment in semi-conductors, we will invest in two areas which are perhaps even more important. The first is the systems techniques for fast generation of integrated circuits, and fast, smooth productions of many types. If you look at our computer systems today, the heart of the central processor is a small part of the cost and most of the cost is in the peripheral circuits, It's obvious that the big cost-

saving
is going to be in doing the odd things, not in doing the center
of the central processor.

Secondly, I would suggest that our strategy be that the packaging
and heat transfer of integrated circuits probably has as much
pay-off as the last steps in increasing the density of integrated
circuits. I would suggest that we have a good team with managers
who are experts in science, and concentrate not only dollars, but
interest and effort in this packaging and heat transfer technology.

SUBJECT: RE: CPU STRATEGY/DECISION METHODS

I think we are all frustrated. Before you tell our designers
to go work for the semiconductor industry, I'd like to be sure
we aren't going to make it here.

Yes, there is a significant push into applications and I

don't
know where the money is going to come from to both forward and
backward integrate. IBM is starting to depend on the semi industry and is apparently coming out with a rash of products based on the intel architecture. They, abandoned their semi group because their group was focussed at the high end. In our case, we are focussed at the low end and our revenue is coming from the mid.

I'm really impressed that we have put together such a good team and that's why I supported Scorpio! We have to continue with our architecture as I see it. The 85+ is really cloudy: semiconductor processing becomes like film processing and we have to all design and get others to build it; or only a few companies build them and we all use them (like Nylon). Given that we are so strongly focussed on use (which I support as hard as I can), then the concern is less with parts ... however, we must have competitive ones (from a performance viewpoint). Architecture really muddies this cause we have a software investment and we also selll architecture.

Let's be calm. We can get through this and all achieve success. Am really glad you have been working in this area and have built our capability. I don't want to demotivate or lose people! I do want to know where we are and how we can be competitive and not lose to others like IBM, Radio Shack r the Japanese by having the pride and drive that forces us to have to do it all ourselves.

WE NEED SEMICONDUCTOR ENGINEERING!

LOC/MAIL STOP: ML12-1/A51

SUBJECT: DRAFT OF BUYING STANDARD SEMIS AND INTERFACING TO SI VALLEY

Subject: Policy update on microprocessors and semiconductor interfaces

The current situation is that we are:
0. developing our own cpu's to get form factor, and other ad hoc chips
1. developing a 2 micron process for cpus, requiring a foundry (2nd source)
2. using the 8080 and acquiring LSI peripherals in ad hoc fashion, although
we are looking at an industry standard for on-board interconnect (II)
3. not connected to any semicomputer company well enough to get advanced info
or to influence their designs
4. likely to need a high performance micro (>20-bit address)
5. building Q-bus modules without benefit of new, one chip peripherals
6. building bounded systems with an implicit bus, versus a planned standard

We should make an explicit decision, like the one to standardize on the 8080,
to have a closer tie with a particular vendor, and satisfying these goals:
1. acquire or jointly develop a 2 micron process for which we have a
production source for chips we design on a second source (foundry basis)
2. standardize on an industry interconnect, II, in order to ultilize one chip
peripherals (buying would be subject to our policy on proprietariness)
3. get advanced information and to jointly specify one chip parts so as to

improve our product lead time and competitiveness
4. select, and possibly use the new, emerging high performance microprocessors
5. determine how to build Q and bounded bus peripherals using the one chip peripherals
6. share CAD, process and product development information to improve us
7. evaluate the strength of various vendors as competitors in their ability to supply machines that will threaten our Small and Mid-range products.

In doing this, we still assume the charter of Hudson is:
1. building our cpu chips that run 11 and VAX-11 programs, given our SW investment and the fact that semicomputer vendors won't design these for us
2. provide a facility for making prototype runs for MOS and Gate array designs
3. do some custom designs, on a rational basis, in order to have capability
4. be the leader in CAD so as to reduce turn around and deal with cpu's
5. be prepared to be a significant design center assuming that in 5-10 years there are standardized processes (foundries) which will make anyone's designs- like Kodak develops film and MOS is the dominant technology because of the high on-chip performance and the inability of bipolar to disipate heat or to be interconnected. Alternatively, the tooling costs are so high that semicomputer companies build all the computer (e.g. Nylon)

We should embark on this selection process with evaluation criteria:
1. ability to work with vendor
2. software and architecture understanding
3. process and CAD capability, past and projected

4. current product array, together with past and projected performance
5. business direction compatibility
6. source of supply as a volume producer.

Should we make an explicit decision now? If so, who will lead us through it?

What are your thoughts on this? Who should this go to? What have I left out?

SUBJECT: ANDY'S SUGGESTION ABOUT SEMIS IN JAPAN

Andy's observed tht TI, Intel and IBM are all going to Japan for engineering especially as it relates to semiconductors. Given that we have larg amounts of tax credits piling up in Japan, then I say let's go balls out and get our engineering there!

They are really leading in semis and in crts and in volume production techniques. We have the architecture, the software and the knowledge about applications.

Hiring engineers is going to be increasingly
difficulty with our increased emphasis on MBA's and the military
spending. The military contractors compete with us for these scarce resources.

Japan is turning out engineers like crazy! They cost less to
operate 80K vs 120K according to IBM, and they apparently work
harder.

Japan is frightening mostly because they have some real deep beliefs and rituals. As a secondary benefit, as we mix with them, we both change a little.

I say let's go for a really aggressive engineering build plan in Japan.

(Also, they do know something about quality. I'd like to learn
this from them. As I re-read my diary when I
visited there 3 years ago, I realize it did have a major affect on
me and attitudes and understanding in this regard.)

SUBJECT: FUNDING FOR NATIONAL SCIENCE FOUNDATION PROGRAM

Please send this MAILGRAM to:

Senator Edward Kennedy, Russell Senate Office Building,
  Washington, D.C. 20510

Please send Carbon Copy MAILGRAM to:

Dr. Wesley Clark, Committee on Labor and Human Resources
  U.S. Senate, Washington, D.C. 20510

25 April 1983

Senator Edward Kennedy
Russell Senate Office Building
Washington, D. C. 20510

Dear Senator Kennedy:

I would like to support your effort to secure additional funding for a National Science Foundation program aimed at two, important classes of Supercomputers: Symbolic Processing and Numerical Processing. Such an effort is needed if we are to maintain the current lead we have in computing.

The Japanese have a strong MITI based effort in both of these areas, and I believe stand a good chance to take over the lead. If this happens, I believe our industry could go from a strong export position, to a net drain as in the basic steel and manufacturing industries such as automobiles. As evidence of their ability to pull off such a program, one should note that their semiconductors program gave them their current leadership position in: high speed circuits (both ECL and potentially new configurations), high speed memories, large memories, gate arrays, and microprocessor peripherals. In fact, the only area we lead are microprocessors.

Such a program must be a balance of academia, the defense department and industry because we have a limited supply of talent. The talent problem will become more acute since the new laws on emigration will further reduce the supply of talented engineers, many of whom we

train.

A concerted program of 10 to 40 million dollars per year would be appropriate. A consortium of companies knowN as MCC (for Microelectronics and Computer Company) is planning to spend about this amount to accomplish the same goal, thus it would be appropriate to have the government spending in roughly the same amount in order to have a balanced program. (MCC's yearly budget will be about 40 million dollars of which 10 million is directed at the computer designs. The remainder is support for the technology and computer aided design for the machines.)

Again, let me applaud your effort and offer any support you feel is necessary.

Sincerely,

C. Gordon Bell
Vice President, Engineering
Professor, On Leave, Computer Science and Electrical Engineering,
Carnegie-Mellon University

His mission:
1. What were we doing? I was vague except to say we're a sales company interested in some interesting product groups and he queried about Schanin who walked in and said hello. He's going to contact both Parallex and Foundation.

2. Get me to give a talk at their AEA.

3. Get me to join their board. It's well financed by H&Q, Perkins et al, etc.

I said what if we joined forces in some form to beat everyone by being able to license board layouts etc. He said: We are open to everything, including financing, joint ownership, etc. the enemy is outside!

He's returning Oct 28 in the afternoon with his marketing person or their president to discuss any next step. We need to talk...!
ALL of us should be present to pursue a discussion.

Here's what would make strong business sense:

1. Joint development across the board. Note for the first time in history a complete second source.
2. We start building and selling their product.
3. We start designing lamP (which they have access to)... and this is our contribution.

With an arrangement like this, I could get a complete premier team (I have a few friends at a nearby company which could be attracted) on lamP at CMU (to move here) and built by Hydra Company.

Dave stated they were doing well. The company is best characterized as a technical version of Convergent Technology... to go after Masscomp. It is not their intent to build a sales force, but to appeal to the technical OEM. I said we were compatible.

He has 35 engineers equally divided into hardware and software. They'll be shipping in about 6+ months with the hardware about to enter debug stage. They are building a performance range UNIX (of course) multiprocessor (1 to 10) on the National part in something like two basic forms. He made strong arguments for it, and said it's equal to the same speed Motorola. He claims the part is doing well with software because all the VAX software is being ported over because the two architectures are so similar. It sounds like Hydra... the board area is 12 x 12... or European version. He was skeptical of the DEC / National bus agreement being significant, since the boards are too small.

CC: DAVE SCHANIN

SUBJECT: GETTING A PERSONAL COMPUTER SERVER ASAP

Bob and BJ, how are we coming here?

We need to move ahead asap to build and test a PERSONAL COMPUTER SERVER under the direction of Bob. Let's use the multi-terminal computer system we are going to put in the stores, but in addition, it should run under some operating system so that it can be a package we offer on existing systems. The system would probably end up on every operating system and would have general applicability in universities (to get our NOR up there), laboratories and large organizations to start with.

The goal would be to use our conventional systems as a Personal Computer Server to store files, print documents (either on a line printer or LQP), and to communicate with other systems using various protocols.

PERSONAL COMPUTER SERVER

FILE SERVICE
Apple II, CP/M, TRS 80 and 278

PRINT SERVICE
LA120, LP05, LA24, and LQP02. Extended to NIP when available.

COMMUNICATIONS SERVICE
3270 emulation, SNA, DECNET and NI

These facilities should be layered on an existing operating system such as RSX-11/M. If we did this, the package would also run on VMS. It probably will have to end up being offered on everone of our systems including: 10, 20, RSTS, M, and VMS.

There should be lots of systems out there we can look at for a
product definition including those in universities and laboratories on everyone of our operating systems.

Can we move to survey what's out there, then define and breadboard this?

GB3.S1.27

Would it be possible to have a software only service organization--given the fact that most of what we'll be selling and installing is software? We could accomplish total service by acknowledging that hardware service today is predominantly board swapping! What do hardware-oriented folks do? If we have a "single" staff, we avoid the cost that other manufacturers have.

This makes our total field product: selling, training, installing (mostly software), service/repair (mostly software), helping plan networks, and possibly managing installations or stockrooms.

What youse think?

GB7.19

26 January 1983

Mr. H. Norman Abramson
Chairman, NAE Awards Committee
National Academy of Engineering
2101 Contitution Avenue, N.W.
Washington, D.C. 20418

Dear Norman Abramson:

I would like to nominate Seymour Cray, who founded Cray Computer Corporation, for the 1983 NAE Founders Award. Cray was nominated to NAE several years ago and ranked number one, but declined membership.

Cray has led the world in high speed computers for the last twenty years by designing and supplying the CDC 6600, 7600 and Cray 1.

I think the former nomination, by Fred Brooks, adequately represents that he clearly deserves the Founders Award.

Sincerely,

Gordon Bell
Vice President, Engineering

SUBJECT: SOME SUPPORT FOR LOW END, SHARED 11'S

There is some market support.

The irony of the push to PC's is that most of us use shared systems in order to share files, printers, modems, etc. and this has to continue until we have good communicating nets ala Ethernet. On the other hand we're rushing into the PC fray yelling me too. The PC folks are rushing at us saying you have to share systems, and I'm just waiting for us to internally start working on shared PC's.

We need to figure out how to make it possible for the buyer to get what he needs. Why such a system wouldn't be sold in a store (not ours) is unclear to me. I know we don't have the resources to sell these directly... as evidenced by the drift to higher and higher systems.

RIGHT ON GORDON.

I HAVE BEEN TRYING TO PUT ONE IN THE FOAC SHOW LATER THIS MONTH WITH A SIGN ON IT:

JUST UNDER 1000 DOLLARS FOR A DECWORD TERMINAL.

IF I DON'T MAKE THIS SHOW, WE'LL MAKE THE NEXT.

YOU ARE RIGHT, WE SEEM TO HAVE FORGOTTEN WHAT WE HAVE IN THE PDP-11. PARTICULARLY THE "LOW END" WHICH IS AS USEFUL AS THE END OF 7 YEARS AGO.

WE ARE STILL PUSHING THEM INTO THE GOVERNMENT.

ONCE WE GET A TEMPEST CABINET CERTIFIED AROUND THE PC FORMAT (KEYBOARD, MONITOR, BOX), WE WILL ATTACK THE LCP.

SUBJECT: SHARED LPC (F AND J VERSIONS) VS PC'S

Having just about gotten a great, personal computer in the 730 as our (Mary Jane and mine... and a few other folks), I would like to advocate a type of sharing that we pioneered and I fear we're about to give up.

The personal folks are telling us that they are going to really
sell a lot of systems (eg. 1.5B in 84 for the 350) and I believe
them. The Decmate II and Rainbow have great projections too.
I'm looking forward to new computers here at home (have 2 DECmate I's)
that can do graphics and have better editors and let us do some
real computing, and the VAX at work will be great because it
has no limits in terms of anything I can think of relative to
what I am able to find time to program it to do..

Let me urge you to push what is I think is our most underrated
system, the LPC with Aztec before others get there from all
other directions.

The shared 11 with 50 megabytes as an incredible machine,
providing over 1, 4 drawer file cabinet's worth of data and
allowing a group of say 8 to 16 have an 11/70 all to themselves.
This is like an 11/70 with an RM03 (or 2 RK07's)! The response
should be fbeat the hell out of any PC for say 16 users.

The cost say for 8 users appears to be about (6.5K + 8 x 0.4) / 8
or 1.21K per user. If you put 8 more terminals on it, then this
comes out to .8K. Both of these beat our lowest cost PC's by
quite a lot. Let me describe the virtues of shared systems. Not
every user has to deal with his own files and systems, thus not
everyone becomes a system's programmer. You can share files,
printers, modems, servicepeople, and this lets you move work
around the system easily and communicate with one another.

We've sold a pile of systems like this (eg. RSTS) and the company really grew to its present 4B size selling systems like this eventhough the systems you have are much smaller in cost.

Furthermore, WANG sells shared systems like this and has also grown to 1B on large systems, not the PC's or standalone systems.

Somehow, we all have to find someone and someway to get this lovely, low cost 11/70 out to the world along with the PC's because it seems that many of the PC folks are making shared systems now too. Also, it would seem that the shared system would be attractive to many of the people who sell and resell and otherwise handle our systems because there's more margin.

During the up and coming budget pass I hope you'll be able to fire people up with the inherently lower cost, higher performance and greater advantages of this type of computer. We need to figure out how to sell them too!

HEURISTICS FOR BUILDING GREAT PRODUCTS (DRAFT)
Gordon Bell, Vice President, Engineering

Five sets of dimensions for building great products need be attended to (roughly in order of importance):

- a responsible, productive and creative engineering group;
- product and design metrics (competitiveness);
- design goals and constraints;
- product evolution, revolution and death; and
- the ability to get the product built and sold.

ENGINEERING GROUP

The Team must have:

- a chief designer/chief programmer to formulate and lead
- management who understand the product space and who has engineered successful products; The most important two jobs of management are:
  - making sure that everyone knows their job; and
  - setting and reviewing work on a timely basis.
- team skills to implement the proposal so that we adhere to the cardinal rule of Digital, "He Who Proposes, Does";
- an understanding of the design, design production (eg. CAD) processes, and manufacturing processes;

Behaviorally, the team must:

- execute the project in a timely fashion;
  - limit projects to less than two years by a small team.
  - not predicate a project on scheduling inventions in the design, process and CAD areas.
- have a written design methodology;
- be open and have external reviews, and clearly written product descriptions for inspection;

- start small, be reviewed and grow on its demonstrated success;
- learn, in order to handle the increase in complexity

PRODUCT METRICS KNOWLEDGE includes:

- products for which there'll be no competitor;
- all product cost metrics
- all product performance and cost/performance

metrics;

. reasons why the product will succeed

. major competitor products by cost, performance and functionality;

. leading edge, innovative, small company products;

. productivity, quality and design process metrics for project management.

DESIGN GOALS AND CONSTRAINTS

. Goals and constraints must be written down and updated from the day the project starts.

. A product can only have a few goals and constraints. The ranking is usually: it must work and have improved cost of ownership, be the shortest time to market, highest performance and lowest cost.

. If a standard exists, follow it or change it for all!

. If a standard is forming go all out to set it.

. Products must be designed for easy translation into in any natural language since we are an international company.

. All products must have be customer installable and maintainable.

. Portability is an important goal.

WHEN TO CREATE, WHEN TO EVOLVE AND WHEN TO STOP PRODUCTS

. Ideas must exist to have products! If we don't have ideas to redefine or extend a market, then we should not build a product.

. A product tree MUST be maintained by each engineering group showing roots, gestation time and life.

Goodness

. offer at least a factor of two in terms of cost-effectiveness over a current product;

. be based on an idea which will offer an attribute or set of attributes that no existing products have;

. build in generality, and extensibility;

. be a complete system, not piece parts;

. be a great system because the components are great;

. if we don't make it, buy it;

Product Evolution

. lower cost products require additional functionality too;

. constant cost, higher performance products are likely to be the most useful;

Revolutionary New Product Bases

. A new product base, must start a family tree from which significant evolution can occur.

Product Termination

. A product evolution is likely to need termination after successive implementations, because new concepts in use have obsoleted its underlying structure.

SELLING AND BUILDING THE PRODUCT

. it has to be producible and work, AND be useful to software;

. a business plan with orders and marketing plans from several marketing persons and groups needs to be in place;

. never build a product for a single customer,

. it must be done in a timely fashion according to the committed schedule, price and functions;

. it must be understandable and easy to use.

Silicon Valley Engineering/Manufacturing Division RFP
To: PSC, frank mc cabe, lou gaviglia,BASKETT,BRUCE DELAGI

Having spent a few weeks in what I perceive as a substantially more active and aggressive Si Valley product environment, I'd like to discuss how and whether we invite proposals on the formation of a group whose charter is to obtain external products and processes.

RATIONALE

PREVIOUS OPPORTUNITIES WE SHOULD HAVE ACTED ON
Some of the product opportunities that come to mind that

would be covered by this approach include:
1. LICENSING THE 3 COM ETHERNET CONTROLLLERS. (Ours cost twice as much, 1/2 the throughput, took 2 years longer, and will probably cost the world the Ethernet standard because IBM will now enter with theirs in the same time frame. In turn, this will cost us the LAN market and require more, poor projects.) This would also include the transceiver and Pluto.
2. SCRIBE AND TEX AS TYPESETTING PACKAGES. We continue to spend multi-megabucks and get no product. Already, LISA has a better package for typesetting than what we offer.
3. LASER PRINTER CONTROLLER. Stanford's had a 1 board product that would drive a printer for 2-3 years. A company builds it, and we could have licensed it several years ago in lieu of the LN01 and LN03, giving us much lower cost and a 4+ year lead on the market.
4. STANFORD'S SUN TERMINAL. SUN Workstations has been formed as a company, and managed by a former DEC employee. This behavior has delayed market entry by several years, plus created several competitors including Apollo. Our Workstations are yet to ship, and a competitive Workstation project is not yet started.
5. ADA SOFTWARE BUYOUT. We're clearly going to be near the last ones in April 85, 1-2 years after DG, to have an ADA, even though we've spent much more and been at it the longest.
6. VIDEO CHIPS AND CLARK'S GEOMETRY ENGINE. The later is truly a breakthrough, and we could have licensed the chip had we moved aggressively at the right time. Not moving means another, significant competitor and product we won't and may never have.

Together, all these mean lost revenue of perhaps only a few hundred million each year. They also cost >10% of our budget. Far worse are the delays and the fact that competitors form and become quite powerful before we can act.

POTENITAL NEW OPPORTUNITIES
Now, there are significant opportunities in CAD, voice and video VLSI (including where we do the designs), database chips, digital PABXes, etc. Forest has several opportunities in the graphics printing area which we badly need for workstations and printers.

Groups are forming routinely to do CAD programs of all sorts from chip to system, and we can use these products to advantage.

THE VENTURE CAPITAL MANIA OF SILICON VALLEY DRIVES THE PROCESS

Although many of the groups that start up are incredibly mundane because they're merely assemblying micros and software to form PC's and then marketing them, there is the aggressive application of technology to systems, and on occasion, the development of technology.

What such an environment provides is a better natural selection process than what we are currently achieving because the people who get together are unusually competent, the group is small, and the motivations are both financial recognition and independence of a large, conservative or lithargic organization.

SILICON VALLEY STANDARDS ALLOW FAST MOVEMENT AND FLEXIBILITY

Everything seems to be Multibus, and then Multibus II. In this way anyone can put together a system by engineering at most one board... and do it in a month. The processor's either an 8086 family or 68,000. Quite possibly the BI could be significant if National went with us, provided we wanted to be in this market.

Programs are in C for maximum portability.

XEROX RESEARCH PARK A SOURCE OF IDEAS

While Xerox has failed to make the transition into products, PARC has come up with many ideas that have been the foundation of products and companies. Specifically:

1. Development of the Mead/Conway technology, and the notion of Si Compilation whereby chips become like publications.
2. Convergent Technolgy is staffed by Ben Wegbreit and other alumni.
3. Adobe Systems just left PARC to form a company to build software for Laser printers.
4. The laser printer for general purpose printing has a company.

5. Apple's LISA is modeled on Alto, and staffed by former alumni.
6. Bob Metcalfe formed 3Com to exploit Ethernet.
7. Surely people who are trying to push their various computers as LISP machines will get frustrated and form a company.

THE INDUSTRY IS GOING THROUGH A MAJOR RESTRUCTURING
In the first and second generations, the emphasis was on circuitry, being able to build a computer, and write some rudimentary programs to allow people to use it. Some first generation folks like RCA and GE didn't make it into the second generation.

The third generation with ssi/msi let many more in (CA, DG, GA, etc.) because circuits didn't have to be built. Peripheral companies also formed by escaping from IBM's disk plant. Computer companies built operating systems and the interface moved to high level languages- Basic, Cobol and Fortran. For the large systems, a software industry formed. In minis, the COEM-type arrangement was used to do the applications.

In the early part of the 4th generation, micros weren't particularly powerful, or especially useful. The industry transition was basically to copy the 3rd where proprietary operating systems were put on standard micros, eg. Apple II, and Basic was the main language. No standardization, except via BASIC. No applications to speak of. Begin to form the applications market segment. This last period of ten years has been a breeze at DEC because we were able to supply machines people could build on for TOEM, COEM, and our customers were good enough to write applications.

In the fifth generation (this one marked by >16-bit address machines such as the 8086 and current 68,000) there is a TOTAL stratification of the industry into many levels of integration:
.Semis-supply the processors, rams; floppy folks; keyboard cos, etc.
.O/S and other system software suppliers including languages. Note

this came about because the semi folks weren't good enough in
software. Venture capital had this form outside of the semis too.
.System integrators and distributors-only assemble or have PC's
assembled for them. CT, IBM, Osborne, etc. ... many, many start
.Generic software specialists: wps, spreadsheets, graphics, comm, db
.Vertical applications. In several cases, we find people also assemblying their own hardware (CAD stations) to get maximum added value.

With the plethora of venture capital money, things will become totally stratified so that as long as a group can show it adds significant value by being a level, it will form. Having a seperate, industry does several things: the real creators take the risk and get the reward; they can be neutral and non-threatening thereby creating standards; and incompatible lower levels can become compatible.
Note this stratification has allowed companies like Apple nd CT to grow at an unprecedented rate, reach $1B with only 4Kp.
The Sixth Generation
I think two phenomena will spur it on: ULSI and AI.

ULSI will remain very tricky and difficult, but can be done. There'll be a publishing business where designers can specialize in an area and make unique chips for different businesses. Now we see this happening by the people who design chips in universities, get a Ph.D for it, and then take it with them to form a major startup. Maybe this won't force them into making systems to exploit the chips because people believe that chips should all cost a few dollars, regardless of their proprietariness, what they replace and whether or not the job can be done any other way.

AI-style programming, or knowledge acquisition in the form of Knowledge Engineering will become commonplace. The goal here is to make a bunch of generic programs (properly generalized, XCON is one such program). The other programs are those listed by the Japanese in the Fifth Generation Report...

which require VLSI too. What youse think? Shall we discuss it? Is anyone interested in being part of this?

OUR CURRENT STRUCTURE/BEHAVIOR
Currently, we're irrelevant to computing except to have Barry building Rainbows out of the fat. Just visit a Computer Store, a new OEM, an EE Department, or several Si Valley start-ups. Engineers are so decoupled from the market and lack of urgency (eg. Ethernet) so much that we simply cannot sustain any growth outside that of our existing, diminishing base in what is **<>** to BUNCH (Burroughs...Honeywell) in the traditional mainframe business.

GB5.62

Having spent a few weeks in what I perceive as a substantially more
active and aggressive Si Valley product environment, I'd like

to
discuss how and whether we invite proposals on the formation of a
group whose charter is to obtain external products and processes.

RATIONALE

PREVIOUS OPPORTUNITIES WE SHOULD HAVE ACTED ON

Some of the product opportunities that come to mind that would be
covered by this approach include:

1. LICENSING THE 3 COM ETHERNET CONTROLLERS, TRANSEIVER AND PLUTO
(Ours cost twice as much, 1/2 the throughput, took 2 years longer,
and will probably cost the world the Ethernet standard becaussIBM
will now enter with theirs in the same time frame. In turn, this
will cost us the LAN market and require more, poor projects.)

2. SCRIBE AND TEX AS TYPESETTING PACKAGES. We continue to spend
multi-megabucks and get no product. Already, LISA has a better
package for typesetting.

3. LASER PRINTER CONTROLLER. Stanford's had a 1 board product that
would drive a printer for 2-3 years. A company builds it, nd we
could have licensed it several years ago in lieu of the LN01 and
LN03, giving us much lower cost and a 4+ year lead on the market.

4. STANFORD'S SUN TERMINAL. SUN Workstations has been formed as a
company, and managed by a former DEC employee. This bbavior

has
delayed market entry by several years, plus created several competitors including Apollo. Our Workstations are yet to ship,
and a competitive Workstation project is not yet started.

5. ADA SOFTWARE BUYOUT. We're clearly going to be near the last ones
in April 85, 1-2 years after DG, to have an ADA, even though we've
spent much more and been at it the longest.

6. VIDEO CHIPS AND CLARK'S GEOMETRY ENGINE. The later is truly a
breakthrough, and we could have licensed the chii had we moved
aggressively at the right time. Not moving means another,
significant competitor and productte won't and may never have.

Together, all these mean lost revenue of perhaps only a few hundred
million each year. They also cost >10% of our budget. Far worse are
the delays and the fact that competitors form and become quite
powerful before we can act.

POTENTIAL NEW OPPORTUNITIES

Now there are significant opportunities in CAD, voice and video VLSI
(including where we do the designs), database chips, digital PABXes,

etc. Forest has several opportunities in the graphics printing area
which we badly need for workstations and printers.

Groups are forming routinely to do CAD programs of all sorts from chip
to system, and we can use these products to advantage.

THE VENTURE CAPITAL MANIA OF SILICON VALLEY DRIVES THE PROCESS

Although many of the groups that start up are incredibly mundane because they're merely assemblying micros and software to form PC's
and then marketing them, there is the aggressive application of
~rtechnology to systems, and on occasion, the development of technology.

What such an environment provides is a better natural selection process than what we are currently achieving because the people who
get together are unusually competent, the group is small, and the
motivations are both financial recognition and independence of a
large, conservative or lithargic organization.

SILICON VALLEY STANDARDS ALLOW FAST MOVEMENT AND FLEXIBILITY

Everything seems to be Multibus, and then Multibus II. In this way
anyone can put together a system by engineering at most one board...and do it in a month. The processor's either an 8086 family
going to a 68,000. Quite possibly the BI could be significant if
National went with us, provided we wanted to be in this market.

Programs are in C for maximum portability.

XEROX RESEARCH PARK A SOURCE OF IDEAS

While Xerox has failed to make the transition into products, PARC has come up with many ideas that have been the foundation of products and companies. Specifically:

1. Development of the Mead/Conway technology, whereby chips become like publications.
2. Convergent Technology is staffed by Ben Wegbreit and other alumni.
3. Adobe Systems just left PARC to form a company to build software for Laser printers.
4. The laser printer for general purpose printing has a company.
5. Apple's LISA is modeled on Alto, and staffed by former alumni.

6. Bob Metcalfe formed 3Com to exploit Ethernet.
7. Surely people who are trying to push their various computers as LISP machines will get frustrated and form a company.

THE INDUSTRY IS GOING THROUGH A MAJOR RESTRUCTURING

In the first and second generations, the emphasis was on circuitry, being able to build a computer, and write some rudimentary programs to allow people to use it. Some first generation folks like RCA and GE didn't make it into the second generation.

The third generation with ssi/msi let many more in (CA, DG, GA,

etc.)
because circuits didn't have to be built. Peripheral companies also formed by escaping from IBM's disk plant. Computer companies built operating systems and the interface moved to high level languages- Basic, Cobol and Fortran. For the large systems, a software industry formed. We pioneered the TOEM structure with the minis. The COEM-type arrangement was used to do software applications.

In the early part of the 4th generation, micros weren't particularly powerful, or especially useful. The industry transition was basically to copy the 3rd where proprietary operating systems were put on standard micros, eg. Apple II, and BASIC was the main language. No standardization, except via BASIC. No applications to speak of.

The applications market segment began to form. This last period of ten years has been a breeze at DEC because we were able to supply machines people could build on for TOEM, COEM, and our customers were good enough to write applications. Also, IBM believed it couldn't manage a dual distribution channel with one product. (Now they believe it can be done, and are doing. We want out of the OEM business for some reason.)

In the fifth generation (this one marked by >16-bit address machines such as the 8086 and current 68,000) there is a TOTAL stratification of the industry into many levels of integration:

.Semis-supply the processors, rams; floppy folks; keyboard cos,

etc.
Also, these are available as board standards.
.O/S and other system software suppliers including languages. Note
this came about because the semi folks weren't good enough in software. Venture capital had this form outside of the semis too.
.System integrators and distributors-only assemble or have PC's assembled for them. CT, IBM, Osborne, etc. ... many, many start
.Generic software specialists: wps, spreadsheets, graphics, comm, db
.Vertical applications. In several cases, we find people also assemblying their own hardware (CAD stations) form the standards
(Multibus, 8086, C, UNIX) to get maximum added value.

With the plethora of venture capital money, things will become totally stratified so that as long as a group can show it adds significant value by being a level, it will form. Having a separate, industry does several things: the real creators take the risk and get the reward; they can be neutral and non-threatening thereby creating standards; and incompatible lower levels can become compatible. Note this stratification has allowed companies like Apple and CT to grow at an unprecedented rate, reach $1B with only 4Kp using the top down, backward integration approach.

The Sixth Generation
I think two phenomena will spur it on: ULSI and AI.

ULSI will remain very tricky and difficult, but can be done more routinely. There'll be a publishing business where designers can specialize in an area and make unique chips for different businesses. Now we see this happening by the people who design chips in universities, get a Ph.D for it, and then take it with them to form a major startup. Maybe this won't force them into making systems to exploit the chips because people believe that chips should all cost a few dollars, regardless of their proprietariness, what they replace and whether or not the job can be done any other way.

AI-style programming, or knowledge acquisition in the form of Knowledge Engineering will become commonplace. The goal here is to make a bunch of generic programs (properly generalized, XCon is one such program). The other programs are those listed by the Japanese in the Fifth Generation Report...which require VLSI too.

OUR CURRENT STRUCTURE/BEHAVIOR

Currently, we're irrelevant to computing except to have Barry building Rainbows -- jus} it visit a Computer Store, a new OEM, an EE Department, or several Si Valley start-ups. Engineers are so decoupled from the market and lack of urgency (eg. Ethernet) so much that we simply cannot sustain any growth outside that of our existing, diminishing base in what is akin to BUNCH (Burroughs...Honeywell) in the traditional mainframe business.

What think? Shall we discuss it? Is anyone interested in being part of this?

SUBJECT: BECOMING A MEMBER OF SIA

Are we going to accept their invitation?

There's a meeting on the West Coast, June 10 that we're supposedly to be invited to by Tom Hinkleman, their director.

I think we should be.

After reading the information on Japanese CAD/Design discipline, I think we ought to reconsider our posture to Intel, via Carol Peters, on sharing of tools!

We're each going to need all the help and co-operation we can give each other SIA may be a forum for this.

Dear Dr. Grassman:

Thank you for visiting us in Maynard last week. I enjoyed hearing about your needs for image computation. We're very interested in continuing to supply these needs. I would also like to understand your image processing needs and the feasibility of addressing them.

I'm looking at the problems of using both sides of RX01 and RX02.

Regarding the VAX question, I'm attaching two letters to Dr. Baur. My feeling is still that Siemens could profitably use VAX in many divisions besides, in addition to your own. I think the low end strategy around the 8086, the 432 and their successors is going to be costly for Siemens.

Again, it was nice to meet you and to show you around our musuem.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Suggest you pick up the conventions for hyphens, caps, names, etc. we used for Computer Engineering from Heidi. CS will have an incredible problem too and now is the time to iron out the potential inconsistencies and get a workable standard.

Call Gwen in late July re. staying in our house in August.

10 January 1983

Professor Steve Director
Whitaker Professor and Head, Department of Electrical Engineering
Carnegie-Mellon University
Pittsburgh, Pennsylvannia 15213

Dear Dr. Director:

It gives me great pleasure to strongly recommend that Dan Siewiorek be given the Frederick Emmons Terman Award. In looking at the exact qualifications and looking at the spirit of the award, I know of no other person that better personifies this award. Dan is completely devoted to both engineering and to teaching!

Dan has excelled in the teaching, research and transfer of knowledge in four areas: reliability, formal description and evaluation of computers, multicomputer architecture, and design automation.

It has been with great pleasure that I have worked with Dan since 1972 in three capacities: fellow researcher, fellow co-author, and fellow-engineer. In all capacities he has really exhibited the traits of a fine engineer and teacher.

Again, let me add my recommendation that Professor Siewiorek be given the Terman Award.

Sincerely,

Gordon Bell
Vice President, Engineering, Digital Equipment Corporation

Subject: **Site Preparation Guide**

To: Don Busick Date: 78 AUG 15

From: Gordon Bell

CC: Jack Shields Dept: OOD

Loc.: ML12-1

Ext.: 2236

follow up 8/29/78

I just had some discussion with Bill Davis and he informs me that the site preparation guide is not a corporate publication, but rather is done on a product line by product line basis.

What in the world is the rationale for this? Why can't we put together a good guide which could be used for all products.

Is that your responsibility, or engineerings, or whose? (I trust it would be sufficiently good to cover various special cases of the subsidiaries.)

SUBJECT: RE: SIGNAL INTEGRITY - DON MARSHALL'S GROUP

I have major misgivings about moving the signal integrity to Bernie and want to discuss at EMC at the very least.

This last organizational change was made to allow groups to focus on particular products. Engineering had gotten to the point where a group was involved in all issues. This kind of cloudy thinking on the responsibility for BI in a totally non-
involved group is what we want to change.

I want people who have the responsibility for success to manage
what they are responsible for and I want to eliminate the dilletantes. Jack and I are the only ones who are allowed to be non involved in specific product responsibilities. Jack is
the manager and I am the architect (city planner) for seeing that our products work together and that we have the right product.

BJ has responsibility for 32, 36 and nets/distributed systems (Bernie and the glue products). These too have to be kept separate. BI is the bus for the next generation of 32-bit products and totally isolated from Bernie and 36-bit Ulf.

In a similar way, I think we have to start isolating the overall software so as to make sure we're going to win and have individuals assigned to this.

BJ and I will discuss and get back to you. Dilletantes don't make the gains, only experts.

Silicon Compilers
105 Albright Way
Los Gatos, California 95030

Dear Phil,

I thoroughly enjoyed the interaction with you, the staff and members of the Board of Silicon Compilers last Monday. My expenses for the trip are attached. I'd like to buy 25,000 shares of Silicon Graphics at your $4 price, and look forward to hearing about the shares I can obtain at the $.20 price level. I'd like to defer payment for the shares as long as possible.

In thinking about the effort, the clearer it becomes that you're going to be limited until a person with significant software engineering management capability is found to head engineering. I don't believe you have anyone on the staff who's shipped a significant software product. It just occurred to me that Carol Peters might be available when she moves to Palo Alto with Peter Christy. Carol has built significant CAD systems. Carver knows her, I believe. She now works in Hudson.

Although I don't really know the field, my suspicion is that you are plowing new ground in some of the programs; as such they might best be described as research. I don't think you can have any programs of this type in the product at all. This work had best be done in the universities. Is there any research in the product?

I talked with Keith Uncapher at ISI and suggested you might have some interaction with them. I think he's interested, and hopefully there's still some kind of relationship with Ron Ayers that could be useful. At any rate, I hope he'll call you.

The model of the business is still of concern. How many of these and other paths could you persue:
1. software only on one or more systems of your choice
2. software sold on an oem'd SUN only
3. franchised tools and training to a small or large company

4. franchised tools and training to a set of independent entrepreneurs
5. tools and training to your own custom design division where you sell design for money, royalty, etc. in a new and clever way
6. Item 5 on a highly geographically dispersed fashion such that you operate near item 4.
7. aren't there lots of other businesses??

It would be worthwhile to have someone construct a business model of each of the components just to see which ones allow you to build the best businesss. Do you have criteria, such as market share in the possible markets, profitability, the best products, largest size, etc. for success? I'd hope the board might look at some of the alternative scenarios by the next meeting.

I think it's essential to have two divisions simply for protection that the tool may take much longer to complete than you think. I really worry about starting to design the perfect tool as the mainline business. Also, if you chose paths 4, 5 or 6 as a major part of the business, you are in effect running today with the present tool!

Anyway, these are just some thoughts which came up as a result of being there and looking at your product plans.

Sincerely,

Gordon Bell

PS
I am sorry, but I'm unable to meet on October 10 or 11, but could be there on the 12th, or any other time in October. I will be at a meeting in Palo Alto on the 26th. Could we set a new date?

2x2x25x.22	22
Total	864.80

Jim says they have a price competitive product with Apollo @37K for diskless, 8 plane color. The performance is 200X the Apollo! For a disk server the price goes to 60K. Their cost has to be low. They're doing a lower cost and higher cost version. It's Ethernet based. The response has been overwhelming.

They're talking to several 2nd and 3rd tier minicompanies as OEMs--but he's not happy. This would get them 250-500 systems (for $20M). Also standard CAD OEMs. Although they'd like to <feel?> end users, they can't do everything. They're interested in talking to us.

They have 100 people, 4 regional offices and a super VLSI group to keep lowering the cost. They're going out for $10M financing to hold them till going public and we just might be able to help one another. They hope to do $35M in CY84. They're owned by Mayfield Fund, with others including Seven-Rosen, NEA, etc.

I asked about making a low cost, compatible version to complement the product line. He said it sounds fine. He says they have a straight A team, and would therefore like to have an A team on sales.

Marvin Goldberger, President
California Institute of Technology
1201 East California Boulevard
Pasadena, California 91125

Dear Dr. Goldberger:

Let me urge you to continue the moral and real support for the Silicon Structures Project that Ivan Sutherland, Carver Mead, and the other members of the Computer Science Department are carrying out. It is unique and refreshing in the interaction between the university and industry, and I heartily endorse it!

We're entering our second year as a member of the SSP and continue to believe that there is interesting and useful work being carried on there. Also, it's one of the few places engaged in training teachers, scientists, and engineers who are capable of dealing with the complexity found in the large, silicon structures we know as VLSI. It is ironic that the academic community has taken so long to get organized in this area, given the large funding in the semiconductors.

Dr. Craig Mudge, who just returned to Digital having spent a year there as a visiting faculty member, is an especially enthusiastic supporter - hence you might contact him for another perspective.

The program is off to a good start, but needs all our support.

Subject: **Emulating or Simulating Other Computers: The Market Possibilities; A Party Line**?

To: Peter Connell

Date: 2 MAY 78
From: Gordon Bell

CC: Marketing Committee, OOD Dept: OOD
Loc.: ML12-1 Ext.: 2236

follow up 5/16/78

In your discussion with Business Week, we should be careful to stay away from the notion of our building computers which are capable of emulating other computers. Emulation means simulating the behavior of another computer in a fashion that is somehow better than the original.

The most common use of emulation is a computer that can interpret a single ISP (Instruction-Set Processor, or Architecture) as in the case of Amdahl, National and various Japanese manufacturers for the 360/370.

There seem to be several uses of emulators:

1. Many manufacturers are and will emulate the 360 and 370. The purposes are obvious: to provide a more cost effective solution than IBM because one has better technology, or lower costs (e.g., hardware, marketing, more production volume). The risks are numerous: lower IBM prices, newer technology, IBM changes the architecture so the software won't operate. The effects are not quite as obvious: the increasing standardization of the 360/370 as the main 24-bit (its address space) architecture and lower costs for the users could occur by the increased competition. Although IBM probably has the patents to stop the emulation, they have chosen not to enforce them. By unbundling the software, they will have to continue to support other manufacturers and because some of the operating system software is in the public domain, anyone can use it.

I hope we never have to emulate the 370, because it will be expensive to do and it will imply that we are in a marketing strategy that is totally IBM dominated...which is why we never consider it now. We believe we can develop and build better architectures than IBM, to be implemented in different segments of the marketplace (e.g., interactive, networks, a larger 32-bit address space, better mapping for executing the languages, and doing applications).

2. We would use an emulator for interpreting another DEC ISP, and possibly our users might use our machines to emulate the machines of another manufacturer. On the VAX-11/780 there is a compatibility mode which permits the interpretation of the standard 11 ISP, while the VAX mode is only a larger address space and different, with cultural compatibility. The writable control store could be used for emulating perhaps another machine.

In an experiment at CMU, with their WCS version of the 11/40, the NOVA was emulated on a reasonably cost-effective basis. We have been asked by various customers to emulate other machines on our WCS computers (11/60; 11/03), and we have in fact emulated a PDP-8 on the 11/60 and run the Operating System at about twice the speed of a regular 8. Emulation could be used, just as IBM did to allow customers to migrate their applications from one machine to another.

3. There is some question as to whether other manufacturers would emulate our ISPs.

We have a patent position with the 11 and have successfully discouraged one company from building a computer that emulates it. A single version of the 10 was built by another company for their internal use, and another company builds versions of the PDP-15 for its own use. We have licensed various implementations of the 11 to Norden for the military market.

Several years ago DCC, recently acquired by DG, built a computer that interpreted the 8 ISP. Both Intersil and Harris have built processor-on-a-chip computers that interpret the PDP-8. (We purchase chips from them.) Of our main machines in production we have patents on the 10, 11 and VAX-11 that would probably preclude or certainly discourage a company from emulating our ISPs.

HEURISTICS FOR BUILDING GREAT PRODUCTS
(DRAFT FOR COMMENT)

Five sets of dimensions for building great products need be attended to (roughly in order of importance):

. a responsible, productive and creative engineering group;

- product and design metrics (competitiveness);

- design goals and constraints;

- product evolution, revolution and death; and

- the ability to get the product built and sold.

ENGINEERING GROUP

The Team must have:

- a chief designer/chief programmer to formulate and lead;

  NO COMMITTEES AS DESIGNERS

- management who understand the product space and who has engineered successful products; The two most important jobs are:

  - making sure that everyone knows their job; and

  - establishing and reviewing work on a timely basis, i.e. MBO.

- team skills and resources to implement the proposal so that we adhere to the cardinal rule of Digital, "He Who Proposes, Does";

- an understanding of the design, design production (eg. CAD) processes, and manufacturing processes.

Behaviorally, the team must:

. do it right the first time;

. execute the project in a timely fashion;

. limit projects to less than two years by a small team.

. not predicate a project on scheduling inventions in the design, process and CAD areas.

. have a written design methodology;

. be open and have external reviews, and clearly written product descriptions for inspection;

. start small, be reviewed and grow on its demonstrated success;

. learn, in order to handle the increase in complexity

PRODUCT METRICS KNOWLEDGE includes:

. products for which there'll be no competitor;

. all product cost metrics;

. all product performance and cost/performance metrics;

. reasons why the product will succeed;

. major competitor products by cost, performance and functionality;

. leading edge, innovative, small company products;

. productivity, quality and design process metrics for projects

DESIGN GOALS AND CONSTRAINTS

. Goals and constraints must be written down and updated from the day the project starts.

. A product can only have a few goals and constraints. The ranking is usually: it must work and have improved cost of ownership, be the shortest time to market, highest performance and lowest cost.

. If a standard exists, follow it or change it for all!

. If a standard is forming go all out to set it.

. Products must be designed for easy translation into in any natural language since we are an international company.

. All products must have be customer installable and maintainable.

. Portability is an important goal.

WHEN TO CREATE, WHEN TO EVOLVE AND WHEN TO STOP PRODUCTS

. Ideas must exist to have products! If we don't have ideas to redefine or extend a market, then we should not build a product.

. A product tree MUST be maintained by each engineering group showing roots, gestation time and life.

Goodness and Greatness = NO CRAPPY PRODUCTS

. be elegant and high quality;

. offer at least a factor of two cost-effectiveness over a current product;

. be based on an idea which will offer an attribute or set of attributes that no existing products have;

. build in generality, and extensibility;

. be a complete system, not piece parts;

. be a great system because the components are great;

. if we don't make it, buy it;

ELEGANCE: WHAT IS IT?

Russ Doane: "every feature contributes two benefits"

RH dictionary: "gracefully refined, dignified, of high quality"
  guality = lack of excess (especially errors)

Elegant design is the use of a part to perform many functions.

Architects say: "Less is more."

Some examples: the stored program computer (use of memory), the   general registers, the Unibus, Pascal, APL.

Several pioneers: "Leave a feature out that can be done another way."

It can sometimes conflict with other goals like orthogonality.

But too much elegance is trickery.

Product Evolution

- lower cost products require additional functionality too;

- constant cost, higher performance products are likely to be the most useful;

Revolutionary New Product Bases

- A new product base, must start a family tree from which significant evolution can occur.

Product Termination

- A product evolution is likely to need termination after successive implementations, because new concepts in use have obsoleted its underlying structure.

SELLING AND BUILDING THE PRODUCT

. it has to be producible and work, AND be useful to software;

. a business plan with orders and marketing plans from several marketing persons and groups needs to be in place;

. never build a product for a single customer,

. it must be done in a timely fashion according to the committed schedule, price and functions;

. it must be understandable and easy to use.

Sat 16:43:43

WHAT IS THE FIFTH GENERATION?

- PR
- TO ENGAGE US (CRITICS, COMPETITORS)
- TO LEARN TO DO RESEARCH
- TO LEARN KNOWLEDGE ENGINEERING AND OTHER AI-BASED TECHNIQUES
- TO GET BY-PRODUCTS FROM FAR-OUT GOALS
- TO REPEAT SUCCESS IN SEMIS AND SUPERCOMPUTERS

THE NEXT GENERATION WILL BE EVOLUTIONARY

.FUJITSU AND HITACHI HAVE RUN THE LIVERMORE KERNELS AT >2 x THE CRAY xmP USING EVOLUTION:

- 25 YEAR OLD LANGUAGE - FORTRAN
- 20 YEAR OLD ARCHITECTURE - 360/370
- 25 YEAR OLD CIRCUITS AND SEMIS--ECL

GENERAL FACTORS IN COMPETING WITH JAPAN

- P = I x E (INTELLIGENCE, ENERGY)
- SOCIETAL VALUES
  - MEDICINE, LAW, POLITICS, ... , BUSINESS
  - SCIENCE, ENGINEERING, ... , MANUFACTURING
- TECHNOLOGICAL INFRASTRUCTURE
  - MATERIALS (SEMICONDUCTORS, MAGNETICS, ...
  - MECHANISMS
  - MANUFACTURING (CONTROL, ROBOTICS,
- MANAGEMENT - ESPECIALLY ENGINEERING AND MANUFACTURING
- QUALITY
- LONG TERM VERSUS SHORT TERM

COMPETING FOR THE NEXT GENERATION

. TURBULENCE DUE TO GENERATION TRANSITION

- NEW INDUSTRIES/PRODUCTS WITH MICRO

- VENTURE CAPITAL <--> ENTREPRENEURIAL ENERGY
  MANY, REDUNDANT, SHORT-TERM PRODUCTS
  THEREFORE, MUCH SHAKEOUT AND LOST EFFORT

PROBLEMS IN RESEARCHING THE NEXT GENERATION

.JAPAN IS BETTER COUPLED TO U.S. RESEARCH THAN AMERICAN INDUSTRY

. RESEARCH ON THE NEXT GENERATION IS HARD

. UNIVERSITIES AND INDUSTRY ARE BOTH ILL-EQUIPPED!
. LACK OF GOALS CREATES LOTS OF POOR PROJECTS
. LOTS OF FUNDING - FEW PEOPLE,
THEREFORE, TURBULENCE AND LOST EFFORT
. LOTS OF POORLY STAFFED, SUB-CRITICAL PROJECTS
. LARGE PROJECTS - LACK OF MANAGEMENT

PARALLEL COMPUTING

NETWORK - WITH LAN OR WAN INTERCONNECT
CLUSTER - WITH LAN INTERCONNECT
FUNCTIONAL - ONE PROCESSOR PER FUNCTION
CLOSE AREA NET CLUSTER - HIGH SPEED INTERCONNECT
TIMESHARING - ONE PROCESSOR PER USER
PARTITIONED - ONE PROCESSOR PER PROCESS

TRANSACTION PROCESSING - PROCESSOR PER STEP
FAULT-TOLERANT - DIFFERENT PROCESSORS ASSIGNED PER
STEP WITH REDUNDANT COMPUTATION
CONCURRENT-TASK - PARALLEL PROCESSING OF A TASK BY
PARTITIONING FOR INDEPENDENT DATA
PIPELINED-TASK - PARALLEL PROCESSING OF A TASK
PARALLEL PROCESSING - PROCESSORS WORK ON ONE TASK

"IF A COMPUTER UNDERSTANDS ENGLISH,

IT MUST BE JAPANESE."

-ALAN PERLIS

THE FOURTH GENERATION

- EVOLUTIONARY USE BASED ON WORD, DATA PROCESSING, PROFESSIONAL APPLICATIONS. EMBEDDED COMPUTING
- INTER-COMMUNICATIONS AND PRODUCTIVITY NEEDS TO INCREASE USE
- WELL-DEVELOPED TECHNOLOGIES, INCLUDING VLSI MICROPROCESSORS, LANS, MAGNETICS, DISPLAYS AND STANDARD SOFTWARE
- NEW ORGANIZATIONS TO BUILD NEW COMPUTERS, BUT
- NEW USES THAT EVOLVE WON'T BE KNOWN FOR A DECADE

THE NEXT GENERATION: REVOLUTIONARY VIEW

- REVOLUTIONARY USE DEPENDING ON VOICE AND NATURAL LANGUAGE COMMUNICATION
- GREATER COMMUNICATION AND PRODUCTIVITY NEEDS INCLUDING ROBOTICS, SPEECH AND NATURAL LANGUAGE, EXPERT SYSTEMS FOR COMPLEXITY AND PRODUCTIVITY
- ROBOTICS, AND ARTIFICIAL INTELLIGENCE, FAST-WANS, ULTRA- AND VLSI AND PARALLELISM
- AVANT GARDE ORGANIZATIONAL COOPERATION BETWEEN RESEARCHERS AND INDUSTRY

THE NEXT GENERATION: EVOLUTIONARY VIEW

- EVOLUTIONARY USE. WIDESPREAD ELECTRONIC MAIL, ELECTRONIC-BASED LOGIC TO ENCODE KNOWLEDGE
- NEED TO HAVE INFORMATION AT "FINGERTIPS" (IN THE SYSTEM AND NOT IN PAPERS AND BOOKS)
- EVOLUTIONARY TECHNOLOGY WITH LARGER, DISTRIBUTED MEMORIES
- NEW COMPANIES. BUILD WITH EVOLVING TECHNOLOGY

A GENERATION IS THE CONVERGENCE OF:

- NEED (EG. THREAT OF ANNIHILATION, GREED)
  FREEING RESOURCES
- TECHNOLOGY AND SCIENCE
  THAT PROVIDE FOR BUILDING MACHINES
- ORGANIZATIONS TO BUILD NEW COMPUTING STRUCTURES
- USE TO CONFIRM A GENERATION (AFTER THE FACT)

THE TRANSITIONS*

TECHNOLOGY TRANSITION

TRANSITION TO DISTRIBUTED COMPUTING BASED ON NI

TRANSITION TO PERSONAL COMPUTERS FROM MINIS AND MAINFRAMES

TRANSITION FROM CONVENTIONAL RACK AND STACK 16-BIT COMPUTERS

TRANSITION FROM TERMINALS TO COMPUTING TERMINALS

TRANSITION TO SOFTWARE FOR END USE VERSUS PROGRAMMER TOOLS

TRANSITION IN HARDWARE DESIGN SKILLS

* TRANSITIONS IMPLY CHANGE (AND PAIN) IN

  . WHAT WE ENGINEER (I.E. PROJECTS)

. HOW WE DESIGN
. HOW COMPUTERS ARE SOLD, PRODUCED, DISTRIBUTED AND USED.

TECHNOLOGY TRANSITION

Transition based on technology evolution is continuing at 20% cost decline per year as shown in the following figure, permitting an incredibly wide range of useful computing devices to be built. The generation* period of seven years** and the seven generations, 55 year period from 1945 to 2000, is described in the appendix on the fifth and sixth technology generations. Economy of scale, also known as grosch's law, does not hold today for any system or component except very large disks, however there is diseconomy of scale for large systems primary memory.

*A generation is concurrence of:

Technology: VLSI = 10^5 trans/chip, Wini,
System(s): Personal Computers, Mini-mainframes,
Need: Communication, Productivity,
Use: (after the fact 1987 we'll know)

A seven year generation is time to:

. get factor of 100 if technology doubles each year
. two design cycles
. factor of 5 if price declines 20%/year
. find a new computer structure (e.g. mini, micro)

From the generations graph, we can observe the following:

- .there is a wider range of useful systems, and these will be appealing to our customers, us and others; (For example, in 1985 we could be selling $1,000 computing terminals with the power of the original LINC, and $600K 10/20's.)
- .the wide range of useful systems will force all suppliers to be more competitive and selective as new suppliers enter on a point product basis and as the 370 becomes a commodity;
- .IBM, Fujitsu, and others are likely to offer a 4341-2 class machine in our $40,000 to $100,000 minicomputer heartland;
- .competitors, could be targetting the following (for 1985):

  - .Cray 1 power, $625K (or in 1990 for $250K);
  - . x3+ Comet power for $100K;
  - . 780 power for $40K;
  - .a sharable VAX (or big micro) in $6.25K to $16K range;
  - .a personal VAX (or big micro) for under $6.25K;
  - .a computing terminal with VT100 capability, and power of Apple II, or original LINC, for $1,000;
  - . computers in $400 to $1,000 range;

.we have not provided aggressive enough products, because:

- .the Q and U bus form factors have constrained system cost and size;
- .the 19" rack and stack, palletable form factor together with poorly packaged components, has been retained; Packaging in other, lower cost form factors enabling carboard box shipment and customer merge is essential.
- .the terminal has not been used as a package; and
- .point products have been insufficiently high quality, software supported, or cost-effective. Even $200 calculators are modular with mass storage, printer, modem and display options.

TRANSITION TO DISTRIBUTED COMPUTING BASED ON NI, INTERCONNECTING:

- departmental and central computers to each other;
- personal Computers to form clusters;
- functional server components to reduce the number of network possibilites that are a product of:
  - hardware systems;
  - the 12 operating systems we support; and
  - the desirable protocols including X.25, IBM, DECnet and other vendors.

By using the server concept each system can be connected to NI, with specialized servers:

- concentrators for interconnecting dumb terminals and personal computers;
- gateways to systems using other protocols;
- repeaters and interfaces to other networks;
- central functional servers for files and printing;
- real time front ends.

TRANSITION TO PERSONAL COMPUTERS FROM MINIS AND MAINFRAMES

Timeshared computers are affected in several ways:

- direct, stand alone use;
- more terminal load can be put on a given computer;
- interconnected clusters of personal computers are a substitution

TRANSITION FROM CONVENTIONAL RACK AND STACK 16-BIT COMPUTERS

The alternatives:

.16-bit microprocessor cards and systems which have 22-bit memory address space and supplied by both semicomputer companies and their OEMS transportable systems such as UNIX are aimed at establishing hardware to be a commodity.
.board and box level systems that are oriented to modern special chip i/o as supplied by the semicomputer suppliers;
.   personal Computer and Clusters,
.   VAX and other 32-bit architectures
. emerging commodity priced 370s in this price class.
.better box-level form factors not possible with 19", FAT produced, Q- and Unibus systems; Systems must be shipped in cardboard boxes, integrated by the customer, and when broken, self-diagnosing with customer replaceability.

TRANSITION FROM TERMINALS TO COMPUTING TERMINALS

The major transition for terminals is semantic, i.e. what is a terminal? Terminals must change in the following ways:

- . larger Personal Computers are an alternative to our conventional, dumb terminals;
- .all terminals introduced beginning in FY83 must be customer programmable with at least firmware ROMS and ram buffers;
- .the interconnection, whether it be U. S. or European Modem, NI, or IBM emulator, must be built into the terminal;
- .decreasing memory cost based on 64K chip will offer fully programmable screens, which in turn will automatically provide graphics; and
- . higher resolution, full-page and color displays.

TRANSITION TO SOFTWARE FOR END USE VERSUS PROGRAMMER TOOLS

We can identify these needs:

.direct use in the office, including providing the ability of OEMs, office managers, organization, and the individuals to tailor their systems;
.better human engineering at screen and in documentation; Documents and help should be built-in.
.all products must be modifyable for use with any natural language;
.applications building tools for particular professional and commercial environments.

TRANSITION IN HARDWARE DESIGN SKILLS

The immediate transitions for system designers includes:

- .standardization and use of general purpose controllers and processors for conventional controllers; We are not using enough standard VLSI! This implies options are programmed.
- .use of gate arrays and other lsi to lower cost of all jelly bean and non-processor logic;
- .VLSI design, where processors and controllers are placed on a single chip;
- .identification of either general purpose or special purpose computers based on VLSI for building the non-processor portion of systems to drastically reduce system cost.

THE UNIBUS HAS TURNED OUT TO BE

"OPTIONAL" SO FAR... IN TERMS OF

PERFORMANCE AND MEMORY SIZE

GIVEN:

1. AMDAHL'S CONSTANT 1 IPs REQUIRES 1 BYTE MP

2. ADDRESS SPACE = 2^{18} BYTES. (.25 MBYTES)

3. 1 INSTRUCTION CAUSES 4 TO 6 BYTES OF ACCESS

4. UNIBUS = 2 MBYTES/SEC.

IMPUTE:

BASED ON SPEED

2 MBYTES/SEC. => .5 TO .33 MIPS = .5 TO .33 MB

> .25 MBY

BASED ON MEMORY SIZE

.25 MBYTES => .25 MIPS => 1 TO 1.5 MBY/SEC.

(1 TO 1.5 MBYTES/SEC.) < 2 MBY/SEC. OF UNIBUS

HEURISTICS FOR BUILDING GREAT PRODUCTS

(DRAFT FOR COMMENT)

Five sets of dimensions for building great products need be attended to (roughly in order of importance):

. a responsible, productive and creative engineering group;

- product and design metrics (competitiveness);
- design goals and constraints;
- product evolution, revolution and death; and
- the ability to get the product built and sold.

ENGINEERING GROUP

The Team must have:

- a chief designer/chief programmer to formulate and lead;

  NO COMMITTEES AS DESIGNERS

- management who understand the product space and who has engineered successful products; The two most important jobs are:

  - making sure that everyone knows their job; and

  - establishing and reviewing work on a timely basis, i.e. MBO.

- team skills and resources to implement the proposal so that we adhere to the cardinal rule of Digital, "He Who Proposes, Does";

- an understanding of the design, design production (eg. CAD) processes, and manufacturing processes.

Behaviorally, the team must:

. do it right the first time;

. execute the project in a timely fashion;

. limit projects to less than two years by a small team.

. not predicate a project on scheduling inventions in the design, process and CAD areas.

. have a written design methodology;

. be open and have external reviews, and clearly written product descriptions for inspection;

. start small, be reviewed and grow on its demonstrated success;

. learn, in order to handle the increase in complexity

PRODUCT METRICS KNOWLEDGE includes:

. products for which there'll be no competitor;

. all product cost metrics;

. all product performance and cost/performance metrics;

. reasons why the product will succeed;

. major competitor products by cost, performance and functionality;

. leading edge, innovative, small company products;

. productivity, quality and design process metrics for projects

DESIGN GOALS AND CONSTRAINTS

. Goals and constraints must be written down and updated from the day the project starts.

. A product can only have a few goals and constraints. The ranking is usually: it must work and have improved cost of ownership, be the shortest time to market, highest performance and lowest cost.

. If a standard exists, follow it or change it for all!

. If a standard is forming go all out to set it.

. Products must be designed for easy translation into in any natural language since we are an international company.

. All products must have be customer installable and maintainable.

.   Portability is an important goal.

WHEN TO CREATE, WHEN TO EVOLVE

AND WHEN TO STOP PRODUCTS

. Ideas must exist to have products! If we don't have ideas to redefine or extend a market, then we should not build a product.

. A product tree MUST be maintained by each engineering group showing roots, gestation time and life.

Goodness and Greatness = NO CRAPPY PRODUCTS

. be elegant and high quality;

. offer at least a factor of two cost-effectiveness over a current product;

. be based on an idea which will offer an attribute or set of attributes that no existing products have;

. build in generality, and extensibility;

. be a complete system, not piece parts;

. be a great system because the components are great;

. if we don't make it, buy it;

ELEGANCE: WHAT IS IT?

Russ Doane: "every feature contributes two benefits"

RH dictionary: "gracefully refined, dignified, of high quality"

guality- lack of excess (especially errors)

Elegant design is the use of a part to perform many functions.

Architects say: "Less is more."

Some examples: the stored program computer (use of memory), the general registers, the Unibus, Pascal, APL.

Several pioneers: "Leave a feature out that can be done another way."

It can sometimes conflict with other goals like orthogonality.

But too much elegance is trickery.

Product Evolution

. lower cost products require additional functionality too;

. constant cost, higher performance products are likely to be the most useful;

Revolutionary New Product Bases

. A new product base, must start a family tree from which significant evolution can occur.

Product Termination

. A product evolution is likely to need termination after successive implementations, because new concepts in use have obsoleted its underlying structure.

SELLING AND BUILDING THE PRODUCT

. it has to be producible and work, AND be useful to software;

. a business plan with orders and marketing plans from several marketing persons and groups needs to be in place;

. never build a product for a single customer,

. it must be done in a timely fashion according to the committed schedule, price and functions;

. it must be understandable and easy to use.

STRATEGY FOR PRODUCTS (81-82)

. A MINIMUM OF HARDWARE AND SOFTWARE VAX AND 11 SYSTEMS WITH:

APPROPRIATE SIZE/AND COMPATIBILITY PRICED DISKS.

. PHASING OVER TO A VAX-ONLY STRATEGY BY 1985, OR WHEN APPROPRIATE

. STAYING BELOW $250K SELLING PRICE (IN ORDER TO KEEP MACHINES AND BUYING WITH THE USE).

<u>BASE HARDWARE</u>

LEVEL OF MACHINE	VAX	11
CENTRAL	780 -> SUPERSTAR*	(NOTE COMPETES WITH LEN

HUGHES' SEL

	(AT 200K LEVEL)	ECL MACHINE)
GROUP	COMET/HYDRA	11/74; 11/74 MP -> 0 (USE COMET)
SMALL GROUP	NEBULA*	11/44 -> FONZ REPLACEMENT
PERSONAL	LSI-VAX*	FONZ
EMBEDDED CONTROL		TINY

*NOT DOING AGRESSIVELY NOW!

BASE SOFTWARE

. LESS 11 ENHANCEMENTS (I.E. DECREASING OR SUSTAINING FUNDS)

IAS, RSTS, HI-END RT; USE M, SCS, TRAX AS BASE FOR COMPATIBILITY WITH VAX. THAT IS, PROGRAMS MUST BE ABLE TO MIGRATE FROM 11'S TO VAX!

. LAYERED, MODULAR O/S FOR SPECIFIC APPLICATIONS (COMMON PROGRAM INTERFACE; COMMON UTILITIES AND LANGUAGES; COMMON DRIVERS)

. VMS - GP BASE; ADD BATCH

. TIMESHARING

. TRAX-32 FOR TRANSACTION PROCESSING

. TUNED REAL TIME

. BASIC+ WITH EXPORT/IMPORT AND RSTS INTERFACE, FACILITIES AND UTILITIES - AT CURRENT PERFORMANCE LEVEL - PROTECT USER PROGRAMS.

THIS IS OUR BIGGEST USER BASE.

.FILE, DISTRIBUTED DATA BASE AND NETWORK

TO SUPPORT DISTRIBUTED

PROCESSING GIVING ABILITY TO COMPUTE/STORE IN ANY NODE.

BASE HARDWARE OPTIONS

. MODERN, MULTI-DROP, HIGH-SPEED COMMUNICATIONS FOR '80S INTERCONNECTING:

.TERMINALS, PERIPHERALS (E.G. LINE PRINTER) AND SMALL-SYSTEMS

PERMITS DROP-SHIP AND CUSTOMER INTEGRATION

. TERMINALS WITH SOFTWARE SUPPORT FOR:

.DUMB, BLOCK MODE AND LOW COST - A TERMINAL FOR EVERYONE!

. OFFICE

.LETTER/HIGH QUALITY PRINT (WITH GRAPHIX/FAX) FOR ELECTRONIC MAIL

.PAGE CRT FOR WORD PROCESSING (STAN), AND

. ANALYST (LENG) - GRAPHIX CALCULATOR/WORD PROCESSOR - THE MODERN (VECTOR, MATRIX, TABULAR) CALCULATOR AND DISPLAY

- FACTORY ENVIRONMENT
- COMPATIBLE AND LOW COST TERMINALS
- DISTRIBUTED PROCESSING TO PROCESS INTERFACE

BASE LEVEL APPLICATIONS

. DOCUMENTS (VIA WORD PROCESSING), ELECTRONIC MAIL, QUALITY

DOCUMENTS
(E.G., BOOKS)

BELL (ATT/BELL LAB) GROUP BUILDING PBX'S

AS A CUSTOMER PUT IT ON WEDNESDAY:

. "ONLY YOU HAVE THE BASIC ARCHITECTURE IN VAX TO COVER THE RANGE WE NEED FOR DISTRIBUTED PROCESSING. WHY DON'T YOU BUILD IT?

. GIVE US A <u>TRULY COMPATIBLE</u> RANGE OF VAX MACHINES.

DON'T CORRUPT IT (LIKE YOU DID ON THE 11). WE WANT A RANGE OF MACHINES:

- 10 X IBM 3033

- CURRENT 780

- VAX-ON-A-CHIP (FOR TERMINAL USE)

. SW BASE >> HARDWARE BASE (CPU'S ARE 4% OF COST)

. **WE MUST HAVE RELIABLE, SECURE COMPUTERS FOR SYSTEMS WE INTEND TO BUILD."**

. **THEY'LL FUND US TO WORK ON NEBULA AND THE VAX CHIP!**

DUPONT HAS THE SAME REQUIREMENTS

SUBJECT: RE: RE: SW BEIGE BOOK

I want to find a way to get us out of this and consider you a key person. Bruce Delagi is going to be staff in charge of longer range planning... and we want him to ask the tough questions of each group so they can get further out rather than just respond or go along in incremental mode based on the past.

I have some faith too, that we can change. Am really impressed with the moves in the interconnect area and the base architecture we are building there. This is turning out to drive the hardware systems (by size) like crazy. My intent is to have Bruce, Dave Rodgers, Si(or Per Hjerppe),Strecker (or Fuller), Keating(or Husvedt), and you meet regularly to try to generally plan out and formulate questions for the various groups. I want the groups themselves to also get very strong and independent in terms of a/d, planning, mkting, etc. with good couplings to manufacturing (where appropriate) at to P/L.

The SW long term is the place I want to get to, given that we will be a viable manufacturer in the face of IBM and Japan (both of whom frighten me most).

Think we have to interact on this.

EXT: 223-2236

LOC/MAIL STOP: ML12-1/A51

SUBJECT: BITING OFF LESS SOFTWARE BLUEPRINT THAN YOU CAN CHU

Yeech! I hope Sam can give me something to say to Yaohan if you need me to be the bearer of bad tidings.

I have a problem with the book, but really feel old, and far afield, so probably don't understand the merits or subtleties.

Doesn't come up to a book like Yourdon. Later, should be better.

Makes the fatal mistake of inventing another god damn set of notations, and languages (SPL) that aren't supported. Hence, I can't imagine the value in teaching it, without the support stuff. Not clear that it is particularly good either.

Tries to capture the whole softare engineering world en passant by mentioning all the concepts, with brief writeups. This goes for everything from information hiding, to an ennumeration of the common data structures.

Misses the whole point of design for enhancement as a criterion.
This is where all the money goes in engineering, not designing
for what it does, but rather what it will ultimately have to do.

The whole book is nothing but a documentation of a big, boring
program that is probably full of errors. There is nothing dealing with what the program is supposed to do, the spec., and
then showing the various ways to get from this to the right blueprint, and on down to build the structure. Am deftly afraid of the segmented approach between architects who make the blueprints and the implementors. By the way the blueprints
are drawn, pretty much specifies the construction. The segmentation just doesn't feel right. House implementors put every 2 x 4 in place from a good set of prints. Therefore I
must worry about the segmentation and feel that I should almost
reject it, as implementation, it turns out is the real killer in
a design. He also ignores the whole building in testability, showing how to test it, proving correctness, etc. The arbitrary
levels (mnemonically called A,B,C) also turn me off.
Looks like an inside out, or bottom up rather than top-down design approach. Also ignored performance, and designing for it and tradeoffs, etc.

Maybe I'm making too much out of the fact that I expected a good book on software engineering rather than how to use blueprint to build the Interactive Direct Execution System... which I'm not sure anyone is motivated to want.

No home problemsor unclear how it could be used in a course.

Had a good discussion with Brigham about the SE course he took at CMU, and their work seemed much more substantive, although the output was to build a big, god damn program too. He might be a good reviewer if one needs another one.

Only spent a few minutes looking at it, so I'd like some corrections to this (surely I missed a lot in the brief scan). Unfortunately, it didn't hold my attention, but that happens too when one gets older (or equivalently much younger).

If I am to be the bearer of bad tidings, then I want to be sure I'm light or wlong? Am I?.

SUBJECT: SOFTWARE ORGANIZATION ISSUES

As we discussed on 10/14:

1. The 32-bit base software would include VMS (with its DECnet interface), RMS, CATS, FMS.

2. Hydra includes CI, standards to HSC50 and Hg (?). Also standards to interface 2080.

3. Interconnects include DECnet standards, co-ordinating all busses, and NI development.

4. The languages include RTE, Datatrieve, DBMS, RDBMS, plus the languages.

5. TPSS-32 is separate but requires support in CATS, FMS.

6. The office program is a set of projects that run on numerous systems as layered products. WPS78/278; WPS200, Word 11 layered, Word 11 bounded, KO WPS, OFIS base going to VMS, RSTS, M; EMS/VMS. Should typesetting be there too?

7. 36/32 co-existence and standards for transportability are part of 36-bit project.

8. RSTS/32 co-existence and standardness for transportability are part of RSTS/SCS.

9. We want a base system as part of KO.

10. There have to be various applications, targets for KO besides the office.

SUBJECT: SOLAR THOUGHT FOR THE DAY

What if we make the pool black. Put it virtually outside with
glass over it.   Make it out of steel and set t on concrete (well
insulated on the bottom) and then make the sides have fins so that
it is a big collector/radiator. Then we put a floor over the
top or at the water level and arrange to have a crawl/ airflow
so that air is flowed into the room from around the sides like:

```
floor.....w..water..w...floor.........
c......,..w         w
c         w         w
c air     w  water  w  air
c         w         w
c         wwwwwwwwwww
cccccccccccccccccccccccccccccccccccccc
```

c concrete
w wall Of pool

We'd have vents in floor to let air from wall of pool that was
steel finned out. There would have to be a cold air return too.

If somethinglike this could be built it could Be mmass produced
an` attached to houses as a "solar furnace/swim pool" The thing
I don't understand is how much heat can we get into it. Also,
we are considering dumping additional Heat from extra collectors
in order o to keep it kInd of pass

pasive.

What you think?

SUBJECT: SOLID WIRE ON PEDESTAL 100'S AND THE WPS200

I can't believe that FS just connected a bunch of VT100's on movable
pedestals to our WPS 200 system with solid wire. These are 20ma connections
and they use a really poor connector. Why don't we use a standard modular
jack such that standard phone cables, connectors and telephone installation
procedures can be used?

What are the installation standards here? Who has this responsibility?
Could you send me the standards we do use? I'd like your groups to get together
and work out what we do use. The WPS200 wiring as demonstrated

in our area
is totally unacceptable as an office product in quality, wiring, reliablility,
noise level and aesthetics. As a system, I think the WPS 200 system is fine,
ignoring the fact that it is unsupported because it is a large 8. Will you
convene and segment the problem and decide who's responsible for what? and what
can be done?

For starters, switching the WPS200 to serial lines for both the Draft and
LQP would help matters enormounsly. It would give us greater distance and
get rid of the eyesore that can not be installed. It would also give us
the needed increase in signal to noise ratio and help reliability...and
even allow interchangeable use of fiber optics. In looking at the specs,
I find that FS didn't need to use 20ma, but could have stayed with the EIA.
This cost us in time and engineering at our floor site.   Here again, I want
to get the number of configurations down a lot so that we can make what we
do sell work! Having these infinite options and FS designs just complicates
the already marginal software package...and in order for us to survive here
we have to start limitin options on the 200!
Bob Gray it is clear you have the leadership here, and I'd like to know what
and when we can expect simplification?

Command >

SOME STANDARDS QUESTIONS

(GOVERNMENT'S, AT&T, DEFACTO)

MUST WE HAVE MORE LOW LEVEL STANDARDS (character set, floating point)?

WILL DEFACTO STANDARDS EVOLVE THAT ARE SIMPLY THE 370 AND A

SEMICONDUCTOR CHIP?

HOW MUCH NETWORKING CAN BE DONE WITHOUT FULLY HOMOGENEOUS MACHINES?

(I.e., can users stand it?)

HOW MUCH NETWORKING CAN BE DONE WITHOUT COMMON LANGUAGES AND A COMPLETE

NETWORK ARCHITECTURE? (WILL GATEWAYS WORK EFFICIENTLY ENOUGH?)

WILL A "CHANNEL-LEVEL" INTERFACE CONSTRAIN PRICE OR INHIBIT FURTHER

EVOLUTION OF BACK END PROCESSING?

CAN WE KEEP TRACK OF THE DATA? (WILL DB'S OR DB STANDARDS HELP?)

Subject: **Sony Video Storage Technology**

To: John Kevill

CC: Jim Bell, Dick Clayton, Bob Glorioso, Grant Saviers

Date: 78 AUG 14
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

Sony has an incredible array of small video recorders and transducers. We have got to learn how to operate with respect to these video devices. One device is a small 3" video cartridge, I think actually a tape, although it could have been a disk, in which a few frames of video are stored. I am not sure what they are going to do with it.

The second is a video disk which stores 10 seconds of video. It is used as a teaching device and will be marketed early this Fall. We have to find out what the interface is and how we can use it. Yu Hata should be requested to get us this information immediately. I am writing to Dr. Iwama about it.

The third thing is called a MAV card which is a magnetic video recording card and is scanned vertically. They also had a cartridge which could be used as a carousel for the card which allowed the user to select any one of I think, 50 of the cards on a random access basis, and display the video images so there was a digital selection by keyboard for these image displays.

They also had a video input device which looked like a copier that took in what looked exactly like a copier and put an image down and the image was then transferred to video or to an image card.

All in all, one has to be impressed with the video and with the Sony technology there -- all emphasis on research -- and I would certainly like to get closer to them.

GB:ljp

D I G I T A L INTEROFFICE MEMORANDUM

DIST: Jim Bell ML3-2/E41 Dick Clayton ML12-2/E71
Bob Glorioso ML3-2/E41 John Kevill ML1-3/E58

SUBJECT: GUIDELINES ON SPACE PLANNING (DRAFT FOR YOU)

In order to get our space plan to meet the 1990 constraint, it is necessary to add some guidelines that we feel will meet the corporate desire to have only 20% of the poplulation in Massachusetts. Rather than require a corporate bogie, we are going to take the position of putting together the most aggressive plan possible...and then see what this is in terms of the effect.

To me, the ideal is reasonably clear: make 495 the highway to connect all sites and to have these sites as close as possible.
Coming off the ideal then, here's the guidelines I'd like each
OOD member to use:

1. No growth in Massachusetts.
2. NH is already commited to an aggressive growth. Grow the Comml and Computer Products Groups in accordance with their growth rates. Leave SR2 as space for growth of SR1. Leave Dist. Processing in TW.
3. Grow systems groups in various volume plants to assist in the move to Dock Mergeable products.
4. Establish a major engineering site in SW for terminals, with
residual in Mass at no growth.
5. Establish a major engineeing site in NE co-located with Mfg. for Mass storage. I.e. this would be the growth site. Furthermore, NH and Mass would be off limits for growth.
6. Plan an organizational move to RI in this go around.
7. Cap building 12 as OCE (office of Central Enginnering) for LP,GB,JM,SF, and MK.
8. TOPS to co-locate in a fixed, no growth building with Will.
As this support and central part of this organization grows, it

would co-locate with systems customers and prototype plants.
9. Consider co-location of low end mass store with low end systems.
10. Point 1, would be subject to allowing only growth for LES (not Terminals) into Hudson 2 as planned.

If we can base a plan on these concepts, I think we have the potential for a better organization with more dispersal to Mfg.
and which starts seed operations in the SW, in RI, and somewhere
else in NE for Mass storage (the growth/product portion).

SUBJECT: SPACE GUIDELINES FOR TOMORROW MEETING

Excuse the poor form as I couldn't go back and edit the draft I sent to John.
One sure gets an appreciation of what systems should be designed like
in using this...but I digress.

The attached is a starting point. In addition, I feel we may be
going wrong direction in SS by having it co-locate in Hudson. Namely,
Hudson is going to expand too in the chips area and I don't understand
where they are going to go. Why don't we just let them expand there
as a semi operation, and not make them go somewhere else

because their
site is all used up with hangers on?

We need some really good thinking in this whole area... and
it will have
to be done by a good team that will be in constant
communication with
us. It will be intense for a month or so while this gets
done. Let's
persevere... it is really the design of our organization...
and is
our job.

Michael D. Scheer
Specialized Book Service Inc.
100 North Street
Burlington, VT 05401

Dear Michael:

Thanks for the specifics on the order processing situation.

I'm forwarding the letter to Del Lippert, head of Educational Services, and Joe Santini, Marcy's manager, and Marcy so that we can get together and discuss the situation. It's quite possible that we can't perform as a publisher, given that we're a computer company. Given the response time, maybe we can make our rules clear so at least you can depend on us. Thus, I hope Marcy can get back to you. It's ironic we have pretty good software for small businesses (probably publishers too).

Given that my role has been as one of the founders, author and strong supporter, I believe in it and want to see it succeed. Hopefully we can.

Sincerely yours,

Gordon Bell

MESSAGE ID: 5177510994

SUBJECT: KEN'S SPEECH DATA

Ken wanted some historical data as to where we were first in regard to the current office automation and networking.
My recollections:

Editing/word processing
early computer editing on pdp-1, expensive typewriter 1962?
Teco, first video editor that had virtually all the features of today's word processors. Pdp-6 1965? from mit
SOS, basic editor that is forerunner of all Personal Computer editors. From Stanford 196? (late 60's)
EMACS- written in TECO, forerunner of future, editors for the professionals
wps78 -75 very early word processor (where historically?)

Typesetting
Larry Buckland on pdp-1. the 4096 x 4096 point scope circa 1963 was a factor of 8 to 16 more precise than anything around.
was used for direct typesetting. the result was Information

International Inc. went off and made a whole company around this technology.
PDP-8/11 newspaper typesetting and required networking.
IN 72 at CMU we set a book directly using a 20 and a Xerox printer without any conventional typesetter. The book was mixed graphics and text, and went directly to be photographed for printing.

Networking
More than x % of the computers on the ARPA net have always been DEC computers. The first paper was in 67 and the network came into operation in ?? (I believe seriously in about 72... it was marginal when I came back to DEC in 72.)
DECnet came out in 75 to solve the distributed computing problem
we created when all the minis appeared. It combined the best of ARPAnet by allowing one to build a packet net, while not forcing extra computers. Today there are ?? DECnets!
(Frank Heart at BBN can give us the key dates if Ken needs more.)

Ethernet. Today there are ? Ethernets in ? organizations. Digital has an engineering network with over 300 computers tied together at 15 sites in what we believe is the world'ss largest net. WE also have 20? Ethernets in operation.

Mail
Came out of timesharing on a single system for communication among its users, starting with pdp-10. I forget the first mail program.
All our timesharing systems have mail among them and hence we have more people doing word processing and mail than any other supplier.
We did a joint mail system with Computer Corporation of America and used it from ? to ? as a test site. During this time, an internal mail system, DECmail was developed on the 11 and

was
put into service in ?.

Timesharing
We had the first commercial system by far. GE later marketed the one built at Dartmouth. MIT, SDC and BBN built the first ones followed by Dartmouth and Stanford. This was one form of personal computer... the goal was/has always been to give everyone their own computer.
The TSS8 at CMU and on quickly to dEC was aimed at lowest cost per user and to show that timesharing worked on small computers.
I wanted to beat the IBM 360/67 by 1 to 2 orders of magnitude in price.
TSS8 trained the designers of the RSTS system which we introduced in 71 as the first, mini tss. It was the true, beginning of distributed processing as we know it today that goes into groups and departments.

Computer games
Spacewar was clearly the first, operating in 1963? and built by steve russel at mit. The world is still disputing this, and the museum spends some time every year showing the origin.

personal computers
The LINC, although it was a bit hard to move around (it had big wheels for this purpose). The definition I have includes being able to have a complete file system and be able to automatically write and run a program without any manual operations on files. (Early computers like the LGP 30 required off line flexo program preparation followed by lots of file handling.)

Please can I have your help, sent dates to KEN and I. Also, please add any products that are relevant here.

MJ,
Please give Ken a recent tree to get the overall relationship in time.

Dear Bob:

It was great to see you again and discuss the SRC and Rutherford Laboratory with you.

I looked at the material and wondered if I could get the first annual report of the distributed computing program from you. Also, is there a report on the Manchester Data Flow Computer? and the CYBA-M? Is there a report yet from the Robert Panel? Any reports you could send would be appreciated.

Sincerely yours,

Gordon Bell

Digital **Interoffice Memo**

Subject: **SRI Visit - Industrial Automation**

To: Jim Bell

Date: 1 NOV 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

F/U 11/8

I enjoyed SRI and have a better appreciation of their ability. Their applications are really exciting versus the ho-hum we do when we copy IBM (e.g. power monitor). They're really sold on the LSI-11 as the hot, microcomputer to be used in industrial applications.

We must push to get both internal use (when we can be a customer) plus OEMs who'll develop the end use built on LSI-11's so we can participate in emerging automation market. (They also need more address space.)

[Win/Charlie/Bill Long, are we?]

Robots

They're working to get UNIMATION (largest maker of industrial robots to be our customer.) SRI has an LSI-11 equipped UNIMATE.

[Bill Long/Ted, are we organized enough to accept UNIMATION orders with less than the usual hassle? Are we even aware of them?]

[Charlie, are these OEMs part of IPG plan?]

Vision/Inspection

GE has a nice low cost, low resolution, CCD camera for inspection applications. SRI's now pushing to get a supplier of the system. GE could be it. Note, Reticon, the best supplier is owned 40% by Intel.

[Charlie/Win/Holman/McBride, could we get someone to look at this as a possible product?] The amount of effort going into inspection is very, very large...hence, there's a high payoff. GM's doing quite a lot, for example.

I believe a small effort could get a truly significant product in 2 years (given the external work). They need faster speed (Fonz 11 or LSI-11 with WCS).

Voice

They're not doing much. Raj Reddy at CMU is switching to LSI-11's, and will have an effective system. He'll use a system that's standard, hence others will be able to get copies. This should also help feed other OEMs, users and us.

Threshold technology as an OEM for LSI-11 is really significant, as it gives us a key input/output transducer.

Charlie Rosen, at SRI, told me about the conference on this sponsored by NSF, Nov. 30-Dec 2, at IITRI in Chicago, that you were attending. Could you make sure someone from IPG and Manufacturing goes with you? (Some of our customers will be there and it'll be good to listen and sell!)

TO: Staff

NOTHING BETWEEN THE CRACKS

PRIORITIES:

Short term:
Today, get overheads and all material for presentation to HOCC.
Get materials to Reno for Winter Report -- it must move.
Schedule Oct. Nov. - see below

Longer term:

Schedule all mailings and make sure people get things on time: <u>we keep the members happy.</u> Harry Huskey invitations should be out on time, with insert letter to "Locals". - Chris and Geri schedule this -- from doing the labels to stuffing etc. using the store women and Bill as appropriate.

<u>Increase membership and financial support.</u>

- At least 25 personalized letter's go out a week -- signed by me or some member of the Board -- to get major acquisitions and get things moving. (<u>Geri</u> let's keep a log of the numbers of personalized letters that go out each week for big bucks. <u>Geri</u>, it's your job to keep me at this and make sure they go out.)

- The December 9th, Pray, Mr. Babbage party should be used for a big membership drive. <u>Chris,</u> your main job is to get the publicity out for this and pull the whole party together. (Huskey should more or less take care of itself...without alot, and Bits and Bites is about done.) The goal should be 100 new members from Pray, Mr. Babbage. Invitations need to go in the mail on November 12th -- want you to use a great big mailing list (get our friends at DG etc., lots of internal Digital -- lets rethink the use of lists). They must send in money for tickets. $5. each for members (who may bring one friend for $5); non-members need to become members for $25 and then pay $5 for themselves and a friend.) -- Get me to call Charlie Conn today and set up a meeting for Friday, when we have all the details of the party and get them to design invites for free, must be done fast to go to the printers by the 5th for a week turn-around. This whole thing has to be quick and dirty, but with lots of style. I want to talk to you and Jamie about it for 15 minutes today. Then lets put the whole thing in final shape on Friday.

- <u>Jamie,</u> after the Pioneer Timeline is complete, then you must drive the planning for the lobby floor space, and the proposals for all the viewing and video equipment.

-

Digital **Interoffice Memo**

Subject: **<u>Adapting Standard Office Copiers for Computer Print Out</u>**

To: Ken Olsen

Date: 14 DEC 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

CC: OOD
Jim Bell
Peter Christy
Ed Corell
Jack Gilmore
Bob Gray
John Gunther
Mark Sebern
Tom Siekman

As much as I'd like to take credit for discovering the notion that future office copiers have plugs or mechanical accessories so that computers can be attached to them, I don't think I did.

In 1970 or so CMU got hold of a Xerox LDX (Long Distance Xerography) which ran at about 200 lines/inch, and it was connected to a 10 via an 11/20. This was developed including editors to generate character sets. Now there are about 20 in operation at various ARPA sites.

Recently we began considering alternative printer technologies (plus I have a desire to have a good printer internally and get us started thinking this way) so I started pursuing getting a Telecopier or high-Q Fax of some sort. We could even use a Versatec (Xerox owns them) to get experience in this sort of printing.

We contacted Kodak and Xerox (3-6 mos. ago) and asked them about low cost machines we could connect to, but so far we haven't gotten a good response. Kodak is to come back to us. The idea appeared novel to them. Xerox is thinking our way. We've asked for a standard office copier that we could cheaply interface to. All sorts of ways are possible...turning out the light and using a laser to form the image is probably the best. However, some modifications would have to be made to standard machines to get timing information to form images on a photoreceptor surface.

The Savin copier now looks to be what we want. At $4K and 3 sec/copy with quality gives us a 66 x 20 = 1320 line/min. printer capable of printing anything, plus being used as a copier.

By not having another mechanical device, a user saves service costs, space, training, capital, etc. The Diablo printer is no way to do things, and I want us to go on to get a copier company to do this. For now, we aren't going to talk about this outside.

I don't know where the idea came from.

It is clear we need to standardize the design information interfaces to maximize the independence and growth of using gate arrays. Every company uses a different design system for layout, simulation, testing, etc. This problem never got solved with ROMS, or custom-except with Cal Tech's Design Files, but is mandatory for gate arrays.

Should we sponsor a small conference of some of our vendors, suppliers, and with other manufacturers?

Lattice Logic
Signetics
Fairchild
Motorola
National
TI
Univac
CDC
Teradyne

Should it be done as part of MCC?

What you think?

April 9, 1984

Professor Steven Yau, Editor-in-Chief
IEEE Computer Magazine
Dept. of Computer Science
Northwestern University
Evanston, Illinois 60201

Jim Greenlee, Managing Editor
IEEE Computer Society
10662 Los Vaqueros Circle
Los Alamitos, California 90720

Dear Steve and Jim:

Enclosed is a double-spaced, revised copy of the paper: Aren't Standards Our Friends? I also enclosed a photo and brief biography for Jim.

Nearly all of your helpful suggestions were addressed. My wife, who has spent much of her life as an editor, made a pass too, but I believe it can still use some more copy editing. There are now 22 references.

Regarding the title-- I still prefer the one I've given, although it could be extended to: Aren't Standards Our Friends As We Do R&D For Future Generations? or Aren't Standards Our Friends As We Build Future Generation Computers? You folks chose.

Am proceeding to work on the Industry article which is due May 15.

I also enclose an article (again sans references) on the Digital Computing Environment that I would very much like to have Computer publish. The work represents the last six years of my own effort in leading Digital's Engineering organization (of 6000) in the building of a system composed of a collection of systems, forming what I call an environment. I believe this is the first paper to address this kind of system. In many respects, the effort is larger than designing a series of computers such as the 360. I'd like to get your reaction to the paper before I add any more sections.

Sincerely,

Gordon Bell
Chief Technical Officer

cc: GVPC: DEPT: ENG STAFF
    PEG: EXT: 223-2236
    BILL STRECKER   LOC/MAIL STOP: ML12-
1/A51

SUBJECT: STANDARDS: WHAT'S OUR POSITION

Please give a presentation at PEG as a prelude to a GVPC presentation.
It feels like there are more standards than ever of relevance to us,
yet we're less active and less ready to use them. Also, we have no
standards policy.

Please plot ALL the relevant standards by level of integration versus
price bands.

It would seem these are the relevant levels of integration:

END USE
Word processing, teletext, etc.

SPECIAL LANGUAGES
Visicalc
Editors

STANDARD COMPUTER LANGUAGES
ADA, Algol, Basic, Bliss, etc.

OPERATING SYSTEM
Human interface - command language, etc.
Terminal interfaces - including the IBM terminals
Links to other machines (X25, SNA, etc.) - not hardware level
Data management and files
Operating System terminals (e.g. UNIX)

ISP STANDARDS
ISPs - Include alphabets, IEEE Floating Point Standards

INTER-COMPUTER STANDARDS
The plethora of LNI's, CI, IEEE 488, etc.

INTER COMPUTER COMPONENT
to disks
to tapes
to terminals
to controllers (i.e. IBM Channel)

INTER-COMPUTER BACKPLANE BUSSES
S-100 and IEEE improved version P696?, Multibus 796, 896, etc.

INTERCONNECT ON MODULES (II, Semicomputer parts)

The chart should show various categories:
- standardized and enforced
- standardized, not likely to be used
- in process of being standardized
- our own standard(s) for an area (e.g. Unibus, Qbus,

CTI)

- where we have a plan to converge
- where we have a plan not to converge
- where, by adopting a standard, we might get more business

We need a policy!

Let me urge you to support the $100K, 2060 grant to Stanford they requested in November. We need more ties. Somehow, I'd like to make/get the $15K that's part of the Semiconductor Industrial Associates Program run by Jim Meindl out of the grant. Also, can we tie this to some internal formal communication channel?

Their brief plea to us is impressive and we can use this work! Also, let's recruit there immediately -- especially LSI.

Professor and Chairman
Computer Science Department
Stanford University
Stanford, CA 94305

Dear Ed:

It was an honor to give the Forsythe lecture at Stanford. Gwen and I enjoyed the trip, the Stanford Computer Science Department, and especially the interaction with you and Penny. I'd like to get a copy of Bill Miller's talk if possible and a videotape of my talk.

Given that Gwen co-authored the paper I gave, I am including her expenses for the two days.

The total expenses were:

Car travel into Boston (25 miles @ .18)	$4.50
Tolls	1.05
Gwen airfare	372.00
Gordon airfare (1/2 shared with DEC)	186.00
Hotel	140.55
Rental Car	46.47
Breakfast (Saturday)	6.82

	$757.39

Since I cannot accept the honorarium, please either do not issue it, or place it in the Stanford Computer Science Department Scholarship fund.

Again, thank you for the chance to visit Stanford and exchange views.

Sincerely yours,

Gordon Bell

Follow Up: 7/11/80

George Pake, VP of Research at Xerox, sent the attached proposal to me. Some of you have already viewed it. I would like to see it made explicitly part of the semiconductor R and D Program as to whether we do or do not consider becoming a member of it. Similarly, we should wait for M.I.T.'s request in this regard too and even solicit it so as to have a better set of data to work with. Berkley has lots of strength here too. Already we are working with Caltech and Cornell and ??.

I visited them and feel we should put a significant program in place to interact with them, because:

0. Stanford is clearly the best engineering school in terms of quality and quantity. Also, they are number one in Semiconductors and Computer Science.
1. Meindl feels the best to me of the research leaders outside of Broers at IBM. The group is the largest outside of IBM and BTL. Overall, they are both quality and very large.
2. Size will get us the most students. The total department is 44 PhD and 170 MS graduates of which they will yield 30 PhD and 100 MS in this program.
3. It would be an excellent place to insist that we have a mid-career updating program for our SSI/MSI/Standard Chip Logical Designers to go and get MS's. BTL sends 50 per year in this regard. I would like to see someone enter Stanford this fall, going to 2 per year next year, with a research affiliate in residence each year starting fall of '81.
4. They process their own chips on a 5 micron line and at least one-up the other programs by providing 3 week turn-around on their local line.
5. They are putting an EBEAM in place this year to even speed up the turn around more. If we could be a part of this, our own EBEAM work could be accelerated to the point of being able to pay for the whole program by getting an accelerated schedule.
6. It seems a West Coast Engineering facility is overdue. I would like to use the Mountain View home to house various people who will work there on real projects and who will interface to the numerous activities there in universities, semicomputers, and systems generated from this industry.
7. Interacting with Stanford on a more organized basis is needed.

Note that we can interact with them without a formal program, but on the other hand, it would strengthen us significantly to become a member.

I made a commitment to have the necessary people visit and seriously review their proposal. Jim and Dick, will you please get back to me on how we can do this?

Prof. Edward A. Feigenbaum
Prof. John Hennessy
Prof. Jeffrey Ullman
Computer Science Department
Stanford University
Stanford, CA 94305

Dear Ed, John and Jeff:

Thank you for the hospitality and stimulating interaction during my recent three week stay at Stanford.

I'll be helping Bruce Delagi and Tom Gannon get a plan for providing research multiprocessors to Stanford. As I tried to point out, I believe that the design and use of multiprocessors, <u>if they are to emerge</u>, can only be accomplished by many different system approaches and a variety of applications. I believe in the immediate short term of using the machine with existing languages on an ad hoc basis will be worthwhile. On a slightly longer term basis, John Hennessy's SAL looks like the way to express and exploit parallel algorithms. Clearly Stanford has the variety and the talent to make significant contributions.

I'm dedicated to helping provide the computation environment and also want to stimulate the much needed research. I look forward to continued interaction at Stanford.

Sincerely,

Gordon Bell

9 June 1983

Professor Edward A. Feigenbaum
Computer Science Department
Stanford University
Stanford, CA 94305

Dear Ed:

I really want to thank you for encouraging me to visit Stanford and for providing the environment for getting well during May. The letter on the machine reiterates my feeling on the need for research using a parallel machine. In addition, I'm going to ask our AI group to move more rapidly in understanding and measuring performance at all levels from LISP to the application. In addition, we have to work hard to provide a better LISP user environment. I hope we can also work with Teknowledge on this.

Am really flattered about the various possibilities to be on the Stanford faculty. I'm still unclear about the future projects I want to undertake, but I hope to have Stanford part of my activities.

I want to interact with your forthcoming research program on Understanding Parallelism in An AI Application. I look forward to reviewing successive drafts as they occur. Perhaps the best way is for me to stay on SUMEX, and to use it regularly for communication.

Again thanks.

Sincerely,

Gordon Bell
Vice President, Engineering

GB5.50

Ed,

I'd like to accept your offer to pay some of my expenses at Stanford. I'd like to share the lodging and local transportation costs equally between DEC and Stanford.

Stanford expenses are:

Car		$207.67
Gas		13.00
Hotel (Bed & Breakfast)	835.55/2	418.27
		638.94

____
Gordon Bell
6/9/83

The State of the Design
It seems like we have:

. text spec of entire machine, since the box names are incorrect, its unclear whether this has any validity
. text spec of boxes, together with some block diagrams, description doesn't reflect the design
. flow charts specifying behavior of a few parts
. behaviorial description, in TUMS of the boxes, non-operational as a complete system. Even if it operated as a complete system, it is unclear what it means due since the timing interaction of interconnect signals like stalls and micro-interrupts are so complex.
. 500 SUDS logic drawings specifying the machine
. 500 SUDS logic drawings for MCAs
. MCA physical layout, simulation description, test patterns, test data as to whether the MCAs meet their specs

What would be the IDEAL state of the Design?
A document describing all the documents and what the design ground rules are going to be. This would
It seems clear that we must have an accurate, structured design at all stages of the design.
Ideally, this design description is in machine readable form so that it can be checked as much as possible by machine. Since the main design tool is SUDS, this implies SUDS compatilble software that must be written asap.

What would be the IDEAL design system?

0. Information only appears once and notification is made to users of information as it changes. Ideally a data base could do this, however, this has shown to be virtually unworkable using DBMS and the IDEA database. Alternatively, there must be batch update to flag changes.

1. Interactive, with access to any part, with protection of data as to the owner.

2. Report writing ability to get parts out as needed when there are large pieces that need to be looked at or put on the wall. No document should be more than 15 minutes away, with instant access to everything else, including access via SUDS terminals.

3. Overnite batch update of key part such as indexes, rule checking, etc. that is less frequently needed.

4. Calculator functions like the clock checker that operate on the data to give the designers quick access for making critical decisions.

5. Data base-like access of critical information that is structured in order of detail.

6. An index and on line access to all signals, giving:
    .name, together with polarity, location, time

generated, and the source drawing it is created on (derived from SUDS)

. a list of all the drawings it goes to and the time the pin expects to see the signal (derived from SUDS)

. a text description of the meaning of the signal (designer input, together with date created,

. a list of all the specifications that reference the signal

. a list of all the other documents that reference the signal

. a list of people who are interested in the name so that they can be informed of changes on some sort of periodic basis

A program would be run each period to update the index from SUDS or from a journal tape generated by SUDS. A program would be available to either automatically, or on demand report all the changes to names to the relevant persons.

7. Mail system so that designers can ask for information from one another and have an easy way of structuring the ambiguities.

Mr. Steve Jobs, Chairman
Apple Computer Corporation
10260 Bandley Drive
Cupertino, CA 95014

Dear Steve:

Thank you for the gift of the Macs and Lisas and the moral support that helped open the Museum on November 12.

The physical realization has turned out to be much more exciting than any plan could have communicated. The staff made a very large "stretch" to open a range of galleries. The reviews have been positive and it is easy to spend a half day in productive learning. Knowledgable teenagers are spending their days at the Museum. The most flattering comment to date has been that it is the first American technology museum to be at European standards. Dr. Oliver Strimpel, who did the Museum's Image Gallery has just become the Associative Director and Curator. Oliver was formerly the Curator of the Mathematics Section of The Science Museum, London. The long collecting period and five year breadboard at Digital really paid off in collecting artifacts, building exhibits, doing lectures (ranging from Amdahl to Zuse) and gaining widescale support from computer people and companies.

I want to see this phase aimed at:

.putting a formal educational program in place,

.continued collecting of artifacts (whether letters, films, manuals or machines) in order to record the significant, information processing events, and

. getting broad public support from computer-knowledgeable people who want to learn more about the past and future history of computing.

Again, thanks for the support.

Sincerely,

Gordon Bell

Subject: **Fixing the Stock Option Plan Before the Next Grant**

To: Shel Davis, PK3-1/C21
Win Hindle, ML10-2/A53

Date: 2/20/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

I have just spent over three hours, and I end up doing this every two months or so, fooling around with my personal finances as a result of having a very complex plan, the

Monheit Case, 16B, and personal cash flow management. I assume there are officers and other people within DEC that have the same situation. In my own case, it was time that I would have spent working on some product or engineering problem, writing a program, or a paper about computers, etc. Thus, I end up doubly frustrated.

This doesn't mean I am not grateful, it only means things have gotten too complex and the only people who seem to enjoy this are those who like to count and/or manage money. Also, even though the amount of stock I received last year was substantial, there surely must be something that's better traded off. For example, the parking space means much more to me and I would have traded the whole stock grant last year for it, because it gives me freedom!

This thing has been hanging too long and, given the presidential guidelines this year, then let's do something really creative and free our people from the time bind (and the associated parasitic money/manager, experts, lawyers, and trappings) that are now implicit in the plan. The responsibility is yours and I perceive that nothing is being done. Why not start?

GB:ljp

To: John F. Smith
CC: Dick Clayton, Andy Knowles
From: Gordon Bell
Date: MON 7-MAY-79 10:01:09 EDT
Subject: Stockebrand in Alburquerque factors

Stocky is in the Alburquerque factory doing advanced development on

terminals.

I sense he has trouble coupling into our development groups although Roy
feels we're all trying hard. I am firmly opposed to his doing any product
development.

His most successful work was in this process area doing the semi-automatic
wirewrap machine. Given the competition is building highly

automated factories for calculators, terminals, floppies, etc. Why couldn't
it make sense to have him re-oriented to process automation, Robotics, and
on-line control. He could still do some video work for engineering as this is
also needed in your work.

Command:

September 21, 1976

Professor Harold Stone
School of Engineering
University of Massachusetts
Amherst, MA 01002

Dear Harold:

I re-read the current material you sent in early September and have some comments. Overall, and by chapter it needs lots more tree-structuring by figures and/or tables. A sketch to structure the memory one is enclosed, for example.

Time lines may be necessary to show what's been used and may be used.

It doesn't make the case that computers have evolved more and faster than anything in the history of civilization. See the enclosed paper and figure from a study by Fusfeld. I've also enclosed some papers you might take data from, and I believe it would be worth getting Montgomery Phister, 927B 7th Street, Santa Monica, Ca. 90403, to send some of his data too.

The introductory material doesn't turn me on; could it be put in an appendix for a reader who needs it...but may not get it from the meager explanation? IT seems unnecessary to include since there are good texts to do it. (Let's reprint a chapter.)

The notion of machine interpretation (ala Turing) is potent and covers microprogramming, machine languages, operating systems, languages, and applications functions in a clear way. The architectural book by Tannenbaum explains this nicely.

There's also a phenomenon that's useful in understanding how machines have evolved which we use extensively here. It's explained in the enclosed paper...and some others by me. Computers evolve:

1. Constant cost, increasing performance giving largest gain to existing users. Hence is a natural phenomenon when users-sales/marketing-and developers feed one another!

2. Decreasing cost, constant performance finds new uses.

3. New structures, (new users...eventually).

Also in (2), the minicomputer, the # of users increases rapidly due to market demand (completely elastic).

A table is needed which delineates machines you talk about - might clearly summarize to help reader know more about machines.

1. calculator, micro, mini, main, super; or

2. hand held, desk-table-bench-top, desk based, rack meeting, room; or

3. log (base 2) of price for computer gives $10 to $10M as the metric.

Some of the dimensions of the table:

1. word length
2. memory size
3. speed
4. logic techniques
5. gestation period
6. population size (1976)

A careful delineation of the logic, RT, and PMS levels might help structure each of the chapters (especially measurement, reliability, and CAD). All the structuring of the field is pretty well discarded the way it's organized.

There's little or no emphasis on problems and opportunities...especially as they relate to the research. The report could harm hardware research vis a vis it's impact by NSF readers.

Overall, it looks like a good starting draft.

Sincerely,

Gordon Bell
Vice President,
Engineering

SUBJECT: WHY I'M STRONGLY OPPOSED TO THE STORE PRODUCTS DIRECTION

While I support the notion of experimenting with ways to distribute computing, including stores, and the need for us to have software for the mass market (eg. doctors, dentists, printers, garbage collection companies, motor cycle shops, and other small businesses and small business-based professionals), I do not support the tactics of your product direction!

As I understand it, your stated product direction is to find OEM developed, successful, (well used) software applications packages in more vertical markets (e.g. dentists) that operated on our DIBOL based systems (primarly the 8) and to purchase these, test them, document them and enhance them for the widest possible audience. The DIBS and WPS packages are prime examples of this in action. Although both DIBS and WPS have been significant efforts in the testing and documenting, they are trivial in comparison to the so called vertical applications packages that you are looking at for the small business and small business-based profession.

I believe this approach may possibly work, although there are many pitfalls, because the OEM who built the package in the first place just may have supplied the critical training, and programming skills to make the fit between the package and what the user was capable of. Furthermore, since the packages are developed asynchronously and independently, there are no standards that are probably needed so that DIBS and WPS (who don't work together) work with any of the other packages and I believe there have to be lots of common formats, data bases and conventions in order that a customer can cope with the complexity of the applications you are going to attempt to build and sell. Alternatively, having very low cost hardware ala APPLE and a bunch of software writers who are trying to peddle applications in a large, free market a low cost, might be an alternative. Until you buy from APPLE (which I suspect will be next year's idea) the hardware is too expensive to ignore the software problem or too expensive to attract and form the software publishing business ala Apple, Radio Shack.

I do not believe what you are actually doing (versus the plan) will work because:

1. You are developing applications in conjunction with specific users in order to get the business (remember, the first contractor in MK?). As you apply heat to the storekeepers for profit (and sales), they will make some pretty bazaar deals that will only exercise our lawyers.

2. Packages like the dentist's office are being done by a single dentist and are in direct conflict with the above policy. Namely, it may possibly work for that dentist, but it will not have been tested in the marketplace the way the DIBS package and WPS packages were prior to the time you bought them.

3. You are going after too many too soon. We will only win on quality and customer satisfaction, not products that are superficial and do a poor job where the customer wonders why he bought. (In essence, the problem with a marketplace of 4-8 million is that it lulls you into a false sense that you have to be good because there just have to be

a large
number of suckers out there.) Any one of the vertical
packages is easily big enough to support the whole store
program and I think we want to be the quality supplier.

As you begin to go under for the next time, it will be to grasp for
more products (like the multi vertical applications...which are really
products) by getting into the 11 line. This pull will be from your
market as they run out of capacity in the 8's and as they hit all the
limits on disk, especially the need for hard disk and for
communications if they have several sites (office and warehouse). As
in the WPS case, using a large 8 is really not possible because we
don't have the support everywhere in the company to make the
8 a viable large systems product. Here, it is diagnostics,
design of the basic software and hardware, field service and
sales training and the field inventory of parts. Also, I
believe you should move to the 11's via PDT's ASAP.

The bottom line is that I resent you taking terminals into the stores,
making money on them and reinvesting in what I consider to be an
ill-founded product and market direction. It seems highly likely that
you are going to fail in your products, and selling the standard
products will mask and prolong this.

SUBJECT: STRATEGIC SPACE PLANNING INTERACTION MATRIX - F/U 2/14/80

To help formulate our space strategy, we're trying to somehow
quantify our organizational interrelationships by trying to
create an interaction matrix among OOD and other groups
within the company. In order to accomplish this, we ask that
you do the following: without regard to existing, formal
organizational structure, define your group in the smallest

identifiable, logical operating units that can be separated at different sites.

The following is suggested as a rough first cut:

Cudmore -

Lyle -

Clayton - Terminals, Micros (chips), Small Systems

Saviers - Memories, Small Disks, Large Disks, Small Tape, Large Tape, Adv. Dev.

Johnson - Languages, Applications, 10/20 Systems, Commercial, Base Systems, Small Systems, Technical

Fagerquist - Large 32 Bit, Large 36 Bit, R&D

Demmer - Mid-range, Dist'd Systems, Interconnect

Holman - Power, Packaging, Quality Assurance, CAD, Diag. Eng. Service, Eng. Info., Computer OPS.

Fuller - SA&T System Performance Analysis (Potter), Standards

Meyer - Personnel

Kur - Finance

Bell/Portner - Engineering Administration

Thompson - Quality Assurance, Technology, Test Process

Other - each P/L, Field Service HQ, Manufacturing site, Finance, Admin., Central PPG, OOP, Training, SWS, etc. (please list any we've left out.)

What we would like each of you to do is to refine, alter or affirm this cut for your group. For example, Dick Clayton might volunteer that terminals could be split into video and printing terminals. BJ will probably rethink the above segmentation.

When we receive your inputs, including other groups external to OOD, a consolidated "line-up" of the relevant groups will be created.

We are proposing a scale which is the "interaction coeffecient" (e.g. 10 = most important, (must be adjacent, always work with) (only incidental contact and for no contact).

The proposed scale is:

Scale	Distance	Location
10-	10'	same room
9	100'	same floor
8	300'	same building
>7	1000' approx. 1 mi	same site
>6	5-20 mi	short car
5	20-50 mi	long car, helicopter
4	50-200 mi	plane
>3	200-300 mi	long plane
>2	>3000 mi	International plane
1	-	formal mail, EMS or phone
0	-	no contact

This list will then be returned to each of you, asking to relate each sub-group to all of the others as defined above. Some conflict may arise. ("A" might feel it imperative to locate with "B", while "B" feels quite differently) and these issues will have to be worked out. What we are working towards is a complete, agreed upon interaction matrix with coefficient from which we can draw strategic conclusions.

If the concept, logic or mechanics of this exercise causes problems please let me know. Ohterwise, please return the organizational groups to me by Thurs. February 14th. We'll send a chart, with the list around on Friday and would like your interaction coefficients by next Wednesday so that we can analyze the data.

follow up 1/2/79

Jack, Charlie, Al and I have discussed the general product strategy and how our internal development can build on and support it.

It seems we should also rethink our approach to all computing that is much more distributed processing versus (the strategy) Central EDP-oriented. This will help us develop a unique (and I believe better) approach. By doing/understanding computing this way, I believe it is not only better, but gives us an edge on IBM.

In this regard we're considering a manufacturing package for the 10/20 from Martin-Marietta that might better be done on VAX. I've asked Bernie to get with Al, Bob and

Charlie in order to make this exploration.

Can we get together and discuss this approach to future internal designs after you meet?

We have one of the world's greatest (most receptive) environments to breadboard fully distributed data processing. Let's take advantage of it.

GB0001/17

BASIC PRODUCT STRATEGY UPDATED SUMMER 1979

Provide a set of homogeneous distributed computing system products so a user can interface, store information and compute, without re-programming or extra work in many styles and the following computer system sizes:

- .as a single user computer within a terminal;
- .at a small, local shared computer system; or
- . via a large central computer or network.

Achieve a single VAX, distributed computing architecture by 1985 (as measured by revenue)through:

- . focusing on homogeneous distributed computing with varying computing styles including high availability and ease (economy) of use as the DEC advantage;
- . building new 11 hardware to fill the product space below VAX;
- .having a new better, physical bus structure and transition plan to replace Q and U busses.

- building new 11 software products that also run on VAX; and
- developing software for 11-VAX migration and 11 base protection.

Provide essential standard IBM and help set international network interfaces.

Define, and make clear statements internally and to our users about programming for DEC compatibility. Tighten DEC user interface standards for editors, forms management, application terminals, command languages, DEC dialects of languages like BASIC, applications languages.

Provide general applications-level products that run on 8, 10/20 and 11/VAX-11 above the language-level to minimize user costs, including:

- word processing, electronic mail, and profession-based CRT-oriented calculators;
- transaction processing and data base query;
- general libraries, such as PERT, simulation, etc. aimed at many professions that cross many institutions (industry, government, education, home); and
- general management libraries for various sized business.

Provide specific profession (e.g. electrical engineering, actuarial statistician) and industry (e.g. drug distributor, heavy manufacturer) products as needed via the product line groups.

Provide cost-effective 8, 10/20 systems through:

- building hardware that runs current operating systems; and
- making market support and DEC-standard language enhancements.

This strategy is intended to cover the full range of DEC's future products. Since technology shifts rapidly and market opportunities emerge that we don't now understand, it may be necessary to provide non-compatible, point products. These should be proposed and reviewed accordingly.

Essence and Rationale of the Strategy

The essence of the strategy is simplicity through adopting a single architecture. This simplicity is needed so that we can build the network and distributed processing structures which our customers are now demanding. The strategy is an evolutionary result of the 1975 choice to extend the 11 architecture and cover its customer base.

Given that the architecture and early customer acceptance are in place, the strategy moves to build our subsequent products on VAX, while continuing to sell 8's, 10/20's and 11's. Focus is imperative in order to avoid the redundant development efforts across base hardware and software, and to move development to fully distributed computing and to applications. The strategy also minimizes manufacturing and field start-up costs and takes advantage of the learning effect by moving to a single architecture.

The motivations for the homogeneous architecture are numerous and include the customer desires for a range of products on which to build products (in the case of OEMs) and applications (in the case of end users). Such a range in size and over time, allows planning and investment of software and it permits computers to be associated with various organizational units (eg. central group, small group, office, the person, or the home) on an "as needed" basis. Although, superficially it appears to be possible to have numerous architectures that are segmented by size and by market, the user requirements to cross both size and applications boundaries are significant. In fact, given that IBM is segmenting its products both by size and application, the main strength of the strategy is to have a single architecture with which a user can be comfortable rather than bounded by a manufacturer segmentation.

The most compelling reason for basing the strategy on the single VAX architecture, besides the technical excellence of the product is the belief that we can not build the truly distributed computing system of the 80's with heterogenous architectures. It is possible to build distributed computing networks as we do today, but the homogeneous architecture approach insures that programs may be assigned to any node, where they will give the same results. There is no need for the organizational and computation overhead signified by different manuals, separate training, recompilation of programs, and translation of data among machines in the network.

This strategy is aimed at beating the competition using our existing highly tuned minicomputer hardware and software to support and grow our existing user base. It provides us with a unique offering in the marketplace of the '80's which is likely to be based on the defacto standard IBM 360/370 architecture and the ensuing defacto architectures coming from the semiconductor companies. Since VAX is fundamentally better than either of these architectures, we must make it the standard architecture via transition from the PDP-11, which has been the standard architecture of the 70's.

The strategy is aimed at high volume through multiple channels of distribution, versus a more stable, low growth through support of an existing multi-system, customer base.

How Can We Win Against IBM?

IBM has or will have: both constant and a decreasing cost a 360/370 line new in the $100 K to $10 M price range with lots of plug compatible competitors, several operating systems to support, a large backlog; a newly announced 8100 for Distributed Processing around the mainframe; RPG-based System 32/34/38 for Distributed Processing and as a Mainframe for small organizations; the aging Systems 3 to 15 for Distributed Processing; the System 1 for the would-be minicomputer buyer; the possibly defunct 5100-series Personal Computers for the scientist, engineer, analyst and small business; and several inevitable products for computing in the terminal. All of these are incompatible, except for the fact that they speak some dialect of SNA. Products are relatively segmented to customer classes and different languages are used to enforce segmentation and hinder application mobility. Finally, they've sold via DPD and GSD, with Office Products no doubt looking on and waiting for typewriter-type entry for electronic mail and word processing.

The 8100 is a radical departure from IBM pricing as 0.5 Megabytes of primary memory and a 60 Megabyte disk are $ 29 K. Memories on all machines are similarly priced. We repriced as a result. The 8100 is exactly in the price range of the systems we sell and where we make most of our revenue. It is the second product in this price range within a year; the Series 1 minicomputer family patterned after the 11/04-11/34 was the first product. The 370 (via the 43xx series) is clearly either in or is coming into our space this go-around or next generation (1984). On the surface, the product is low priced, with lots of capability, but it also has a new communications structure (versus the one we have used substantially unchanged since 1961). This structure permits easy peripheral and terminal interfacing for both the office and factory environment. There is an extensive range of peripherals, terminals and communications to the 360/370. Since the product is sold by DPD, the strategy seems to keep account control and to make the money on software and the numerous locked-in, generally overpriced hard to emulate terminals.

SNA seems finally under control and we must be concerned because it has future built-in capability (e.g. word processing, typesetting, packetized voice). Their strategy seems to be to slowly unfold it, make it the standard, pay no attention to other standards and to make everyone follow their gyrations. A strategy based on being tightly coupled to them (e.g. with terminal emulation or fully compatible across the board) is really risky. We must interface to them "carefully" and be very, very aggressive in our own interconnect plans (both in performance and capabilities). We must collaborate with ATT and the international standards community to set standards.

We must watch how the System 38 is used vis a vis its 48-bit address because it can lock us out and cause others to generate many dead end architectures. It may be a E/H series follow-on breadboard. We can't succumb to this.

Terminals have to play a major part because we can get the cost and volume to lower our system costs. We have to follow the strategy and push co-existence with our earlier systems, but homogeneous networks must be understood and pushed. VAX has to be kept tight with emphasis on performance to avoid the O/S proliferation of IBM (and 11's). Also, the tightness represents the performance/cost edge we have over the 370.

<u>How Can We Win Against Other Competition</u>?

There are established competitors too, such as DG, HP and Prime. DG and Prime have very simple, single architectures and have been most profitable and have grown most rapidly. HP is converging on a single architecture around the 3000, but it will have to be extended eventually. The NOVA will also be extended. The large manufacturers (Univac, Honeywell and Burroughs) which operate with an established base are less profitable, have grown slowly and have multiple, poor architectures. Honeywell, with a simple, but adequate minicomputer architecture seems to be doing well by selling minis to its old line, mainframe base. There is no evidence that they're developing or pursuing the mainframe business actively.

There are probably more significant threats from the companies that can be easily founded to build systems into OEM Winchester disks by using the newly announced zero-processor-cost, 16-bit microprocessors which have 22-bit address spaces and 11/34-11/45 performance. These architectures need to be extended for multiprogramming and to handle larger virtual memories, but many point products, such as RSTS, can be built easily and cheaply and can quite possibly target a specific existing, trained user base.

There are also the Japanese and TI which can be lumped together because of their similar behavior. Both believe in targeted, high-volume products with forward pricing. Neither have an adequate architecture. TI is strictly limited to 16-bits with almost no escape the Japanese are aimed at the 360/370 using U.S. companies (e.g. Service Bureaus) to distribute hardware, <u>and</u> at high volume point products that will go into stores, no doubt.

The strategy supports very high volumes for dumb, pre-programmed (smart) and programmable (intelligent) terminals using the 11 until VAX is appropriate in terms of price and functionality. In the mid and high priced minis, the strategy is compatibility and volume, phasing as appropriate from 11 to VAX. For example, since there is not a high priced 11 after the 11/74 and the 11/44, there is a phasing to VAX (through COMET) and lower priced 11's based on 11 microprocessor implementation. The question here will be how fast we can provide high performance microprocessors using HMOS and narrower line VLSI technologies.

PRODUCTS IN 1981-82

HARDWARE COOMPONENTS

HMOS LSI, with first "test" product

Interconnection hierarchy with software compatibility
1-10 Mhz and/or 10-100 Mhz inter-computer bus ICCS;
50+ Khz comm.-compatible multidrop for terminals, peripherals, and small systems;
0.3-19.2 Khz comm.-compatible for low cost terminals.

Significant competitive memories
Solid state modules for software
Low end floppies and low cost tape
Removeable and low cost disk RL04
Hi-volume mid- and hi-end disks in R80/R81 with backup

Terminals for everyone!
Low cost (dumb) and block mode (VT162)
Office environment for quality printing, electronic mail, and move to full-page text as quick as possible
Professional using graphics (and/or color) with target application software
Factory environment terminals and interface systems

HARDWARE SUBSYSTEMS

Remoteable printers, job entry, concentrators, sensor-control
Communications concentrator - Mercury
Memory (Hierarchy) Management - HSC50 for high end
for R80/R81, RL04, tape and disk cache

KERNEL SYSTEMS based on processor-disk-communications (see family tree figure)

780 replaced by Venus (const. price >3x performance)

780 - Memory Manager - Comm. Concentrator
780 - Multiprocessor
780 - RP/R80-81 + RL02-04
780 - RK/RL04

Comet - RP/R80-81 + RL
Hydra (Including Memory Manager - Comm. Concentrator)

Nebula - R80-81 + RL
Nebula - RL02/RL04 (higher cost, quick to market personal computer)

LSI VAX - RL04 - Graphics Terminal (personal computer)

11/70 with no hi end replacement
11/70 - multiprocessor
11/70 - RP/R80

11/44 replaced by HMOS LSI-11 with >256 Kbytes (J-11) and 11/70 performance

11/44 -
RP/R80-81 + RL

11/44 -
RL

11/24 -
Unibus Fonz RL based on new backplane replaced by HMOS >256 Kbyte

11/23 -
Q-Fonz RL

11/23 -
Q-Fonz - RX (floppy)

PDT Fonz - RX (floppy)

PDT Fonz - TU58

Tiny chips,

SOFTWARE

Diminish the 11 software investment for mature products (RSTS, IAS, MUMPS) and provide only minor enhancements to recent 11 based products (TRAX, PDT Software) to extend the market life and limit the VAX transition risk. Orient new development on VAX and 20 toward IBM compatibility and explicitly invest in tools designed to permit easy customer movement between VAX and 20. DEC 20 development will be aimed at timesharing, high level tools and applications support. Shift the bulk of the PDP-11 software investment to VAX, tracking VAX hardware and aggressively moving to round out commercial capability.

Develop a single VMS operating system to span the product range if technically and operationally feasible; "low end" products will mask the VMS capability for the unsophisticated users or, if efficiency demands, new code compatible at all interfaces with compilers and utilities will be developed. VMS will offer full mainframe capabilities allowing concurrent batch transaction, processing, and time-sharing, along with limited real-time.

. Provide superior data-base capabilities in the two -

three year time frame.

. Focus on data access and data manipulation tools for the non-programmer, heavily based on graphics terminals.

. Provide word processing and electronic mail as applications on the general purpose VAX systems.

. Data integrity will be a feature available independent of high-availability (non-stop) operation through Hydra.

. High-availability (Hydra) will be a standard attribute of VAX systems at the customer option.

- Fire-wall funds to stimulate acquisition of cross-industry applications packages. Provide industry specific applications via internal development or acquisition. Leverage field resources by investing heavily in product quality assurance and self installing systems capacity including remote software update and diagnostic strategies.

- Move systems-level code for 11 based software (RSTS, TRAX) to VAX compatibility mode if technically or strategically viable (under investigation now) otherwise provide user-level compatibility via native mode VMS layered products.

- Shift DECNET strategy to international standards and stronger IBM interconnect and VAX binary image compatibility for distributed processing; constrain PDP-11 DECNET FUNCTIONALITY EXTENSIONS; speed up DEC 20 DECNET capabilities.

- Converge on ease of DEC 20 to VAX movement through common language definitions, (common implementations where feasible), common user-level utilities and data conversion routines. For each new DEC 20 or VAX customer, as time progresses, make the movement between systems more attractive.

Why Change the Current Strategy?

We have arrived at the current strategy by integrating our past customer needs, with the result that nearly every past system we have ever built is being evolved. This evolution creates too many systems with converging functionality. By prolonging the phaseover to VAX, we're unable to invest enough in VAX due to continuing and evolutionary support costs. Also, we're unable to provide applications, or have any slack resources to respond to competitive threats (eg. large micros or focused products such as the 8100).

We are just beginning to get a feel for the expense of putting new software systems in the field, and there are other systems still to come. Since we provide many choices, we find our sales and customers have difficulty deciding what to sell and buy. This makes us difficult to understand and to do business with. Lots of low volume products mean we don't have adequate volume to amortize the start-up manufacturing, sparing and training expenses.

Why Not Aggressively Evolve All Four Base Hardware Architectures?

In reality, our past strategy has been almost a divisional product structure. Customers can choose among the 4 basic hardware computer systems with 2+3+7+1 models and then select the appropriate software system, among 2+2+7+1 software systems for 8, 10/20, 11 and VAX respectively. This gives us several hundred systems. The number of alternatives is too large, resulting in small and decreasing volumes of each of the systems as all architectures are extended to cover a full range that we believe our customers require. We can not afford all the necessary enhancements to support four architectures over the range of size and use that our customers demand.

While any of the architectures can be implemented at any size down to and including LSI chips, there is no significant differential cost of the processor between the 10/20, VAX and an 11 with commercial and scientific instruction-sets. An evolved 8 to handle the strategic range would even be the same cost. The main differentials are: the cost of the memory to hold the tasks and the size of the operating system software. The 10/20 operating systems have been oriented to generality, and while VMS and TOPS 20 have roughly the same functionality, the 10/20 requires 512K bytes of resident memory, whereas VMS require 256K bytes. This occurs because TOPS 20 has evolved and because of the efficiency of VAX architecture. VMS also has real time capability. Similarly, it is now inappropriate to consider 10/20 based architecture for terminals and personal computers, when compared with VAX, because small problems cannot be encoded to be competitive with modern 8- and 16-bit microprocessors. Furtheremore, extensions to the 10/20 architecture would require basic work in the operating system and languages to build a VAX competitive product.

Why Not Segment Products By Market?

Since the 10/20 has significant commercial software and since it is believed that our customers are insensitive to architecture, we might simply have a market segmented approach and use 11's at the low end and 10/20's in the high end. Lower priced 10/20's would be implemented over time as appropriate.

Our technical users (EDU, ESG and even LDP) do not segment computer purchases into commercial vs scientific. A "control" customer such as DuPont doesn't segment its applications either. Even NASA wants COBOL to off-load their mainframe and to do administrative EDP. Universities likewise want a single machine, and hence the software will be "pulled" into existence. Version 4 of VAX COBOL executes faster than the 20's already.

Since there is basic incompatibility between the 11 and 10 architectures, the migration problem is enormous. Now our large commercial customer base is with 11's. Our users perceive VAX and 11 are of the same family.

The 10/20 still requires basic changes (CIS, 30-bit addressing) to bring it up to VAX performance and capability together with compilers and some basic software (eg. multi-keyed ISAM). TRAX-36 and RSTS 36 will also have to build off our 11 base. In short, while it might be feasible to build 10/20 software so that our 11 users could meet our strategic goals for distributed processing, we would still fall short of the distributed system one can build with a single architecture as described in a subsequent rationale.

How Do Customers Preceive The Situation?

In mid October, a group at Bell Laboratories, building PBX systems visited us and made the comments:

> "Only you have the basic architecture in VAX to cover the range of products we need for distributed processing. This includes: terminals, offices and large offices.
>
> Give us a truly compatible range of VAX machines,

starting
with a VAX-on-a-chip and extending through the IBM 3033.
(Don't corrupt VAX, since as in the 11, we must preserve our
software base, given that the processor is only 4%
of the cost.)

The machines must have a reliability and security orientation.

Why don't you do it?

We will help fund the development."

Recent discussions with Stanford, ITT, CERN, NASA (Ames) indicate concurrence even though they are large 10/20 and 360/370 users. MIT is proposing to build a homogeneous VAX-based network. DuPont wants a similar structure, but is less rigid on the need for a homogenous architecture even though they've standardized on the RSTS machine internally for many of their systems. (There's a videotape describing their needs and ideas.) CERN, and NASA (Ames), for example, feel that the large mainframe may be on the way out as we offer small group-level computing with VAX. There are probably 10/20 customers who feel strongly that we should base our future on 10/20's. The main reason to focus on the single architecture is that it is part of the 11 family.

Why Have A Single Architecture?

There are technical, marketing and economic reasons for choosing a single architecture at this time on which to base a major part of our future. However, this does not mean that we must neglect our 12- and 36-bit user base.

While computer networks can and have been built with heterogenous computers and IBM is betting that it can build distributed computing systems with only similar machines, a single architecture is the most effective for distributed computing systems. The homogeneous (identical) architecture approach insures that software will give the same results no matter where executed and therefore programs may be run anywhere in the network, data stored anywhere and programs moved about in their object form without the overhead of recompiling or translation as data is transferred. This also insures that the human interface to the system remains constant, because identical software is executed in different machines instead of relying on software that is specificed to have identical interfaces (e.g. languages, command languages, file systems, utilities).

From a user viewpoint, the homogeneity is ideal, and the success can be verified by reviewing the history of IBM's decision to build the 360 (and not continue with the 1401, 1410, 7070 and 7090 series machines), even though there was an incredible base of these machines. This was also the time that Honeywell established itself with the 200-series and RCA with the 301. The homogeneity provides a simpicity for the entire DEC organization and its customers, and lets us all focus on end use applications rather than choosing a particular operating system and language. Currently, we have too many low level, incomplete choices and the software efforts of us and our users are not focused. An applications base can only be built effectively on a good, stable architecture.

Economically, a homogeneous architecture is essential because it allows us to concentrate and become a focused, high volume manufacturer and take advantage of learning curves. While 10% learning curves mean a doubling of manufactured quantity causes a 10% decrease in cost, they also imply that having two very similar products at one-half volume causes 10% higher costs in each. There are similar effects of learning in hardware, software and sales training costs, although the learning costs are small in comparison with the logistics and start-up costs associated with our many, different though functionally equivalent, products. We become difficult to do business with in the process.

Why Base The Architecture on VAX?

Although we went through the arguments in the spring of 1975 when we decided to build VAX instead of building lower cost versions of the 36-bit architecture, we now have a real machine that met its development goals and has user acceptance on which to base future products in a natural, evolutionary fashion.

Mostly, the choice of VAX in 1975 was based on having a large, PDP-11 user base. Furthermore, the choice to stay with the 8-bit byte was of convenience because of the IBM and communications worlds.

The VAX architecture was designed to permit the building of a range of machines with sizes that are important to us. Our targeted range of implementation was 1000:1 and this is attainable with an LSI implementation for terminal applications in January 1982. This is why a small page size and simple paging system was chosen, versus a larger page size and more complex scheme that would have been particularly oriented at large systems. However, it would not be wise to build the machine 1000 times as large in 1982, because it would take the system size beyond the suggested $250 K selling price limit and into mainframe price and customer expectations territory. Thus, in January 1982 the LSI VAX could sell for several hundred dollars at a board level. An ECL technology machine might be configured to sell for $ 500 K, giving the 1000:1 in price and a range of 64 Kbytes of RAM and ROM for VMS in the terminal to as much as 32 Mbytes in the large configuration (4000 64 K chips, costing $60K and occupying 20 PC Boards).

VAX was also designed to address the high cost of programming. Already VAX has been acclaimed (by a customer in our ads) as the best machine for implementing software. The large address space eliminates the need for much of the effort we spend encoding large programs into overlays. The architecture has instructions for the important data-types, the addressing is independent of the data-types and the important language constants are built into the hardware. There is clear separation among program and data. The procedure call instruction allows more sub-program sharing than with architectures that are dependent on conventions (e.g. 360 and 10/20) and it eliminates a class of systems programming errors resulting from the multiple assignment of general registers among different programs.

The 32-bit address space of VAX appears adequate for the computing needs in the foreseeable future and there is extension capability given that any special needs arise. The address space and protection modes also give us a capability to run sub-programs written in different languages as a single program. This capability is unique and may turn out to be the single most important attribute of the machine. Since only one other computer has the capability, we don't understand it or how valuable it will be.

Another technical reason is based on the encoding efficiency of the VAX instruction-set. The VAX architecture can encode a Fortran program in about 1/2 to 2/3 the space of a comparable large computer such as a 360 or our 36-bit computer, while providing 32-bit addresses versus 24 or 20 bits of addressing for the 360 or 10/20. Benchmarks in BLISS and FORTRAN show this now, and the Common Family Architecture studies also indicate similar results. While memory cost is decreasing, memory is still a significant fraction of system cost. Three years of cost decline at the historical rate of 20%, is required to get factor of 2 the cost difference back. That is, from a memory cost viewpoint, we have a 3-year cost edge on the market. More importantly, there is a similar effect on performance. By having only 1/2 the bits to move between primary and secondary memories, the performance is higher due to disk-MOS memory swapping bottlenecks.

Finally, we have an 11 user base on which to build that is approximately 7 and 50 times as large as our 36-bit base in terms of installed equipment dollars and installed units.

Why Not Use The 10/20 As The Base?

The software and user base on the 10/20 is the major reason to not arbitrarily reject the architecture. On the other hand, since the 11 user base is larger and has grown more rapidly, its software base is larger and we have to protect and build on it as a higher priority.

Right now, the 10/20 requires incremental investment to make it competitive with VAX and the rest of the mainframe market. Extension to provide a large address space, to extend the floating point range to fulfil customer commitments, and to give a competitive commercial instruction set for COBOL are needed. Making these hardware investments requires comparable software investments and we must again wait to compete because there is a new machine and software to support.

Subsequent implementations for small systems will be expensive both in terms of new software and start-up because TOPS 20 has been oriented toward large mainframe generality. Smaller systems will require contractions. Also it stands to only cloud the market more as alternatives for mid-range systems will include 2 VAX and 1 or 2 11-based systems. As small systems are implemented there is a need for compatibility with the even larger 11 base.

Why Distributed Computing?

Distributed computing keys off our strength in interactive computing through timesharing, small systems, real time computation, terminals, and networks. Furthermore, we believe this is what our customers want. The issue is not distributed computing, but solving the problems that it creates.

To: Roger Cady
CC: Ulf Fagerquist, Bill Demmer, Bernie Lacroute, Larry Portner
From: Gordon Bell
Date: TUE 23-JAN-79 08:25:05 EDT
Subject: Basic Strategy and Transition machine

The strategy wording got changed by win. I prefered the tighter wording, but
the intent was to not change the meaning. The changes put much higher degree
of standardization on all systems and then addressed applications only
(>>>>I mean ONLY) if they were done in a transportable fashhion and
preferrably an application should be done simultaneously on all systems at
once.

I would like to get you, Larry and Per/Ulf together on this

issue so we can
get the wording you want. To me, your need s can help in the tightening.
I would like to get more stringent, because it helps the phaseover ...and
may even make it possible.

In regard to the phaseover machine, I agree with your urge/need to get it
defined immediately. Ulf, will you Per, Dick Snyder, Lary, and Bernie and/or
Bill, and Bill Heffner, and Dave Rodgers rendevous with Roger in the next
day or two to brainstorm and define Dolphin in these terms...or say that it
can't be done. Rather than issuing the strategy again (as corrected), I
would entertain a tightening as you suggest, but only if you , Ulf, and Marc
agree. In this way we can avoid sending the 1/10 version out and just make
an ECO if we can agree.

SUBJECT: SOME CHALLENGES FOR US IN THE NEXT 0 TO 5 YEARS

Prompted by the Japanese visit and sitting many hours in meetings, we have an incredible number of challenges ahead:

0. We have the greatest product array and strategy in existence
today based on VAX-NI-CI compatiblity and as such should easily
continue our position. We do have to follow it though! DEC has
promoted a major style of computing which has evolved for 22
years that is much deeper than the cabinet skins. (About 7 years
ago I went to a hardware session at DECUS and almost no one
showed up.)

The Japanese approach computing totally as a commodity supplier
problem without a feeling as to what computers can and should do.
Ironically, I think it is the language and Kanji character set
that puts up the boundry. As they get human interaction, they'll
become an even bigger threat because their higher intellect will
enable everyone there to become programmers. Recently, Dr.
Kobayashi, the chairman of NEC stated that every employee MUST
have and use a personal computer.

Right now I don't see us being a great commodity supplier because
the technology depth, and manufacturing aren't good enough. The
DEC versus Brother Keyboard is a good example. We've built an
obsolete, lower technology, relatively poorer keyboard... maybe
because it looked easier or who knows why.

This requires even stronger architectural leadership because
there are so many opportunities around and this is the best

differentiator we have. Most products are dead ends or don't allow enough control or are really poor. (Robin and Rainbow aren't off to a very good start, but they could/should be.)

The bottom line of this point: now our strength is our incredible
architecture and it must remain so. If we are going to be serious in the commodities (eg. floppies, keyboards, monitors)
and commodity computing (8086, 68,000 and 16032 x CP/M, UNIX),
we'd better put the management and resources to succeed. We can
not win at trying a little bit of everything! I don't think there's any way to even look at and decide on some of these issues because we (OC) encourage EVERYTHING and decide nothing.
Making incremental decisions ultimately kills off a direction.

1. Getting everyone settled to sell what we've got and what we
could easily have especially since Patti Seybold blessed us.
Office/tp/data management/dp are the greatest and we've got to
segment and approve the organization now. Julie's great here.

2. Segment the part of the organization in either a quasi or real
divisional structure so that common engineering, manufacturing
and marketing are together. Also, then ask these group

leaders
to come with some recommendations. In this way, the various operational committees can be cut down to manageable sizes and
aligned to a common goal set. The notion of commodity terminals
and personal computers seems like a natural. Also VAX and the
main systems business are another natural.

Right now, decision making seems to be very slow because it has
been clogged by the low end problem for the last 2 years. In engineering complex systems it has been observed that the design
time is proportional to the number of people involved squared.
The meetings are just too large to get the work done. People just want to know what the NEW DIGITAL is and what to do.

3. I'm very excited about the pipeline that's been established
from: technology boutique (expensive, fast response, competitive,
state of the art); systems (constrained to be compatible); and
commodity (designed in Japan or Taiwan) for cost. I don't think
an engineering/manufacturing group can be in more than one mode
at a time. For example, it's crazy to ask a group making state
of the art products to do low cost, third time around products.
This is impossible emotionally for engineers. I've decided to be
less involved in these products, but will continue to provide some direction including sending ideas into the hopper.

4. I share your view of having a great small business computer,
but am concerned about whether you can be articulate enough

as to
what it is to get someone to take on the charter. The parameterized software looks like a key here, but it's the first
pass. Is it the motorcyle shop or the engineering department or
the manufacturer with $10M sales (I can show you a company who's
using a 780 in this mode, including mail)? The range is immense
and hard to define. Given your intense interest, and the ambiguity of the space, you might ask: Is anyone smart enough to
do the job, too smart to avoid the job because of personal risk?

5. There are the Japanese and I hope we get concerned before it's
too late. Fujitsu has 10,000 engineers at Kawsaki all determined
to make them number one. I intend to push to join the Alpha Omega and packaging consortia parts of MCC because they are really a way to reduce the development costs and get the vital
research we need. This would be coupled to the work I would like
to do aimed at a high performance machine structures.

6. An approach is needed to build machines. They aren't fast enough now, nor can they be designed. There are several approaches. This is the highest priority of all, especially since the recent announcement of the Japanese to TARGET MINICOMPUTERS because NTT has asked the big 3 to supply them

machines for distributed processing (again, expecially now that
they've conquered supers and mainframes and are en route to commodity personals). I don't have the answer now, but only understanding that we are headed toward a cliff.

This is the area that I must work in, even though I would also
like to remain part of the management team on an as needed and as
desired basis.

7. Going with National. I fully support this and we must make it
happen!!! They will supply the peripherals (can not be underestimated) and the marketing outlet. I see our leverage and
control as software. This means we would command a premium for
MicroVMS and NOT sell it on look-alikes. This means it is bundled!! We could also bundle UNIX in a similar fashion, or we
could allow it to become a commodity that all the random unicee
suppliers support... probably the best way to not support unix.

8. The organization does bother me both in content and form because I see it becoming typically American and it is the antithesis of the Japanese companies. I looked at the top 17 of
NEC: 13 are engineers, there's a lawyer, salesman, and 2 accountants. About 8 are PhD's. This is typical of a highly divisional structure. Similarly, I had dinner with the head of
engineering of Sharpe, who was a very deep and thoughtful engineer (he has Maxwell's Equations chiseled in stone at their
research center); three days later he became President. They believe in and do real, very directed research (eg. a class 1 room and 0.8 micron line width at Hitachi Central Research) and

this pays off. We have little directed research or advanced development outside of a tiny bit in semis and in disks.

The organizational form is of concern: they have NO marketing groups per se. Marketing is done in either sales or in engineering. This is the famous 3 body problem or 3 stage pipeline. We must get back to this before it's too late. For
example, we've allowed the real time response of our systems to
be dissipated because the engineers only see customers at DECUS.
NEC has the two groups meet quarterly for a week where sales and
engineers listen and present to each other.

To: Ulf Fagerquist, Jan Lounsbury, Roger Cady
From: Gordon Bell
Date: WED 4-APR-79 09:37:44 EDT
Subject: PREPARING FOR 4/11

Talked with Kiester (Commercial) and Shingles. They will input to us on
Monday and include Barlow's "technical comments". Kiester (Commercial and
not Data Services) believes we can (1) minimize follow-on investment by fixing
10/20 problems first; (2) not do follow-on hardware.

I suggest that we do the following to be reworded for DECUS (we must keep our
promise):

1. Small fire-wall effort (PDP-8 model for now versus PDP-15 model).

2. Support 10/20 especially RAMP and multiprocessors (possibly).

3. Cut 20/20 price and 20/60 prices.

4. Cost reduce KL (newer RAMS, 11/24, and better power supply) with spares
by a compaction.

5. Interconnect KL and 2020 with ICCS VAX.

6. Do follow-on machines after resources required for 4 and 5 have completed
the tasks.

7. Build coexistence with VAX and other 10/20s through ICCS. Do not
suggest migration structure, but provide a path so that

users can:

A. Put new work on VMS and communicate with old programs on 10/20s.

B. Do front-end, e.g. editing and filing (off loading on VMS in compatible editing, and do computation off loading with VMS by selecting migration when standard languages permit, especially FORTRAN and COBOL).

C. Buy eventual cost-reduced hardware.

**The above dictated but not seen by Gordon.

SUBJECT: RE: CORPORATE FINANCIAL STRATEGY

Al,
You shuould understand we have about a dozen engineering groups now... not 1, or were you proposing we go from a dozen

to 2?

We can manage about any kind of split the OC wants us to.
Ken wants
the OC to decide, from the 12 engineering groups that are
presenting
as to where to put the resources. These include all flavors
of
technology, manufacturing process, engineering process
(computer
aided design, etc.), and products. The pressures are clearly
to
get more products abut we must resist, or happily fund.

The transitions from 16-32, 36-32, and doing multiple Personal computers while at the same time, being required to fund the breadbasket (mid range shared systems and dumb terminals), and starting up the office program puts hellish demands on products. With discipline, it is possible to get the transitions to take place so that we don't have to fund all systems forever. Two years ago, we made two very significant errors in not following the product strategy we accepted: Not moving to build an 11 PC, versus perpetuating the 8 AND not moving to make transition software for the 10/20 versus building a transition machine.

SUBJECT: THE SECURITY DEMO AND NEXT VERSIONS OF VMS

I would like to help you schedule a demo and a presentation of results of the security project put on by R and D. There is both an impressive demo and a report on security that I feel must eventually be part of VMS. This is not to try and dictate the functions of future versions of VMS, it is to say that as planners of our future products, you must be aware of what the possibilities are. Right now, we have a capability and I would like us to continue working in this direction in an Advanced Development mode, as well as looking at areas, such as the NI where it is mandatory to build in more secure capabilities.

Virtually all of our competitors are developing products based on sthe secure kernel approach. Given that we have capability to do this, I would hate to get into a mode where our customers tell us to do it and we have to come from behind. I think you have the responsibility to find out where the competition is precisely, and when you think this is going to be a necessity as opposed to a nicety. I'm sure the product lines can provide this information. (This has to get factored in along with all the other pulls like Hydra, Personal Vax, better real time, etc. Can you try and sort out these classes of pull so as to not make the whole
evolution of VMS appear like a giant game of rugby whose every release is a happening based on who has yelled the loudest for the next feature?

How about asking Paul Karger for the demo and presentation of results? (When will the new auditorium be available in SR?)

SUBJECT: PLS CONSIDER VAX (NEBULA) IN THE 23, 23B, 24, 44
POSSIBILITIES

It seem to me with all the churning (ie the Task Force on
What
to Introduce) that is going into the issue of how many of
which of these machines to build (all of which cost about the
same amount) we should refer back to the base corporate
strategy
that we all agreed to last year:

Build VAX's over the long term and build only 11's where we
have to because of the low cost. Putting more 11's out there
where we are acquiring commitments for extensions in the

software
(albeit minimal compared to what we imply with large, mainframe
or central-type computers) is not a good idea.

What I'd like to see:

1. only evolve the 23 to the 23B (with 22 bit address)
2. make 34's as needed, but see if there is a lower entry cost version of the 44 that lets a customer grow
3. hurry up and get Nebula (with 65K rams now available) to the
low end market so as to get the users on VAX asap

Please understand point 3 is for two, VITAL reasons:
1. implied support on multiple operating systems
2. nearly all customers who are buying follow-on type systems will
inevitably outgrow the 11 and will have to switch to another architecture.

THE LONGER WE PROLONG THE MOVEMENT TO VAX, THE HIGHER RISK WE RUN IN LOSING THEM AS CUSTOMERS, BECAUSE THE FUTURE OPTIONS ARE:
a. low cost IBM machines
b. low cost IBM-compatible machines
c. low cost semicomputer company-based systems (whether they be
   made by the semicomputer company or put together by IBM, Apple,
   the Japanese, etc.

These are all better than future 11's with its architectural limits.
Thus, let's get them over to VAX now! Can we please start?

Subject: PROCESSOR STRATEGY

I need your help re-directing and implementing our strategy so we can move to aggressively attack the following critical needs we have identified:

1. Networks
2. Interconnects and communications (hardware/software)
3. Multiprocessors
4. 10 Follow-on
5. "Hurley nets"

As you know, we are headed in the following direction:

1. Drop D36 but look at the MCA technology for use on 32-bit machines.

2. Relocate Venus to Marlboro. We clearly need the Venus staff to move with the project!

3. In addition to Venus, we need to be sure D36 people have the opportunity to look at work on the 10 Follow-on and the other critical programs above.

I'd like to consciously mix Marlboro and Tewksbury people on these projects to maximize the benefits of their collective expertise and experience. If we can move quickly, this is a great opportunity to get people working on the critical programs that have fallen off our lists over the last weeks for lack

of budget and people. These programs are really essential if we are to move
ahead with the Engineering Strategy and win against IBM. Please ask your
people to help us understand how to best make this transition while minimizing
their pain.

I feel really good about what this strategy can do for us in the marketplace,
but am worried about the personal disappointment such a major change causes.
So let's move as quickly as we can on this and stabilize the organization next
week.

SUBJECT: THOUGHTS ON ENG. BUDGET AND STRATEGY EVOKED BY BILL DEMMER

Bill's recent pulse to me on the budget allocation stimulated
several thoughts. We plunge into areas sometimes without looking
and rarely do we plan their long term costs. Also, we have
always looked at funding/NOR (the basis for all engineering) and
this now seems wrong. We have to fund according to area or range
needs so that if we have products there, they are the best!

This
ought to be the theme of the April meeting. Instead of
feeling
sorry for an engineering manager whose $/NOR is decreasing,
we
should reward them on the basis of the strength of their
products
in their charter. Similarly, we carefully allocate charters
and
funds so they protect themselves from the do everything
syndrome.
Note that each product area has a different gestation period
depending on the commodityness, size and market maturity (eg.
high end systems 6-8 yrs, terminals and personal computers
less
than 4 years, disks 6 to 4 years). We must also watch the
over
funding because we want and love a product syndrome could
kill
the group by growth. Fund to win!

In the recent past, we have made decisions that reduce
products
and hence we have to manage the budgets (and efforts)
downward by
redirecting the persons to other areas like Bill did when
taking
on the Network area with the resources from what had been
11's.
His mid range manager has a problem emerging when the 24, 44,
Comet and Nebula complete because there is probably only a
Comet
follow on prior to the availability of the Scorpio chip.
Note
the phaseovers (reductions) we must manage: 10/20 to VAX,
larger
11's to VAX until VAX gets down to chip level, 8's to 11's
(we
blew), terminals to personal computers, using server based
model
on the NI versus extending every system, and generally moving
to

generic (eg. OFIS) and specific applications. Fortunately for us, all area reductions are balanced by demands for other area products and the need for lower cost (process funding).

In the systems area it would seem we end up with groups (A/D, and Development) in disks and cpu's along the X 2.5 price bands:

>250K (single group)
100K-250K Comet and its follow on
40K-100K Nebula and ? follow on (an 11/24J to cover all)
16K-40K depends on Scorpio and Aztec,
<16K terminal based depends on Scorpio

Scorpios or combinations packaged with the right disks seem like the way to cover the low end part of the range. We should err to have holes and go for lower prices, driven by semis and disks. We should think multiprocessor or cluster (NI) to get more range.

NI should change the way we design and sell systems, and I'm sure we should head for the clusters approach verus covering range by individual machines.

The Personal Computer (and Clusters) structure is something we really blew by perpetuating the 8 one too many generations. CT100 should have been on the market today and the CT50 could have only been limited by Tiny. Hopefully we have other things to sell and people will wait and not buy PC's instead of our timesharing and terminal based approach. We have to get the 2.5K- 6.25K and 6.25-16K band PCs now, followed by better technology and production processes in both PC's and terminals.

For now, we have to redundantly fund Terminals and PC's until they merge, probably in the middle of this generation. To the terminals folks, this means having computers there that can be programmed: VT200 and LA200 with the computer in the keyboard. (The terminal or computer in the keyboard with a few line display should give us about the cheapest, most portable terminal.)

I see the 5th generation (80-87) as a consolidation generation where having built so much hardware, the market may be limited by useful applications work. It's theme will be the communications, clusters, and personal computers (versus terminals) for everyone especially toward 87. Given the incredibly lower costs we will see across the range, there will be pressure by the big personals on our bread and butter, mid and large scale timeshared systems. The emphasis is clearly going to be on cost, time to market, applications, and various ways to distribute.

It feels like the 6th generation (>87) will be accompanied by some very different capabilities for and structures of machines: voice, and vision; solution to security; never fail, fully redundant and totally different repair/replace structures unlike no other man made systems. We'll have our VAX version of the CRAY 1 at 250K, 400$ the $400 Apple PC's, PC's distributed in every tv and telephone.

Software will change too this generation from tools for programmers (operating systems, languages, data management, and

communications). Our efforts should evolve to support applications programmers who have knowledge about specific domains such as small businesses by providing higher level tools.
The Product Lines then would write specific applications (eg. dentists, structural engineers). The OFIS program is quite different because it provides the package for end use. Finally,
we have to explore tools for the end user to define his own programs, with Visicalc being perhaps the first. We'll continue
our conventional ways to generate software: OEMs, our P/L's, the
field, and probably most important, the independent software publishing business that's evolving to support the PC marketplace. It is important to understand this whole investment
structure now!

The 6th generation should really have a different method of programming when knowledge based systems come into existence. This means that computer science as we know it now (i.e. where
programmers are trained) takes on a role like physics and mathematics, with every discipline taking on its responsibility
for writing down its knowledge so that machines understand it,
rather than relying on papers.

Am not sure what the bottom line is for all this is except to evoke your thoughts. For it to become an active guideline, it has to be "processed" and then incorporated into our strategy.

For now, What youse think?
What's right and wrong with it?
What's lacking?

Date: 5 OCT 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

Let me congratulate you, Ken, Cherylene, the presentors, and attendees for a worthwhile engineering (LSI) soiree. I feel remiss in not recognizing the need to provide a products/hardware technology congress for engineers and managers which this meeting nicely addressed. Hopefully most were able to present their different perspectives, have the messages received and get feedback. The amazing thing was the quality and quantity (2 days at 14+ hours/day) technical interaction...I came back relatively fresh and encouraged (as opposed to bored and depressed, attendant with large group meetings).

Ken's talk was worthwhile, well integrated, while providing the engineers a chance to query him...providing much food for thought in terms of his view of "engineering management". (Please transcribe the video tape of that section so that it can be edited and possibly digested for complete circulation.)

Given the good precedent of distributing the presentation figures before the conference, a voice cassette for each session could be made available (including the Q and A). (The videotapes appear to be unreadable and add little.) In this way, non-attendees can check out the talks from the library...but in a controlled way.

Would it be worthwhile having a 1/2 day early tutorial ahead of time reviewing physics, manufacturing technology, and the specific technology details?

Next year, could you not change this year's charts, but merely update (ECO) them to show how your projections agree with reality? On the wall charts giving what each chip does, development cost, time, cost/gate and time/gate and other metrics might be useful...and then publish it. The users are really begging for catalogs, ways to estimate their design costs and times, and better interfaces on the design process. If you cut them adrift, which I hope you will soon do to encourage their independence, clean interfaces are mandatory.

follow up 6/25/79

The tapes are tedious to watch. There are too many ah's, jokes, and noisy gaps. They should be able to be cut by at least a factor of 2.

Could you get together and get a priority for retaping them or cutting parts out all together?

In some cases a written synposis or summary is adequate - eg. Cullen's talk can collapse to a 1-3 page paper.

<u>All</u> tapes would have a 1 page summary and slides...then make the tape optional. Prioritize things into a pert flow in terms of must see. I only saw 9 tapes and my strategy. Of these, let me recommend: 1) the strategy talk (only first hour)... and even the 1 1/2 hours could be edited to an hour or less; 2) Plowman's talk - could be cut or have him redo it. 3) Sam's talk, which needs more time. The IBM and network talks could be cut, converted totally to written form and made optional. The marketplace talks can be drastically cut or made written (in outline). I don't know what the other critical talks are.

Let's take the time to get a good set that everyone can use! The total viewing time should be in modules of 1/2 day and we shouldn't expect more than a 1/2 - 1 day of viewing.

Next year, let's use questionnaires to guide, determining what's important.

GB:swh

Note to Dan - all tapes, except the Strategy are enclosed. The library has 2 sets of the strategy - the original is at Bedford under the care of Mike Dick (245-2237).

Citation:
For contributions to the understanding of program behavior in the design of multiprocessors, cache and memory hierarchies; and the development of VAX and the Digital Computing Environment

6a
Chief Architect of VAX-11 with significant contributions in the design of every model, including its memory hierarchy, cache, intercomponent structure and the actual logical and physical implementation.

Bill has been devoted to the deep understanding of computer systems starting with languages, programs and how they behave in real systems of networks, clusters, uni- and multiprocessors. He has developed and applied this knowledge to the engineering of DEC's computer systems, especially the hardware part, for cost-effective and greater performance program execution. He has shared some of his insight in clear papers.

In addition to direct contributions, he has become the technical leader for many all of Digital's products. Bill's capability and contributions rank with today's great computer builders, including Amdahl, Brooks and Cray.

6a-significance

The VAX-11 has become the benchmark machine for all minis and micros. For example, the National 32000 architecture is nearly VAX compatible with the same goals, constraints, instruction-types, data-types, etc. subject to patents. VAX removed key program limitations in computers, thereby becoming the basis for extending the state of the art in programs (eg. CAD/CAM) by its: memory addressing and memory hierarchy, mapping of files and program into a single address space, procedure calls, program sharing and multiple languages to be used for a single problem (process). The architecture efficently encodes the standard languages (Basic, C, Cobol, Fortran, Pascal, PL/1) better than any existing computer. VAX was designed to execute the operating systems, VMS and UNIX (C) efficiently, extending architecture appropriately.

VAX is not only a compatible range (1:1000) of models, but extends the concept of range to be a hierarchy of model types and uses (micro/PC, mini, and mainframe). With the VAX-compatiblity basis, all types and models can be interconnected to provide a single, hierarchical environment, the Digital Computing Environment (see 6b and 7).

6b

Chief Architect for the Digital Computing Environent, a hierarchical, homogeneous computing environment based on VAX, including:

- CI-Computer Interconnect, for VAX Clusters (Chief Architect);
- VAX Central and Distributed Clusters (Contributor);
- BI-Backplane Interconnect (Contributor, Co-inventor);
- NI-Network Interconnect (Ethernet) 802.3 (Contributor), for forming Local Area Networks and distributed clusters.

With the compatible, homogeneous computing environment, a user can bind the location of computation, at anytime (purchase, logon, process calls) to a particular node in the hierarchy to meet cost-effectiveness, performance, security or availabilty criteria.

The FIRST model of a symmetrical multiprocessor analyzing the processor and i/o to memory access contention. This work, his PhD dissertation, is the clasic reference in every dissertation or paper on multiprocessors. It's main benefit is to show that multiprocessors can be built and are not limited due to memory access contention.

Mr. Larry Sumney
Semiconductor Research Cooperative
1925 North Lynn St. Suite 404
Arlington, VA 22209

Dear Larry Sumney:

Enclosed is a copy of a program which several of us have defined to improve the technology position of the U.S. computer and semicomputer companies.

The motivation of the program, given on page 5, describes the problem of overfunding research relative to technology. I believe SRC may exacerbate the problem of "knowledge spilling" and hasten the demise of U.S. semis, semicomputers and computing. We need substantial collaboration in the development of technology - which is very expensive to do alone.

I know this is hard to think of for firms that have been so competitive in the past.

I'm delighted to see that your presenting the SRC at DEC on September 17 and I hope we can meet then.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Enclosure - Post vN Computing

March 5, 1979

Professor Philip Kraft
SUNY at Binghamton
Binghamton, New York 13901

Dear Professor Kraft:

I tried to contact you several times in Boston and failed, so I think the best way to comply with the commitment I made is to try to answer the questions this way.

1. I don't think the supply of programmers has much effect on the design of machines. They are used both for diagnostics and for microprogramming (defining the machines). With many more, there might be more data types in machines; with less, there would be less machines. So far, the ideas for what is in machines come from knowing what the problems the machine has to address are: scientific (moving from integers, to floating point, and now to vectors and transcendental functions), commercial (the Cobol and text data-types), real time (events, Boolean equation solution, control equations, queues), and the operating system (address manipulation, protection and security, queues). With fewer programmers, there might be fewer lanquages, but then again, it seems that most of the significant languages are coming in one way or another from the applications domain. (E.g., SPSS, COGO, Circuit Simulation, Drafting.)

2. Distributed Processing's main effect will be distributed use and programming, too. Programming of this kind, where so many people will be doing it won't be of the procedure kind we have now, but will be more for handling text, pictures, files, and generating simple reports, and communicating with other systems. It's hard to believe that the mix of programmers will drastically increase, but rather, people who are not now using computers, such as I'm doing this instant, will start to use them in the ways previously outlined. I don't think the past use will change too much in the short run, because they are within established organizations, supplying established needs and operating in a self-perpetuating mode. By rights, these central control oriented people would be more effective if part of the distributed processing trend, but I don't think they will. They will simply be the clearing house, do some of the old tasks, the same old way, and maintain the data interchange and ad hoc distributed data base that will grow up around them.

3. Machines are designed for specific workforces all the time. SPSS is for social scientists, COGO for civil engineers, PCLS for people who have to layout Printed Circuit boards. We built a machine, PDP-14 for discrete control and use in controlling transfer machines as used in the auto industry. It was designed so that it could be installed by the particular set of electricians around these plants, and programmed by the engineers who had previously used relays to solve these control problems.

4. Nearly every machine (where by this I mean a piece of hardware or a software machine) is designed to solve a particular class of problems, in a particular applications domain (e.g., Fortran for scientific and engineering calculations). All of these start out a particular way and ultimately evolve, just as natural languages do, to fit the task. They get all the data operations etc. You might look at how Fortran evolved as an example. From the original it got double precision and complex data, it recently had strings added, and there have been constructs to do better in terms of minimizing the errors that are possible to write in a program. Similarly, there is a well-defined set of subroutines surrounding it that all libraries for all machines have. It's hard to have predicted all these changes. We have had mixed success as we get into more specific application domains (e.g., design of a system to help around a clinical lab). These do get evolved too, because rarely are they right the first time. They have to be done by a combination of computer scientists and people who know the application area... the later being the most important. There are many kludgy systems that we would shun, but since they solve the application problem, the users live with them and like them. Any in-elegance is made up for by the fact that it gets the right answers faster and cheaper than by any alternative. In general, the most successful systems come out of the user environments, and the least

successful come from our trying to put together systems that we think they want, unless we are really coupled to them carefully. Ours are usually more elegant and more powerful and more general, but are less likely to be immediately useful.

I hope this answers the questions.

Sincerely,

Gordon Bell
Vice President, Engineering
Professor, Computer Science and Electrical Engineering
Carnegie-Mellon University, on leave

GB0001/40
to; roy moffa, reid brown, bob glorioso cc: psc
subject: everthing's in a name... let's use Supermicro

SEAHORSE
The DECwest folks were concerned about the 4 digit numbering of Seahorse. I'm less concerned about this right now because I think the basic machine class name isn't right yet. Scorpio would be similarly named.

In the past, it has been important to use names to help position a product, particularly a new one. It is also very useful when we can become identified as the leader with that product.

Names have evolved somewhat along these lines:

```
        super
mainframe
            midi
        mini     supermini
                 micro    supermicro
                   pc
```

Namely, the Supermini (eg. 780) is an evolution of the mini. It does the work the mainframe used to do, and has the large addressing.

The Supermicro is an evolution of the micro (one chip) does the work the mini used to do, and has large addressing. It's in a new price, package and performance class. This also puts it in a new use class.

VENUS AND NAUTILUS POSITIONING
I don't know how we should position Venus except as a mainframe. This would please our 10/20 customers to know that we're going to build large machines. It would also let us price higher than the 780 it was supposed to replace, and then Nautilus could be priced lower than the 780. I don't think there's a new class name here.

We really do need a super name.
Can you folks make the change?

DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: SUPPORTING 16-BIT PRODUCTS AND DOING EXEMPLARARY ENGINEERING

There are several reasons a Digital Engineer might not like to
work on 16-bit products:

1. The natural pull of learning about 32-bit products.

2. Pushes from public statements by you that 16-bit products
are
dead, new ones are no good, and the engineers are not very
good.

3. Undermining products being introduced by redesigning them
just
as we are introducing them. Our product phases allow YOU to
do
design, and to have design input, but at the proper time.
The
11/23 you breadboarded, only increases the floor space
required.
Based on past experience, all a new package is likely to do
is to
increase product cost, take longer and increase development
cost.
Please don't redesign the 11/23, the market needs it. We
need
your help NOW to design the customer mergable AZTEC based 11.

4. You are a frightening 16-bit team member, and I don't
believe
people work well when they are insecure. External threats
are
enough to keep us sharp out of fear. The manager or team
should
either be replaced or redirected; not harassed and undermined
on
an ongoing basis.

5. Both of us have problems as designers, because we are not
full
time, nor can we follow-up as the design proceeds through its
critical stages. This causes people to believe we design out
of
emotion, rather than on a rational or business basis. I
believe
our work has to be exemplarary in terms of analysis, ideas,
and
overall quality, since we must raise, not lower the quality
of

engineering. Designs done by us are likely to get derailed in
implementation, causing misuse of resources, and high product cost, particularly when we design by the power of our position,
rather than the power of our ideas. Fundamentally, we have to be
careful that product design responsibility doesn't become ours
for designs responsible engineering teams do not like. When this
happens, the group will prove that it is no good.

You are one of our brightest, and potentially most promising engineers. I value your good design ideas. Unfortunately, like
us all, you have other ideas that aren't so hot, and it is hard
for the organization to sort these out.

I would like to help make you a more effective engineer.

GB2.S6.57

November 7, 1978

Ivan Sutherland
CS 256-80
California Institute of Technology
Pasadena, California 91125

Dear Ivan:

Thank you very much for the CAD Symposium talk, as there have been several favorable comments about it. My family was also delighted to see you again.

I look forward to working with you and hope we can make some sense in the NSF report, even though I'm very depressed about NSF. Right now, I'd even welcome a bright MBA there. The ARPA policy of rotating people through those jobs is essential! How can we get the policy to apply to NSF?

Again, thanks for the help.

Sincerely,

Gordon Bell
Vice President,
Engineering

SUBJECT: RE: SUVAX

I just found out that it was in its current state, requiring funds to go to market, given that only 14 were made. I don't know where the money should come from, but I believe we must do it. I have asked the group to consider not doing the cost

reduction boards that give it comm and disk control, and hence
this would give an apparently higher product cost. My own belief is that the product cost would be lower because there would be no FAT, as the system sans disks would be done in Burlington and site merged with disks coming from Colorado.

This gets us a 2 cab config, but the cost should be less due to FAT charges and inventory (due to less wip). Here we are modelling this.

This project is at very high on the list I believe we must have, and I would like to vote on all the bottom ones to get it! I've been clear that I think we are doing a disservice to our customers, and stockholders and company by delaying the introduction of it and the introduction of the 24. We have to get our customers on VAX, else run a very high risk of losing them when they must ultimately switch. ESG is most vulnerable of all. (What really scares me is the terminal
with a 370 in it that the Japanese are working on, given the 2 chip processor they've built. Such a terminal would be the right workstation to off-load with, given some sort of kernel monitor approach)

In ESG's case, I hope you'll do anything to get it, and not introduce the 11/23 based work station, but go flat out to get this.

If it has to wait, so be it. Our customers will demand it. We can wait, introduce a yawn like the 24, and then scurry to introduce it after the Zenith, Appollo, Three Rivers, and IBM, PRIME, all introduce their own Technical Workstations.

I like leadership products, and want to do it. We'll end up with a perceived followership product the way we're heading.

SUBJECT: RE: RE: SUVAX AND ARPA

Am delighted you'll be the focus for the ARPA contractor's sale of Suvax's. I think if we go out and get this business with ARPA (Universities), it'll really get us business at large with the rest of the government community.

Some time ago, I advocated a sub product line under one of Andy's to work with this community that would be solely aimed at an advanced, marketplace... especially the research institutes and universities engaged in research. I'm getting real concerned about our ability to be response to this very small group AND I think it is even more important now to interface to them than it was in the past, cause we need better research and ideas for our products on a long range basis.

This distress comes from the fact that as we've gotten larger and had to provide more past contintinuity driven by a large OEM and Commercial base, our product introductions turn to be conservative. For example, we are driven to support all 11's for all time, and this keeps us from driving hard to get this other business.

What we should look for is a way to segment things so that we
can
operate the various parts independently so that we are able
to
keep the on going business, yet interface to the new source
of
ideas we need for future products. If we go to a West Coast
facility, then we might consider putting the "ARPA Product
Line"
there with our engineering group. This could be a formidable
team.

What you think.

SUBJECT: GETTING A SUVAX AS A COMPETITIVE PRODUCT IN OUR
LIFETIMES

(I'm going to be in TW early Friday morning and
would like to discuss this with Bill. Can you get this together?)

No one is doubting this need. No one has any faith that we can deliver... either funds or shear process delays. Now, it seems that Nat and Don are looking at the possibility of using a micro (say 68K) and having a simple blt
with interface. Several of these could be attached to a Unibus to give a more cost effective multiterminal personal interactive computer.

Bob Glorioso is also looking at the same device.

Stanford will license their connection to a multibus, called the SUN workstation.

Why can't we in the next month, decide on a structure
and then build this?

If we go this way, do we abandon Suvax with its great color, and alternative monitors, etc.?

Can you guys get together and get this running?

I think we want to make this part of the great Personal Computer
announcement in May. This would mean that we would have to have in running sometime by Jan. 1 and then be able to go into
a mode to deliver some time in the summer. This looks completely reasonable in the time frame, if we compare it with
what was done in Robin and what Avery is gearing up to do with
his new CRTs.

Bill,
Maybe you should get with Bob and work out how you guys can build
a highly tuned, pipelined design system so as to get work

like
this done in the 6-9 mos we are going to need in order to remain
in business. I trust we can now have your space in the mill.

Note, this is not an isolated example of our needs. We are dying because of our response time for options in communications,
and we are going to need several voice modules to build various
kinds of human interface ssytems. We do need this kind of design
system.

SUBJECT: INTERIM SUVAX (IN MY LIFETIME) FOR THE GREAT MAY
ANNOUNCEMENT

Am delighted to see that we are proceeding quickly. My other
candidate is to license the SUN workstation and connect it to
a Unibus (versus the Qbus). Can we look at this?

The big reason is that there has to be software and if we

wait
there will not be software for another couple of years!!!!
Rather than designing our own graphics architecture, can we take the CMU or Stanford architecture in its entirety? (I have
absolutely no faith in our ability to do terminals architecture
given what we have done in the alphanumeric area and with Gigi
and the vt 125. You all know that you have this mess to fix first.)

The goal of interim suvax is to have it part of the BIG
May announcement of Personal computers where we do:
CT, new 278, new cp/m, vt200 new, and interim suvax.

We must put these very HARD CONSTRAINTS ON THE INTERIM SUVAX DESIGN:
IT MUST FIT ON 1 HEX BOARD, IT MUST USE THE SAME HIGH REOLUTION
SCOPE AS WE ARE USING ON THE NEXT 200 (NOT THE ULTIMATE SUVAX
RESOLUTION... BUT THE ONE THAT STAR USES), AND MUST NOT
TAKE OVER SAY 150 IC's! IT MUST BE DEMONSTRATABLE AT
NCC IN MAY!

SUBJECT: SUVAX ORGANIZATIONAL REQUEST (SEE BELOW)

SUBJECT: SUVAX ORGANIZATIONAL REQUEST, NOMENCLATURE AND TARGET SCHEDULES

I've asked Bill Demmer to suggest a program or project manager who would co-ordinate SUVAX among the various groups so that we can move more rapidly to a product. This would include product definition and organization role definitions. There might even become a single, focussed line organization.

I can't identify what our target date for SUVAX is. To some, SUVAX is only viable in 1985 when we have the Scorpio Chip Set, a high resolution scope, and a disk capable of being stuffed in a tube. I think this is crazy...the market will have passed us! It's important to get to market much earlier in order to understand it, so that we can target the appropriate product in the mid-80's. Also, I do not even want to wait for the ideal packaging.

Note, we have the following component schedules: Nebula (2RL) Q182, COMET Q481, Nebula (Aztec) (Q2-Q4)83; the VT125 (Q481 - protos Q281) and the high resolution scope (Q2-Q382); interface to the Canon printer?; and SUVAX chips FY8X?

This could yield these target systems and dates:

Name	Hardware	Software	When

SUVAX Breadboard COMET + Breadboard HR Scope Handlers
Q481
VT125/RL/SUVAX   Nebula/RL + VT125   Handlers
Q182
SUVAX RL   Nebula/RL + HR Scope   Handlers
Q382
SUVAX   Nebula/Aztec + HR Scope   Generic
Q2-Q483

SUBJECT: RE: THE SUVAX PROGRAM MANAGER ROLE

I hope you got my answer.

Hire him for this! He could really be good in the OA role, but Stewart is going to do this and I don't see how to change that decision. Also, the OA role is strewn with landmines, aligators, and a swamp that we built.

I think the SUVAX charter is clear and I will fight to get it a project where the resources are under his direct control, versus a program that has to somehow influence all the projects
that are seperately funded and have different goals. Notice that the project doesn't have to have the direct management, but it does have to have the control of the budget and the project. (I.e. I assume that the Marlboro folks builds what Harry says, even though they will be managed by Snyder. This is a subcontractor role for them.)

Getting through this won't be trivial, but then again I don't see it as being the hassle of Hydra where there was a real push on the main direction of VMS.

Larry and I will help like crazy.

Now let's get him and get the product versus the 11/23 workstation. (How is the thinking coming on this?
How close can we come in price vs the 23?)

Let's go. We need a great innovative high end personal computer.

DEPT: OOD
EXT: 223-2236
LOC/MAIL STOP: ML12-

1/A51

SUBJECT: SUVAX: WHAT DO I TELL THIS TROOP OUT WITH THE TINCUP?

Here's a really significant product. Meanwhile, LDP is making
a full page terminal after their abortive VT105; Graphics Arts is
building another CRT for us to persist in a market where we have
been, are, and are headed to be above all ... LOSERS, the
terminals product line is making a VT134 tht is guaranteed to be
a loser!

Behavior follows directly from your speech #1:
We have ultimate protection of a bunch of losing product line
based products which are supported by the products that I
am responsible for and you consistantly deride me for... and
occasionally get me into a feeling that I must for some idiotic
reason, defend. This, like right now, does occasionally bother
me. Mostly, it's tragic though, because it probably would
be worthwhile to really not bring all these abortions into the
world, even though they are supported by your bill of rights in
speech #1. (As an aside, that's why we are here panicing after
persisting too long with the 278, and trying to sell the PDT.)

Fortunately, Nat didn't ask me why we can't fund SUVAX while
continuing to build the toy hobby stuff. Hopefully, I can
get someone to put money in the cup. The secret weapon I have
is that I know that there will be a bunch of competitors there
who's get the product lines to panic... and then fund.

Hopefully, it won't be too late because the designers will have
left in frustration in having a good design that is overshadowed
by one of these abortions designed by midgets for midgets.

Why don't you spend a few minutes talking to the Suvax design team. We really do need them! If you don't have the time, then just tell me what the party line is and I'll talk with them.

SUBJECT: MEETING ON THE SUVAX TERMINALS STATUS

I just heard from the software developers that we are going to be another year or so in getting the suvax terminals.

What's the story?

There is a general misunderstanding about advanced development:
it apparently is not done with rigid schedules and doneness criteria. In this case, I can't really find the commitments written down in a hard and fast way. Now, I find out that Jim Marshall is no longer involved... which means he is off the hook? No way do I want to see this happen. George should be able to subcontract here, so that Jim is able to fulfil
his commitments to the Corporation.

I would like to meet with you this week, perhaps on Wed en route to MK where I have an OC woods and discuss what is happening
here.

My understanding (which I will get into if necessary by looking up the commits) is that the 20 were to be delivered about
6 months ago. We can not continue to survive given our cavilier
attitude about getting work done in a professional way.

At the meeting, I'd like to just get the written situation about
what our promises have been and where we are on them. This is
simply the witch hunt data... nothing else. I don't want to go over this at the meeting or flog the people.

At the meeting, I want to get the poop on how we are going to get the terminals done? and when, on as near the original schedule as possible?

We may be able to avoid a meeting by getting this information transferred via EMS. This would seem like a good starting point. How about getting it by Monday evening?

SUBJECT: SUVAX STATUS AS OF 3:45PM 12/2/81

George is going flat out to build two, high resolution compatible displays for May announcement:

1. 2.2K b/w make based on the Research Group Zebra. Zebra is being produced as a breadboard on a subcontract basis to George.
Zebra is ahead of its schedule for 1/31/81 and is being wirewrapped now. This display will be capable of being used alternatively as color. By replicating two boards, it can be used
with higher resolution color.

2. 6K b/w or color buyout. George and ESG will make a recommendation asap! We will do NO development work, but will
get the supplier to make the necessary microcode changes to meet the SUVAX architecture.

The two displays will be implemented with some kind of
microprocesor
which will be invisible to the VAX user and NO user program
will
reside in the display processor option. The resolution is
roughly 1K by 1K pixels for both displays. Both are
architecturally compatible.

In addition, George's group will reside in MR near ESG in a
space of about 20K sq ft that Landlord Andy will provide.

George MUST have an experienced engineering manager that has
put a product into production right now! In addition, George
will look at desireablity of completing current SUVAX
breadboards.

The Software group will be strengthened and operated only as
a site team at MR, and not as embedded in the 10/20 group.

We must get the necessary software support system for
whatever
microprocessors are in the various displays.

SUBJECT: SUVAXES: WHO ARE WE GOING TO WORK WITH?

Dick Eckhouse is going to send around a proposal by Andy Van Dam of Brown who wants to work with a manufacturer to get a system like the one that's being contemplated at CMU, MIT, Berkley, U of Washington ... and potentially in every other CS Department once the word is properly spread.

We are going to visit MIT to hear what they are doing as the guest of Dertouzous.

My question is why wouldn't it be significantly better to work with either Brown or MIT instead of Berkley or Washington, given the proximity?

Brown would be especially good given their size. MIT is closest.
Before we go any further, it would seem to make sense to weigh some of these other alternatives.   Also, what do we hope to gain by getting these machines out at all?

It is important that we all remember that the primary goal of a research department is the discovery and dissemination of knowledge. No matter what they say, or what they sign, the information will be broadcast (they are not malicious). They win points among colleagues by transmitting information. This has to be a consideration in what we are going to do...already I think we should see some of the effects.

SUBJECT: RE: FINDING $ FOR SUVAX

There was some money assigned to it for program management, plus there are two software groups and a kitty for Cutler if we can entice him to do it. Just as soon as we get the machines, I want to start selling him!

Andy and I are pushing about as hard as we can to get the business with ARPA and to get going. I believe we have the bucks that can do it, although I'm sure we could spend more. Right now, we have to be careful about the overall timing so we don't blow the quality and blow big bucks cause we aren't ready. We could sell these like crazy to academe and to ESG if we had them, but I don't know what the shape of the program is overall.

We can't give any iron clad guarantees, but it is the right macchine on which to start planning for what is Andy's Technical Dream Machine that has Scorpio, high resolution graphics, and hopefully a good sized disk all in the form factor of the CT.

Overall, it's pretty high up in my wish list.

SUBJECT: RE: MISSING THE BOAT WITH SUVAX

Somehow, I don't see how we have the money to do two, if we are tight on just the one now. I'll look at the funding again. Somehow, though, I don't see NOT doing CT, as all the interesting applications seem to take a little more storage and i/o and I have trouble seeing it done on a CT25.

(Would you help Pete Smith and I talk Denny Doyle into doing it in Canada and getting some research funding there?

ARPA says they will pay 54K for 40 of them within the next year. I really want this order like crazy, cause it does all the critical work for the personal vax based on scorpio. Can we do something to do this?

SUBJECT: RE: RE: PETER JANSEN & ECS

Sorry,

I'm just pissed at all of us for not getting the low end products. The iterrible irony of it is that I was finally just
too tired to take this one on. We did spend tons of money doing
lots of low end terminals and personal computers: VT55, 105, 103, PDT, gigi, VT's for typesetting, LA's for special customers
with attached mass storage, vt 78 and 278, and no where did we
address doing it right by getting the 11 done.

I would love to do the CT25! It would really be ideal if we want to go into the market with guns blazing. I don't see that we have the money unless we go after a few of the flaky terminal projects.

(Note in the top list, none of them were centrally funded... we were too busy doing the rack and stack that turned out to be too general and too expensive and too big, although at least we made a pile of money with .) MINC seems to be the only exception in the morass of mediocre terminals.

On the 10/20, I think the issue is more the issue of mainframes
in a university. Frankly, I think a number have already said: "We've bought our last mainframe"... we are going to install departmental minis (ala 780) and we are going to{ get incremental student capacity via PC's... look at the incredible difference in cost per terminal of an Apple II vs a large 20... (According to the J/F 81 10/20 Buyline, our best cost is about 8K sans terminal, and for say 9K, you get 3 Apples, with the ability to get more out of the existing system.) Ususally the unis signal a trend, and I think we may be looking at one here! Anyway to tell for sure?

SUBJECT: SUVAX: WE GOT THE COMPTETITION (PULL), NOW THE

PROUDCT (PUSH)!

I think we'll get the pull now. What concerns me is that engineering isn't driving hard enough to get the product done and have considering it too much as an Advanced Development project with no one wanting it. Now we have the boggie, let's
makee it happen! (I trust that this also falls in Mary's area of responsibility.)
Ed Feigenbaum said it looks like we are about 1 year behind 3 rivers, and it sounds like we are 1 year behind Apollo. Ed wants us to talk with Sclumberger, who he consults with cause they are looking at 3 Rivers, and all would give their eye teeth for Vax instead. If we aren't careful, the world is going to get started this other way, and we'll have the pain fo having to woo them back.

Andy is clearly driving to get the product out and sold at Arpa and we are solidly with him. Hopefully, Denny will take on a key role which Andy and us will work with him to define.

Tell me that the schedule's fine and we're on target!

PH/RL0:7.34

Yesterday, one of my old customers from the Computer Science Department at a Swedish University tried to call me. I called
him back and the reason he was calling was that he wanted to find out if we were doing anything in the personal computer domain. They had been looking at APOLLO which they found very
interesting. He said that several universities in UK have ordered or are ordering APOLLO systems. He also said that APOLLO will be opening an office in UK in March. He told me that he would prefer to stay with a DEC solution as that would
be easier for them to integrate into their network, as they already have three 10/20's, as well as several 11's and VAX's.

Unfortunately, I was not able to give him any information at this point
in time. However, I feel it is becoming more and more important to
make sure that we get SUVAX to the market ASAP.

SUBJECT: DESIGN OF AN INTERCONNECT SOFTWARE ARCHITECTURE

TO: Bill Strecker TW/A08 **DATE:** December 20, 1979
Tony Lauck ML5-5/E97 **FROM:** G.Bell/L.Portner
Dick Hustvedt TW/D08 **DEPT:** Central Engineering
Cc: Bill Demmer TW/D18 **LOC.:** ML12-1/T32
EXT.: 3-2236/3-82471
Bill Johnson ML12-3/A62
George Plowman ML5-5/E97

Digital clearly needs an Interconnect Software Architecture for its next generation of systems. It is also clear from recent reviews of key programs such as Interconnect, HYDRA, Venus, and the new I/O subsystems that we do not have a consistent, stable, complete approach to an interconnect architecture as yet.

We need to resolve when to use intrasystem, and when to use intersystem communication mechanisms; and in general, what model(s) of communication will be used across the range of distributed systems used by our customers in DEC's future systems.

This is too central a problem to remain unresolved and consequently we are asking the three of you to accept the task of defining the structure of DEC's interconnect architecture. Sam Fuller will devote whatever time is necessary to provide the support, planning, resources, etc.; and ensure the Interconnect Architecture is reviewed and supported by the necessary development groups.

This is a difficult assignment and we won't propose any arbitrary deadlines or schedules, but there is certainly an urgent need to get the Interconnect Architecture resolved.

As an initial task, Sam Fuller will be working with you to establish a realistic schedule and approach for the design effort.

GB1.S1.40
Had an hour discussion with Jolitz on Saturday afternoon. He was confused about the possible scenarios we put forth, but is anxious to have us be an investor, mentor and help market the product.

His still wants and perhaps needs our blessing to make a deal with a first tier VC which he says will come in if we invest. He says its ready to go when we are.

WHAT HAVE THEY ACCOMPLISHED?

. May 1 opened an office
. Aug 1 got $5K
. Aug 26 GOT $150K (TECH. FUND INC, CHARLIE COKASH)

. Sept proto running (1 month)
. Nov software running (3 months)
. Dec demos to VC and potential customers (4 months)

They have gotten a great deal further on essentially no money by favors and by getting people who might join them to moonlight.

NATIONAL PART
They have access to a number of National people to hire; also people who have gone elsewhere (eg SUN) would come to them on a startup. They have access to National workers (eg. Vakavelli?) for understanding the National part idosyncrascies that appear to continue to go on forever! This interface to a sub-culture around the National part, inlcluding people from Greenhills (Steve, please check this out) could be invaluable.

THE MODULES
Their first products are made of the following modules:

. Processor, 4 serial i/o, connection to front panel, centronics port and 32 parallel i/o lines

.Memory with parity of 512K using 64K chips or 2M using 256K chips. By using surface mount (there are several vendors in the valley) one gets double the density. He says there are 3 vendors including TI for surface mount 64K chips. While I agreed that this is clearly the wave of the future, it scared us. He understands that UNIX works with 1 Mbyte.

. Disk, floppy, DMA controllers and interface to IBM PC bus

.4 Port memory for forming clusters of computers. This uses the TI memory. This permits a tightly connected cluster to be built using shared memory for message passing. In effect, he quoted CMUs Cm* computer as the model for this. This is also like the DDE product.

. Processor, but with a slightly modified interface to the shared memory.

. Small, clean table top box which has 4 3 x 6 x 9 cavities and power supply. Note that a floppy or wini are this size. This also allows a card assembly of 6 x 9 x 5 cards. The cards are put together with stacking crimp-on pins forming what amounts to a bus of approximately 50 wires of a normal microprocessor bus.

The modules use what amounts to a PC Board bus that is kept short by not being a bus. It transfers 4 Mbytes per second, which allows a National 16K to run at 10 MHz without any wait states. They are doing a reduction on the number of ICs, including the use of PALs and the PC bus interface design. This interface is not in the IC count of 170 (for .5 Mbyte).

THE PRODUCTS

From the modules, one can build:

. ordinary multi-user system

.server oriented computer with shared memory at the hub and interconnected computers for serving the various users. They are thinking about driving the new low cost laser printers.

. fully distributed network using Ethernet. This is done by using a PC card for the Ethernet interface. Berkeley 4.2 supports this form of networking.

They would like to extend the product offering using the following module types:

. a personal ws using a high resolution tube interface

. a large system using the 32032, enabling a larger system. This would be built from larger cards, and fit in a backplane. They know that all their old modules have to work with this. He said they did and could.

. a portable computer using the CMOS 16K part. This would also use the modules.

In short, I was quite impressed that their thinking did support the low end of the products that he described.

OTHER PRODUCTS

He also said they were interested in building a symmetrical multiprocessor, but this was a dream. He said we would have trouble with the 32032 used as an mP because the chip does too much looking ahead for instructions without being smart about stopping the flow if branch instructions are encoutered. I will get with National on this because if true, really does impact performance including fouling up the cache.

The ECL processor is a dream of Mr. Billings who has built special purpose ECL machines. They also have other people thinking about this dream who would come to work for them.

THE FOLKS

I ask why they thought 30 people could do so much. He said he thought they could ship 1000 systems assuming that all work is subcontracted off shore to both module and FAT house. This is still far fetched with 300K per person.

The notion of clusters of 30 people for tasks is probably quite reasonable. We took it to mean 30 people who did the whole job. He said that wasn't their intent at all.

The plan. He said they need help with it based on how its sold. His glib answer is OEMs.

BOTTOM LINE

They are one of the more inarticulate groups that we may meet.

I should have coached them in their presentation because:

- they didn't listen
- they were too philosophical. Philosophy is boring, but incredibly boring by a 27 year old.
- the product range was too grandiose. This was especially boring to me as a grand product dreamer.
- they walked into what is fundamentally a market driven shop and laid out a plan that was nigh on impossssible. They didn't ask for help.
- they didn't simply play their strength of a simple working product that does have an impressive ability to be expanded and contracted. That is:
  - they built a very impressive product in a very short time
  - they do have a product vision around a few modules that could be the basis of a very good company
  - a set of competent people and access to others

I think they are fast learners!
KEN

We need you at the meeting / dinner with Sys. Dev. Foundation/SDF on Sunday March 13. SDF IS GIVING AWAY THE $100M THAT BURROUGHS PAID FOR SDC.

The minimum we might get is 50K/year (for a historian).
The maximum we would like is a major building.

The guest list, the SDF Director + Board would like are:

- You
- Everett
- General Doriot
- J. Forrester
- G. Bells

Acceptable Others:

Charlie Bachman (will come + I want to hire him)
Pat McGovern, head of IDC/Computer World
Oliver Selfridge
Ed Schwartz

Subject: **SYSTEM INTERCONNECT AND TEWKSBURY CHARTER**

To: Bill Demmer, TW/D19
Tewksbury Engineering Managers
OOD
Ken Olsen, ML10-2/A50

Date: May 2, 1979
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

In keeping with our Corporate Product Strategy and it's emphasis on distributing processing, we are redefining the development charter at Tewksbury to include a strong engineering focus on the entire system interconnect area. That is, focus is on links, not just nodes.

This general direction is described in the recent Bill Johnson Interconnect Task Force Report. To this end, in addition to the Mid-range Systems Development responsibility I am asking Bill Demmer to accept responsibility for the Interconnect Architecture and Systems Structure. He will provide the leadership and control processes within Digital for these functions. These include the definition of individual hardware linking mechanisms as well as the total networking system structure and topology.

Specific implementation activity should occur wherever it is appropriate. However, many of the new initial implementations will be driven by one of the Tewksbury development programs. Tight communication and control links should be set up with each system component implementation function to insure that our complete Corporate Product Strategy is implemented in a timely and highly focussed fashion. I would expect to see the Tewksbury organization positioned to support this endeavor by the end of the fiscal year.

SUBJECT: RE SYSTEMS AND CCEG ENG CHARTERS

Congratulations to you, Herb and Brian. It sounds like you are on the right track in making clear charters that will get us a minimum number of systems that are field integratable. Although it sounds great, I have been sceptical and look forward to this output.

Please work to get the charter of commercial hardware engineering to be aligned with the direction that Jack Smith has set to eliminate FAT and to have our systems built at the various point of manufacture and field integrated.

I want to make it clear that Shanzer (Low End Systems) and Croxon (mid rang Systems) are not CPU groups, although there are people in these groups that do design the Processor and Primary Memory structures and how other components connect to them (What I call a PMK... for processor-primary memory-controller for disks, comm, printers, etc.). These folks have the word systems in their group names and I hold them responsible for ALL the systems aspects of a customer configuration up until the point that a customer adds on foreign vendor equipment or that CSS has taken over this responsiblity when they build a system with special

equipment.
Here, if it is a CSS option that has been certified, I still hold the system groups responsible for the integrity of the system. Similarly, I want them to take the responsibility for special options that a specific Product Line builds and adds somehow (it is this area you folks might work on clarifying).

Here's the dilema: you could create the need for continued special, low volume products that require FAT, customization plants. Jack Smith, I and the various systems groups are trying
very hard to eliminate the various FAT plants and to build systems in various category types as follows:

I Hand held
II Terminal based (a single entity)
III Desk based (a set of components in individual boxes that connect together (terminal, printer, disk cabinet housing the computer) Includes the 78, minc, 315, old 310, and newer stuff that'll be in a 14" filing width cabinet under the desk and holding disk and computer (like your 315).
IV System in a cabinet(s) like 23RL, WPS200, ... 44, Nebula.
V. Systems built from a collection of field mergeable units: terminals, disks in a cabinet (RK07, RM's, R80, RP's... not

RL01 because it is integrated in IV.), plus a seperate cabinet
that is built in a volume PMK (processor-primary memory - all the controllers for comm., printer, disks).
VI Systems that are built from a set of usually type V systems
and interconnected via CI

I and II are from single volume plants
III the individual components would all be merged either at the warehouse of one of the component lines, or field merge th whole thing.
IV. Generally move away from these. Several possibilities: FAT sites (don't believe in), volume build the PMK part and field or warehouse merge with the disks that have been stuck in a cabinet in Colorado. The RL01 cabinet effort has been

aimed at cleaning this us. Here the target to clean up:
23RL, 24 RL, Nebula (make it right from the start), 44RL.
V Should be no problem as every component is field merged.
Build
PMK cabinet in volume and have no interplant transsshipments.
VI. We have to direct appropriately.

What I fear:
We don't yet have or are directed toward this clean
segmentation.
Systems mutate... options get added and there are a large,
no.
such that a volume plant can't be a point of manufacture.
Here
is what I worry about in your charter cause you work too
closely
with Salem. I'm trying to eliminate the FAT in Salem and I
view
your specials will necessitate them.

We have to change our way of living:
I believe our inventories are at least 2 x what they should
be
due to having sperate stocks and no good trading mechanism,
having too many products by continuing everything back to
05's
and pdp-8's, and mostly because we have FAT plants that give
us an extra pipeline stage, interplant transsshipment time,
more
stockrooms, and high costs by pulling previously tested parts
like the RL out of boxes and breaking them or breaking disks
by having so much handling.

The Japanese are coming! (No way can they build and ship
like we
do... we are one full inventory turn/year too high and a
factor
of 2 too high inventory last year this required an EXTRA
$300M
in working capital!)

Please join Jack Smith, who has agreed to eliminate the FAT

and
I. Do not make this proliferation continue or this low volume
customization necessary!

It sounds like you folks are on right track. As soon as you get it clear, let's get the same clarity with your counterparts
in manufacturing.

Keep up the good work.
g

Grant Saviers, ML3-6/E94
Will Thompson, ML1-5/E29
Dave Thorpe, ML1-4/P11

Here's a cut at the systems between now and 90. Note - we're going to have more than ever before! It doesn't include: the interconnect or Type II and III* systems - but only rack/stack, and free standing. Also it doesn't deal with the standalone high end communications (Mercury) and Mass Storage (HSC50) computers; i.e. Hydra isn't counted as a separate system even though they'll be built this way.

The interconnect structure is going to have some effect:

1. The BI, new backplane, interconnect is basically just a UNIBUS replacement, but will help in being less unbounded and easier to test.

2. The CI, Computer Interconnect, is really just a very high speed DECnet link - but may require testing as a large, Type VI. Large systems, will be built as combinations of Type V, PMK Kernel components (2080, Venus, 780, COMET) AND the HSC50 Computer for Mass Store with associated disks and tapes AND communications controllers (Mercury).

3. The NI is a high speed DECnet link. It will affect systems by:

   a. Eliminating communication controller in systems thereby easing the pain of configuring you go through now. However, this will pop out somewhere else as it is necessary to interconnect to non-DEC systems and non-DEC links (current communication) by some standalone box.

b. Allowing simpler cabling in a hi fi like approach for systems of Types III and possibly Type IV.

*System Types are:

I
Hand held
II
Terminal held (PDT 110, VT103)
IIIa
Table top, bench top, (inst. case), floor stand (PDT-150)
IIIb
Desk (now 19" mtg, possible going to file drawer width

standard of 14+"
IIIc
Cart (MINC)
IV
1 or more connected cabs with internal mtg. of disks (11/23T with RX, 11/44 RL)
V
1 or more connected cabs for PMK Base (Processor-main Memory-Controller for comm, disks, options) with free standing Mass Storage Components.
VI
Multicomputer systems (Hydra)

SUBJECT: CATEGORIES OF SYS. TYPES (>1 PAGE)

SUBJECT: Categories of Systems Types by Housing (and Potential Build Process) and System Assembly Process Alternatives

System Types (By Housing)

At our next meeting, let's lie on the fact that we have to "type" the systems by category and work on them in a segmented way.

Currently everything is a single glob, and very hard to work with.

Type	Housing type	Examples
I	Hand held	translator, memo writers, calculators
II	Terminal	VT103, VT138, PDT 110, LA124
IIIa	Table top, bench top or floor standing	PDT150
IIIb	Desk	VT78, VT278
IIIc	Cart	MINC
IV	1 or more connected Cabs (not broken apart)	11V03, 11T23, 11/44 RL
V	Type IV, but with free-standing peripherals	11/44 with RK, RM, RP;

11/780, KL,
20's
VI Multicomputer in room housing combinations of type V

Types III-IV include free standing terminals in addition to any
Processor-Memory-K Controller Basic Component.

There are many issues based on type, for example:

We have a problem with type IV systems from a logistic viewpoint with
respect to the disks. All the systems have a problem when we deal
with the vast array of communication controllers and cables. We have
to decide how the various internal controllers for disks especially
and memory are spec'd and added. How the cables are distributed.
Etc.

How's this for the system types?

Manufacturing Process

We need a similar set of definitions for the manufacturing processes.
Are there anymore of them:

Two Stage, FAT Based

1. Conventional FA & T. (Call it FAT) - stationary build and test.

2. Also called S.I & T. (Call it SIT)

3. CSI for a small + medium systems which moves product on an auto line or a build to order basis.

4. MSI?

5. Cold Staging?

6. Dock Merge?

All these currently now run at least one disk and none are true dock merge!

Direct Volume Ship, No FAT Plant

7. Site Merge by Field Service.

8. Site Merge by customer.

I don't feel there are good definitions of these processes. Can we get them?

Digital **Interoffice Memo**

Subject: **T-11 Product Applications (memo direction)**

To: Roy Moffa
CC: T-11 Active/Interest Group

Date: 10 NOV 76
From: Gordon Bell
Dept: OOD

Loc.: ML12-1 Ext.: 2236

I'm concerned that T-11 will focus on a one chip cpu to the exclusion of:

0. A policy to help all our users and marketers now.

1. Eleven or 8 i/o chips (including using the really nice, recent 8080 peripheral computers (e.g., SDLC, Floppy, CRT).

2. The 8 chip...still the most competitive with 8080 **NOW**! (We appear to have a blind bias to 11 or even 8080...as evidenced T-11 group.)

3. A faster 8 chip.

4. Fonz 11 which is good enough to compete with the new 16-bit Intel computer (8086). Please see the attached concern.

5. Using current chips in low end.

Overall, our marketing of LSI-11 has been misguided. This looks like another classical product mistake in the process vis a vis knowing what we'll be versus competition in the future. Is it possible that we're responding to what we see in the marketplace that's old (i.e., the 8080), and that the newer competitive machines will be even better (e.g., 8080 with 8K bytes in the time frame you're planning)?

Hence the process is assumed designed to produce 2-3 year old products?
Overall, I heartily support T-11 (or preferrably T-S (Tiny Systems) and would like to come and interact with the group especially in helping us understand cost to implement an 8 vs 8080 vs 11 ISP. Please get the Woods Meeting too. Also note a T-11 in 80 time frame will have address problems (see

recent editorial in BYTE).

Dear Dr. Yang:

It was a great pleasure to meet you during my recent visit to Taiwan. I was greatly impressed by the drive, intellectual capability and growth I saw in the Chinese Electronics and Computer areas. For many years I have admired and worked with Chinese engineers and finally it was great to see them in their own habitat. The engineers at Digital, Taiwan are really good.

The research work I saw was quite good and clearly the kind needed to make R. O. C. a leader. I was struck by an interesting research idea that I'd like to share with you: Why not install Local Area Networks at the major universities and research institutes and then interconnect these in a single network? This would provide two major benefits: it would let a variety of computing resources be widely available to a larger community, thereby letting more work get done; and it would let distributed processing work be done on an operational network.

It was also a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce. Dr. An Wang is also a founding member.

The museum also needs artifacts and is dedicated to their preservation. The list is included in the report and grows rapidly.

I'd welcome being able to show you the growing museum whenever you visit this area.

Sincerely,

Gordon Bell

SUBJECT: THE USE OF TAIWAN VERSUS AUTOMATION FOR COST

HISTORY (FOR US)
Several years ago when I got the Gardner Denver people to come in and sell us Wirewrap because the 6 couldn't be made error free enough to be built with mortals versus lots of talented technicians, you were sceptical about whether it was worth the investment. The real payoff was to make the 8 cheaply and establish the mini industry. In contrast, SDS had very good machines that were checked automatically,

but wired by hand at only slightly more cost and longer time and were limiting in manufacture.

HISTORY OF OFFSHORE MANUFACTURE IN SEMICONDUCTORS

The US industry went offshore to package semiconductors, even though the invention of automatic lead bonding was strictly American. Today, Hitachi has the world's fastest bonders and materials handlers. They also have the biggest market, and they assemble using high labor rates of Japan versus the cheaper places like Singapore, Indonesia, Philipines, etc. and even the US and Mexico. The US industry is still trying to catch up in this area simply to reduce the wip and have the necessary QC that an integrated line has. This required investment in Mfg. Engineering and in equipment, versus taking the easy approach to hiring more bodies.

RELEVANCE TO US

Today, the Japanese, especially Sieko and Sharp are heavily automated. They are our competitors in the low end terminals, PC's and your small, portable computer. I don't think we want to be their merchandisers, but we might want them to take our designs and have them manufacture for us. Clearly, we are on a collision course where they are going to wipe us out vis a vis the manufacture of these low cost, high volume parts. They've already done it in printers (EPSON=Sieko).

Dick Clayton has a videotape that shows where they are in automatic assembly. I have the calculator that was assembled this way. Let me urge you to watch the tape and look at the calculator and question whether you think offshore assembly is the answer for very long.

SUBJECT: RE: CT05 - ENGINEERING IN TAIWAN

I'd strongly support this. We do need a breadboard and some better specs. Dave Shanin probably has the nucleus of the design as it is substantially better than what we have been doing in the past vis a vis getting the size down. We should be very careful about the ease of doing this. It is easy to build a computer, it is hard to build a cost-effective reliable one. Right now, I don't think I see that many really creative designs coming out of our engineering here. Maybe this is the way to get better designs, but I'm skeptical until shown. Can we make sure the designers there have the latest info on chip availability, and micros design techniques. If they have been in the plant 7 years and not kept up technically by lots of readings and courses, they will most likely build obsolete stuff.

Let's try it. We could win big.

GB3.S1.39

CHALLENGES (TO COLUMBIA) IN GENERATING THE NEXT COMPUTER GENERATION

In June 1980 I helped Bill Miller and Joe Traub and others open Margaret Jacks Hall at Stanford. I hope with this convocation, we can open the CS building as successfully -- and maybe even somehow return to dedicate the Microelectronics and Computer Corporation, center in Austin someday which is another approach to applied research.

Even before the Japanese told us about the 5th Generation, I've been interested in CG's. This fascination surrounds the work on a C structures taxonomy essential for the C. Museum and understanding computer evolution. In the Museum we must have a way to contain and segment our ideas: by generations and by PMS structures whether they be components, computers or programs.

Richard DeLauer, of DARPA, claims we are working on the Nth generation, and I believe that the 5th Generation is already cast. LANS and powerful PC's are the main structures. So the issue now is what is the 6th Generation, what will it look like, and how can we continue to provide interesting computers?

Mostly, I think we all need to be concerned about the future; I'm going to dwell mainly on what we might observe from the past and present in creating it. I have been impressed with the Japanese evolutionary approach to engineering and how they had leveraged the world's Research. I also think they understand the notion of very long term process. On the issue of original research... it is crazy to think we are somehow creative and they aren't. Research is a luxury, not a necessity and they will teach us much. Now that they can afford it!

Last week AJP spoke at the CM, and in passing gave a number of his Pearls:
"If a computer understands English, it must be Japanese."

My concern is that the Japanese have already won. In the past, no one was interested in a race, contest or game. In fact our strength was that everyone was off inventing different kinds of games: board games, physical skill games, simple intellectual games like chess or complex ones like GO. NOW as a guerilla warfare army, we've been drawn into some sort of contest where we seem to be forced to compete! In short, we've been sucked into a contest where we have no knowledge of the rules, we have no notion of how to pick teams or whether the game is played with teams or individuals, whether more money or less money counts.

In the midst of all this, we have all types of forces moving people from institution to institution.

In a recent talk, Mike Dertouzous says there are 4 ways to beat the Japanese in the forthcoming new generation race:
. 100-200M to develop high speed computers with ai functions
. an open policy toward foreign workers in industry and academe
. tax credit for long range and in accord with national policy
. careful reexmination of antitrusts to permit consortia
He argues for forgoing the traditional short term gain at the expense of long term R and D.

While I concur, I am concerned:
. Where's a reasonable plan that would spend 100M? I've only seen one university based plan that's credible based on a record of accomplishment and with experience. What's worse... are there enough people to manage the research.
. open door is fine... but closed or open is probably irrelevent. Debating is time consuming and simply keeps us from working.
. there is no national policy or plan, so why have more R and D credit? I've seen this R and D credit go right to the bottom line to reduce spending in R and D and increase earnings. Similarly, most corporations aren't equipped to do either credible or useful research. Even A/D can be a conflict because so few managers understand the differences between Product Development, Product enhancement, let alone concepts of Basic and Applied Research. On the other hand, it's unclear to me that those engaging in research understand it that well either. There is no public understanding of these activities and clearly we can't manage the flow of ideas through the stages.
. antitrusts may not be the issue, figuring out how to work together and how to do these large, goal directed Research projects is hard and something that I'm afraid we don't know how to do.

We can learn from Japan about how to define, establish and then execute projects of this type. Here, I see the Fifth Generation effort as being 3-5 years ahead of us because they understand large scale, long term interacting processes and they have a plan that started in 1980 and based on the world's research. In contrast to their more directed approach, we have nearly 10 projects aimed at designing and building supposedly revolutionary but highly similar, single instruction, structured data machines here, MIT, Stanford and elsewhere which I believe will be pretty much a red herring...giving us only a few side-effects. I prefer to call these "structures for analogous computation." All, violate the historical notion of evolution since they start with a structure and not science and technology, but are loosely related to a problem. How many of these can we really afford (if the goals is to really manage them to completion with data gathering etc.)? Do revolutionary machines make sense? Are we prepared to run these 10 year, very high risk experiments? This involves incredible personal commitments. I hope to hell we can't afford them all, most likely we'll start them all and finish none. We should be able to learn from ARPA's speech research activity of several years ago, which I regard as highly successful when it was prematurely terminated.

WHAT IS A GENERATION? (Now that we know we need a new one!)
convergence of need that frees resources,
technology, science and ideas to build from, and
a basic structure.

Finally use will tell us that it's a generation after the fact. I can tell you lots about the first and second because of the lst 20 years but the others are

WHAT IS THIS ONE, I CLAIM THE FIFTH ONE WE'RE ENTERING?
Need is intercommunication, technology is MicroProcessor which in turn allows building: small shared, PC's , fault-tolerant structures, etc. and a new technology of LANs for intercommunication

This has created a product-fragmented, stratified by level of integration industry of many entrepreneurs!

A generation has a cyclic nature, much like a cyclotron. The concept to "do a machine" is injected into the accelerator at some stage... I'd like this to be needs driven to a large extent. Technology is the first stage, architecture and design are down stream, followed by the actual building. Software further accelerates the electron. Algorithms and use with critical evaluation (which we often ignore) provide the final stages... and of course by now, the particle has gone around once provided the people don't leave after the first six years. And now it is ready to be accelerated again and attain the critical energy level necessary to use or for going around again. For many generations, going around twice constitutes a new generation. The first time around a new structure is formed, and the second time around it is made useful and gains acceptance. Clearly the PC was like this: the very first PC, the LINC, cost about 40K in 65 and is in the Computer Museum, but not until 75 with the Micro was it really practical. It took about 3 trips around to reach an interesting energy level... which occured in 81 with the IBM PC. Now a trip around takes less than 2 years. This process is highly evolutionary with all parts of an industry providing energy to accelerate.

Note, the Japanese understand the notion of generations and evolution beautifully. The concepts of AI and AI workstations have existed for years in the lab. They started with plenty of cycles on a KL10, are making the very best hardware they can in a computation <?> to execute Prolog at a factor of 10-20x! In parallel, they're working on significant real applications and trying to develop the engineering discipline. Finally, they'll do evaluation on this, and will then go around again with a much higher performance station. They plan about 2 more trips around the cycle by 1990: use with critical evaluation, architect, build, deploy, then repeat the use and evaluation stage to start around again. Mostly I believe the important thing to do is start with use NOT architecture!

WHAT THEN IS THE 6TH GENERATION?

ai...and it will be wonderful or so we believe. One probelm is that I can only identify two "expert systems' that are in operation. Thus, it's hard to evolve a computer unless we have a model of what it is to do. A revolutionary machine is likely to fail--at least if it follows history. What would a new structure look like (usually a new generation has breadboards operating in one of the previous generations)...

So where's a computer like this we can view?

For a revolution--I don't think we have a common view of the future. I believe the Japanese have a better view of one, albeit fuzzy. Therefore, our notion of a 6th Generation may not be realistic at all, if it violates the evolutionary, and needs-based notions of generations.

WHO ARE THE PLAYERS? THE JAPANESE, GOVERNMENT, UNIS AND INDUSTRY

Let me strongly urge particpation in the game plus definition of some new ones by everyone. I wish the effort were better directed though--much like the speech research project. Even a guerilla army needs some leadership. In the past, DARPA has provided much science for industry: Timesharing, speech (only partially completed, but more progress and better focussed than anything else)... it may be poetic justice that the person who cut this off now has to work in developing speech progress, it is also noteworthy that a DARPA researcher wrote the Speak and Spell product description and outlined the basic design, General computation by AEC to form Illiac I... and indirectly all of Cray's machines, Graphics, Packet Switching, and most recently VLSI.

Since the University played such an important role in the past, it's vital and even more necessary now.

Forrester, who headed MIT's Whirlwind, made several comments on building machines in Universities that still hold today: "Experimental equipment merely for demonstration of principle and without inherent possiblity of transformation to designs of value to others does not meet the principle of systems engineering".

I've observed that this lesson should be a law that governs experimental machines: Unless a machine provides about an order of magnitude more power to the individuals who may use it than is available to them, there will be insufficient pull to attract users and test the basic idea. In other words, don't build toys.

WHAT CAN WE LEARN FROM BUILDING PAST MACHINES?
Harvard played a role in the beginning. Aiken was not particularly gratitious to IBM who actually built their Mark I, which at first glance one might consider to be an impossible machine, were it not for IBM's incredible engineering. In fact, this interaction proves to be grist for the computer history mills. None of the later Marks were near the state of the art in technology, and as influential. The most important effect was to train a large number of individuals who are influential in computing.

Columbia was influential too when Wallace J. Eckert got IBM to build the SSEC computer, a first, pre-computer generation machine composed of relays and vacuum tubes.

Eniac at the U. of Penn. was the truly revolutionary machine because it provided several orders of magnitude more performance than the Marks or the Bell Labs relay machines! Out of it came the stored programs concept. The work lead to Edvac, IAS, and the Illiacs directly and indirectly to the computer industry. MIT was evolutionary in structure, but revolutionary in technology with Whirlwind. TX-0 and LINC were even more successful. TX-0 took about - to design and then was in use over 10 years. The circuits were the basis of starting Digital. (Mostly, I believe a machine can only pioneer one thing.)

UNIVERSITY OF ILLINOIS MACHINES

Since I was just at Illinois last week, let me tell you what I learned from their machines and compare them with some of the observations of CMU:

Illiac I 9/52 operated
Concept-use: 4   Project start-use: 3 Concept-retire: 14
Use: 10   Use/lifetime: 33%

Conservative engineering for Aberdeen (Ordvac), copies were made for many other institutions. Design was spec'd at IAS. Implmentation project, not a total project of architecture, software, hardware, etc.

Illiac II 6/63 operated (3 years after 160, PDP-1, 1401, 1604, 7090, etc!)
Concept-use: 5.5 Project start-use: 3 Concept-retire: 9
Use: 3   Use/lifetime: 33%

New architecture, new technology, software took long. vehicle for timesharing, wiped out with commercial machines, Mistakes: Ge vs Si transistors, asynchronous logic (takes twice as long... something many folks still don't understand), didn't trust PCBs and used chassis, Memory was too small, too much to do yet it was far too conservative.

Illiac III isn't talked about. Use/lifetime: 0

Illiac IV Solomon 62, operted 11/75 @ 60 hours/wk
Concept-use: 12 Project start-use: 8.5-10.5   Concept-retire: 20
Use: 6.5   Use/lifetime: 33%
Processing rate: 250 Mips, Mp: 1/Mby, Mp.core: 2Mby MS: 139 Mby

Dan Slotnick, the designer of the Illiac IV a revolutionary machine commented last week:
Agreed that most machines come about through evolution and that's counter to the notion of original research which is

suppposedly the basis of university rewards. The activity of building a machine for study entails a major amount of engineering, something that can be at conflict with science. ("Hamming once engineers science, math, than seat of their pants. Furthermore I am ? the conlift among the theory, engineering and AI parts of CS because it distracts and destroys.????

"Am convinced unis can't and shouldn't build machines. There are too many ideas. I used to have to stop the flow of ideas on interconnection every week. Too much bureaucracy. In a state uni it takes 90 days to get an IC. Too much democracy and too little discipline."

Larry Roberts who headed DARPA, claimed that it was absolutely clear that the machine should have been done with TTL and not ECL technology. People complain bitterly, but in the end, conservative technology seems to work out better. This is what I like to define as a tradeoff as either instructions per second versus instructions per month. The clock was 13 vs 25 Mhz and only 64 PEs were made instead of 256. I worried at the time that the clock for a simple machine by the same vendor was designed to run at 20 Mhz and actually ran at 10 so they may not make such an aggressive goal!

Contributions: got a number of good people working on parallelism at Illinois and elsewhere. Pushed the semiconductor ram somewhat faster than it might otherwise have gone. I IV did operate as the world's fastest machine for some problems and some time... until the Cray 1 came along in production. The fast rams were essential for the Cray 1. Most likely the biggest effect was to stimulate alternatives: TI's ASC, CDC's STAR and the CRAY 1.

With this, let me distinguish between 3 cases of machines: null, evolutionary and revolutionary. The null (make a copy of a previous Instruction set...), evolutionary, (do what is needed to enhance performance based on the knowledge of using the previous machines,) and finally revolutionary machines which are controversial. In the commercial world, the null is risky if the basis isn't there. The evolution such as the Cray 1, or VAX, taking advantage of all we know is probably the safest but still hard. The revolutionary machine is ... well revolutionary, and predictably bloody.

In 1949 Wilkes commented on the null case: "When a machine was finished and a number of subroutines in use, the order code could not be altered without causing a good deal of trouble. There would be almost as much capital sunk in the library of subroutines as the machine itself and builders of new machines in the future might wish to make use of the same order code that the subroutines could be taken over without modification"

Bottom Line about Illinois' machines
The Null Case, taking the IAS Instruction set turned out to be the most influential. Very good engineers were trained and theory of building machines posited.

Their evolutionary machine wasn't good enough. In fact, I believe that the tradition of providing vanity or proprietary instruction sets has cost computing (ie wasted more resources) than any other factor. There should have been significantly fewer machines. Watch what is happening with the IBM PC--finally there's some use, given there's a standard.

The revolutionary machine only had some side effects, but like all revolutions accompanied with much bloodshed. Unfortunately, like the case of Content Addressable Memories, Associative Memories, thin film memories, and CCD memories the world moves on an evolutionary trajectory, and rarely pursues two approaches for the same function!

Now they want to build a msmP at Illinois and the options:

1. Cheap labor of graduate students... brilliant, but unpredictable. Not recommended!
2. Professionals which create a second culture that is very hard to manage and basically unstable. But essential if you build the system. This is what has been done at the CMU projects.
3. Jointly with a company. A hardware/software split may be

the right division of labor. This was used in the pc generations. Why not do it again? It's being used at CMU with IBM for products. The Japanese companies build machines for the various universities, e.g. Tokyo.
4. As a seperate company outside the university and fueled by venture capital...now let's see if it's really venture. (TMC).

Now, let me go on to look at CMU's machines that were somewhat more evolutionary and which had more side effects and cost only a small fraction of Illiac IV to build.

CMU'S MULTIPROCESSORS

I have always been intrigued with multiprocessors, because an engineer likes to solve problems of performance by replicating a simple design intead of massive redesign. In fact I built an early 4P in 66, and have subsequently been involved in a half dozen other mP's. My only interest is trying to understand them so they can be applied to real use.

We started studying multprocessors at CMU in the late 60's, and I became intrigued with them when Bill Strecker's 1970 thesis showed how to compute the performance for p processors accessing a common memory of m modules.

This is the main reference work for multiprocessors, and I'll eventaully forgive the referees--in another 10-20 years--for rejecting the first paper because they didn't understand it or didn't think it ws relevant. There have been dozens of subsequent theses and papers on the subject, embellishing the topic, and they all reference the work. The Transaction just had an article on the subject. In fact, while I was in academe, I was finally successful in getting logic circuit switching theory mainly removed from the IEEE Transactions on Computers. Now, I find that switching theory is back where the object is to show how to switch a large number of processors (say 1000-10,000) to a similar number of memory modules. These papers have the same object: get someone tenure... the result is the same as the irrelevant circuit switching. Computing might go forward faster if we could simply grant the tenures and then have people go to work on the project. The miserable irony here is that I came home, looked at an interesting mP that's just come on the market and it has a switch that far outstrips the theoretical ones that could be operating in 4 years for the cases of interest. One researcher pointed out that he would get off the project of 32 if it couldn't be exended to 1000! These idiotic statements completely ignore the engineering nature of building a machine and mask getting on with the difficult job of building and perhaps impossible job of using the machine.

The issue is not the switch performance now or finding exotic switching structures simply: getting on with finding out whether multiprocessors actually work which is a combination of architecture, system software, language and algorithm design.   I believe that if anyone can demonstrate that an ssmP of say 10 can work routinely in production, we can extend this to lsmP of 100 and then to 1000 rather easily.

In May 71, we proposed a ssmP of 16 processors for AI research which had a one gigabyte, very high bandwidth memory called C.ai. One of the students, an undergraduate, Tom McWilliams was in the seminar. C.ai roughly outlined the Stanford SI and SI, Mark IIA which is being built at Livermore. Unfortunately they became enamoured with building the world's most complex processor.

In August 71, a much simpler design was in place using the PDP-11 as a processor module. The project became known as C.mmp, a 16 processor Multiprocessor.

C.mmp
Concept-use: 5   Project start-use: 4.5 Concept-retire: 9
Use: 6   Use/lifetime: 66%

The project had 2 goals: a capablility based Operating System based on changing the PDP-11 and to examine the use of mP's. The addressing problem using the PDP-11 became a major issue and problem. Ironically, at least a few folks on the project didn't learn this. They went on to make the same mistake, plus a few others when doing the Intel 432. The project is well documented about what was learned in Wulf's book. Maximum speedups were hard to obtain. It is unclear why. I think because it wasn't used long enough!

Cm* a set of computer modules for building a msmP (50) in an open-ended fashion. First paper in Mar 73.

Concept-use: 4   Project start-use: 2 Concept-retire: >10
Use: >6   Use/lifetime: >60%

This was an evolution on C.mmp, also, we forsaw the cluster of functional mP's that are present today and described them for adaptation in machines like Intel's multibus and Convergent Technology's Megaframe. It used the same OS concepts, even though any P could access any Mp, there was a preference to a local Mp, or that within a cluster of 10, and finally to memory outside the cluster. Thus, the machine is problem idiosyncratic. People began to understand this notion of the structure of computation and data with respect to particular physical structures. This is the key to these "structurally analogous computers".

There is still an incredible amount of science (and engineering) needed before these machines can work harmoniously in gangs of 50 without lots of work by anyone other than their trainers.

More interesting: evolution from C.mp in a project sense really paid off. Furthermore, the machine is still being used to collect data on parallelism. This is why it appears to me that CMU is so far ahead, say 10 years, in CS research.

For Multiprocessors, the progress has been slow. In each generation, I renew my optimism in the concept. I said this in the mid 60's with large computers and I said it in the early and mid 70's with minis, and now it just has to be true because the smallest unit is the very high performance processor with the characteristic that the smaller it becomes, the faster it goes.

Maybe there are reasons why mP have never been used:
the most likely, will we always find a simpler way using technology or instruction set to provide the same

performance?
has engineering been too conservative?
the market not there?
too many other designs to try to avoid working on this?
too stogy and too compatiblity constrained?
or we simply don't believe users or compiler writers can cope? Clearly they can't if we don't try them. Happily there are several existing commercial machines at the small to medium scale level emerging with 4 to 32 processors, so maybe the technology will come.

If it does evolve, I would like to plead the case for universities to stay or finally get deeply involved even though you can buy them. Universities stayed remote from semiconductor research too long, and not until their involvenment was there the beginning of VLSI understanding.

As we work on parallelism, I regret that human organization theory can't help us except in an anecdotal fashion. More than a decade ago, Mel Conway wrote that people build computer structures like the human organizations they know. This explains why n people build n-pass compilers; IBM build hierarchically structured protocols like SNA; ARPA has to have a store and forward net independent of its users; DEC believes in democratic (anarhaic) structures like Unibus and Ethernet and multiprocessors and DECnet.

One researcher at Illinois commented that he could see merit in all sorts of physical structures like Illiac, Connection Machine, CAMs, Grids and Tree machines. It may be worthwhile trying various physical structures as you are doing here. To me these interesting physical structures may be premature because I don't think we have enough basic understanding of the notion of computational locality in order to map them into these particular, physical structures. I think this could be the basis of theory and building could be held off until the theory is built. Clearly they are not general purpose! Thus for the sixth generation, I would prefer to bet on highly tailored VLSI for performance like the geometry engine instead of these "general, highly special purpose computers." Therefore, the universities are crucial to develop the basis...my current bet for the 6th G.

If we could use human organization theory it might shed light on parallelism from structures that are connected together in exotic ways. It might also explain, like humans, why its difficult to get more than 6 processors to work together--unless totally top down directed with clear goals (like, take a beach or hill). (For now, I'm mostly only interested in the general case of multiprocessors because I don't know how to do it with the ultimate in connectivity... the memory, let alone by slow or restricted networks such as LANs, trees, hypercubes, etc.

At a time when Amdahl's constant of 1 byte/instruction has increased by at least an order of magnitude, I don't understand how something with a gop (giga-op/sec) can be content with a few megabytes! This kind of computation, I've called "Structurally Analogous Computation" because we're trying to make a physical analog of the computation. In a way, it resembles the very old analog computers that were patched together to solve particular problems such as network flows, simulation of all kinds, filtering of data as in a database, etc. I reiterate, I don't think there's enough basic understanding to do this mapping and hence build many machines.

OTHER PROBLEMS IN BUILDING REVOLUTIONARY OR EVEN INTERESTING C'S

Contrary to popular belief, I am quite concerned about the plethora of money which will mostly just cause excessive swapping and the erroneous, economies-based notion that money can be traded off for science ideas, and talent! The money comes from two sources:

1. The government. This acts to simply churn the small number of capable folks in universities and some labs, moving them from place to place. The nice effect is to raise everyone's salary. Yesterday's NY times contained a report of Aiken's quote.

Since the projects we're talking about are fairly large, they require professors to be very good project managers in a university environment designed for teaching. By being good managers, the reaction after a few years is simplpy: why work at somewhat lower pay and lack of freedom? (I enjoyed a very large pay cut to go into a university because I believe the issue was simply a tradeoff in the power/pay vs freedom plane. But with large projects, the freedom is diminished without the corresponding increase in power or pay. This provides a target for industry to scoop up kernels of the seed corn. In effect, the seed corn is really now poped corn. People have two choices: the established industry and becoming an entrepreneur.

2. The Venture Capital world which draws people from established industries and academe into what are often mundane or low tech products. For example, one high tech company started up in March and were shipping your generic 68,000-based UNIX product in 9 months, the standard gestation time. I recently saw a company of 4, build one board and assemble a UNIX product. Others build NOTHING at all but merely assemble.

Today the goal of a PhD is a chip, a program or algorithm, or system that is capable of starting a company. Recent examples include the Geometry Engine, the Timing Verify of Widdoes/McWilliams, the basis of the Valid Company, and the SUN Terminal, the basis of SUN Microsystems. So finally people can have freedom, fame and riches concurrently...but I doubt it.

Many folks believe that entrepreneurism is the way to beat the Japanese. Maybe it is because it unleashes such an incredible amount of focussed energy... but I wonder if the Japanese are going to feel threatened by 123 different kinds of ??? 68,000 based workstations! On the other hand--it is the basis for real applied R&D as with Amdahl's Trilogy Corporation.

I don't know what the final answer is, but we've got to get organized. Or in the words of Pogo, "we have met the enemy and he is us."

11/29/83 Tue 15:33:49

GB8.14ip, a program or algorithm, or system that is capable of starting a company. When I was at Carnegie, I looked at the jobs. The dean's jobs were the hardest. Turf everywhere to fight for and protect, with finite budgets, more programs than money, and everyone with ideas to spend more money, and no action on programs you consider vital by an obsolescing or otherwise inert faculty.

Several of us were called in to a university a couple of years ago to sort out CS... where did it belong? It grew up as programming in the math department which was part of the school of science, the EE's did their thing, and the provost asked for a blue ribbon committee. Several of us, all engineers who do a lot of computing, unanimously recommended that it be part of Engineering. At last look, a new school was established for computing. I thought how dumb... but maybe something good will come out of it. It agrees with my model about the importance of computing. Maybe you'll try it. I'll argue this later, but not very hard.

I remember Herb Toor aging about 10 years in 2 years, as CMU's dean, followed by a heart attack. In february, my heart stopped for awhile, and shortly thereafter had a bypass operation.

I can relate to this, I have many groups that do various kinds of engineering that result in either products, components or processes to make components. In a sense, it's a lot like being a dean.

Why am I here?
The usual rationale. My stacks of books to read on engineering education has grown to where I couldn't see over them. If I have to give a talk, I'll learn the subject matter... just like the reason to teach a course... why else would one ever teach a course except to learn it?

Also, I wanted to take my mind off my problems, and turn them to yours for diversion. As you can see, as a typical engineer, I'm a problem formulator, and occasionally a solver.

What do I see as the issues in engineering education today, and do I have anything useful to add?

As an activist, I feel I must make some comments NOW that I have you that I hope are relevant. Not that I can speak to everything that's relevant. The issues can come from a single problem statement:

HOW TO SUPPLY THE DEMAND FOR QUALTIY, HIGHLY TRAINED ENGINEERS, IN THE FACE OF TECHNOLOGY CHANGE BOTH HERE AND FROM ABROAD (JAPAN) NOW.

THE USUAL WORRY IS WHETHER THE DEMAND IS REAL AND SUSTAINED WITHIN THE TIME SCALE OF UNIVERSITY DECISION MAKING,

THIS REQUIRES MORE TEACHERS: THE BUDGETS ARE FIXED AND THE LOADS GO UP MAKING ACADEME LESS ATTRACTIVE

QUALITY HAS TO GO WITH LARGER COURSES.

TECHNOLOGY IS CHANGING, BUT HOW DO YOU MOVE THE PROFESSORS?

TECHNOLOGY IS CHANGING, BUT HOW DO YOU TRAIN THE AGING ENGINEERS?

THIS REQUIRES $ AND COMPUTING (MY INTEREST) FOR BOTH TEACHING AND RESEARCH!

I HAPPEN TO BELIEVE THAT COMPUTING IS DRIVING A SUBSTANTIAL AMOUNT OF THIS CHANGE, AND I DON'T SEE THE BROAD CHANGE

THAT'S REQUIRED ACROSS ENGINEERING. THIS MEANS THAT MORE EXPOSURE TO COMPUTING IS NEEDED!

FINALLY, THE JAPANESE ARE BEATING US IN THE WORLD MARKETS, INCLUDING COMPUTING.

NOW, TO TOP IT OFF, THEY'VE ANNOUNCED THE 5TH GENERATION OF COMPUTING IN WHICH THEY OPENLY CLAIM THAT THEY'LL OWN COMPUTING BY 1990!

THERE YOU HAVE IT: ENGINEERING DEMAND UP, TEACHER DEMAND, FALLING QUALITY, CHANGES IN KNOWLEDGE IN THE FIELD CAUSING AN OBSOLESCENCE BOTH IN THE FACULTY AND IN INDUSTRY, LACK OF RESOURCES... ESPECIALLY SINCE COMPUTING IS AT THE HEART OF THE CHANGES, JAPANESE COMPETITION, AND THE FUTURE! NEARLY ALL THE PROBLEMS YOU... LET'S SAY WE FACE!

HOW TO SUPPLY THE DEMAND FOR QUALTIY, HIGHLY TRAINED ENGINEERS, IN THE FACE OF TECHNOLOGY CHANGE BOTH HERE AND FROM ABROAD (JAPAN) NOW.
The report, by the NAE in 1981 Academe/Industry/Government Interaction in Eng. Educ exlored the overall issue. George Lowe's opening address was especially insightful.

concern- reward teaching. I've asked several of our groups, and they say you're doing a good job! Let me congratulate you.

Since I'm more remote, I have some concerns: I asked where's the best school? San Luis Obispo. Why? They don't do research, they teach! Their teachers do and teach engineering.

I think the supply is diminished by driving them out with publishing requirements that may be difficult to meet in experimental fields.

I've seen this in virtually every school, especially those who work in building systems, as a sure road to non-tenure. Illinois vs CMU; Northeastern, U Mass drove one of our best engineering managers to us by a non-tenure decision. The students stopped building and we don't get as many students from there anymore. In other cases, they're driven out into high paying jobs and start ups where they become millionaires.

THE USUAL WORRY IS WHETHER THE DEMAND IS REAL AND SUSTAINED WITHIN THE TIME SCALE OF UNIVERSITY DECISION MAKING, Computing has been on an uncontrolled growth since its beginning, and many faculties simply cannot accept the fact that information processing is as fundamental as mathematics, or mechanisms. It took 15 years ater the computer and profession was established, BEFORE a department of Computer Science could be formed in the first university. I know if the computer to were to vanish tomorrow, it would be at least 15 years to get rid of it.

We're also losing them to MBA school, which I regard as a waste of time. You could give a short course and give honorary MBA's. There's even a book.

THIS REQUIRES MORE TEACHERS: THE BUDGETS ARE FIXED AND THE LOADS GO UP MAKING ACADEME LESS ATTRACTIVE
believe that people in industry could help (I'm on the academic board of the Wang Institute of Graduate Education... requirements teach very well, be a great engineer, can do research and knows several particualar fields, yet can teach all the courses. It turned out that the quiz they gave every applicant was a graduate seminar... and they all flunked! no wonder. Unless you've spent enough time, you can't speak the language. Having gone from industry to academe, I had to learn, but people were willing to gamble. Probably couldn't make it into CMU today.

It's important to figure out how to communicate with industry. Dean Louis Padulo of BU suggested a Dean of the Month program, where we communicate between our engineers, the dean, and various department heads. We have a similar program with researchers, where we describe our problems.

QUALITY HAS TO GO WITH LARGER COURSES.
I don't understand why much of the increased load can't be handled by TVI?

I think maybe the pendulum has swung too far to specialization, especially in EE where Computing can occupy a large fraction of a person's curriculum. 10 years ago I was on a series of Computers in COSINE... computers in ee. to get some changes to the curriculum and the courses. about 6 courses.

Now, I think we have to go back into some fundamentals where discrete and continuous mathementics are taught. I noted that YOU folks are taking these courses right here at these conferences.. Digital signal processing, or how to get those functions into a form the computer likes.

TECHNOLOGY IS CHANGING, BUT HOW DO YOU MOVE THE PROFESSORS?
MIT's Centennial Celebration focussed on Continuing Education. They have an excellent report. I urge you to NOT have another task force, report, etc. and simply adopt

theirs. My fear is that nothing will happen, the report took so much work.

Who can blame them? The faculty already is overworked: they can't spend all the money that's been foist on them by ARPA and IBM, the loads are high, and they haven't any time for any more teaching.
consulting, co-operative courses,

TECHNOLOGY IS CHANGING, BUT HOW DO YOU TRAIN THE AGING ENGINEERS?
we badly need continguing education programs
we have to have your help
This is an excellent way to start and improve the necessary relation that must exist between university and academia.

THIS REQUIRES $ (AND COMPUTERS) FOR BOTH TEACHING AND RESEARCH!

COMPUTERS IN TEACHING
lots of reports, and occasionallys some money. I think you'll find that this problem will go away shortly. The $25 slide rule that engineering students used to buy would now cost $150, or about the price of what is becoming a useful computer.

COMPUTERS IN RESEARCH
Let me recommend the recent report by the NSF, U-I Research Relationships: Myths, Realities and Potentials

Here, we have quite a lot of positive experience, and the recent posture of various funding agencies is hopeful, by virtually demanding that we work together. It isn't easy because of the conflicts about owning knowledge, and deadlines that we insist on.

One of the healthiest relationships has been between DEC and CMU to build experimental machines. The only problem in retrospect, is that we should have done more to make it work. Starting in 1970 CMU built about 3 parallel machines.   As a result CMU knows more about parallelism than any other university. I'm sadened by the proposals I read to do research in this area that will yield results that were known 10 years ago.

Several of us with Jerome Feldman put together a successful plea to get computers for CS research. Even more successful than the grant was the idea that companies would get extra benefit for computing equipment. This became a law, and equipment's starting to flow.

Focussed Research Institutes are GREAT: Robotics, Semiconductors at CIT, then Berkely and Stanford, Magnetics at San Diego and possibly CMU, Some fundamentals in optics, ceramic material... we ain't making it folks.

Then there's manufacturing engineerng.

I HAPPEN TO BELIEVE THAT COMPUTING IS DRIVING A SUBSTANTIAL AMOUNT OF THIS CHANGE, AND I DON'T SEE THE BROAD CHANGE THAT'S REQUIRED ACROSS ENGINEERING. THIS MEANS THAT MORE EXPOSURE TO COMPUTING IS NEEDED!

GIVE THE PAGE OF STATISTICS OF COURSES AT THIS CONFERENCE

cs should be difused 4 years ago I wrote an appeal to the CS&ERB to revamp the thinking about computing so that the other disciplines start doing their share. The problem is that computing people won't let them.

Computers are things to be taught not to fear and to be ordered around view (MBA school... where you know enough to order up some programmers, tools (analyzers, displays, drawers), simulators, and
then they become components of the systems you build.

I'd like to see ALL of this, but I'm greedy, I want more. I'd like to see engineering faculties become entrepreneurs by encoding their knowledge in programs. It already happens; in vlsi Stanford and Berkely have been doing in for years. Cogo and Stress were done years ago. NYIT builds some of the world's best graphics systems, which by the way it sells extensively. It is the only university I know that's also an OEM. After all, what's wrong with packaging this knowledge in a program and getting a royalty? Professors have been doing that for years.

Now there's more work to be done in the form of expert systems.

What are they, what are some examples: interpretation, prediction, diagnosis, design, planning, monitoring debugging, repair, instruction, control.

Let me talk about the system, XCON... XSEL...

Here, I may be reminded of the doctor, lawyer and engineer that were to be guillotined. The first two were spared because they rope ws binding. The engineer just had to redesign it so that it worked.

FINALLY, THE JAPANESE ARE BEATING US IN THE WORLD MARKETS, INCLUDING COMPUTING.

5 years ago was my first visit, last summer my second. I consider them to be the world's greatest engineers.
The threat's described in Feigenbaum's book: The 5th Generation

The issue is the building of computers that can behave as experts, say like engineers or engineering professors, or engineering managers. I've already started one to be me.

The expert system is built by a combination of knowledge engineer and and expert. The design problems enclude knowledge reprsentation, and then getting sufficient knowledge to be able to solve problems.

NOW, TO TOP IT OFF, THEY'VE ANNOUNCED THE 5TH GENERATION OF COMPUTING IN WHICH THEY OPENLY CLAIM THAT THEY'LL OWN COMPUTING BY 1990!
knowledge information processing systems
knowledge engineering

To me this means certainly everyone has thereown machine like I described. This is being done right here at RIT, Clarkson's doing it, and CMU has an institute dedicated to it. Other institutions are moving forward including Standford and MIT that I know of.

Every student will have one. YOU HAVE NO CHOICE, THEY'LL BRING THEM IN WITHIN A FEW YEARS.

It can comunicate with all the others in a community. YOU HAVE A PROBLEM: CAMPUSES MUST BE REWIRED TO SUPPORT THIS. Like our engineering net. We have over 1K computers in the net.

The machines are doing more than communication, but are teaching, allowing people to design by positing, analyzing, simulating.

Expert systems should play a major role in this future by allowing knowledge to be encoded and used, versus being static like in books.

P.O. Box 1500
Huntsville, Alabama 35807

Dear Charles:

Although I am honored to be nominated for this talk, I must decline because I have already committed my fall speaking capacity.

It is with deep regret that I can't accept this because I firmly believe in this style of computer and have devoted a great deal of energy to developing products for it.

Sincerely,

Gordon Bell
Vice President,
Engineering

<title>VAX-11 TALK OUTLINE
<event/date>ANNUAL MEETING-10/77
<>

I'm honored to have this award for three reasons: First as an author, second as a founder of the Digital Computer Museum, and third as an engineer in the tradition started by Eckert and Mauchly.

As an author I needed a deadline. The talk is evolutionary and I hope it will be the basis of the middle section of a biographical monograph on Computer Evolution. Although the examples are historical, I can't claim to be a historian only a biographer. This section is about evolution of computers, and the role of computer scientists and engineers.

As a founder of the Digital Computer Museum, this talk gives me a chance to tell you about it.

<>Entrance DCM. When I talk about the Digital Computer Museum, the image in my mind is of the American Museum of Natural History -- where twelve acres are devoted to the collection and study of the natural world. Similarly, the Computer Museum will collect and preserve all computing history for its study and interpretation. Computing is large and important enough to have its own, special, centralized Museum. Science is too large. National, corporate and local museums don't provide good comparative history.

<>Another gallery. The Digital Computer Museum is a public non-profit charitable foundation whose purpose is to preserve the history of all of information processing. That means that you and your organizations can give the Museum equipment and money and receive a full charitable gift tax deduction. The Museum, in turn, is obligated to preserve artifacts.

<>The Collections poster. The Museum collects the whole range of components that Allen Newell and I outlined in the PMS notation, that is the Museum collects not only computers, but also calculators, memories, links and switches, transducers, controls, and robots.

<>Whirlwind exhibit. Already the collection has grown to the extent that we can claim to have the most comprehensive exhibits of the origins and evolution of computers. DEC got

it started with salvaging Whirlwind.

<>TI exhibit. Its fitting that I'm speaking in Texas because Texas Instruments was our next big donor giving us the heart of an ASC and really helped establish an industry wide effort.

<>Another shot. I want to invite all of you to come see the Museum, join the Association so that you can receive its quarterly report, and consider it for a depository of the important papers and artifacts of computing history. (And, by the way maybe this will help me lure Pres Eckert to come and give a Museum Lecture -- He has a standing invitation from us.)

<>ENIAC with people. Third, as an engineer I am very proud to have the award, and I have many others to thank for it. Like Eckert and Mauchly, I worked with and built on the work of others. Most computer innovations are not made by one person: As a writer my co-authors, especially Allen Newell, and also Dan Siewiorek, Craig Mudge, John McNamara, and John Grason need to be thanked. As a museum founder, Ken Olsen and Gwen Bell, who is now the President of the Museum Corporation, are important. And as an engineer, the first people to thank are Ken Olsen and Ben Gurley, who were responsible for conceptualizing a commercail computer, the PDP-1, based on their development of the TX-0 and TX-2. I

want to acknowledge Ed DeCastro who implemented the PDP-5 and 8, Alan Kotok who worked with me on the PDP-6 for the first timesharing system. Roger Cady and Harold McFarland on carrying ideas for the 11 and although I lead the early design group on VAX, it's really Bill Strecker's work with Bill Demmer leading the development. Dave Cutler was responsible for the design and building of VMS.

<>Computer Generations Cycle. The revolution that the ENIAC started set off this evolutionary cycle. The need for making ballistics calculations started the cycle. This generated resources that allowed a team to integrate technologies into a new machine to be used to satisfy the need. The moment ENIAC started to calculate, it's use set the cycle off again. Users identify new things to do with computers and provide the market resources for new machines. Fred Brooks makes this point clearly in THE MYTHICAL MAN-MONTH, stating, "the incompleteness and inconsistencies of our ideas become clear only during implementation." (p.15) If idea generators, and builders aren't involved in use, they won't understand the evolutionary trend enforced by feedbacks. Closing the loop results in computer evolution -- not revolutionary new machine design.

Like all cycles this one has periodicity. New technologies, needs, or uses can trigger a small spurt -- and the coincidence of all three mark a new generation and a branching of the family tree of computers.

<>Light bulbs. Technology provides the base tools from which computers are developed. Inventor's ideas are the bright lights floating between technology and societies dreams. At the dawn of a new generation a number of inventor's concepts converge into a project. I believe that Atanasoff's work had bearing on the ENIAC, and the team included inputs from Arthur Burks, Sharpless, Goldstein, von Neumann and many others. With each generation, the technological floor becomes higher and user's aspirations also raise, maintaining the gap needed to spur invention.

<>Generation tree. Computer generations can also be seen as a tree, starting with its roots in scientific and business calculation. Here Eckert and Mauchly again are interesting since we would call ENIAC a scientific and UNIVAC a business machine. In the first generation there was really only generic scientific and business machines. In the second generation, super computers, from the scientific branch split off and continue on an evolutionary path determined by Seymour Cray. There's really a merger of the early scientific and business into general purpose for the mainframes covering a price range of 100 thousand to 10 million. Although the idea of the mini, for minimal computer as in the PDP-8 was developed at Digital in the second generation, based on earlier machines like Cray's 160

and our PDP-1, which in turn was based on Whirlwind, it flowered as its own branch in the third generation where IC's permitted numerous companies to start and develop their machines. The minis covered a price range of at least 50 and could be purchased in several levels of integration from boards to turn key systems. The fourth generation is marked by the branching of the micro processor on a chip. It's too early to see the fifth generation, but either it or the sixth must be identified by a means -- such as ethernet -- for all classes of computers to communicate on a network forming a computing mesh; there's an interlacing of the branches to keep them from collapsing by their own weight.

<>Op rate. During the 400 year, ten generation period from 1600 to 2000, the technological change is roughly a factor of 10**12. using the product of processing rate and the memory size to measure computing power, then the computer has evolved almost 20 orders of magnitude since stone-based, manual, single register devices for counting supplemented fingers and toes.

<>Generation is marked by. As the original model showed, three ingredients are needed to create a new computer generation:
a steady supply of funds, useable technology, and the machine design.

<>Babbage. Babbage worked alone because he had no funds to maintain an organization. He was always grovelling for funds and tried everyone's patience by not completing or producing any results but promising the "fantastic" if only monies were available for the next machine that he had in his mind.

Two of the three is not enough. And having only one of the three -- only the machine design as Babbage had -- dooms a project to failure.

<>Stibitz. George Stibitz at Bell Labs had the funds and was working on the same type ballistics problems as Eckert and Mauchly, but felt constrained by the technology of the telephone company; thus his machine had alot of telephone relays.

<>BTL1. The 1939 machine was the first calculator that could do complex arithmetic and operated via Teletypes in an interactive fashion. In September 1940, the computer was demonstrated at a meeting of the American Mathematical Society at Dartmouth College. An interface to the teletype designed by S.B. Williams allowed attending mathematicians to transmit problems from Dartmouth for solution by the calculator in New York. Bell Labs produced four advanced versions of the machine, and by the mid-fifties this line had died out.

Thus, it can be seen that a useable, but traditional technology is inadequate in forming a new generation.

<>Anal engine. Between 1833, when Babbage was working on the analytic engine and 1945, all component technology for the computer had been developed: teletype equipment for i/o; magnetic recording in the form of drums; diodes and triodes; <>flipflop. the Eccles Jordan flip-flop; and switching algebra.
<>Cycle. ENIAC had all three: enough funds, (with the aid of Herman Goldstine), pushed new technology (with the careful engineering of Pres Eckert), and with a new machine design (inspired by John Mauchly) - it went through the entire process and resulted in the first electronic computer.

<>Process. In any machine design, a number of separate, concurrent processes give rise to decision points leading to suspension, continued development, or recycling.

<>Generating a computer structure. The diagram shows seven interacting processes of a complete cycle for evolving a new computer structure.

The first process involves defining the problem: understanding the constraints, setting the goals, and determining the objective function of the design. Then, three mutually exclusive decision processes determine the architecture. Selecting the null architecture is calm and peaceful -- not exciting until faced with virtually insurmountable technology issues in its implementation; selecting to evolve an architecture in order to cope with new technology ideas or needs, is like guerrilla warfare -- a few people die on the line and some get caught in the crossfire; but generating a new architecture means a bloody revolution.

The process of physical design for implementation is concurrent with the architectural design process.

The building process requires complete understanding so that no unplanned side effects occur. The complexity of building computers is so great that even with the greatest care side effects are free. For the lucky designers they're also positive!

The final Process, using the machine, is essential for understanding the next step in evolution and the issues that could lead to revolution.

Within the context of the whole cyclical feedback, each process will be considered individually. The process of problem definition sets the constraints, goals and the objective function based on cost, performance and other measureable factors. The physical laws governing materials with respect to electromagnetic energy and heat transfer are obvious constraints. Yet engineers still try to violate them. And they never win.

<>ENIAC. ENIAC was bounded by the reliability of both vacuum tubes and plugboard programming. Nevertheless, Mauchly was unconcerned. He reasoned that even if ENIAC only ran a few minutes it would accomplish more than Bell Labs slow relay machines. It contained 18,000 vacuum tubes each with a predicted 500 hour life. If the machine had been designed using the tubes at capacity, the exponentially increasing repair time for multiple tube failure of 18,000 tubes each with a 500 hour life would have bootstraped the machine to its death, that is, if it ever lived. Goldstine recorded that by derating the filament and plate only three tube failures occurred per week. The actual failure rate of about one million hours was achieved only by very conservative engineering.

<>ENIAC cabling. Because of the potentially compound problems of tube failure and plugboard connections all problems were run twice to insure accuracy. Franz Alt, commenting on the 40 plugboards and extensive cabling, estimated that the overall effective rate was five percent utilization. Taking into account the amount of time the machine ran, it was 25 to 50 times faster than the relay machines. The fact that such a large system ran is a tribute to careful, conservative engineering, mostly on the part of Eckert.

<>Whirlwind AC Bit Slice. In contrast, Jay Forrester, on the Whirlwind, tackled problems at their source. Concerned with highly reliable, real time computing, he knew that the estimated tube reliability of 500 hours had to be increased by several orders of magnitude. An outside review prodded at the gradual failure mechanism of the tubes and led to marginal checking. By understanding the tube failure mechanism, the manufacturing process, and introducing marginal checking, reliability was raised to five million hours.

<>Von Neumann. At the beginning of a generation suppliers of new technologies are becoming constraints.

<>Selectron tube photo. In the later forties Von Neumann, determined to build the stored program computer, put his

faith in the RCA team that promised to produce a fast parallel memory, the Selectron tube. After two years of work, with vague but optimistic quarterly reports, not one had worked. Julian Bigelow reports, "no one in the ias team was sufficiently expert in electron tube design and manufacture to be able to assist it, but in conference with Von Neumann I made an attempt to list the variables which would have to be kept under control to produce a 50% yield of successful selectron tubes, covering a range of digital capacities from the original goal of 4096 digits per tube, down through 2048, 1024, 512, etc. It appeared that...the goal of 4096 per selectron was far too ambitious, and that acceptable production yields might be far sooner attained if the goal were reduced to 128 digits per tube." This 256 bit Selectron finally became available in 1953 for Rand's Johnniac.

What did Von Neumann do for his memory? He sent an expedition to Manchester where Fred Williams had built random access memory tubes with 1,000 bits, each.

<>WW Tube Memory. The two Mhz clock and 50 K ips speed using MIT adapted Williams Storage tubes cost $1 per bit, or $16,000 per month. Impressive, but expensive.

Searching for a better solution Jay Forrester started to investigate using magnetic cores.

<>Ceramic Core. At first they used wound magnetic tape Deltamax cores. Then beautifully made, but little understood, ceramic cores were found at Philips. According to Forrester, the manufacturers claimed that they could not be used for storage. Theoretically this was true, but it didn't stop Jay Forrester from trying ceramic cores and succeeding.

<>Forrester and Core. Don't be undone by theory, especially if the art is much ahead of it. Forrester commented, "This is an example of where the art was substantially ahead of the theory. Cores worked and could be made by trained ceramicists. Years later scientists understood how and why, but for many years production of ceramic cores was a materials art."

Recognized needs generate funding and provide an objective function against which to make tradeoffs. After initial funding, most of us take ourselves as the archetype user.

<>GB and average man. All of us, including myself, want to design computers and languages as if we're the average man. This proves it to you. I'm absolutely average, so I can do it and tell others how to as well.

<>Wilkinson or Pilot ACE. In 1958, I visited Wilkinson, who

with Turing designed the Pilot ACE. I told him about a symbolic assembly program that two of us built to optimize instructions in a delay line in conjunction with a backing drum memory to give what was one of the first one level memories. He asked me for a benchmark. I compared it with the results using a new program language called Fortran, which he was even more skeptical of. A matrix routine could be coded in only a factor of 4 slower than using Fortran, but a factor of 10 faster than the current method of hand allocating, assembling and key punching programs in row binary. He said that it didn't matter because he could write any matrix program in machine language in 15 minutes: why should we waste the machine's time in doing it? Fortunately, Wilkinson has concentrated on numerical analysis and not designed any computers. A Fortran was ultimately people for Deuce and used our assembler as a base in a hierarchical fashion.

<>Photo of PDP-14. A greater pitfall than designing for yourself, is designing for a proprietary user. Paraphrasing a remark by Charles Wilson of GM: "What's good for General Motors may not be good for anyone else." I don't know how many of you recognize the PDP-14 for controlling transfer machines. [It executed a single loop every 20 milliseconds, and had no real instructions for control or processing data other than the 1 bit accumulator used in Boolean expression evalution. Each time a new problem came up, such as counting

the number of operations or diagnosing itself, a new feature had to be put into the machine. Having started from a special purpose controller, it evolved into a really poor general purpose computer.] This doesn't mean we shouldn't have built a machine to solve the control problem. The designer should formulate the NEXT problem for the machine, not just the one at hand.

<>Military. The ultimate in vanity architectures are computers built for one of the world's largest organizations, the Defense Department. I've never met ANYONE who admits to being either the designer or specifier. The current Military Computer Family effort is designed to take incredible engineering resources out of circulation, guarantee high prices, and worst of all, insure obsolete equipment. Their Russian counterparts base computer designs on US commercial architectures and probably their implementations. No real benefits will come from building the MCF VANITY architecture.

<>Generating #1. While need orients designs and generates resources; as the sole constraint, exact need is detrimental to progress.

Standards represent the ultimate in constraints. Getting the right standards at the right time is essential for widespread implementation. If a defacto standard exists, such as the IBM channel and Unibus, let it be. If a standard is needed, then go all out to create it so that others can avoid the hassle of having to invent in an area that will generally make work. Alternatively anarchy can reign until IBM makes an ad hoc decision, and then it can be accepted in a de facto fashion and we can all try to implement it. [If there's anything I can do to hasten the settling of details surrounding the proposed 802 standard, I would be happy to work on it.

<>Ethernet. My own view is that Local Area Networks are one of the key technologies of the Fifth Computer Generation, and therefore we must settle the standard so we can all start building. DEC intends to interface ALL its products to Ethernet.]

<>Generating #2. The ultimate in standards is implementing a computer based on an existing architecture. [The Null Architecture process is one I highly recommend when deciding to build a new computer.]

<>EDSAC. Maurice Wilkes, who took the 1946 summer course on the ENIAC and EDVAC at the Moore School, returned to Cambridge University and built and programmed the EDSAC. This first, full scale operational stored program computer, was based on a simplified version of the EDVAC and IAS.

In 1949, only one month after EDSAC was operational, Maurice

Wilkes perceived the value of a series of computers sharing the same instruction set. He stated, "When a machine was finished, and a number of subroutines were in use, the order code could not be altered without causing a good deal of trouble. There would be almost as much capital sunk in the library of subroutines as the machine itself, and builders of new machines in the future might wish to make use of the same order code as an existing machine in order that the subroutines could be taken over without modification."

<>EDSAC or Maurice. This advice is even more applicable today than it was then and must constantly be reiterated to us all! In a recent editorial in Computer Design, the editor in chief commented: "the microprocessor revolution ... has more or less stiffled CPU architects except for those involved in mainframe and military or highly specialized system. ... the upswing in 16-bit microprocessor chips is again going to put somewhat of a crimp in architectural innovation... The real renaissance in smaller cpu architectures is just within grasp as the VLSI gate array moves into the realm of the smaller computer manufacturer ... Once again the CPU architect can return to innovations in internal cpu structures."

New architecture, particularly hardware architecture, should be the last resort because it is the beginning of what is fundamentally a six or seven stage work amplifier.

Given that I've introduced null architecture, building successor machines that are compatible with or built on the past, I feel duty bound to state a lesson that RCA ignored and the Japanese eventually learned. [Recent examples include the repackaging of the 3330 into high speed gate arrays in the ???, and the part by part, micrometered copy of the 3850 Mass Storage unit by Hitachi, NEC and Fujitsu (ask Bloch ??).]

If you copy a machine, do it exactly -- not just closely. The test has to be that the software, including all user data and files can't know the difference between the original and the copy. Furthermore, if there is a desire to attract, and then entrap, a given set of users to your machine (or language), then build it with extensions that other machines don't have, and that your users will feel duty-bound to use.

<>Fortran. When no process for standardization exists then a plethora of language dialects develop like Fortran V, stemming from Fortran IV. Similarly, the designer of the 8080 added instructions to the architecture and created the Z80, insuring two architectures, and the attendant waste, when one was adequate.

On the other hand, conservative users and manufacturers want to preserve their economic and emotional investments as long as they can. Enticed by a user base, almost every company produces one too many of a given machine design.

<>Hollerith. The card which was the savior of the 1890 census became so tied to some corporations approach to computing that they could see no alternative methods for input or output. When the 80 column card was on the way out, true believers in card computing evolved a 132 column card. This too was an expensive evolution requiring new equipment. This dinosaur, a large beast created on a small bone structure (or architecture) was created just when the technology should have been let go.

The key is to know which machine is one too many, -- to question whether the bone structure will support the architecture -- and if the limits are close, don't build it.

<>Generating #3. Compatibility extends life in the process of evolving an architecture.

<>abacus/soroban. The original Chinese abacus represents up to 15 in a digit with a combination of 5 and 2 beads. It is similar to what computer engineers invented several times and call the bi-quinary system.

<>SOROBAN.   Ultimately the Japanese refined the abacus, first using 5 and 1, and then 4 and 1 beads for lower cost and faster operation while not radically affecting the installed

base.

<>soroban/calc. This 1979 calculator/soroban is ideal in several ways: low cost storage of a second number is provided; simple operations can be done traditionally and more rapidly on the soroban; users can be gradually trained on the new machine without losing any traditional computational capability; the market is larger; and a culture is preserved.

<>PDP-1 and 4. One of the earliest computers I worked on was the PDP-1, an 18-bit computer, grandchild of Whirlwind and a child of the TX-0. None of us thought of using the Whirlwind ISP, because we needed 2 more than the 16 bits of Whirlwind. Both Whirlwind and TX-0 had excellent system software. Then with the design of the great grandchild, PDP4, to tune the implementation exactly to the architecture saving at most 10% over the PDP-1, I introduced a further ISP and switched to two's complement. Thus, in a family tree of 4, three architectures were probably unnecessary. The world ended up being modulo 8 bits anyway, just as in the original Whirlwind. Perhaps an even greater sin was committed by Computer Controls Corporation because they changed the name PDP to DDP and added a bit to the PDP-1 to come out with the DDP 19. They only sold a half dozen and became part of Honeywell.

<>12 bit. The history of 12-bit computers is similar. The architectural differences of the CDC 160, the LINC, PDP-5 and 8, the 6600 and 7600 ppu's, and those of Honeywell and SDS whose names I forget weren't significant. If we had all copied the 160 the implementations could have remained unique. In Digital's case, they led to the notion of dedicated real time control computing and minicomputers.

<>PDP-5. Computer architects and their implementers who did not make either exact or evolutionary copies of a predecessor machine have cost the entire industry unaccountable billions. In the second generation all that a number of our architectures provided were noncompatible versions of Whirlwind and the 160.

<>Generating #4. New architectures are needed for new forms of computing. Obsolete computers are characterized by inadequate bone structures for coping with different, more modern environments. Several companies who tried to go into business by buying up a bunch of old computer designs, had no chance of high growth. They were self-limited by existing conservative users of these machines. Growing by user base acquistion is like trying to get fat eating tapeworms.

High growth comes from the new architecture of new organizations like Apple, or converting to the VAX base at Digital. But, believe me, when you're dealing with an existing organization with a set of happy and content users, suggesting change, and implementing it, is difficult, but critical, for success.

Now that we've looked at both null architecture and architectural evolution processes, what will the architecture of a revolutionary machine look like?

<>Thomas arithmometer. At the beginning every new structure appears to be quite complex. When Thomas manufactured a calculator using the stepped drum principle of Leibniz, the machine appeared to be very complicated to scientists used to simple slide rules with two moving parts. In 1849, SCIENTIFIC AMERICAN wrote, the Thomas machine "is said to be one of the most astonishing pieces of mechanism that has ever been invented, but to our view, its complexity shows its defectability."

<>Millionaire. Subsequent manufacturers streamlined the machine for manufacture, adding a digit at a time multiplication and continued to make and sell them into the twentieth century.

<>Deuce Drum. In 1957, when I saw a moving head drum on the DEUCE computer, I was awestruck. Two independent 16 track read and write heads were used to select 1 of 256 tracks. The control was via a potentiameter sense in an open loop

fashion. The complexity was beyond my imagination. I was also biassed because the assembler program also turned out to be the best diagnostic.

<>CDC 6600 refrigerators. When Cray's 6600 was introduced in 1964, the refrigerators in each quadrant seemed to create a complex maze of plumbing. But it's really a simple and natural method after its understood. With the high power densities, a built in refrigerator is the best way to cool a computer.

<>Generating #5. The principles of design help in understanding essential versus non-essential complexity both in architecture and it's implementation.

<>Communications Poster. In 1968, Melvin Conway hypothesized that organizations are constrained to produce designs that copy the communications structures of their own organization. This tells us why n people may create an n pass compiler, or why several strong persons will partition a design into separate functional units. [We can see this clearly when looking at the way networks and computers have been designed.]

<>Dupont. One of our customers conceptualized their need for interconnection as nearly total communication among nodes.

<>First level of the tree. Yet, when the network was designed the thoughts, like the organization turned to a three level tree, the first level of which is shown here.

<>IBM telecommunications tree. [IBM's SNA architecture evolved from a tree structured approach to computing where all the terminals and remote job entry stations were hooked to a single mainframe. In some cases loops were provided to connect multiple terminals to a single computer. With needs for total interconnections, the tree has to be cross-linked.]

This explains the difference why SNA,

<>ARPA network. [Packet switching evolved from an organizational model of peer researchers of ARPA. The designers also recognized that not all the peers could be counted on for transferring packets to other peers, nor was it necessarily economical for peers to ship messages, hence a totally separate set of central system computers were provided for message switching.]

ARPA-net,

<>Engineering net slides from EN talk. [Like ARPAnet, DECnet assumes peer communication, but with bottom-up evolution in our style. Hence we provided a network that could be built and operated by responsible peers without central switching.

Our own engineers put together a 300 node network in a dozen sites for own use, with no top-down edict. Just as peers are being loaded with carrying messages for their friends, it looks like Local Area Networks will save them.]

and DEC's approach to networking is different.

<>Unibus. [Unibus as implementing organizational structure allows autonomy of all the nodes.] With the Unibus each computer component operates to a well defined protocol and can be developed and evolved independently of any other one. Hierarchy is imposed by use and convention, not by structure. In this way various groups inside and outside of DEC could build components to a common protocol. This is also why the structure was copied by all micros.

<>Ethernet. Ethernet, a direct evolution of the Unibus, ties computers together without central networking functions, dependence on central power, or on a particular node. [Ethernet will be the Unibus of the Fifth Generation and allow computing to form over a local area, such as a University, research complex or corporation.]

<>IBM 360. The IBM 360 mirrors IBM. Memory is the focus for all work and the single central processor controls all significant decisions in the 360. [A relatively large block the processor is signficant but i/o fans out in a tree. Each

of the i/o processors gets its work from the memory, where it is kept under very strict control. The authoritarian chain is imposed to the extent that the channels and i/o processors are kept so dumb that they can't even diagnose themselves. If anything of significance needs to be done, they must interrupt the central processor.] This authoritarian top down structure has fat but not very smart subordinates doing the i/o.

<>CDC 6600. In the Cray computers, everything is oriented around a single, very high performance processor at the center. [Memory is it's link to the peripheral computers that support it.] Unlike the IBM approach, these lovely peripheral computers operate autonomously of any central control. [Their purpose is to work independently and serve the central master where the work is done. In some operating systems, control is delegated to one of the computers.]

Considering this depressing fact: we should design it right or it's likely that we'll have to do it over. As Watts said: "Designers always build the 3rd best system. The First is ideal and the Second best takes too long." [European modems engineers. These modems permit 1200 baud from the central office to the subscriber, but only a 75 baud back to the central office; this is slower than my typing rate! European designers must think that an enormous amount of information is stored centrally, and subscribers don't need rapid transmission, or to communicate with other subscribers. The system can't be effectively used until all the modems are transformed to 1200/1200 baud symmetrical channels.] We should avoid building the 4th best!

[In the U.S., we aren't exactly stellar in creating effective modems. Vadic selected signalling frequencies to make the best use of the telephone channel. AT&T selected alternative frequencies using the second harmonic so that acoustic couplers couldn't easily be used. Not only are the two standards a pain, but I find that with a poor line, the acoustic coupler will work, whereas the offical standard won't.   Why can't we learn not to foil others; because you will only get trapped in your own foil.]

<>Wilkinson quote. Not only should it be designed right, but designs should be kept simple: Keep It Simple, Stupid. Jim Wilkinson tells how Turing's obsession with building the highest speed machine was kept in line: "in deciding whether or not a feature should be included, the question we asked ourselves was, could we do without it?"

<>Hoare quote. Tony Hoare's statement can be reduced to three design criteria: 1) exclude what you can, 2) only include what you know and 3) since a machine never diminishes over time, allow for growth - don't build to it's limits.

Increasing memory sizes based on continually decreasing cost of memory insure that users will demand extensible machines. [If a 20% per year memory price decline is assumed and a user spends a constant amount on memory, then] Every 3 years another bit is needed to address the memory.

If a machine is extended over once, the design may take on the character of a camel with the bone structure of a dinosaur. It's quite unlikely that a design can be extended gracefully more than once.

Large committees usually violate principles of simplicity, in fact guarantee complications. A corollary of KISS, for Keep It Simple, Stupid might be coined KICC, or Kill It by Complexity and Committees. ADA, as it is proceeding; and Algol 68 are good examples of KICC. [When David Packard was Deputy Director of Defense, he initiated a cheap, light weight fighter that could be mass produced so a large number could be available, numbers and maneuverability are the keys to winning. By the time it was produced, it became just another very expensive, slow fully general purpose fighter, trainer, bomber for decoying and doing everything else that could only be built in 10's not 100's.]

<>Simplicity, naivete, elegance, generality trickery. The wheel of complexity starts with simplicity. Extreme

simplicity, or naivete', is one reaction to too much generality, the last point in the wheel.

No one of us ever wants to introduce unnecessary complexity. But one person's simplicity can be another's complexity. For whom is it simple? The conceptualizer, or architect? The person who has to implement the machine? The person who has to write the compiler? or the ultimate user of a system? The hardware stack mechanism as embodied in various machines is simple for only one small part of the compiler writer. For everyone else, this extreme simplicity can easily result in comlexity.

<>Bowmar & HP. Don't get me wrong, stacks are great but I believe they have limits; I've always put in hardware to support them. If they are the central theme of an architecture, they can create complex implementation. The system programmer will have a complicated problem because there's too much bound in hardware. While stacks have little or no effect on the ultimate system user, nevertheless they slow down machines. [Or two calculators one for reverse and the other conventional. If you give the stack to the ultimate user, that's fine, but several hundred years of the parenthesis convention for algebraic formulation must be unlearned. Of course, calling the new convention reverse Polish notation certainly only made a confusing joke of it all.]

[In 1959, I helped Hamblen in Australia with an interpreter called George which turned the Deuce into a Polish postfix machine. English Electric liked the idea and put it into the KDF9. Over the last 15 years an increasing amount of stack control has been put into DEC's computers, but all of it is accessable to the system programmer, and none binds the hardware to particular stack management. In Computer Engineering, there's an essay comparing the similarities and differences of truly general purpose registers and a pure stack ISP. Stacks represent a naivete in what appears to be simplicty for someone (although I know not who). Furthermore, this naivete trades off complexity for everyone else.]

<>Comptometer Keys. True simplicity is pure elegance. Russ Doane, a DEC engineer, defines elegance as: Every feature contributes 2 benefits; every working part has to do double duty, insuring that excess is left out. Building architects say Less is more. Note how complement arithmetic allows every digit to represent one of two numbers. [In early comptometers, a separate subtraction mechanism was not required as in a sign magnitude representation.] Thus, the user had to do the complementation and was reminded of it by having the digit and its complement written on the keys.

<>Comptometer Ad. A trained operator could do addition and

subtraction faster than on machines with complentation mechanisms.

<>Burroughs. Burroughs original calculators that used sign magnitude were difficult to maintain and their physical elegance contributed to bank managers desks.

<>Burroughs copy. Burroughs then copied Comptometers to get the elegance of operation through simpler, faster and thus cheaper mechanisms.

One's complement arithmetic used to be popular because the Boolean instruction for complement was the same as the arithmetic change sign, [if you forget about the case of having both positive and negative zeros.] Unfortunately, when doing multiple precision arithmetic, the automatic end around carry gets in the way, and it turned out to be difficult to use for doing arithmetic primarily because too much was done automatically for the user. [Similarly, sign magnitude wasn't used for the same reason. In fact, one's versus two's complement was one big reason we built a totally different 18-bit computer when we already had the one.]

The highest leveled elegance, generality, may increase complexity somewhere in the system.

<>Cover of EDVAC Report. The ultimate in generality is the

general purpose stored program computer. Eckert commented on this how the stored program concept came about. Various priced memories elements were available to use as memories, such as Williams tubes, delay times, and drums. Von Neumann coined the phrase "memory hierarchy". The ENIAC team speculated that it would be very difficult to determine how much memory whould be available for various kinds of data, functions and programs. This led to the notion of a common memory pool and the stored program computer which we all know and love.

<>Eniac. The ENIAC was elegant. Nearly all of its parts could be used for two purposes: multiple accumulators carried out arithmetic in parallel and were temporary memory; the function tables, originally used for storing constants and functions, ultimately stored sequences of a program; and the relay buffers for i/o were also fast access memory; the calculator as a whole was ready for generality, or the exploitation of elegance.

[<>Multistable state device.] In my own case, I've gone for generality, three times but I'll only talk about the general register. [The first is taking an elegant idea, extending the flip flop to store multiple stable states. This was invented to simplify the problem of making controls with a few states.

<>Model for interconnecting computer components. The Unibus idea resulted from trying to make a general model for how computer components interconnect when I was writing computer structures.

<>Unibus. The observed model was a series of switches for interconnecting the hierarchy of memories, processors, controllers and devices. In trying to explain that any component must talk with any other component, the Unibus fell out.]

<>Table of General registers use. Strachey invented the notion of general registers for the Pegasus in 1956. In the sixties the 635 and 3600 were evolutionary 1 address, 1 accumulator machines. Then, the Univac 1107 was first with relatively general registers, and the 6600, 360 and PDP-6 all used them. The 6 provided the most generality for use. Now, high performance machines usually are based on having a large number of registers for fast access to immediate data.

[<>ASC. The designers of Texas Instruments Advanced Scientific Computer -- the ASC - a large pipeline machine built in 1970, built in generality even though they were commissioned to build a Seismic Computer for Geophysical Services Inc., TI's division involved in oil exploration. Several of the machines are used for Seismic analysis but the generic aspects of large scale number crunching also made the machine desirable for others - hence the change of the name from Seismic to Scientific. The extra sales, allowing TI to produce 7 at about 10-25 million and not four.]

<>Wheel of reincarnation. If done right, each time complexity is added to peripheral controllers to obtain more generality there is one more turn in the wheel of reincarnation as Myer and Sutherland outlined in 1968. The first stages seem simple; adding a few instructions and possibly an autonomous Direct Memory Access path increase performance without adversely affecting complexity or cost. The critical step is when the controller gets its own program counter. At this point a system should have its own program and the autonomy to execute programs either as a conventional multiprocessor to handle the increased I/O load or as independent computers for I/O as in the 6600. The interesting points are whether a controller executes an instruction or a complete program. Anything in between doesn't seem right!

Three pitfalls may be associated with extreme generality: trickery, loss in performance, and impracticality.

<>CTSS manual photograph. One example of trickery is the concept of operator overload by allowing redefinition of operators. Multics and the IBM 360/67 TSS were the second

system reaction to CTSS, written for the 7090. In Multics' case, while it appears elegant to have files mapped into memory, thereby extending primary memory generality to yet another function, and hence increasing generality, loss of performance resulted.

The reaction to Multics done jointly at MIT and Bell Labs, and to IBM's TSS was back to simplicity with Unix at Bell Labs, and CP/CMS at IBM.

<>Stretch. The last pitfall of increasing generality is caused by using every known idea. Stretch used and pioneered many ideas of the time: The simpler 360 was a reaction to the complexity of Stretch.

Lots of ideas always exist. Trying to use them all in one design is fatal. Huffman coding to have the fewest bits conflicts with simple ISP's that usually require longer strings to express a program. RISC can be carried too far if the data types the programs use aren't included. The notion of not having interrupts because they interfere with reliable software may conflict with building a real time system. Predication of multiprocessors conflict with cost. Building a wholly distributed system on a local area network may conflict with cost, performance and reliablity. Very secure or very reliable systems conflict with, easy and shared access to data, etc.

The reduced instruction set computers is a reaction to the complexity that occurs because so many data types are bound in the architecture because microcode looks so cheap. With RISC, the idea is to get back to a machine that perhaps has NO microcode, thus another wheel of reincarnation, a return to the simple machine all built in hardware, like Seymour Cray always builds. It runs fast and the complexity is in the compiler and for fast machines, in the implementation.

Whether the instruction set is large or small, we should remind ourselves that an instruction set of some sort must be bound versus building the fully general purpose microprogrammed interpreter. Recall the slowness and expense of several machines built about 1975 that allowed binding to the bit for the ultimate in generality. Papers, academic acclaim, and the talks about them reminded me of the trickery of the snake oil salesman because they could do everything. They could if you had enough money and could wait long enough. Decide exactly what's to be executed and then encode the machine to do it. The classical saying is form follows function.

[<u>Groups tend to design at the level they know best</u>. Bodies in motion tend to remain in motion in the same direction unless acted on by an outside force. Because the group is usually structured to the task based on intellectual disciplines, the control of a project is usually at a low level of integration. This gives rise to the old notion that hardware was designed so it could never be programmed by anyone. This saying was so popular that we now say a machine was designed by a team of software engineers.

Preoccupation with the low level, may mean the machine never gets built. Chips are often managed by circuit engineers, and the big effort is to have elegant circuits and also very many types. Only now do we measure and try to manage regularity, the ratio of total to unique circuits on a chip.

<>Microprogramming. With the advent of practical microprogramming, all users wanted to design their own computers. Fortunately high level languages came into existence and the machine language users didn't have a chance to dive into the details of programming the hardware machine. This is another case, like changing the circuit, that the user of a level believes that he can build a magnificant structure if he can only change the shape of the bricks and possibly make them all different.

A similar observation can be made about machine language programming versus high level languages; and the need of systems programmers to first implement a new language before they can do applications.

The alternative of having a machine that's designed by circuit persons is to have a machine that's designed by users such that it can't be built. Now, we can also worry whether the machine can be built or not because the designers, or architects of a machine don't know how to construct machines. PL/1 is a complex machine specified by users and unbuildable for quite sometime for anyone but a very large engineering group. This may be explained by: Conway's law, or a conscious business decision to build the unbuildable for either competitive or user demand reasons. After all, PL/1 came from Share, IBM's user group.]

Let's turn our attention from design of the architecture and implementation to building.

<>Generating #6. Building is sixth of the seven subprocesses of generating a computer. Carver Mead argues for the tall, thin man, a person who understands all parts of chip design including architecture. I'd like the individual to be even taller including the design of the operating software and then applications.

<4004 ad>. Ted Hoff and Bob Noyce wrote about the small team effort for first microprocessor, an example of the tall thin man approach, and the process of Generating a Computer Generation.

The 4004 was designed to be useful in a calculator, yet was not constrained to be only used to build calculators. LSI PMOS technology enabled several thousand gates to be placed on a chip within the base of knowledge in computing. Ted's first experience was the PDP-8, and he knew the power of the minimal computer.

Without this knowledge of minimal, general purpose computers, or had Ted only used a 360 or Fortran, the micro might have been invented several years later. Here, function, (the computer) follows form (the chip).

<>Cray 1. Cray is the only one person who architects, implements and then designs and builds the software. For the last 20 years, he has built the highest performance computers

and provided a catalog of ideas to use in other computers.

Brooks make a statement about segmenting the technical direction from adminstration. He says, a man with strong management and strong technical talent is rarely found. "Thinkers are rare; doers are rarer; thinker-doers are rarest." Musashi tells us to understand the way of the carpenter as both architect and builder.

My own role is now that of a foreman carpenter or perhaps a city planner and developer. I worry about the architecture of the set of buildings and how they relate to one another, together with where the roads go. Architecture of Networks and Local Area Networks in particular are extremely important. The location of the streets, viaducts and sewers have been permanent; Rome has witnessed great stylistic architecture changes.

<>vax. In the case of VAX, DEC started with a small architecture task force consisting of the most talented people we could find who kept the architecture, documented it, built the first machine and wrote the base software for it. If this was second best to having a single individual do it, it was the only humanly feasible way to get to the market fast. The designers were all experienced in design and had all warmed up on other computers, operating systems and

languages.

If at all possible, don't separate architecture and implementation at least more than a few feet. The iteration process is clear and tightly coupled. Fortran, Pascal, the first Basic are other examples of great designs of single individuals.

The super kludges come from committees because they usually contain no designers of any kind. Designers are typically doers and not committee goers. A large committee occasionally produces a useful design, such as Cobol, because the committee can get commitment from its constituents.

[While machines and languages may be cleanly designed, no single architect has emerged for communications protocols probably because no single organization controls the links and nodes. Often there are more than three independent organizations. The evolving communications interfaces to deal with data switching are so baroque and bazar that I fear we'll be set back many years just implementing them. In the past we were lucky in letting AT&T settle this with the international bodies. By splitting AT&T, there's even a free for all to decide who'll represent the US at CCITT.] The three rules I'd like to see for people who attend standards meetings: 1. the attendees should have implemented something; 2. proposed protocol or standard should be in operation somewhere, and; 3. the committee members are responsible for building what they design!

<>Teledial and pushbutton. Communications protocols are very hard to design because everyone wants to specify, design and have the option to change them. They are best understood as an extension of our natural languages and culture. Many dialects of x25 exist. Decades after all the countries had local dialling worldwide dialling was introduced. [In the case of Ethernet, DEC, Intel and Xerox always had many offers to help in the design which we graciously turned down. Now, we have to convince the IEEE the bits are in the right place and that it should be adopted. Honestly, it's well engineered and honestly the bits don't matter. Please get 802 so we can all get to work building... enough arguing.]

Small groups are not only essential for design, but all segmentation has to be kept to minimum. The greater the division the larger the time and segmentation. This is how we get n pass compliers when one should do, separation of operating system and language, partitioning of the secondary memory into blocks, records, files, data managment, and database languages.

Segmentation may be necessary to build large systems quickly and to get the right disciplines applied to the right level. Make it work for you, otherwise the reverse is to have everyone always working with and redesigning the lower level components and not the overall system.

Base the design on a small set of well defined components. If all the designers have done their jobs properly, then the set of components from which one builds a system will be elegant, yet complete. In this way, higher levels can be aggregated quickly because the behavior of each part is well defined. The Cray 1 was built from 2 IC types. The chips that never get completely finished are usually filled with circuit tricks, which aren't enumerated or understood.

<>Babbage. Don't be so ego-centric that you can't borrow ideas and technology. Babbage himself freely used ideas of others. The Jacquard card-driven loom gave him inspiration for program storage sequencing machine control.

<>Jacquard loom. Jacquard only made a minor tweak on
<>Bouchon loom. Bouchon's card controlled loom.

<>Early Computer. If the Computer Pioneers would have used each others ideas more then the computer revolution might have happened faster. The Harvard MARK I could have used relay technology and some of the design techniques developed for the Bell Labs machines; Bell Labs and ENIAC could have used some control mechanisms of MARK I avoiding the large

tube counts.

<Atanasoff drum>. For example, Atanasoff's capacitor drum memory, using regeneration, is the basis of many memory schemes.

Having received the ideas, be gratuitous about crediting everyone who contributed to the machine. The ENIAC and Regenerative Memory patent claims were so broad that they could not be enforced.

[In 1946, Von Neumann, Burks, and Goldstine understood the value of early communication in getting overnight funding to build the IAS machine in Princeton. Part of the agreement was to send working drawings to Los Alamos Laboratory, the University of Illinois, Oak Ridge National Laboratory, Argonne National Laboratory, and the Rand Corporation. According to Julian Bigelow, who led the engineering team on the IAS, at the outset "we anticipated that any mistake we might make in sending out piecewise the fruits of our efforts would be exposed to possibly hostile or competitive criticism leaving us no place to hide, but in fact problems of this sort never arose, and communication with people at these laboratories was entirely friendly and stimulating."

Today, the ARPAnet is a prime example of continued cross-communication - one of the few good things the defense department supports.]

<>PDP-6 bit slice. Borrowing, can help avoid changing everthing at once. I learned this the hard way in designing the PDP-6 about 1964. This bit slice module is my memento. We thought we could change everything, that there would be little risk in doubling the circuit speed using a new mechanical packaging technique placing connectors on both the front and back of the modules in order to get the requisite numbers of pins; specifying a new architecture with a megabyte address when everyone else was at most 256K; organizing a flexible structure that would permit building a large multi-processor in an evolutionary fashion so that we could build subsequent machines on the same base; presenting a straight forward interface which as a side effect probably started the whole idea of third pary vendors at Stanford, and predicating the design on timesharing -- a concept that was just being breadboarded at BBN, MIT, Stanford, and SDC.

Only 20 PDP 6s were made and several are still in service. The team stayed together and gained experience for the PDP 10. I would have hated to say to customers at the time that we were selling them an advanced development effort for our own, and others, interactive computing. Thinking of the 6 as a breadboard, probably the main mistake was not changing the packaging more to allow wirewrapping. Then the mechanical

problems of building the PDP 10 would have been to allow wirewrapping. Wirewrapping was the second generation, a technology that allowed computers to be mass-produced and not handcrafted. This was the key to the formation of minicomputers and the explosion of the computer population.

<>Illiac IV. [A more recent example is the ILLIAC IV, built at the beginning of the 3rd computer generation for scientific use, based on the yet undeveloped technology of semi-conductor memories. ILLIAC had a steady, seemingly, inexhaustible supply of funds that were thought as the universal solvent making up for under-developed technology and a trivial but complex architecture.]

<>Whirlwind. [Whirlwind is one of the great success stories: First running in 1951, the ANFS Q7, a production model built for the early warning system is still running and protecting us. The Whirlwind design team investigated other machines and technologies to design a machine for solving significant, real time, interactive, and control problems. Every other computer built in the forties was either oriented to arithmetic computation or data processing. The original task of project Whirlwind was to build an Aircraft Stability Control Analyzer, requiring real time simulation of an aircraft. This need constrained the problem in three ways: reliability, accuracy, and speed. Over 100 simultaneous equations, with an accuracy of .1 percent, had to be solved

at a 10-20 herz rate, forcing a parallel organization.

<>Bush. Like ENIAC, the program was conceived as an extension of the work on analog and differential analyzers in MIT's servo-mechanisms lab. As the work progressed, the transition from analog to digital was based on a suggestion by Perry Crawford who worked for Vannevar Bush. Crawford's ideas, based on his 1942 thesis on digital computation, were critical to the decision of both ENIAC and Whirlwind to become digital computing projects. The MIT team, led by <?> investigated the efforts of ENIAC and EDVAC. They made two unusual design decisions for the period. The serial approach was ruled out in favor of going to a parallel computer. They also moved from the 40 bit word length convention to a 16, bit word, 32 feet long. To a large extent the word length was chosen to gain speed and accuracy within the size and cost constraints.]

It's really a good idea to build in generality, so that systems may be used for some different purposes than those intended. Whirlwind also had significant spinoffs. It was built to demonstrate the SAGE air defense system using real time input from radars whose information was transmitted via phone lines. It also had the first crt's and light pens. In addition, Whirlwind was used for at least two purposes not conceived in its design but that fell out of it: the first computer speech research and Linvill's work on sample data.

<>WW Module. Build real things, not toys. The Whirlwind modules were taken verbatim by Burroughs and by ERA for the 1101, and the machine itself was built by IBM to serve the SAGE system. ENIAC was the breadboard for the UNIVAC machines. These real, engineered efforts at universities were significant spurs to American industry, the economy, and computing.

<>WW. Forrester was interested in sound engineering practices, stating, "Experimental equipment, merely for demonstration of principle and without inherent possibility of transformation to designs of value to others, does not meet the principle of systems engineering." MIT never got into the computer business -- but the Whirlwind did provide many businesses with proven designs and trained engineers.

[The abacus, a simple calculator, started well before my categories of pre-computer generations. It is such a good idea and simple device, that it has been claimed to be invented in Egypt, the Roman Empire, and China. If it is a good idea, then everyone will take credit for it.]

<>Core. At MIT, Forrester did not depend on outside suppliers but did his own experimental development on the core memory. MIT's University Research Corporation did not

see fit to patent the core because they considered its commercial applicability would be negligible. Forrester got MIT to patent it, and to his chagrin (and probably many others) kept many patent lawyers in business for years. He stated, "The Patent effort and litigation took about 1000 times the effort of the design. It took six years to convince industry to use the core and then six years to convince them they hadn't invented it." In this case, IBM lost the suit against Forrester and MIT, but they still will not readily admit it. I was recently told that IBM invented the co-incident current core memory; An Wang and Jan Rachjman of RCA also claim invention of the core. It was such a good idea at the time, everyone wanted the credit, just like the abacus. The idea did come from the university environment where openness across disciplines and cultures are much more likely to occur than in industry.

<>Generating #7. The cycle includes using the machine -- something I've always wanted to have more time to do. Eckert, Mauchly, and Babbage, were often thinking about the next machine before they realized the full potential and had all the bugs out of the one at hand. Eckert and Mauchly left the Moore School and the ENIAC project during the infancy of the machine and never lived with the UNIVAC systems very long.

<>WW. Forrester not only realized computers should be used but that understanding and training about a revolutionary new device requires the device. Can you conceive of universities without the computer? In 1948 that was the case. when forrester argued: "if a high speed computer capable of 1 to 20 thousand instructions per second were sitting here today, it would be nearly two years before the machines were in effective and efficient operation. ... this represents one-half of the viscious cycle in which an adequate national interest in computer training cannot be developed until the equipment is actually available." I believe this two year period should be called the Forrester constant.

The problem is still here. The 1979 Feldman report argued for funding for equipment for experimental computer science. Carnegie, Stanford, and MIT, still need more computing power for training tomorrow's pioneers.

<>Fortran. Perhaps the overwhelming reason to use computers before you build them is that Hardware follows Software. Nearly all mechanisms that appear in computer hardware structures start with software implementations. John Backus of IBM tells the story on the introduction of floating point. He observed that many customers were running their 701s with a floating-point interpreter, slowing the machine to 50 multiplications were second. He tried to get the engineers to include floating point hardware, but they were more interested in speeding up the drum. He then created, "The most incredible design for building floating point into the 704." It involved adding four or five new registers, which was unheard of in those days. At the next meeting of the engineering design committee, he remembers, "I stood up and spent an hour describing my insane design and people listened. At the next meeting Gene Amdahl got up and said, 'Backus, you're an absolute idiot; you can build in floating point without adding any registers at all to the computer, and it will cost almost nothing, and here's how to do it.' And that's how it happened."

<>Turing. The one level store of the Atlas came from using Mercury. The assembly program I wrote had a one level store, because the two levels were so difficult to program. Furthermore my reaction to program a Turing designed machine, which really made the programmer work, established in my mind that the machine ought to be understandable.

Thus, one of the key results of using is the whole notion of the adversary design. The one level stores were invented to overcome the hardware. The invention of the stored program I started with was a reaction to the unreliable and inflexible way of programming the ENIAC, iterating that hardware follows software and that we learn from advesary designs. The ASC and Cray 1 seemed to be reactions to the inflexible, ILLIAC IV.

<>Fortran. On occasion, software may follow hardware. This is rare and often wrong. The first Fortran had instructions to manipulate the sense lights, sense switches and tape of the 704. Also, the DO loop was oriented to the index register instructions. Some of these primitives have stayed with us, but most were dropped. I believe all the algorithmic languages should have been extended to handle vectors and arrays. Had this happened, we would have these operators in machines. The Cray 1 is causing this extension so that software is following hardware.

<>Pencil Evolution. Finally, use it and describe it so it can be evolved. Go around again. Those who build machines describe, it's like playing Pinball. The reward of building the machine is to build the next machine. No matter how good a design is the next one can always be better as Pentel, has shown in their evolution of the homely, but important pencil.

TALK: GENERATING COMPUTER GENERATIONS

I'm honored to have this award for three reasons: First as an engineer in the tradition started by Eckert and Mauchly, second as a founder of the Digital Computer Museum, and third as an author. First, as an engineer I am very proud to have the award, and I have many others to thank for it. Like Eckert and Mauchly, I worked with and built on the work of others. Most computer innovations are not made by one person: As a writer my co-authors, especially Allen Newell, and also Dan Siewiorek, Craig Mudge, John McNamara, and John Grason need to be thanked. As a museum founder, Ken Olsen and Gwen Bell, who is now the President of the Museum Corporation, are important. And as an engineer, the first people to thank are Ken Olsen and Ben Gurley, who were responsible for conceptualizing a commercial computer, the PDP-1, based on their development of the TX-0 and TX-2. I want to acknowledge Ed DeCastro who implemented the PDP-5 and 8, Alan Kotok who worked with me on the PDP-6 for the first timesharing system. Roger Cady and Harold McFarland on carrying ideas for the 11 and although I lead the early design group on VAX, it's really Bill Strecker's work with Bill Demmer leading the development. Dave Cutler was responsible for the design and building of VMS. Many others also contributed.

As a founder of the Digital Computer Museum, this talk gives me a chance to tell you about it.

<>Entrance DCM. When I talk about the Digital Computer Museum, the image in my mind is of the American Museum of Natural History -- where twelve acres are devoted to the collection and study of the natural world. Similarly, the Computer Museum will collect and preserve all computing history for its study and interpretation. Computing is large and important enough to have its own, special, centralized Museum. Science is too large. National, corporate and local museums don't provide good comparative history.

<>Hollerith. The Digital Computer Museum is a public non-profit charitable foundation whose purpose is to preserve the history of all of information processing. That means that you and your organizations can give the Museum equipment and money and receive a full tax deduction. The Museum, in turn, is obligated to preserve artifacts. The collection not only includes computers, but also calculators, memories, links and switches, transducers, controls, and robots, that is the whole range of components that Newell and I outlined in the PMS notation. Already the collection has grown to the extent that we can claim to have the most comprehensive exhibits of the origins and evolution of computers.

<>TI exhibit. Its fitting that I'm speaking in Texas because Texas Instruments was the first outside donor giving us the heart of an ASC and really helped establish an industry wide effort.

<>Another shot. I want to invite all of you to come see the Museum, join the Association so that you can receive its quarterly report, and consider it for a depository of the important papers and artifacts of computing history. (And, by the way maybe this will help me lure Pres Eckert to come and give a Museum Lecture -- He has a standing invitation from us.

<>Computer Generations Cycle. As an author I need a deadline -- like this one. The talk is evolutionary and I hope it will be part of a biographical monograph on Computer Evolution.   Although the examples are historical, I can't claim to be a historian only a biographer. The focus in this talk is the middle of the evolutionary process, that is, the computer engineering needed to implement ideas before they become obsolete.

The revolution started by ENIAC generated this evolutionary cycle. The need for making ballistics calculations started the cycle. This generated resources that allowed a team to integrate technologies into a new machine for satisfying the need. The moment ENIAC started to calculate, it's use set the cycle off again. Users identify new things to do with computers and provide market resources for new machines. Fred Brooks makes this point clearly in THE MYTHICAL MAN-MONTH, stating, "the incompleteness and inconsistencies of our ideas become clear only during implementation." (p.15) If idea generators, and builders aren't involved in use, they won't understand the evolutionary trend enforced by feedbacks. Closing the loop results in computer evolution -- not revolutionary new machine design.

Like all cycles this one has periodicity. New technologies, needs, or uses can trigger a small spurt -- and the coincidence of all three mark a new generation and a branching of the family tree of computers.

<>Light bulbs. Technology provides the base tools from which computers are developed. Inventor's ideas are the bright lights floating between technology and society's dreams. At the dawn of a new generation a number of inventor's concepts converge into a project. Eckert and Mauchley are rightly given the major credit for ENIAC, but Atanasoff's work preceding it is recognized as influential, and their colleagues -- Burks, Sharpless, Goldstein, von Neumann and many others -- also deserve credits. With each generation, the technological floor becomes higher, the user's aspirations rise, and the gap that spurs invention is constant.

<>Generation tree. Computer generations can also be seen as a tree, starting with its roots in scientific and business calculation with ENIAC, a scientific; and UNIVAC, a business, machine. In the second generation, super computers branched from the scientific root and continue on an evolutionary path determined by Seymour Cray. At the same time early scientific and business machines merged into the class of general purpose mainframes ranging in price from 100 thousand to 10 million dollars. Although the idea of the mini, for minimal computer as in the PDP-8 was developed at Digital in the second generation, it flowered as its own branch in the third generation when IC's permitted numerous variants and companies to start. The fourth generation is marked by the branching of the micro processor on a chip. It's too early to see the fifth generation, but either it or the sixth must be identified by a means -- such as ethernet -- for all classes of computers to communicate on a network forming a computing mesh with an interlacing of branches to keep them from collapsing by their own weight.

<>Op rate. During the 400 year, ten generation period from 1600 to 2000, the technological change is roughly a factor of 10**12. Using the product of processing rate and the memory size to measure computing power, then the computer has evolved almost 20 orders of magnitude

<>toes. since stone-based, manual, single register devices for counting supplemented fingers and toes.

<>Generation is marked by. Three ingredients are needed to create a new computer generation: a steady supply of funds, a useable technology, and the machine design.

<>Babbage. Babbage only had the machine design and was destined to work alone because he had no funds. He tried the patience of government agencies and friends by repeatedly requesting funds without producing results. He always promised the next machine that he had in his mind if only monies were available, even though the technology was not within grasp.

Two of the three is not enough. And having only one of the three -- only the machine design as Babbage had -- dooms a project to failure.

<>Stibitz. George Stibitz at Bell Labs had the funds and was working on the same type ballistics problems as Eckert and Mauchly. He was constrained by the technology of the telephone company; that is to use ... alot of telephone relays. The 1939 machine was the first calculator that could do complex arithmetic and it operated via Teletypes in an interactive fashion. In September 1940, the calculator was demonstrated at a meeting of the American Mathematical Society at Dartmouth. An interface to the teletype designed by S.B. Williams allowed attending mathematicians to transmit problems from Dartmouth for solution by the calculator in New York.

<>BTL2. Bell Labs produced four advanced versions of the machine, and by the mid-fifties this line had died out. Thus, it can be seen that a useable, but traditional technology is inadequate in forming a new generation.

<>ENIAC. ENIAC had all three: Herman Goldstine insured a steady flow of funds from the Army; a variety of technologies, including

<>tubes. vacuum tubes, teletype and card equipment for i/o; magnetic recording in the form of drums; diodes and triodes;

<>flipflop. the Eccles Jordan flip-flop; and switching algebra were available for use under the careful engineering of Pres Eckert, and a new machine design was inspired by John Mauchly.

<>SubProcess. In any machine design, a number of separate, concurrent processes give rise to decision points leading to suspension, continued development, or recycling.
<>Generating a computer structure. Seven processes interact in the evolutionary cycle of a new computer structure. The first process involves defining the problem: understanding the constraints, setting the goals, and determining the objective function of the design. Then, three mutually exclusive decision processes determine the architecture. Selecting the null architecture is calm and peaceful -- not exciting until implementation when almost insurmountable technology problems emerge; choosing an evolutionary architecture that copes with new technology or needs, is like guerrilla warfare -- a few people die on the line and some get caught in the crossfire;   but generating a new architecture means a bloody revolution.

The process of physical design for implementation is concurrent with the architectural design process.

The building process requires complete understanding so that no unplanned side effects occur. The complexity of building computers is so great that even with the greatest care side effects are free. For the lucky designers they're also positive!

The final Process, using the machine, is essential for understanding the next step in evolution and the issues that could lead to revolution. Within the context of the whole cyclical feedback, each process will be considered individually. The process of problem definition sets the constraints, goals and the objective function based on cost, performance and other measureable factors. The physical laws governing materials with respect to electromagnetic energy and heat transfer are obvious constraints. Yet engineers still try to violate them. And we never win.

<>ENIAC plugs. ENIAC was bounded by the reliability of both vacuum tubes and plugboard programming. Mauchly reasoned that even if ENIAC only ran a few minutes it would accomplish more than Bell Labs slow relay machines. It contained 18,000 vacuum tubes each with a predicted 500 hour life. If the machine had been designed using the tubes at capacity, the exponentially increasing repair time would have bootstraped the machine to its death, that is, if it ever lived. Goldstine recorded that by derating the filament and plate only three tube failures occurred per week. The actual failure rate of about one million hours was achieved only by very conservative engineering. Because of the potentially compound problems of tube failure and plugboard connections all problems were run twice to insure accuracy. Franz Alt, commenting on the 40 plugboards and extensive cabling, estimated a five percent utilization rate. Taking into account the amount of time the machine ran, ENIAC was still 25 to 50 times faster than the relay machines. The fact that such a large system ran is a tribute to conservative engineering, mostly on the part of Eckert.

<>Whirlwind. In contrast, Jay Forrester, on the Whirlwind, tackled problems at their source. Concerned with highly reliable, real time computing, he knew that the estimated tube reliability of 500 hours had to be increased by several orders of magnitude. An outside review prodded at the gradual failure mechanism of the tubes and led to marginal checking. By understanding the tube failure mechanism, the manufacturing process, and introducing marginal checking, reliability was raised to five million hours.

<>Von Neumann. In the later forties Von Neumann, determined to build IAS, put his faith in new undeveloped technology for a fast parallel memory promised by RCA. After two years of work on the Selectron tube, with vague but optimistic quarterly reports, not one had worked.

<>Selectron tube photo. Julian Bigelow reports, "No one in the IAS team was sufficiently expert in electron tube design and manufacture to be able to assist it, but in conference with Von Neumann I made an attempt to list the variables which would have to be kept under control to produce a 50% yield of successful selectron tubes, covering a range of digital capacities from the original goal of 4096 digits per tube, down through 2048, 1024, 512, etc. It appeared that...the goal of 4096 per selectron was far too ambitious, and that acceptable production yields might be far sooner attained if the goal were reduced to 128 digits per tube." This 256 bit Selectron finally became available in 1953 for Rand's Johnniac.

What did Von Neumann do for his memory? He sent an expedition to Manchester where Fred Williams had built random access memory tubes with 1,000 bits, each.

<>WW Tube Memory. Jay Forrester did the same. The two Mhz clock and 50 K ips speed using MIT adapted Williams Storage tubes cost $16,000 per month to operate. Impressive, but expensive. Searching for a better solution Jay Forrester started to investigate using magnetic cores.

<>Ceramic Core. At first they used wound magnetic tape Deltamax cores. Then beautifully made, but little understood, ceramic cores were found at Philips. According to Forrester, the manufacturers claimed that they could not be used for storage. Theoretically this was true, but it didn't stop Jay Forrester from trying ceramic cores and succeeding. Forrester commented, "This is an example of where the art was substantially ahead of the theory. Cores worked and could be made by trained ceramicists. Years later scientists understood how and why, but for many years production of ceramic cores was a materials art."

<>Forrester and Core. Forrester did not depend on outside suppliers but started his own experimental development on the core memory. MIT's University Research Corporation did not see fit to patent the core because they considered its commercial applicability would be negligible. Forrester got MIT to patent it, and to his chagrin (and probably many others) kept many patent lawyers in business for years. He stated, "The Patent effort and litigation took about 1000 times the effort of the design. It took six years to convince industry to use the core and then six years to convince them they hadn't invented it." In this case, IBM lost the suit against Forrester and MIT, but they still will not readily admit it. I was recently told that IBM invented the co-incident current core memory; An Wang and Jan Rachjman of RCA also claim invention of the core.

<>Turing. In 1958, I visited Wilkinson, who while working for Turing, designed the Pilot ACE, the prototype of English Electric's Deuce that I had been programming. I told him about a symbolic assembly program that two of us built to optimize instructions in a delay line in conjunction with a backing drum memory providing one of the first one-level memories.   He asked me for a benchmark. I compared it with the results using a new program language called Fortran, which he was even more skeptical of. A matrix routine could be coded a factor of 10 faster than the current method of hand allocating, assembling and key punching programs in row binary but still a factor of 4 slower than using Fortran. He said, none of this matters, "I can write any matrix program in machine language in 15 minutes: why should we waste the machine's time in doing it?"

While, I admit that the Turing influence was extreme, after initial funding, most of us still take ourselves as the archetype user.

<>GB and average man. All of us, including myself, want to design computers and languages as if we're the average man. This proves it to you. I'm absolutely average, so I can do it and tell others how to as well. A greater pitfall than designing for yourself, is designing for a proprietary user. Paraphrasing a remark by Charles Wilson of GM: "What's good for General Motors may not be good for anyone else."

<>Photo of PDP-14. I don't know how many of you recognize the PDP-14 for controlling transfer machines. This doesn't mean we shouldn't have built a machine to solve the control problem. The designer should formulate the NEXT problem for the machine, not just the one at hand.

<>Military. The ultimate in vanity architectures are computers built for one of the world's largest organizations, the Defense Department. I've never met ANYONE who admits to being either the designer or specifier. The current Military Computer Family effort is designed to take incredible engineering resources out of circulation, guarantee high prices, and worst of all, insure obsolete equipment. Their Russian counterparts base computer designs on US commercial architectures and probably their implementations. No real benefits will come from building the MCF VANITY architecture.

<>Generating #1. While need orients designs and generates resources; as the sole constraint, exact need is detrimental to progress. Standards represent the ultimate in constraints. Getting the right standards at the right time is essential for widespread implementation. If a defacto standard exists, such as the IBM channel and Unibus, let it be. If a standard is needed, then go all out to create it so that others can avoid the hassle of having to invent in an area that will generally make work. Alternatively anarchy can reign until IBM makes an ad hoc decision, and then it can be accepted in a de facto fashion and we can all try to implement it.

The ultimate in standards is implementing a computer based on an existing architecture; this is the null architecture design process.

<>EDSAC. Maurice Wilkes, who took the 1946 summer course on the ENIAC and EDVAC at the Moore School, returned to Cambridge University and built and programmed the EDSAC. This first, full scale operational stored program computer, was based on a simplified version of the EDVAC and IAS. In 1949, only one month after EDSAC was operational, Maurice Wilkes perceived the value of a series of computers sharing the same instruction set. He stated, "When a machine was finished, and a number of subroutines were in use, the order code could not be altered without causing a good deal of trouble. There

would be almost as much capital sunk in the library of subroutines as the machine itself, and builders of new machines in the future might wish to make use of the same order code as an existing machine in order that the subroutines could be taken over without modification."

<>EDSAC or Maurice. This advice is even more applicable today than it was then and must constantly be reiterated to us all! In a recent editorial in Computer Design, the editor in chief commented: "the microprocessor revolution ... has more or less stiffled CPU architects except for those involved in mainframe and military or highly specialized system. ... the upswing in 16-bit microprocessor chips is again going to put somewhat of a crimp in architectural innovation... The real renaissance in smaller cpu architectures is just within grasp as the VLSI gate array moves into the realm of the smaller computer manufacturer ... Once again the CPU architect can return to innovations in internal cpu structures." I couldn't disagree more.

New architecture, particularly hardware architecture, should be the last resort because it is the beginning of what is fundamentally a six or seven stage work amplifier.

Given that I've introduced null architecture, building successor machines that are compatible with or built on the past, I feel duty bound to state a lesson that RCA ignored and the Japanese eventually learned.

If you copy a machine, do it exactly -- not just closely. The test has to be that the software, including all user data and files can't know the difference between the original and the copy. Furthermore, if there is a desire to attract, and then entrap, a given set of users to your machine (or language), then build it with extensions that other machines don't have, and that your users will feel duty-bound to use.

<>Fortran. When no process for standardization exists then a plethora of language dialects develop like Fortran V, stemming from Fortran IV. Similarly, the designer of the 8080 added instructions to the architecture and created the Z80, insuring two architectures, and the attendant waste, when one was adequate. At least the Z80's a superset.

On the other hand, conservative users and manufacturers want to preserve their economic and emotional investments as long as they can. Enticed by a user base, almost every company produces one too many of a given machine design.

<>Hollerith. The card which was the savior of the 1890 census became so tied to some corporations approach to computing that they could see no alternative methods for input or output. When the 80 column card was on the way out, true believers in card computing evolved a 132 column card. This too was an expensive evolution requiring new equipment. This dinosaur, a large beast created on a small bone structure (or architecture) was created just when the technology should have been let go.

<>Generating #3. The key is to know which machine is one too many, -- to question whether the bone structure will support the architecture -- and if the limits are close, don't build it. Compatibility extends life in the process of evolving an architecture.

<>abacus. The original Chinese abacus represents up to 15 in a digit with a combination of 5 and 2 beads. It is the bi-quinary system we invented several times.

<>SOROBAN. Ultimately the Japanese refined the abacus, first using 5 and 1, and then 4 and 1 beads for lower cost and

faster operation while not radically affecting the installed base.
<>soroban/calc. This 1979 calculator/soroban is ideal in several ways: low cost storage of a second number is provided; simple operations can be done traditionally and more rapidly on the soroban; users can be gradually trained on the new machine without losing any traditional computational capability; the market is larger; and a culture is preserved.
<>Core. And like the core memory, the idea is so good that many claim the invention.

<>PDP-1 and 4. One of the earliest computers I worked on was the PDP-1, an 18-bit computer, grandchild of Whirlwind and a direct descendant of the TX-0. None of us thought of using the Whirlwind ISP because we needed 2 more than the 16 bits of Whirlwind. Both Whirlwind and TX-0 had excellent system software. Then with the design of the great grandchild, PDP4, to tune the implementation exactly to the architecture saving at most 10% over the PDP-1, I introduced a further ISP and switched to two's complement. Thus, in a family tree of 4, three architectures were probably unnecessary. The world ended up being modulo 8 bits anyway, just as in the original Whirlwind. Perhaps an even greater sin was committed by Computer Controls Corporation because they changed the name PDP to DDP and added a bit to the PDP-1 to come out with the DDP 19. They only sold a half dozen.

<>12 bit. The history of 12-bit computers is similar. The architectural differences of the CDC 160, the LINC, PDP-5 and 8, the 6600 and 7600 ppu's, and those of Honeywell and SDS whose names I forget weren't significant. If we had all copied the 160 the implementations could have remained unique.

<>PDP-5. Computer architects and their implementers who did not make either exact or evolutionary copies of a predecessor machine have cost the entire industry unaccountable billions. In the second generation all that a number of our architectures provided were noncompatible versions of Whirlwind and the 160.
<>Generating #4. New architectures are needed for new forms of computing. Obsolete computers are characterized by inadequate bone structures for coping with different, more modern environments. Several companies who tried to go into business by buying up a bunch of old computer designs, had no chance of high growth. They were self-limited by existing conservative users of these machines. Growing by user base acquistion is like trying to get fat eating tapeworms.

High growth comes from the new architecture of new organizations like Apple, or converting to the VAX base at Digital. But, believe me, when you're dealing with an existing organization with a set of happy and content users, suggesting change, and implementing it, is difficult, but critical, for success.

Now that we've looked at both null architecture and architectural evolution processes, what will the architecture of a revolutionary machine look like?

<>Thomas arithmometer. At the beginning every new structure appears to be quite complex. When Thomas and successors manufactured a calculator, the machine appeared to be very complicated to scientists used to simple slide rules with two moving parts. In 1849, SCIENTIFIC AMERICAN wrote, the Thomas machine "is said to be one of the most astonishing pieces of mechanism that has ever been invented, but to our view, its complexity shows its defectability."

<>Millionaire. Subsequent manufacturers evolved the machine and continued to make and sell them into the twentieth century.

<>Deuce Drum. In 1957, when I saw a moving head drum on the DEUCE computer, I was awestruck. Two independent 16 track read and write heads were used to select 1 of 256 tracks. The control was via a potentiameter sense in an open loop fashion. The complexity was beyond my imagination. I was biassed because my program also turned out to be the best diagnostic.

<>CDC 6600 refrigerators. When Cray's 6600 was introduced in 1964, the refrigerators in each quadrant seemed to create a complex maze of plumbing. But it's really a simple and natural method after its understood. With the high power densities, a built in refrigerator is the best way to cool a computer.

<>Generating #5. The principles of design help in understanding essential versus non-essential complexity both in architecture and it's implementation.

<>Communications Poster. In 1968, Melvin Conway hypothesized that organizations are constrained to produce designs that copy the communications structures of their own organization. This tells us why n people may create an n pass compiler, or why several strong persons will partition a design into separate functional units.

<>Dupont. One of our customers conceptualized their need for interconnection as nearly total communication among nodes.

<>First level of the tree. Yet, when the network was designed the thoughts, like the organization turned to a three level tree, the first level of which is shown here.

<>IBM telecommunications tree. This explains the difference why SNA,

<>ARPA network. ARPA-net,

<>Dec net. and DEC's approach to networking is different.

<>Unibus. With the Unibus each computer component operates to a well defined protocol and can be developed and evolved independently of any other. Hierarchy is imposed by use and convention, not by structure. In this way various groups inside and outside of DEC could build components to a common protocol. This is also why the structure was copied by all micros.

<>Ethernet. Ethernet, a direct evolution of the Unibus, ties computers together in a local area without dependence on central networking functions, central power, or on a particular node.
<>IBM 360. The IBM 360 may mirror IBM. Memory is the focus for all work and the single central processor controls all significant decisions in the 360. This authoritarian top down structure has fat but not very smart subordinates doing the i/o.
<>CDC 6600. In the Cray computers, everything is oriented around a single, very high performance processor at the center. Unlike the IBM approach, the peripheral computers operate effectively autonomous.

Keep in mind that we've looked at some very good designs. Now consider what Watts, the Father of Radar said: "Designers always build the 3rd best system. The First is ideal and the Second best takes too long." Clearly guidelines are needed to avoid building the 4th best.

<>Wilkinson quote. Jim Wilkinson tells how Turing's obsession with building the highest speed machine was kept in line: "in deciding whether or not a feature should be included, the question we asked ourselves was, could we do without it?" This can be translated into Keep It Simple, Stupid.

<>Hoare quote. Tony Hoare's statement can be reduced to three design criteria: 1) exclude what you can, 2) only include what you know and 3) since a machine never diminishes over time, allow for growth - don't build to it's limits.

<>Cost per gate. Increasing memory sizes based on continually decreasing cost insure that users will demand extensible machines. Every 3 years another bit is needed to address the memory. Lack of understanding of this phenomena has been the fatal flaw in nearly every design since 1950. Most designs cannot be extended gracefully more than once.

Large committees usually violate principles of simplicity, in fact guarantee complications. A corollary of KISS, for Keep It Simple, Stupid might be coined KICC, or Kill It by Complexity and Committees. ADA, as it is proceeding; and Algol 68 are good examples of KICC.

<>Wheel of complexity. The wheel of complexity starts with naivete, or extreme simplicity, usually as a reaction to too much generality. No one of us ever wants to introduce unnecessary complexity. But one person's simplicity can be another's complexity.

<>Simplicity. For whom is it simple? The conceptualizer, or architect? The person who has to implement the machine? The person who has to write the compiler? or the ultimate user of a system? The hardware stack mechanism, the theme of various machines, is simple for only one small part of the compiler writer. For everyone else, this extreme simplicity can easily result in comlexity.

<>Bowmar & HP. Don't get me wrong, stacks are great but I believe they have limits; I've always put in hardware to support them. If stacks are the central theme of an architecture, they can a create complex implementation that runs slow. The system programmer will have a complicated problem because there's too much bound in hardware. Stacks usually have little or no effect on the ultimate user.

<>Elegance. True simplicity is pure elegance. One of our engineers says elegance occurs when Every feature contributes 2 benefits; every working part has to do double duty, insuring that excess is left out. Building architects say Less is more.

<>Comptometer Keys. Note how complement arithmetic on a Comptometer allows every digit to represent one of two numbers. Thus, the user had to do the complementation and was reminded of it by having the digit and its complement written on the keys.

<>Comptometer Ad. A trained operator could do addition and subtraction faster than on machines with complentation mechanisms.

<>Burroughs. Burroughs original calculators that used sign magnitude were more complicated and thus more costly to maintain. Their physical elegance and simpler operation insured their appearance on bank manager's desks.

<>Burroughs copy. Burroughs then copied Comptometers to get the elegance of operation through simpler, faster and thus cheaper mechanisms.

<>Generality. The highest leveled elegance, generality, may increase complexity somewhere in the system. The best example is the general purpose stored program computer. Eckert commented on the how the stored program concept came about. Various priced memories were available such as Williams tubes, delay lines and drums. Von Neumann coined the phrase "memory hierarchy". The ENIAC team speculated that it would be very difficult to determine how much memory should be available for various kinds of data, functions and programs. This led to the notion of a common memory pool and the computer which we all know and love.

<>ENIAC. The ENIAC was elegant. Nearly all of its parts could be used for two purposes: multiple accumulators carried out arithmetic in parallel and were temporary memory; the function tables, originally used for storing constants and functions, ultimately stored sequences of a program; and the relay buffers for i/o were also fast access memory; the calculator as a whole was ready for generality, or the exploitation of elegance.

In my own case, I've gone for generality, three times but I'll only talk about the general register.

<>Table of General registers use. Strachey invented the notion of general registers for the Pegasus in 1956. In the sixties the 635 and 3600 were evolutionary 1 address, 1 accumulator machines. Then, the Univac 1107 was first with relatively general registers, and the 6600, 360 and PDP-6 all used them. The 6 provided the most generality for use. Now, nearly all machines have a large number of general registers.

<>Trickery. Three pitfalls may be associated with extreme generality: trickery, loss in performance, and impracticality. One example of trickery is the concept of operator overload by allowing redefinition of operators. Multics and the IBM 360/67 TSS were the second system reaction to CTSS, written for the 7090. In Multics' case, while it appears elegant to have files mapped into memory, thereby extending primary memory generality to yet another function, and hence increasing generality, loss of performance resulted. The reaction to Multics done jointly at MIT and Bell Labs, and to IBM's TSS was back to simplicity with Unix at Bell Labs, and CP/CMS at IBM.

The last pitfall of increasing generality is caused by using every known idea. Stretch used and pioneered many ideas: The simpler 360 was a reaction.

Trying to use all the new ideas around in one design is often fatal. Huffman coding to have the fewest bits conflicts with simple ISP's that usually require longer strings to express a program. RISC can be carried too far if the data types the programs use aren't included. The notion of not having interrupts because they interfere with reliable software may conflict with building a real time system. Predication of multiprocessors conflict with lowest cost. Building a wholly distributed system on a local area network may conflict with cost, performance and reliablity. Very secure or very reliable systems can conflict with, easy and shared access to data.

<>PDP1. The reduced instruction set computers is a reaction to the complexity that occurs because so many data types are bound in the architecture because microcode looks so cheap. With RISC, the idea is to get back to a machine that perhaps has NO microcode, a return to the simple machine all built in hardware, like Seymour Cray always builds. It runs fast and the complexity is in the compiler and for fast machines, in the implementation.

Whether the instruction set is large or small, we should remind ourselves that an instruction set of some sort must be bound versus building the fully general purpose microprogrammed interpreter that's always looked so enticing. Recall the slowness and expense of several machines built about 1975 that allowed binding to the bit for the ultimate in generality. Papers, academic acclaim, and the talks about them reminded me of the trickery of the snake oil salesman because they could do everything. They could if you had enough money and could wait long enough. Decide exactly what's to be executed and then encode the machine to do it. It probably can not do everything well.

<>Generating #6. Let's turn our attention from design of the architecture and implementation to building, the sixth of the seven subprocesses of generating a computer. Carver Mead argues for the tall, thin man, a person who understands all parts of chip design including architecture. I'd like the individual to be even taller including the design of the operating software and then applications. If at all possible, don't separate architecture and implementation at least more than a few feet. The single designer is better still: Pascal is the sole product of Wirth.

<>7600. Cray is the only one person who architects, implements and then designs and builds the software. For the last 20 years, he has built the highest performance computers and provided a catalog of ideas to use in other computers.

Small groups are not only essential for design, but all segmentation has to be kept to minimum. The greater the division the larger the time and segmentation. This is how we get n pass compliers when one should do, separation of operating system and language, partitioning of the secondary memory into blocks, records, files, data managment, and database languages.

Segmentation may be necessary to build large systems quickly and to get the right disciplines applied to the right level. Make it work for you, otherwise the reverse is to have everyone always working with and redesigning the lower level components and not the overall system.

<>vax. In the case of VAX, DEC started with a small architecture task force consisting of the most talented people we could find who kept the architecture, documented it, built the first machine and wrote the base software for it. If this was second best to having a single individual do it, it was the only humanly feasible way to get to the market fast. The designers were all experienced in design and had all warmed up on other computers, operating systems and languages.

<4004 ad>. Ted Hoff and Bob Noyce wrote about the small team effort for first microprocessor. The 4004 was designed to be useful in a calculator, yet was not constrained to be only used to build calculators. MOS technology enabled several thousand gates to be placed on a chip. Ted's first experience was the PDP-8, and he knew the power of the minimal computer. Without this knowledge of minimal, general purpose computers, or had Ted only used a 360 or Fortran, the micro might have been invented several years later. Here, function, (the computer) follows form (the chip).

Brooks make a statement about segmenting the technical direction from adminstration. He says, a man with strong management and strong technical talent is rarely found. "Thinkers are rare; doers are rarer; thinker-doers are rarest." Musashi tells us to understand the way of the carpenter as both architect and builder.

<>Distributed. My own role is now that of a foreman carpenter or perhaps a city planner and developer. I worry about the architecture of the set of buildings and how they relate to one another, together with where the roads go. Architecture of Networks and Local Area Networks in particular are extremely important. Rome's streets, viaducts and sewers have been permanent, although great architectural changes have occurred.

Base the design on a small set of well defined components. If all the designers have done their jobs properly, then the set of components from which one builds a system will be elegant, yet complete. In this way, higher levels can be aggregated quickly because the behavior of each part is well defined. The Cray 1 was built from 2 IC types. The chips that never get completely finished are usually filled with circuit tricks, which aren't enumerated or understood.

<>Kludge. The super kludges come from committees because they usually contain no designers of any kind. Designers are typically doers and not committee goers. A large committee occasionally produces a useful design, such as Cobol, because the committee can get commitment from its constituents.

The three rules I'd like to see for people who attend committee meetings: 1. the attendees should have implemented something; 2. a proposed protocol or standard should be in operation somewhere, and; 3. the committee members are responsible for building what they design!

<>Babbage. Don't be so ego-centric that you can't borrow ideas and technology. Babbage himself freely used ideas of others. The Jacquard card-driven loom gave him inspiration for program storage sequencing machine control.

<>Jacquard loom. Jacquard only made a minor tweak on Bouchon's card controlled loom.

<>Early Computer. If the Computer Pioneers would have used each others ideas more then the computer revolution might have happened faster. The Harvard MARK I could have used relay technology and some of the design techniques developed for the Bell Labs machines; Bell Labs and ENIAC could have used some control mechanisms of MARK I avoiding the large tube counts.

<Atanasoff drum>. Having received the ideas, be gratuitous about crediting everyone who contributed. The ENIAC and Regenerative Memory patent claims of Eckert and Mauchly were so broad that they could not be enforced. Atanasoff's early capacitor drum memory, using regeneration, is the basis of most all primary memory schemes.

<>PDP-6 bit slice. Borrowing, can help avoid changing everthing at once. I learned this the hard way in designing the PDP-6 about 1964. This bit slice module is my memento. We thought we could change everything: that there would be little risk in doubling the circuit speed; or using a mechanical packaging technique placing connectors on both the front and back of the modules in order to get the requisite numbers of pins; specifying a new architecture with a megabyte address when everyone else was at most 256K; organizing a flexible structure that would permit building a large multi-processor in an evolutionary fashion so that we could build subsequent machines on the same base; presenting a straight forward interface which as a side effect probably started the whole idea of third party vendors at Stanford, and; predicating the design on timesharing -- a concept that was just being breadboarded at BBN, MIT, Stanford, and SDC.

<>PDP-6. Only 20 PDP 6s were made and several are still in service. The team stayed together and gained experience for the PDP 10. I would have hated to say to customers at the time that we were selling them an advanced development effort for our own, and others, interactive computing. Thinking of the 6 as a breadboard, probably the main mistake was not changing the packaging more to allow automatic wirewrapping. As a side effect, wirewrapping then allowed computers to be mass-produced and not handcrafted. This was one key to the minicomputer population explosion.

<>Generating #7. The cycle includes using the machine -- something I've always wanted to have more time to do.

<>Whirlwind use. Generality allows systems to be used for some different purposes than those intended. Whirlwind was built to demonstrate the SAGE air defense system, the forerunner of modern air traffic control. In addition, Whirlwind was used for at least two purposes not conceived in its design but that fell out of it: the first computer speech research and Linvill's work on digital control.

<>WW. Forrester was interested in sound engineering practices, stating, "Experimental equipment, merely for demonstration of principle and without inherent possibility of transformation to designs of value to others, does not meet the principle of systems engineering." MIT never got into the computer business -- but the Whirlwind did provide many businesses with proven designs and trained engineers.

<>WW Module. The Whirlwind modules were taken verbatim by Burroughs and by ERA for the 1101, and the machine itself was built by IBM to serve the SAGE system. ENIAC was the breadboard for the UNIVAC machines. These real, engineered efforts at universities were significant spurs to American industry, the economy, and computing.

<>WW. Forrester not only realized computers should be used but that understanding and training about a revolutionary new device requires the device. Can you conceive of universities without the computer? In 1948 that was the case. Forrester argued: "If a high speed computer capable of 1 to 20 thousand instructions per second were sitting here today, it would be nearly two years before the machines were in effective and efficient operation. ... this represents one-half of the viscious cycle in which an adequate national interest in computer training cannot be developed until the equipment is actually available." I believe this two year period should be called the Forrester constant.

The problem is still here. The 1979 Feldman report argued for funding experimental computer science equipment. Universities still need more computing power for training tomorrow's pioneers.

<>Fortran. Perhaps the overwhelming reason to use computers before you build them is that Hardware follows Software. Nearly all mechanisms that appear in computer hardware structures start with software implementations. John Backus of IBM tells the story on the introduction of floating point. He observed that many customers were running their 701s with a floating-point interpreter, slowing the machine to 50 multiplications were second. He tried to get the engineers to include floating point hardware, but they were more interested in speeding up the drum. He then created, "The most incredible design for building floating point into the 704." It involved adding four or five new registers, which was unheard of in those days. At the next meeting of the engineering design committee, he remembers, "I stood up and spent an hour describing my insane design and people listened. At the next meeting Gene Amdahl got up and said, 'Backus, you're an absolute idiot; you can build in floating point without adding any registers at all to the computer, and it will cost almost nothing, and here's how to do it.' And that's how it happened."

<>Fortran marked..

On occasion, software may follow hardware. This is rare and often wrong. The first Fortran had instructions to manipulate the sense lights, sense switches and tape of the 704. Also, the DO loop was oriented to the index register instructions. Some of these primitives have stayed with us, but most were dropped. All the algorithmic languages should have been extended to handle vectors and arrays. Had this happened, we would have these operators in machines. The Cray 1 is causing this extension so that software is following hardware.

<>Drafting. Finally, use it and describe it so it can be evolved. Go around again. Those who build machines say it's like playing Pinball.

<>Pencils. The reward of building the machine is to build the next machine. No matter how good a design is the next one can always be better as Pentel, has shown in their evolution of the homely, but important pencil.

GEORGE BALL TALK
OFFENSIVE: A PERIOD DECAY

<u>WHO PAYS FOR THE 80s?</u>

G. BELL
10/13/80

Consider three islands: one manufactures goods, the second supplies energy, and the third is their customer and advisor. Since advice has no real economic value, the wealth will shift until the manufacturer and energy supplier own the customer.

How did we ever get in the position of being bought out?

As presumably the most intelligent and educated nation of people in the world, we think that everyone should have a high prestige job -- the ones that lawyers and mba's get -- without putting our intellectual resources to the supply of primary and secondary goods; thus becoming non-competitive in these areas. The pull is to the tertiary, sales and service sector, and to the quaternary, legal, education, and information sector, and into our national overhead, that is military spending that takes money and provides NO output.

Fundamentally, the US consumes and spends more than we produce or supply creating fundamental instability. We must have self sufficiency otherwise we have no base of power or influence, let alone the ability to own our own land!

We can achieve self sufficiency in the long run by changing practices to build for quality. The cathedrals that have stood 600 years are among the most cost effective buildings in the world with uses ranging from hospitals and schools to the most magnificent ceremonies. Our national automobile industry looking at short life and high maintenance costs is doomed -- they might have made out okay building for the sheiks if the Japanese had not come in with a quality product with lower operational cost, thus changing the rules of the game.

Self sufficiency is necessary for international power. Just remember the golden rule: He who has the gold rules. Since we have no gold, we can't rule. Consider the Japanese loan of 24B to China versus our loan of 2.4M. Who will China trade with and listen to? Certainly not the US State Department that has neither military teeth nor an economic base.

Our own military can smother us and further decrease self sufficiency both directly and indirectly. As we all know: productivity is output divided by input. Billions in to defense, nothing out, (except some sales to places like India that could blow up in our face). Self defense as an ultimate goal would lead to a military state and consume everyone's output. At present the situation is abysmal: DOD only sells hope, for defense...not defense. Furthermore, the secondary effects of the military are insidious. Business, universities and government conspire as a mutually supportive, non-questioning alliance. Universities are supported by defense grants and won't speak up. Businesses won't reject the military. They are good customers, selling paraphenailia in turn to Germany and Japan (our strongest manufacturing competitors for real goods). These countries have the advantage of then deploying their creative and productive work force to compete with us in real markets, not the business of building rusting and corroding junk to be maintained and obsoleted by massive military bureaucracies.

U.S. industry is no longer competitive, and hence there is no one to pay. We are being beaten from within due to an obsolete goal framework. The young in the U.S. are not challenged by the discipline and hard work associated with technology and manufacturing, the seamier kinds of work. Everyone wants to manage; to get ahead by increasing the roi. Right now the highest roi is achieved by marketing and distributing Japanese products like TRW, a large defense contractor and now Fujitsu's computer distributor. Our best people sell out to them, and we have no goal structure that stops us from committing this fundamental error. Recall the classic story of the Monkey's Paw:

> In this story an English working family sits down to dinner. The son leaves to work at a factory, and the old parents listen to the tales of their guest, a sergeant-major back from service in the Indian army. He tells of Indian magic and shows them a dried monkey's paw which, he says, is a talisman that has been endowed by an Indian holy man with the virtue of giving three wishes to each successive owner. This, he says, was to prove the folly of defying fate.
>
> He claims that he does not know the first two wishes of

the first owner, but only that the last was for death. He himself was the second owner but his experiences were too terrible to relate. He is about to cast the paw on the fire when his host retrieves it and despite all the sergeant-major can do, wishes for 200 pounds.

Shortly thereafter there is a knock at the door. A solemn gentlemen is there from the company that has employed his son and, as gently as he can, breaks the news that the son has been killed in an accident at the factory. Without recognizing any responsibility in the matter, the company offers its sympathy and 200 pounds.

If you ask for 200 pounds and don't express the condition that you do not wish it at the cost of the life of your son, 200 pounds you will get whether your son lives or dies. What kind of an environment do we leave?

The Bad News is that we won't make it: we will be bought out. The Good News is that we can have a back up strategy based on three ideas:

1. Let's recognizie that we're the smart ones and have fun-- let the Foreigners be the working stiffs supplying us with goods and energy. I'm confident that young people will discover that inventing and engineering can be more interesting than twiddling the roi functions that are really pretty dull and playing the semantic accounting games that lawyers and politicians play. Then we'll be ready to build things again if we have to and can remember how to work.

2. Let's use computers to keep good control of who owns our resources. Let the Japanese teach us, and even own us as indicated by the three island model. They'll probably do a better job.

3. Let's remember the banana republics. When we're ready and if they don't treat us right we can simply kick the 'em out.

GB1.S7.31
10/13/80
Ken Olsen

The engineering group is kind of nervous this morning and in order to make them at ease we've given cards to this table and they're going to rate every speaker from one to ten and we'll keep score up here as to how they do.

You see they have a tendency to try and make elegant presentations and some of them have prepared colored slides and they really wanted to sound like brilliant technical people and even Gordon finally got around to making some graphs on semilog paper. In the Woods Committee the Operations Committee jumped all over Gordon. With his truly brilliant graphs he put a lot of things in perspective. It was the inconsistency between what he was saying and what he said when he read off the specifications of IBM's new machine. He said "We'll kill em -- We'll kill em"; but he didn't put that in his strategy. All his brilliance didn't show how we're going to get IBM. So yesterday we really shook up the engineering people. We said what we really want to know is what are you going to do to get IBM. Now this kind of upset them because all the colored slides that showed how brilliant they were didn't show how we're going to get IBM. Now you guys in the audience (most of you) are part of the problem because you always want to work on certain hard problems and skip the whole strategy. They know what you want. There are some questions to which there are not obvious answers to because it doesn't make any difference which way we go. You could flip a coin and after ten years it makes no difference.

Like - Do we do all our commercial work on the 2020 or all our commercial work on the VAX or do we do it on both. In twenty years it would make no difference. In five years it would make no difference. We as a group of technical people would love to spend the next five years arguing that question. It almost seems unethical not to settle that one first. Meanwhile, we'd be dead because we don't have a plan. Now what we're trying to get engineers to do today is if they don't sound like they've got the slick presentation, we want to know what the strategy is to get IBM or protect ourselves from IBM.

IBM has an awful lot of money but they don't have much experience in our market. Gordon is convinced we've got everything. Now without much notice we've changed their presentations to try to figure out a way how we're really going to get our act together to do just the right things and don't leave any room for the competition. Don't trap people on the hard questions that don't make any difference which way you go. It's sort of like taking your kids to MacDonalds -- Do you get a whopper or a double hamburger. You can spend all day arguing over that question and it doesn't make a bit of difference. There are more important questions. Now lets see if we can stick with the important questions. How are we going to leave no room for the competition? And if anything looks hard forget it -- remember, it probably doesn't make any difference at all. And make sure we have plan. Now, I hope they didn't prepare too carefully. I'm a little worried about their slides. I gave a presentation with Cal Mowen ?? at the Chicago financial analysts a few years ago. And my daughter and her husband were going to school there so we got them invited to the luncheon. I prepared particularly well for that talk; maybe because my daughter and her husband were there. I wrote it out and it was a good speech. My daughter afterwards said "that was a terrible speech - the only good part was in the middle where you had to break and ad lib something". So, if they're not completely prepared, I think it's going to be better because we'll get what they're really thinking. So, encourage them, say the questions, make sure we stick with strategy, not just the hard questions which have been an excuse to keep us from doing marketing and sometimes an excuse to keep from doing engineering for many years. Let's get on and leave no room for the competition.

Gordon Bell

I want to start by introducing two people whom I invited with Andy's approval and the host's approval. They are Bill Strecker and Dave Cutler who are senior consulting engineers. There are only two of them in the Company so, in fact, you can tell they're important. This is the highest rank we have within engineering for people who do things. We give other kinds of titles for engineers who manage. The purpose of the managers, of course, is to make an environment where these people can really do work. Bill Strecker is the VAX architect and in addition provides a lot of the technical basis for many of our machines, including the 11/70 and how those machines operate. Dave Cutler is both the software architect of RSX-11M initially and now most recently VMS. This title of "senior consulting engineer" is not very well defined. Personnel go wild of course because it's not defined with all the sheets and things, but it's a secret process by which I have to approve it, somebody has to recommend it and then I tell Ken and that's how they get there. What the real meaning I'm coming to is, however is that if the products that they're involved in are really of key significance and probably sell over a billion dollars then that's good enough for me for a title. So I'd like you to welcome these two people to the group.

Now on with the strategy. I'm starting from a competitive standpoint. This is the IBM A100 which is essentially last in competition. It's the only product outside of a selectric that I think I would personally want that IBM has ever made. I have several selectrics and I hope our new typewriter of the third world will do us well so that I can get rid of the selectrics. It's a very impressive piece of hardware: four megabyte address space, low cost, $29,000 for half a megabyte of memory and a 60 megabyte disk vs what we're looking at for about 100K right now and it's right in our heartland if you looked at where we're getting our revenue, very good communications and I think our communications is probably down in the 1961 era. That's the last time I did a piece of communications hardware and it seems to all be patterned after that. There's an incredibly good range of peripherals for both the office and the factory and then they've got some unbundled software for other things.

On the surface that's an excellent product and IBM will make a bundle with it. On the other hand, here's (by the way, I'm not an IBM watcher and if you spend all your time looking at IBM or even much time this is about as much as I know, then we're sure doomed for failure because we don't have time to do anything else -- just looking at IBM would take all of our time) IBM 80-100. It looks like (what we've found) IBM has a lot of Digital watchers and this is why I want to go into what they've got now. I don't even know the price ranges here but this is like $10,000, $100,000 megabuck and ten megabucks. So the 370/360 architectures 370 architectures in here. Here are the 3031's, 3032's, and so on. This is what all the plug compatible people are going after. There are a lot of operating systems in that range all of which are incompatible and there's an 80/100. This is a new 80/100 which comes down in this range. Very neat products for something called distributed processing. This is done by the data products group. If you go down here, there's essentially the distributed processing group which is doing system 7, 3-15, and 32 34 and I don't know where their prices fall but their in there somewhere. It looks about like that with the accuracy of my felt tip pen. And of course, since somebody told them why Digital was getting all the market they had to get a mini and so there's the mini. Then there's a personal computer and they built a 5110 which is down there. Somebody ought to tell them you've really got to have a computer in a terminal and hopefully they will respond to that and put in something like the PDT's. So, in fact, it looks like they have really watched us and they've emulated our strategy and have every possible way of doing everything with a whole bunch of organizations. In my view, there is no way to distributed processsing with that. My marketing actually consists of the last customer that I talked to. I want to be very up front about it. On Wednesday I talked to a customer and he wanted a lot of (of course this is the peverbial if we do this he's going to buy a lot of computers and so on and this a customer billing PBX's, this is AT&T) and essentially what they said is something that at least I feel too and this the strategy that I put forward on Monday (or Tuesday or Wednesday) of the Operations Committee. Essentially, we're the only ones who have the basic architecture in VAX to cover the range we need for distributed processing. Why don't you build it? Give us a truly compatible range of VAX machines. Don't corrupt it like you did on the 11. We want a range of machines. That is something that a program will run on any of those machines and they said start with something that's about ten times the 3033 in power. Something with current 780 and then going down with the number of machines here with a VAX on a chip or terminal use. Their software base is much much greater than their hardware base. Cpu's tend to be about 4% of the cost. And then they wanted realiable secure computers for the system. Something that we're just dabbling in now. And, here was thing because they said hey, if you're having trouble funding it, we'll put up the money for a couple of your products. So we're ready to go outside to get some funding here for some of these products, I believe. I sat in on a DuPont presentation and they had basically the same requirements. The strategy of the day before that I had outlined was essentially this which is: the main part of this is to provide a compatible set of distributed computing products and that got ammended to be products on VAX 11 so provided a compatible VAX 11 set of distributed computing products so a user can compute in a transparent fashion in any of the following styles and sizes without extra programming or extra work. Either within the terminal small local shared system for a group or in a large system serving several groups. There's a style of computing here that's an economic style that you apply the machine where the work is and if the database gets distributed appropriately. So, it's this and that's in essence what the strategy proposal is.

In terms of what that means, I'm going to get down into hardware but essentially some of you might ask "Why have one architecture?" and I don't want to be too contencious with Ken today but we have a number of architectures and we have DECnet and we try to link them all together in that way and I think we do probably a most impressive job of being able to have those machines communicate.

There is an issue of sort of volume and learning curves in terms of whether we have a special system. Whether we go and market in what is fundamentally a special systems way or whether we're big engough in every area and every system that we make ala IBM, namely everything. IBM can do about any product they want in a point space because presumably they're big enough to not care. But in fact we observe that we've got a thing called 10% learning curves on most of our products which means that every time you double the volume you get 10% less cost. You build two products in exactly in the same then it turns out that you paid 10% more for each of those products which means that your fundamentally more uncompetitive in that way.

There is a technical reason and that is that it really is the only way to build the distributed systems that I'm talking about. That is, if you want to compute dynamically or even statically and move jobs from machine to machine there has to be much more compatibility than we have right now. Right now we're spending most of our machine power in communications -- that is, translating from machine to machine we've got to get a lot more basic level of compatibility. Formats are different, answers are different; if you fundamentally start with a multi-machine, then tie it together with the DECnet. So, in fact, I believe distributed processing as I know it or as I want to know is: we're not there, we're just in the embryotic stage. I believe must have a single family and it's clear to me that IBM is absolutely going down a disasterous path vis a vis their approach to distributed processing because it's going to introduce so much overhead in the way computing is done. I would also point that, in fact, some of our profitable competitors, DG and PRIME, have single architectures and it really is a bitch competing with that and even HP is beginning to close their ranks. I like, frankly, to build something besides cpu's and operating systems.

On the issue of why I am basing the strategy on VAX -- We designed it for a wide range of use, that is, the idea of implementing a bunch of machines over like a 1,000 to 1 range. What does that mean? It means that we have plenty of address bits so that we can address a lot of objects. We can't address all the objects that you would have in a network -- too much. But, in fact, there's a reasonable address space here like four billion things. So there's kind of an issue of addressing that we can really look at a whole bunch of things. There's a very contentious issue that you may hear something and if don't if this works small page size if you get into an argument with somebody and they say well your page size is too small, let me recommend an excellent book called "Computer Engineering" which has just been published by Digital Press that discusses this to a certain degree. But, fundamentally the issue of that was to allow one to build small programs so that we really did orient the architecture so that we could build a computer in a terminal and have it be transparent in this network space. We did also something called very good encoding. That is we took the primary language constructs and put them in hardware and assuming we believed that the hardware for the processor was going to be cheaper and cheapter in the future and in fact it is. So that if you compare us say with the 370 or you compare us with actually even a PDP-10, what happens here while still having much addresses we are able to encode the same programs in somewhere around a half the space. So half the space you say, well half the space -- memory is cheap, it doesn't matter, who cares? Well it turns out the memory cheap argument is one thing but it turns out every three years, that is at 20% reduction per year which is what memory does. You got memory to the dollar now, next year it will be .8 and the year after that it will be .64 and the year after it's like .51 so you could say well all I have to do is wait three years and I'll have a competitive product. So for starters, we got like three years on IBM just in that encoding alone, namely, we can express the same problem in the scrunched space. There are problems that in fact if it's all data of course that doesn't hold. But basically we've paid a lot of attention here and that helps in the small systems area but the interesting thing is that it really helps in the high performance end too because it means there's less bits to move around so that essentially big jobs are smaller and you can get the work done faster. We have a lot of data types that give a lot of power and essentially it builds on the 11 base. And also IBM told us in 1964 when those three guys went up on the mountain in New York state that the world should be an 8-bit byte. Well, we didn't totally believe them but we believed them enough to build the 11 that way.

What does this mean? What am I proposing? Fundamentally, here is the product strategy that I would like to see and I think this is the way to get at the products like the 8100 so in the 81-82 time frame I'd like to have a minimum hardware and sofware VAX and 11 systems and then a phasing with VAX and 11 with the appropriate size and the compatiblity priced disks. So we've really got to build disk systems at this point phasing over to probably a VAX only strategy by '85 or whenever it's appropriate. That's strictly technologies issue in terms of when is really cost effective to do that. We've already made the decision in the high end through this last strategy thing. And then the other is I want a really stay below the $250,000 selling price level just for a number of reasons because that's where we are right now and also that that turns out to be a system that is really a nice size system because it goes into the group level and 250K is about what it costs to operate a professional in an organization if you amortize this over a few years it turns out that's like one other person. So it means an easy decision in terms of whether you want a computer in your group or not. I tend to think of computers as should be useful helpful things. This means, here I say I'd like to see the sort of 81-82 time frame essentially base hardware that looks like this. 780 this a thing called superstar which essentially is an echo base machine at the current price leve, not the $250,000 price level. I want to warn us here that we had a fellow with us called Len Hughes who just went to SEL. Well Len was in the semiconductor area and Len happened to be working in with Motorola on the echo work there and Len knows all about what we knew about the echo chips and we can be damn sure that we're going to see an SEL machine in probably two years when Len goes down there and drives them and they get that machine. If anyone wants to bet since this is off DEC premise and I think that's illegal I would certainly be amenable to wagering in this particular thing. I know Ken says you can never predict the future but I'm willing to go out on a limb in this particular case. After all we did train Len and I think I know how he thinks in this domain and if he doesn't think that way, SEL will. So first there would be a machine at a central kind of level which is essentially the level that we've got got now. There's a machine here at ???group level which is essentially a machine that we're building called common hydra -- you'll hear more about those. In the 11 domain we're going to introduce shortly a really very hot commercial machine. That is a machine with the instruction set that's oriented more to Cobol. In fact I just got the performance figures on that last night. I think it's going to be a very respectable machine here. We're also introducing a multiprocessor system there. Down here at the group level, here is the machine I would use. I'd get that thing out, put a disk with it and add a half megabyte of memory and sell it for like $20,000. That's what I'd do. We could do that very easily, get it in there and go after the bloody 8100. We would make pulp out of the 8100 if we did that. It would be so terrific. It's embarrasingly trivial to do.

Our pride would probably get in our way because it's so easy.

LSI VAX and that's one that's really important in terms of getting some technology base and using it at the personal level. And I really think it's important to put the computers in the terminal as we've started with PDP's and as we would do in the future. On the 11 side we've got various LSI replacements that will be available in those same time scales. Which are the machines that if you can't move an application then one would stay on 11 in a much more bounded way. So we would give a choice there for quite some time.

Basic software strategy is fundamentally 11 enhancements, that is either decreasing or sustaining funds in IES, RSTS the high end RT. I want to use DM, SES, TRAX as a base for compatibility with VAX. And that is, we're not doing this right now. I want to be able to build current 11 program based and move in exactly on to VAX in the commerical domain and in the TRAX and in the real time area. Those programs have to be built so that anything we do there move over. Layered modular operating systems for specific applications -- that is really treat it oriented to domains which means to us a common program interface so that one can write a program in any one of these computational styles and then run it within another system or in another operating system. Common utilities and languages so that we don't have redundant efforts there and that we have compatibility and then common drivers so that we don't have a range of hardware support problems. Right now we have a system called VMS which I would call a general purpose base pretty much for interactive computing. There are some things to do to make that more toward VAX those can be added. There are some things that perhaps we might to make it more oriented to some of the time sharing facilities although it's quite good in that domain. TRAX 32 which is an upward compatible version of the TRAX that we've just announced for transaction processing and then some very small tuned real time systems for the real time market.

I'm assuming the BASIC+ is something that our users -- we've got an incredible base there vis a vis RSTS. I want to be able to provide an export import package that is a way of moving from this system to that system which really means a file transportation mechanism so that and this would mean that we would have a language on VAX. WE would have the same facilities and the same utilities at at least the current performance levels so that users could take those programs they've written, protect that investment base they have in RSTS for BASIC+ programming. Not RSTS programming -- BASIC+ programming. Move them over. And then the key to the whole thing is really building a distributed data base, distributed file systems so that we can really network in the way that I'm advocating.

There's other parts to the system and that includes some other base hardware things to make a system like this go. And that means first getting a really cost effective communication system via some form of a multidrop or loop kind of network. IBM's announcement had a loop approach. There are two or three other approaches. We happen to use multidrop. We must have this kind of capability. IPG has a multidrop ??up there?? and we'd use something like that. Much higher speed because in addition to the terminals I think it's essential that we have all the peripherals or most of the peripherals and that we couple to other small systems. That is, compute in the terminals. This, incidentally, because of the nature of this communication allows a drop shipment. In this way we essentially can plug together systems that are really going to work at a customer site simply by the nature of that serial communication link. We have terminals with software support for and I'll say first that the theme we came up with yesterday or something, and we didn't even have a marketing person there, is we need a good word. With the persistence we're putting in, we want everyone to have a terminal. Where a computer is located within a group, everyone's got to be on the terminal, so in essence that means having a lot of the current dumb terminals that we have today -- I think they've got to be generally block mood oriented because we're wiping out our systems -- that is transmits data by block instead of a character at a time. Our systems are dying because of our interactive heritage here and they've got to be low cost and cheap so we want a manufacturing posture that's aimed at high volume.

In addition there's an issue of having these programs or these terminals for different environments. The key thing is the office environment here and this is a printing and how to do that whether its a letter quality kind of thing ala the queme the weelies or whether one using the acupuncture approach and lots and lots of pins and does it in a Digital fashion, but that looks quite good. I hope we can do it the Digital way. I think it's the right way to do it because it gets us graphics, it gets us one product, it gets us volume, it gets us a more reliable system, it gets us a quiet system. The letter quality things really make a racket. The other thing is a page crt for word processing and then a terminal here that I hope Dick was going to show. I don't know whether he did or not. This is a modern graphics calculator word processor for what all of us would have. That is, it deals with vectors, it deals with matrices, it deals with tape tables. It's a calculator and once you calculate on a table it then displays the results in pi charts or graphs or what have you. In a factor environment we clearly have to have the terminals and the interface. So that's all I have. That's a framework for looking at this, looking at the various sizes of systems and technologies and for looking at software.

John Kevill

I'd like us through the strategy that we're on in three areas: hard disk, floppy disk, and tape; where we're making the investment today, where the technology's going, and where I believe DEC has to go. In floppy disk, we're trying to track the independent suppliers of floppy disks; Shuggart, Memorex, Calcomp. We are not up with the state-of-the-art and in the next three years we need to close that. If we look at the volumes you're projecting, we're talking about 50,000 to 75,000 floppy spindles a year. It's definitely we have to leverage and get control of. I can't speak for our progress -- we've had some problems.

In the disk area, we've split it up into three areas. I believe clearly with the introduction of the RL and later this year the introduction of the RL02 we have got a leadership product on the low end. In my experience, I believe we're building the lowest production cost removeable disk drive in the world. I know we're beating some former companies I was associated with. I believe we have techniques that we can apply to the low end to cut our costs even lower. The key is volume and automation. If any of you have been to Rockrimon, they are producing a production out there which is to give us excellent costs on our low end disks. Today in the mid-range DEC is investing the maximum amount of money that I spend in the product called the R80 and I'll talk about this product in detail later. That's where we're stepping out of the volkswagen era and into the Grand Prix race car era. It's the highest technology product in disks this company has ever attempted to product and it's a major step forward. We also believe we cannot abandon the mid-range removeable market. The architectures Gordon is talking about I believe will require some media removeable. So we're making a concentration in two areas in that market of fixed disk high technology and a removeable media drive to be its companion.

In the high end we are in a position today of buy-out. However, when I make the R80 I will have gone some 80 to 90% of the way towards a large disk. Mechanics set has to change. We've done the basic technology work. I believe, given the success of that product, we can talk about making high end disks large capacity for the large system market as a family concept on top of our mid-range investment.

In the tape area, we are evolving to $62.50 per coated recording. It's becoming the industry standard. It will be the major data interchange path. Today it is the only way we data interchange with an IBM computer and we believe it's important. It's a buy-out program at the current time. I don't believe we possess the technical capacity to take it on at this point. We're short engineers who understand tape technology. We have chosen to build a low end product that's come through a significant piece of difficulty but it's on the road to success.

In the tape sub-system area, as we go into large capacity fixed disks, we have to back them up some way. We've got to be able to get the data off. We're going to have to tie our high end tapes and our disks together in some sub-system intelligence which can move the data back and forth between tape and disk and back our high end up.

When I look at disk metrics and how we measure them, we can come down here. I want you to point to the top one. It is the most important measurement of the disk, aerial density, tracks per inch ?? bit per inch. It starts with the media and heads. It's the most important entity we have to design a product. It is the one which we have the lease control over today. And a major piece of my strategy is to make Digital independent and capable of supplying its own media and heads. Today we've got to wait for somebody else to develop the surface technology and the head technology in order to design a product around it. That means we do not control technology entry point in a product that I think we're making a lot of money off of.

When I look at the high end of the line, we measure the performance of the disk at cost per megabyte. But cost isn't a linear function and when I go to the low end of the line I've got to talk about an entry price.

We're trying to restructure, at this point, mass storage engineering so we have a group focussed on low cost at the low end. There are some things we have to do. Dick and I have talked about this. We've got to start integrating mass storage or the storage products in terminals and small systems in with the system.

A COMPUTER STRUCTURE TAXONOMY WITH A CRITIQUE OF THE STRUCTURES

A taxonomy of computer structures is given in Fig. ? designed to show the difference in hardware approaches for providing computational parallelism. The PMS notation and definitions are used to form the taxonomy:

Csimplecomputer := Pc - Mp - Xio

Cmultiprocessor := Pc(1:n) - S - Mp

Xio _
Pcprocessor := Kprog - Dpe (a controller

Mpmemory (for program and data) := Mpr|Md

S

Quite surprisingly, there are only four different approaches to obtain parallelism:

The single instruction processor which

Subject: COMMENTS ON THE TAXX

To: Mike Leis
Bob Peyton
Chuck Youse

Date: 10/21/77
From: Gordon Bell
Dept: OOD
Loc.: ML12-1
Ext.: 2236

Follow Up 11/5/77

I'm delighted to see a really tiny structure for the TAXX mechanics. Let's hope the real thing is like the breadboard. As we move into the final definition of the product, I hope we can keep our options open vis a vis packaging for the multiple possible uses. Let's make this an OEMable component and get the whole market since there are NO competitive suppliers!

The goal should be to allow sales and/or use of the unit in any of the following configurations:

1. <u>OEM mechanics only, no electronics</u>. Here, a user would use our recommended r/w electronics, interface and algorithms to control the tape. The algorithm would be specified in either or both 11 and 8080 code. This would cost $50 (at the outside) and sell for $100.

2. <u>An interface that would get out to an 8080/T-11 bus</u> so that the host computer would control it. The characters are assembled in the interface. Here we probably should assemble characters versus bit-banging simply to give the most flexibility in the program and operate the system at full tape speed (E.g. suppose this is the way the cassette is integrated into the LA or VT100). This would give a system cost of only $125 and maybe sell for $250. People like Heathkit might even buy at this level.

3. <u>A fully integrated system</u> as you are proposing with all the electronics <u>on 1 board</u> and <u>coming out to a serial/line</u>. This would be packaged in several configurations, depending on the use, or people would integrate it into products in a more expensive fashion. Preferrably the control computer would be a T-11! (We must continue the prototype and layout with the 8085 however. T-11 designers note how great it would be if we could simply plug in a T-11 (8-bit mode) <u>with no board</u> <u>change</u>. Please consider helping do this!)

4. <u>A basic computer system or a performance enhancement</u>. This would have options to 3 for a second serial line and to enhance performance using as much CCD or RAM buffering as needed. This would give us the performance and line splice market. Applications programs such as the BSR should also run in the splice simply to reduce cost. Here, we need a version that is implemented with the T-11 (versus 8080) for doing fancier applications and giving file support.

Note with a T-11, a user merely adds a terminal and he has his own computer system...in a fashion identical to the RXT11. (TA versus floppy--the cost for the system would hopefully be 1/2 that of RXT11)

What do others think?

What is the right direction?

SUBJECT: TECH. COMP CENTER FOR BENCHMARKING AND EXPERIMENTING

We must set up this system in MR area so that we can start to

run
customer benchmarks and work on performance enchancements:

```
      _____________________________L(CI)____________________
     |                                                      |
     |----Pc+Mp--------------------------                   |
     |                   |.-------------|.---------Mp+Pc----|
     |                   Mp('MA780)     Mp('MA780)          |
     |                   |._____________|._________Mp+Pc----|
     |----Pc+Mp__________|______________|            +Pfps
     |----HSC
```

Where: Pc=11/780 CPU, Mp=Primary memory, L=Link, Pfps=FPS 164

This is two, 782's, connected via CI and having one system with
an FPS 164. It could be run as 1, 2, 3 or 4 computers, depending
on the number of operating systems used. It would come up as a
single system with Pfps, then a 782, a second 782 forming the 4
processor 782 and finally the CI.

The work would proceed in sequence for Uniprocessors, array
processing, microprogrammed extensions to VAX, multiprocessors
and multicomputers:

1. Benchmark the 780 and establish the set of benchmarks. Understand them and their operation on other computers.
2. Add the Pfps, benchmark and understand the performance.
3. Using 780 microprogramming and working with compiler and architecture people, make enhancements to the 780 both specifically and generally to the VAX architecture.

4. Open the multiprocessor for customer benchmarks. LASL's interested and might like to have one for

experimentation
among their 50 780's. Compare with others.

5. Work on multiprocessor benchmark enhancements.

6. Start the work on multicomputer understanding using CI and
especially HSC in terms of system throughput.

We aren't starting this crucial work. It would also sell VAX's.
We desperately need a leader to drive this both within and across
the various organizations: ESG/LDP, and VAX/VMS architecture (for
microprogramming tools and enhancements).

Can I please have a list of leaders, workers and projects?

THE ENGINEERING OF THE VAX-11 COMPUTING ENVIRONMENT

ABSTRACT

The VAX-11 architectural design and implementation began in 1975 with the goals of a wide range of system sizes and different styles of use. While much of the implementation has been "as planned", various nodes (eg. computers, disk servers) and combined structures (eg. clusters) have evolved in response to the technology forces, user requirements and constraints. The future offers even more possibilities for interesting structures.

follow up 5/30/78

- Someone I can talk with regarding technology and use (needs in products) -- respected in technical community.

- A staff role...responsible for measuring/controlling our technology resources just as we do with people (personnel), space, and $(controller).

- Monitors and characterizes technology capabilities of groups including productivity.

- Owns R&D, RAD process money.

- Matrixed into existing or future organization (e.g., NMOS, Bipolar, ECL Technology, System Development Managers).

· Maintains directory of standards and procedures

? Architecture role-up

? Entire space of tau = Res, A/D, Dev, Product support, Mid-life kicker

? Responsible for past sins, ala chief engineer, problems, etc.

· Entire levels-of-integration

· Entire processes/products -- stays out of product development except to evaluate

? Reviews special programs: RAMP, RAMEP, PAMP, Packaged System Program (PSP).

· If we have TEE POT (see attached), he is Strategy Manager.

16:38:40 050 1
To: Jim Cudmore
From: Gordon Bell
Date: TUE 3-JUL-79 16:38:40 ED
Subject: Presentation of technical papers

I'd like to get your paper on guidelines for technical papers more widely
accepted within ood.   I would eliminate any reference to discussing product
ideas before they product comes out!

I am really pissed about the paper on Comet your people are putting out
becau

1. They should be working on the product..not wasting time on the paper 2.
Bittner, who is apparently the presenter of the paper is giving the paper is
giving something on which he has no jurisdiction or authority and he did not
even do the work. The Comet CAD stuff was not his work...he should not
present this work It is immoral and unprofessional and should get you a lot
of professional rivalries..which are justifiable 3. No, NEVER talk about
the product until it is done! 4. The COMET is not at the state of the art,
even if it did work as a circuit. It will get a polite yawn. When we ain't
got taht much to how being mysterious is a hell of a lot better.

5. the Fonz
stuff is pretty good, the product is interesting and the work should be
described.

Subject: **A Quick Analysis of The Cost of New Products**

To: Bruno Durr, PK3-2/S56
Gene Gross, PK3-2/A55
Ted Johnson, PK3-2/A55
Gerry Moore, PK3-2/A66
Dick Pascal, PK3-2/A66
Jack Shields, PK3-2/A58

Date: 30 OCT 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 11/13/78

I have posited a product strategy that aims to minimize the number of products that we sell and support. In presenting the strategy to the Ted Johnson staff, the intent was to get specific criticism of it, and possibly gain general support. The lack of useful response was frustrating, but I realize the conflict between the service organizations that want a small number of products and sales who want more products and to keep all products.

Now, I would like to ask you for help in trying to analyze the effect of the current and proposed product strategy. This could take various forms, but perhaps the simplest way would be to study the effect of the multiplicity of say VAX, 11/70-74, and 2020 so as to be concrete. Here, I would ask, what would the start-up be if we only had just 1 or 2 of these? (Say, eliminate the 2020 and study what the costs would have been.) I'd like to see this in all three of the organizations, and I would hope that it isn't a big deal, that is you can just send me information now or do a back-of-the-envelope analysis to prove or disprove the point.

Let me reiterate. Could I emplore you to send me a simple analysis on multi or incremental product sales, field service, and software support effects (cost, efficiency, profitability, inventory, or whatever)?

Help!

Mr. Edward A. Feigenbaum
Teknowledge Inc.
525 University Avenue
Palo Alto, California 94301

Dear Ed:

I thoroughly enjoyed the interaction with the Teknowledge Advisory Board and Board of Directors and hope my inputs were useful. Enclosed are comments on the questionnaire. Teknowledge has the highest fraction of capable individuals devoted to a single enterprise that I've ever seen.

Teknowledge's share of my expenses for the trip were (DEC will pay the rest):

Airfare (one way)	$405.00
Hotel	80.13
Taxi to S.F. Airport	32.00
Total	$517.13

I'm requesting that the DEC BOD allow me to serve on Teknowledge's Advisory Board.

Sincerely,

Gordon Bell
Vice President of Engineering

MESSAGE ID: 5191029518

SUBJECT: TEKNOWLEDGE TECHNOLOGY BOARD PRODUCT INPUT

GB4.S1.33

I'm on this board which meets quarterly, on Saturdays in Palo Alto.

They're looking for a workstation on which to build their product.
They'd OEM this. The current list of candidate hardware in

order:

1. HP 98 with bit map. Can have up to 8 Mbytes. Uses 68K, expect
68020. Good image. Lots of options. Good company. Runs UNIX.

2. IBM 9000 uses 68K -- may not have enough storage -- but CMU may
help 'em and provide SPICE.

3. SUN Workstation -- Forest's 68K based system that Stanford
licensed to many vendors.

4. Apollo -- when the new prices hit, this may be a competitor.

5. DEC -- ? Good supplier. Like VAX. No product.

6. Xerox -- Good product, but company's impossible.

I said we'd like to sell them a product. They weren't convinced MicroVAX was the way to go, until I told them about range. Unfortunately, all of them spent their lives on 20's and they all want their own, private stations !

I believe HP may wind up with the order, if they go this way because Portable Standard LISP (PSL) IS BEING USED BY HP RESEARCH LABS NOW. It runs at about 1/2 x 780 using the 68K at 12 Mhz. For 50K, one gets B/W, color at 3 bits/pixel.

I'm arguing that they should distribute a PSL for several systems and not get into the proprietary workstation business. They might also put up GLISP on top to improve the programming environment. They'll put up other utilities.

They're looking for various packages including screen drivers, etc.
Raj Reddy recommends IBM's/CMU Canvas -- based on Spice.

We should sell them our tools, like FMS, CMS, etc. to facilitate programming.

Let's go out there and get the order.

E41

SUBJECT: TELECONFERENCING STRATTON V: EXCEPTION TO PLAN

LORRIN GALE HAS BEEN ADVOCATING THE USE OF TELECONFERENCING FOR STRATTON V TO INCREASE THE AMOUNT OF OVERALL PARTICIPATION.
HE HAS BEEN IN CHARGE OF A SUB-COMMITTEE THAT HAS BEEN DIS-CUSSING THE FEASIBILITY AND COST OF LINKING SIX SITES (TEWKSBURY, MERRIMACK, COLORADO SPRINGS, MARLBORO, AND TWO

IN MAYNARD) TO STRATTON, THEREBY ADDING ABOUT 250 PEOPLE
TO THE MEETING. THE COST IS EXPECTED TO BE IN THE $50K-$75K
RANGE.

THIS COST WAS NOT INCLUDED IN THE ORIGINAL STRATTON BUDGET PRESENTED TO OOD ON 20 DECEMBER 1979. HOWEVER, LORRIN SAYS HE HAS DISCUSSED THIS WITH GORDON AND HAS RECEIVED APPROVAL TO SPEND AN ADDITIONAL $50K.

IN ORDER TO MONITOR THE TELECONFERENCING EXPENSES, AND EVENTUALLY TO ANALYZE ITS COST EFFECTIVENESS/RETURN, I AM ESTABLISHING A SECOND STRATTON PROJECT ACCOUNT, SEPARATE FROM THE ORIGINAL APPROVED STRATTON BUDGET. IN EFFECT, I FEEL ACCOUNTABLE TO MANAGE OUR APPROVED FUNDING LEVEL, I ALSO AM ALERTING YOU TO AN OVERRUN AS A RESULT OF TELECONFERENCING.
SINCE I HAVE NOT RECEIVED ANY NOTIFICATION OF ADDITIONAL FUNDS
BEING ALLOCATED, NOR ANY FEEDBACK REGARDING THE USE OF TELE-CONFERENCING PER SE (EXCEPT IN A 2/15/80 MEMO FROM LORRIN REFERING TO A CONVERSATION HE HAS HAD WITH GORDON), I AM, AT THIS TIME, TREATING TELECONFERENCING AS AN EXCEPTION TO PLAN.

SUBJECT: RE: TELECONFERENCING

I would fundamentally like to see a video link that includes Marlboro, Spitbrook Rd, Merrimack, Tewksbury, and Hudson. IN my planning thoughts, this is part of a backbone link that goes up 495, perhaps with Hudson a switching center for MR

and
Maynard.

I couldn't be more frustrated with our leadership, or rather lack thereof in telecommunications on this point. I had hoped
and assumed we would have our first experimental data point between ML and MK by now such that we would be in this next planning and implementation phase.

It is important to point out that the microwave link was proposed in 75 and could have been easily installed then, it had a year to payback at that point, I believe, assuming it carried some voice. Now it probably can't be installed (it takes multi approvals), and we are forced to go with the phone company and they will put it to us in the future vis a vis tariff, making the whole thing only a factor of 2 or so better than the helicopters.

The bottom line: yes, I believe we need it; I'm going on a limb, assuming this is going to be a useful service/facility that will pay off. You have my support, but that ain't worth a hell of a lot when dealing with the communications morass. Please try and get it done, the more who try to push the spaghetti, the more chance we have of something moving.

Good luck!
gordon

SUBJECT: HIGH PRICED TELECONFERENCING DECISON

Please forgive me for not being able to fulfil my part of our agreement when I encouraged you to make the teleconferencing proposal. Please decide how to proceed and I will vigorously support you. I see three options:

1. Continue to wait and let nature take its course. Given your
recent MBA degree, watching this will be post graduate study.

2. Turn the project back to CORPORATE COMMUNICATIONS. Advise those responsible and get back to direct product engineering. Minimize interaction, especially recommending a colleague.

3. Forget the whole thing today and get back to products.

I believe option two is the best because:

.I see only risks.

.The project will have continued and interminable hassle through
AT&T, space (rooms), and all self-proclaimed television experts.
It seems to be the epitome of a self-stopping project, which everyone has enjoyed reviewing and stopping. I see no change.

.It might not work (remember the Picturephone?). Although great
for discussing rational things, it's not clear that as leaders we
can get our point across without being physically there.

.Video conferencing is part of a bureucratic morass which has no
clearly defined processes, criteria or documentation.

.There is no clear way to tradeoff among space, capital, expenses
or computers. Furthermore, there is no trade-off among these among customers and various DEC functions. I think it is vital
for it to follow the corporate guidelines for review.

.Finance who approves this, also runs Administration and the helicopters. We all love helicopters. Helicopters automatically
get the $'s using the linear growth model we use.

.It is a clear, new line item, albeit one which is only 0.1% of
the requests for capital. The first rule of budget trimming is
to cut the most visible, newest line item, especially if it is a
small one both to perpetuate the old and to feel good.

.Finance has no understanding or methodology to permit the tradeoff of capital for expense because they also operate Administration which always has infinite demand for its services
because the cost is zero. They can't understand the concept of
using direct expense budget to control it.

."Management" has at one time, probably "opinionized" on this and
as such everyone is afraid to either mention this or let us go
ahead, lest they get tarred by the same brush if it fails.

.When it is really obvious or when the phone company thinks it is
good for us, then it will be available. You might try to get the

phone company to build it as a service at an obscene rate.

.Communications is Al's responsibility. Please join me in continuing to encourage him into accepting this responsibility
and providing the service we should contract for.

.Not working on teleconferencing fits what I think is good practice for an engineer:

.Be productive and build things in an environment where you
are needed, appreciated and people know how to say yes (not
just no) and thank you.

.Avoid people and groups who practice irrational thought whether for reasons of size, their incompetence, my incompetence, or malice.

.Offer suggestions and help to those who have the responsibility so they may behave responsibly.

In short, enjoy building, help all understand and expand their own capabilites, but leave when the pot you're about to
be boiled in has fire under it.

.Most of all, we need your help on products, both Hypervax and
Suvax are important in terms of providing significant computing.

Let me know what you want me to do here.

Gordon

PS. You're right, it's a hell of a high price to pay for a large company. I don't intend to live within this kind of environment.

SUBJECT: WOULD LIKE YOUR HELP TO RESOLVE THIS CONLICT

I think I have followed the process for identifying conflict with
another member of the Operations Committee. Al and I talked about video conferencing for engineering several months ago. The
conclusion of the meeting was general agreement to go ahead with
the project subject to detailed review by Al and his troops. After no written feedback from Al, we met again last week. I could not detect that any review had taken place and that they
had only sat on the project. After this meeting, Al and I weren't even able to carry back the same report.

Larry and I thought the late June meeting results were:

1. Al's in favor of the project.
2. We (engineering) felt that it had sufficiently high
roi and benefit in terms of time for engineering, that we would
pay for it directly off the top of our budget in the next 2 years
as the analysis showed that we would end up spending less overall. Hence we would get more engineering done for same $'s
with less travel time and expenses.

From his ems on Monday Al added that "it must be included in FY
81 Capital Budget -- prioritized list -- for Corporate decision-making on what to exclude." I don't even know what the
hell that is, furthermore, I don't even know why he had

wasted
our time meeting to discuss the subject.

Subsequently I called Al, and learned a bit more: He implied you
were ambivalent on it, hence I believe he was. This is ok too,
but just tell me directly so we don't waste time.

Although you clearly have the perogative to live according to your own whims, I think it is important for the rest of us to have and use clear cut open rules. We simple engineers need them.

SUBJECT: TELECONFERENCING- I DOUBT IF A DECISION WILL BE MADE

Alan,
Al and we met with Larry finally when Al could do it.

Al sent a memo to me stating what he thought we agreed to, which
was not the same as we thought we agreed to. In essence it was:
1. He supported the proposal
2. It has to be done as part of the Capital Budgeting as part of the FY 81 to be part of someting called the priotitized list
as to what to include... as part of the corporate decision making.
3. We would be willing to reduce the Engineering budget over the
next two years to directly fund it.

We thought it was only items 1 and 3. We propoposed 3 simply to
show that it is possible to tradeoff expenses for capital when
one has a good plan. His memo after the meeting was a blow which
I will never recover from.

The offer was to reduce complexity and to show how one can
trade-off expenses for capital in a simple way got shoved
under the table.

Al, Win and Ken are running the company from building 10. All
decisions about Space, Who gets what equipment, and what the
capital equipment budget is are made there in what appears to
be closed, unclear processes in a top-down arbitrary way. The
fact that I thought I could approve a plan, or comit to a product
plan based on an expense budget (where capital or computers or
space is implied in the numbers) seems to be a farce, given that
these other variables are controlled somewhere else in an
arbitrary, capricious way. Somehow, I feel responsible for
results (including getting us better facilities) and that there
is no way to perform against these plans, is tying me in a knot,
and I don't want to be a party to wasting any more time on this...
either yours or mine. Therefore the answer is:

We should not bother to engage in anything having to do with
teleconferencing between ML and MK due to the problem of getting
any way to do the planning or approval of capital equipment. It
is a hell of a frustrating way to do anything.   This, like
computer equipment and space is another issue that I, nor my

peers can not discuss in any kind of rational fashion, let alone
straighten out.. Furthermore, I can not even read a memo or listen to what is generally a content free discussion on any of
these subjects because it is such a waste of time and so frustrating.

Order processing is an example of another such process but we in engineering have been spared this. I have been been only mildly harassed as a bystander, but have had to listen to the vacuous arguments.

My reasons why it is not worthwhile persisting any longer are based on a whole set of things:
1. None of these 3 areas have any formal processes, objectives
or responsible persons assigned to them, nor is there anyway of judging one proposal against another.
2. If there is any need to cut the budget, I believe it will be
this 400K, even though we will pay for it in 1 or 2 years (a
hell of a lot highert than some of the squirrely projects or capital that it would compete with. The cut is obvious because it
is a clear, line item. I recall us spending 30 minutses cutting
the library budget back to a flat budget (requiring layoff) severl
years ago, while allowing several fat, incompetent groups to grow
at a 20% rate, simply because "libraries can get out of control"...
despite my cries to the fact that our output in the library and
cost per unit output (books, information delivered) has been declining. At the same time we built a brand new library in a
building far away from here that spent more than the library budget.

The issue was that this part of a 20M$ expenditure where there
was no visibility as to the 50, 400K line items that formed it.

This year, I expect another 1 or 2 helicopters and airplanes to
be approved simply due to the linear growth way we do planning.
We've all liked these since our childhoods and will support getting
more due to the hassle we get into at airports and the fact that
we can't plan what to do if we have to drive or spend the time.
Never mind the fact that just this afternoon 10 people met
with Larry, BJ, and I this afternoon for 2 hours, with 2 hours
of driving to discuss the WPS Product development . (Here
we spent only about 10M, lost revenue of maybe 100M, and lost
some of the market share and customers that we need. All of
the concerned parti
parties who fouled it up will suffer probably with only 10%
raises and only average stock options granted worth about 5
times what a very good, unique individual contributor will
get for developing a product that will bring in 1-2 billion
in revenue.

3. We have gotten so big in some sort of sick way that the old
Do the right thing rule is absolute bullshit in light of mediocre
bureaucrats and people who only exist now to check on anyone
who comes forward with a proposition. I think we will get to
a situation soon where there won't be anyone coming forward.
Cutler is extremely concern, and I have to go off and work
with Jack Shields to find out why Jack requires 50 signatures
before a product can be released to the field. Presumebly
these 50 add something, but NONE are categorically capable,
in some real sense of tcarrying Dave's listings. Here, I don't
want Dave to leave, so this fight is not optional. If the 50

would leave, I think I would personally sponsor the going away
party, it's clearly not company policy to allow any rewards
like parties for jobs well done, except in the sales
department.

(Maybe we could get milk from this sacred cow because
teleconferencing obviously could be used to minimize these
needs. ... but don't hold your breath.)

4. We have to also support not only the checkers in 3, but also
the studiers in tgroups like telecommunications who are asking
when we should build such a system. I have tried to tell Al
that when he goes to play golf with all the other large
corporate executives who play with the real golf players that he
could really one up em by telling them about our
teleconferencing.
My guess is that we have spent more than 400K on studying
teleconferencing in Al's department alone to get paper.

This would get him pioints and even a golf game, but he's worried
about how he's going to make this big 4ooK decision in light of
a 400M request... and I'm glad he's worried. I'd be petrified
given our state of decision making, ability to discuss, to have
any clear criteria, etc. Therefore, again, I can't blame Al,
he's OK, it's just that the company did him in. Therefore he
has to say no to someone, and it had best be to you instead
of the 21M$ board shop in Phoenix.

5. We have to spend money doing dumb things like sandblasting
your conference rooms rather than putting insulation up which
would save money because there was a rule someplace apparently
and the space people are afraid to change anything that is
working becuase space has such high level concern about

what it is. This has resulted in more expensive buildings becaue
no one wants to make a mistake here. At a recent meeting a number of us were present who had earned our golden plummer's helper and golden shovel awards (I only have the plummer award,
but an honorary golden crowbar award... for taking care of the
Mill for a few years and for making a bunch of changes including
the sandblasting which apparently no one can undo now, just as
I had a bitch of a time doing the first one) You get the shovel
if you put up a building. We all agreed that it was the worst
experience that we had. We get all the bad things: relatively
expensive buildings and questionable results. The capital budgeting favors open offices and I am now ready to wquestion this wisdom given the noise, etc. But it appears to be cheap and you can write the furniture off in a few years.
Again, notice that we budget (control) the input, not the results.

6. Our capital is really stetched because of inordinately high
inventories. This comes about for a few simple reasons including
the way (where) we build (a design problem in manufacturing and
engineering), forecast (strictly bottom up by clerks with no concept of what people buy) , and flow (through every god damn
plant in the country and Far East) prodcucsts. This is a disaster of vast proportions.
There's conservatively about 150M in i
inventory carring charges and waste work in flowing products in this morass as a conservative estimate.

7. We can and do hire, creating expenses of vastly more than the 400K. A helicopter pilot creates a lifetime expense of

something like several million doollars, vastly more than this experiment. There is no process to validate hiring requests
versus capital equipment which we can get rid of through depreciation. People are a much greater drain. The good ones
get trained, tired and turned off (and leave). The slow ones just say no or ask others to do things. (One of the joys of work to me now is the museum and its because we all do work including putting on lectures, building exhibits, archiving, writing papers, understanding)... however, when I interface to
a large group to get a piece of equipment, or information or make a slide or a poster or generally do anything it is so depressing because there are intermediaries who manage and generally only screw things up. Again no concept of quality and
output, only input. For the 100K we spend, we do more work than
just the cost of the interface people alone. Now I begin to understand all those books nd papers on big bureucries and groups. I don't think DEC is especially worse, it's even better
than most, it's just the size and so we might as well all go back to our desks and cancel something. (There are some bad people though, one of the "management" in MR thought he was entitled to some of the building's plants, so he took them because he had the right as a part of his status and power.)

Well, Alan I am not going to help you anymore on this one. You have to decide whether you want to keep pushing. I still feel that it is very important process, but I have no idea what the so called prioritezed list - for Corporate desion -making on wh
what to exclude list is that Al told me about. Based on my past experience on space, buildings, getting computer equipment, getting EMS slots, ... etc. I can't begin to tell you when or how or where or who to talk with (Ken likes t make sure things like this are presold when the9 come before the Operations Committee, but make damn sure you do it carefully, because we all hate politics.) Buy I doubt if the Operations Committee will get involved in

this one because it's only 400K, unless there's a good chance to say no and let us show the world what hard headed, tough minded, results oriented, down tto earth, futuristic (Ted just went to the Aspen Institute), solid (we eat lots of carbos) business men we are. If you want to bring it before us, I'll gladly stand behind you (especially if you have presold it), and if it looks like it can't go through, then I'll probably be a hell of a long way behind you.

As to bringing in a competent person. If they are a friend and has to work in the middle of this dreary bunch, I say no because I think you should valuable your friendship more. If the person can work in anothe group where he can really feel good and get something accomplished, then why not get them there? On the other handthere are days I worry about getting things done i
too.   Which reminds me: I think it is time we got to work on the array processor in earnest. .. assuming we can somehow get the machine to use for this.

Let's really concentrate on projects that will produce results... my tendency is to forget the whole damn thing.

Let's get together and figure out the possibilities, there's never been a better time to do engineering.

ATTACHED: MEMO;30

TO: GORDON BELL DATE: WED 2 JUL 1980
5:30 PM EDT

FROM: ALAN KOTOK

cc: ARTHUR DEAN DEPT: OOT

SAM FULLER   EXT: 223-7381
LOC/MAIL STOP: ML3-5/H33

SUBJECT: VIDEO CONFERENCING DECISION

I have not heard whether you, Larry and Al Bertocci discussed the proposed system, and whether or not we have a go-ahead. This thing has dragged on so long, that my patience is almost expired. I now gather that the thing is somewhere in some budgeting cycle, looking for money. If it was worth doing last year, it ought to be worth doing this year.

Although I realize we cannot make decisions based on hiring a particular person, I really believe we have a first rate guy lined up to do this project, who can only be hired if we have a project. He presently has an outstanding offer from another firm, and can only wait until Tuesday.

It seems as if nobody can make any decisions in this company anymore. Is that the price of giant size? It may be too big a price to pay.

GB1.S5.41

Messages 9/25

1. It is all arranged for Jim Bell to give the presentation Thursday the 28th to Connecticut General.

2. Harvey Nathanson (412) 256-7544 from Westinghouse Research Lab called. Re: Taming Westinghouse on GAAS Development Program.

3. Dick Clayton called to say today was Ed Corell's last day.

4. Wayne Rosing (8-247-2322) called. Re: NDS

5. Mary Breslin, X7535. Would like permission to hire Peter Czukor -- 8 years experience as programmer/operating systems.

6. Kathy Johnson (Bill Demmer's secretary) called to invite you to a DEC Family Day open house at the Tewksbury facility on Sunday, October 29. They will also be inviting some town officials.

MJ - messages September 25

1. Call Bob Puffer -- no message.

2. Nancy Hilsinger - Re: John needs 1 hr. with Gordon as soon as possible.

3. Joyce Gray - X5518. Re: scheduling a meeting for October 17 with Stan.

4. Linda (Mike Tomasic's sec.) X7558. Re: 1 hr for Mike and GB - Subject: EBOD process.

5. Bernie Stoler (301-588-7358) called Gordon. Re: He is from Century Graphics (A division of Anken Industries) and would like to know about our useage of microfilm/fiche. Sounded like you would probably be able to fill him rather than Gordon.

6. Myler Kelley X2752. Would like to set up a meeting with Gordon, Bruno Durr, Larrry Portner, and Bill Johnson for 1 hour on October 23 to discuss software/software services issues. (I'm not really sure if her name is Kelley Myler or Myler Kelley -- can't find either one in the book -- sorry.)

7. Jan (Bill Heffner's sec.) X2091 Tewksbury. Re: setting up a meeting.

8. Cheryl Maynard in Tom Rarich's office called: Re: She sent a memo to Gordon today and forgot to enclose the attachment. Throw out the first one without the attachments -- She will send another complete package. It was to Gordon and Bernie Lacroute and the subject is Performance Information.

TO: MARY JANE FORBES DATE: WED 1 OCT 1980 8:51 PM EDT

FROM: GORDON BELL

cc: MURRAY COPP
AL CRAWFORD
ALAN KOTOK

DEPT: OOD
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: AT&T SERVICE ON (223-3525). I WANT HELP AND ANSWERS.

Please forward or copy this to the appropriate person for our quarterly report on service. Gwen, my wife, talked with someone today about our absolute disgust with the phone service
on this extension. Apparently, we are being labelled as "paranoid", whatever that means, or we are expecting a level of service that is well outside of what anyone expects.

For the record:
All I want is to be able to transmit information at 1200 baud using either of the 2 modems I have at home. One operates using the Bell compatible frequencies and the other uses the Vadic scheme (and operates when the line is really bad). We have two for reliability! Also, the line is so poor that

I have to use one at 300 baud when I call into the ARPA network at a number in Cambridge (Massachusetts, not England).

I don't really care if voice is as bad as it is, somehow I can listen and talk over the cruddy line.

You may note that I requested that a NET&T person work the weekend of Labor Day to get me a new line so I could work. Somehow the phone line finally worked, and I said go ahead and fix it for real some other time. We have had a cadre of troops through our house, starting with the installer, who I recalled because he left the house in shambles with a big, black board in the middle of the living room and a telephone jack that had fallen off the wall. Still, based on looking at the phone bill on 259-9144, which I use as a backup, there is a very high probability that the phone will not allow me to communicate.

I really don't want to spend anytime recording this saga. Aside from the phone bill and memories of talking to various people, none of which have been able to provide reliable transmission (yesterday it kept hanging up all day), I have not kept a log of the effort expended to try calling and to use the line. I still don't intend to record the events, unless it is necessary.

Therefore, all I ask:
Is asking for 1200 baud unreasonable? (If so, then get me a radio link or some reliable form of communications.)
(I'll consider moving to a closer site where I can get a decent data rate as an alternative.)

Do you want me to log the out of service events? Can you supply equipment for me to try and diagnose the line so that I can give a clue as to what is happening?

Are there any other services that I can investigate to get a line?   (I know that we can put a lot of signal processing at both ends of the line so that the meager number of bits per second I want can go through.)

Am I responsible for getting information at 1200 baud over the
line or can the phone company do it?

Who do I call when the various lines won't get me through?
(and can they do anything to help?)

Please, please, all I want is the 1200 baud, sans voice.
What can I do?

Could you please reply in a formal fashion? (Here, I expect to use the information to decide on a further course of action
... get rid of all phones, radio telephone, move to Maynard and install a private link, build or buy better modems that will work over any type of line, etc.)

Please help!

gordon bell
vice president of engineering
Digital Equipment Corporation
PS
I might add that already working over this phone line has changed the way I hope others others will connect terminals to
computers. Henceforth, I have asked that we build no more terminals which do not have adequate error checking and retransmission capability. While it will take several years to
accomplish this, I feel, based on this experience that I don't
believe any other user should be subjected to this kind of line
or inability to communicate when using telephone lines.

GB1.S7.25

<u>Customer Segment Letter</u> - <u>Sample Only</u>

Dr. Joseph Lassiter
Vice President of Engineering

Teradyne, Inc.
183 Essex Street
Boston, Massachusetts

Dear Joe,

I enjoyed our discussion the other day and am glad to try and help you in regard to setting the future direction of computing at Teradyne.

Since we very often face the same dilemma within engineering here, let me assure you that even though there is an increasingly large development effort centered on VAX, I can heartily recommend buying a 2020 to run TOPS 20 so that you can begin using BLISS immediately for your system's programming on 11's and VAX's. Since there are other programs of interest to our community that run on TOPS 20, then I don't see any conflict. These currently aren't available on VAX and won't be for a while and some may never be. It is imperative that programming be in a standard language (certainly never in a machine language), and I would think that most of it should be on VAX for new applications. For the old applications, leave them on the 20, and it may be necessary to get more 20's as long as production work is designed to run on either machine.

We are really proud to have you back buying 11's and VAX-11's from us for use in testing systems. Furthermore, I hope we can work with you in the definition of the testing problem as we see it, and possibly share programs with you.

Sincerely,

Gordon Bell
Vice President,
Engineering

ALTERNATIVES FOR TERMINALS AND TERMINAL BASED COMPUTING SYSTEM

ENGINEERING
(AND A PROPOSAL)
(G Bell, Independence Day, 1981)

BACKGROUND

There are various reporting structure alternatives for the printing, video and computing terminals engineering organization. These groups, along with 16-bit systems, reported to Si as a former engineering manager. A recommendation for a structure is given, together with the rationale and alternatives.

In late April, Si and I proposed to the Operations Committeee that these areas be part of BOTH engineering and The Computer Products Group in a dual reporting fashion. Therefore, all the alternatives connect to Bell/Portner in some fashion.

RECOMMENDATION

Mike Gutman is now in charge of conventional, multi-user 16-bit systems.

Obtain a replacement for Si as a Product Engineering Group (PEG) manager for terminals and computers built into terminals. Have that manager organize the work for maximum product autonomy, while building on common components and architecture.

This structure permits a team formed with Si to focus on the marketing, manufacturing and engineering aspects of products.

SUMMARY

The following sections describe the recommendation:

- Si's Old Job AS Engineering Manager
- The Proposed Organization (Product Group Level View)
- Win's Four Organizational Alternatives
- Proposed Organization (Detailed)
- Rationale Based On Many Organizational Design Criteria

Why Not One Of The Other Proposed Alternative Organizations?

SI's OLD JOB
Si...
16-bit Qbus hardware
Also, VT278 hardware for WPS and Retail Products
16-bit Unibus hardware subcontract to Tewksbury

VT/LA and Terminal based hardware components (monitors/kbd)
Computing Terminals (CT), both hardware/software
Technical Director and A/D coupling

Mike Gutman now has the responsiblity for our conventional, multi-user, 16-bit systems based on the Qbus and Unibus. Both the Micros and Semiconductor groups supply chips and boards for these products too. Bill Johnson subcontracts the software and Grant supplies mass storage.

The following engineering (outside this area) is also associated with terminals and table-based, personal computing systems:
CT software
Disks, subcontracted and independently funded
WPS 278 software
VT278 software for Retail Products Group
Terminals engineering who are building 2 Computing Terminals
Modems for terminals
Special semiconductors and PDP-11 microprocessors

THE PROPOSED ENGINEERING ORGANIZATION (PRODUCT GROUP LEVEL VIEW)

Bell/Portner
(Product Engineering Group, PEG)
32-bit systems
Large computer systems
[Terminals and table-based (personal) computing system]
16-bit systems (part of Si's old job)

Networks, communications and distributed systems
Software
Mass storage
Semiconductors
Power, Packaging, Physical Interconnect

Technical Director (Standards, architecture, R&D)

(Engineering Administration Staff)
Administration
Finance
Personnel
Technical Operations
Strategic Planning
Corp. Product Management
Quality and Operations Analysis

Recording Secretary

The product area, [Terminals and Computing Terminals] is the group and work being examined as to how it can be best organized.
Engineering Staff total is 20 persons... and has become basically ineffective as a team or problem solving group.

PEG has the product responsibility and is beginning to function as a team, although it runs the risk of becoming too large at its current level of 2 + 9. The members and the team are good.

WIN'S FOUR ORGANIZATIONAL ALTERNATIVES
Win suggests the following alternatives:

1. B/P manage the details of how to get Si competitive products
B/P
    8 Current Product groups
    CT
    VT
    LA
    Technical Director
    7 Current staff groups

2. Keep all computers together and all terminals together
B/P
    7 Current Product Groups
    16-bit
        CT
    VT
    LA
    Technical Director
    7 Current staff groups

3. Combine CT and VT in one group and LA in another group
B/P
    8 Current Product Groups
    CT/VT Products
    LA
    Technical Director
    7 Current staff groups

4a. One form of the Proposed Organization
B/P
    8 Current Product Groups
    Terminals and Terminal Based Systems
        CT
        VT/LA
    Technical Director
    7 Current staff groups

There are several other alternatives based on having all the engineering associated with the products that Si's group will be marketing together. I like the following one, for many reasons.

PROPOSED ORGANIZATION (DETAILED)

4b. Maximum autonomy for the various products
B/P
    8 Current Product Groups
    Terminals and Terminal Based Computing Systems
        CT
        VT
        LA
        VT278 (including hardware and ALL software)
        Common components (keyboards, modems, CRT's)
        Strong, Common Advanced Development and Architecture
    Technical Director
    7 Current staff groups

There are several variants on this, including putting all the components under one person and all the products under another. I'd like to hire the engineering manager and have him organize the product area to get the best performance for these criteria:

RATIONALE BASED ON MANY ORGANIZATIONAL DESIGN CRITERIA
The reasons alternative 4b feels right:

Bell/Portner and Other Product Engineering Self-Preservation
There are a large number of Product Engineering Groups. For the first time in several months, it looks like we have a management structure and set of managers that really work. Based on recent experience with Bernie, having an effective manager can turn around a group in a week, converting a set of warring peers into a team. Even though there are a very large number of technical issues of concern, I have confidence in the current PEG members. Having someone take over Si's job should provide the added quality we need in engineering management.

Many Engineering Areas Need Our Attention
Taking on the work that Si did is going to significantly delay our work on quality, productivity and engineering training. Also, it saps us of any spare, problem solving capability.

Technical Issues In Terminals and CT's Are Open
A strong manager will create a strong team and we really need a strong team to compete in this area. We must have at least one more strong, technical manager in order to both survive and win. Aggressiveness, new products, control of architecture and interfaces with other engineering groups are of concern. Although Avram (an entrepeneural leader) and Bill (a very good manager) are both highly qualified, the product space is very large, dynamic and most competitive. We need help here!

Protection From Me (and Passers By)
Currently the projects have little protection, or any overall management structure to say no to off the wall suggestions. All the projects in this area appear to be "flat out" trying to do work. Requests put the projects in a state of pandemonium, requiring preparation time for presentations and not work.

Strong, Autonomous Product Focus
It provides us with a very clear product by product focus, while letting us get any economy from the many common components and technology.

Separation of Terminals and Computing Terminals
If there is a transition away from dumb terminals to computing terminals, we can take advantage of it. However, both groups are retained allowing common architecture and technology.

Strong and Clean Coupling With Si's Team
Basically, the main products that Si is selling are in one group: VT, LA, CT and WPS's. This will give us the best coupling with the market for direction, while at the same time let us also drive and be decoupled technologically.

Strong and Clean Coupling With Manufacturing
VT's, LA's and CT's are manufactured within Esten's plants at Westfield, Phoenix and Albuquerque. This is all these plants build. Floppies are made at Springfield and various components are made in the far east.

Very Good Coupling For Shared Technology and Work
These products all share a lot in common, and hence within the group there could be a very strong function that we must have at critical mass. The common technology across all parts:

modems
power and packaging, including noise and radiation control
keyboards
monitors (although the LA's don't need them, VT/CT do)
use of roms for more intelligent terminals
common modules for terminals and computing terminals
including: comm., rom, some video, printers, mass store

architecture of communications to operate on non-DEC systems
architecture for use on DEC systems (badly missing now),
especially VT and VT (graphics)
human factors for much of the design, including editing
imaging based on dot matrices for fonts and graphics
common approach of servicing and customer installation
use and programming of standard VLSI

Printers have unique problems of printing, paper handling and possibly printer-only editing, if we build them.

Computing Terminals require mass storage and programming. Hence, there is the need for software both within and outside DEC.

Provides A Strong Technology Focus For All These Areas
We are late in the video area with respect to both lower cost terminals or for high resolution, one page displays. The later exist or are needed soon on WP Systems.

Minimal Amount of Interaction With Other Parts of Engineering
A single group can manage the interaction with other parts of engineering. This means all engineering will be more effective. Note, that when two groups providing the same function approach a third group about an interface, there is an inherent arbitration function (actually a fourth group) needed.   Hopefully there are only these interactions:

Common terminal architecture interface with software
Mass storage (CT and VT)
Semiconductors (all, and all have unique VLSI too)
Ofis software (for both CT and VT)
Other operating system software for CT

The Revenues In These Market Directed Products Are Similar to other product groups. Both the terminal and computing terminal revenue streams (in $B) are less than the other areas.

FY	VT	LA	CT/278	16-b	32-bit
81	.16	.16	.05	1	0.6
82	.2	.2	.06?	1.1	1.0
83	.22	.27	.13	1.2	1.5
84	.29	.3	.4	1.3	2.0

The Proposal Is Similar To Other Parts Of Engineering
While not a reason per se to reject other alternatives, I would like someone else to manage the people who manage projects. Note,

B/P(level 2)
- Mass storage (level 3)
  - CX (Level 4)
    - Big Drive Projects (level 5)
    - Controllers (level 5)
      - Specific controller project (level 6)
- ...
- Large Computers
  - Venus Program
  - 36-bit
    - Jupiter
- ...
- Terminals and Terminal Based Computing Systems (Personals)
  - CT family of products
    - CT Product Management
    - CT Hardware manager
    - CT Software
    - CT product assurance
  - VT products
    - VT project

- LA family
  - LA200, etc.
- Components
  - Keyboards, monitors, etc.
- Single VT278 mogul
  - Product manager
  - Software, including WPS, RPG, etc.
  - Hardware

... etc.

Prior to Si's leaving, we seemed to getting improved focus on products. This has to continue, but we need help to do it.

Having The 278 In The Group Is Desireable, Though Not Necessary
We still need better focus and drive around the 278, especially the WPS software. The three parts can remain seperate: hardware, software (and Product Management) and WPS software. Mike Gutman should also focus full-time on PDP-11 Products!

WHY NOT ONE OF THE OTHER PROPOSED ALTERNATIVE ORGANIZATIONS?

Alternative 1
Alt. 1 adds two more direct reports, plus requires Bell-Portner to see that the various charters are established among the groups as to the plethora of components and architectures. It would require the establishment of a functional equivalent to that of the proposed organization. This function would could be in one of the three groups, and while it might be clean, we would often end up as arbiter. I don't know how to handle the advanced development and architecture that is getting us into the current trouble.

Alternative 2
Alt. 2 has nearly all the problems of 1, except that there might be something gained by having the two types of computing systems together. It could surpress the focus on CT and thereby limit building the personal system. Historically, we have not been able to focus our management attention in such a way to build a personal system because the pressures are to perpetuate time shared systems.

Probably the worst problem is that it puts in jepordy the conventional 16-bit business which we must have. Mike Gutman has to focus here!

Alternative 3
While alt. 3 allows video technology to be shared across VT's and CT's, we run the risk of doing a poor job in both areas by having resources go to either area. It has problems similar to alt. 1 in that someone has to take on many common functions. Alt. 3 may be better than 1 because it groups our lagging video together.

Alternative 4a
This alternative would certainly be acceptable and let us focus on both terminals and computing terminals. Similarly, there could be a strong advanced development and architecture function which we need for all terminals. Computing terminals have unique and intense problems which are going to consume Avram for the next 3 years! It is just about as good as 4b.

SUBJ: TERMINAL SPECIALS (E.G. LA124)

Date: 8/20/79 Mon
From: Gordon Bell

TO: Distribution

Dept: Office of Development
MS: ML12-1/A51
Ext: 223-2236

Why don't we have CSS build the custom terminal specials? They are modifying for character sets anyway, and special terminal will be geographically sensitive (e.g. UK GPO, Japan Kanji characters, Bell Canada).

Of course, we would need a better link to CSS so that the important features (e.g. file systems, editors) that cross all the markets migrate back into general purpose products.

SUBJECT: WHY WE MUST BUILD A GREAT PORTABLE TERMINAL/PERSONAL COMPUTER

TRIP TO JAPAN, STIMULATE THESE MANY THOUGHTS:

MOTIVATION
0. Japanese consumer electronics makers are entering the computer market both with components (eg. TEAC is 1/2 digital with floppies and Wini's) and systems (eg. Sony).

1. Lots of small, portable, relatively useful products are

now on the
market including:

a. Computing calculators with narrow paper, and mass storage
b. Sony typecorder
c. Brother $200 thermal ribbon typewriter and calculator
d. Viewman
e. Purse-sized computer terminal
f. Low cost Timex computer
g. Grid systems using Sharp EL panels

2. Emerging Components:
    a. EL and LCD panels
    b. 64K CMOS rams and many other CMOS parts;
    c. 256K rams & large roms
    d. Sony micro diskette
    e. Modem chips, codecs, telephone interfaces
    f. Voice synthesizers and analyzers
    g. A plethora of 2K-8K gate CMOS gate arrays.
    h. Videoprocessors

3. Personal need of a product like Dynabook that does the functions that are emerging in today's personal computers.

4. The size would help drive the cost, styling and the market. We need a more aggressive cost and functional target to push us.

5. Our manufacturing technology is not good enough to build low cost terminals. If we get some reasonable distribution channels going, then we could do a joint venture with high volume supplier such as Brother, Sharp, Sony or some other supplier who is good at low cost, high volume units. They'd teach us.

6. This product is inevitable and I think possibly more desirable

than current, bulky PC's. We must work on it before we find that we're behind and that someone else is taking the market.

7. Within a few (say <5 years) a unit such as this will provide the functionality of today's large PC's. This is more than many users can handle anyway.

SOFTWARE FUNCTIONS - What it does

- Standard, correcting typewriter mode
- Good word processor
- Visicalc
- Scientific calculator (possibly compatible with TI and/or HP programmables)
- Business calculator
- Virtual Terminal (for all common terminals)
- Terminal compatibility with new very small terminal system
- File transfer to/from DEC system
- Standard Basic?
- Games (optional)
- Very fancy alarm clock
- Calendar keeper ala WPS
- Forms entry/WPS math for expense account data, order entry, etc.
- Datatrieve (eg. for names, addresses, comments, fields)
- Voice would ideally be the interface. Failing this, we could use handwritten input and keyboard. Voice annotation and dictation are a must.
- Telephone message interface

HARDWARE REQUIREMENTS

	IDEAL	GOOD	ACCEPTABLE
Display**	24-66 lines;1Kx1K	8 lines	1 line or 8 lines
Print* qual.	"LA100"		"LA12" none?
Graphics	yes	video text	none
TV i/o	yes		none

Keyboard	Brother "std"	--	Brother "portable"
Handwriting	yes (notes)	--	none
Voice	recognition	"Pro 350"	none
Modem	"LA12"		300 b acoustic
Fax	full	no scan	none
File	Sony Micro flopy		Micro cassette
Pc	VAX	don't care	
Mp	256K		65K
Power	solar	6-12hr. batt.	AC
Size	"Typecorder & Sony floppy"		Briefcase/2
Weight	2#		5#
Clock	yes		yes

* Need not see printing if display is good.
** (Ability to browse & deal with multiple, overlapping windows)<-too wild?

COMPUTER AND CALCULATOR SIZES AND PRICE RANGES

Wrist watch watches	25 - 160	Casio
Purse/shirt pocket calculator	10 - 62.50	thin
Hand held/coat pocket	10 - 62.50	HP35
(Programmable)	62.50 - 160	
Paper stack sized	160 - 1000	Typecorder
Portable typewriter	160 - 400	
Typewriter	400 - 1000	?
CRT-based PC	1000 - 6250	VT182

DISPLAY - I met the head of engineering who has subsequently become head of Sharp. They have various solid state displays and will soon have an 83X8 line LCD. He commented on the Grid System portable computer. Sharp also has Maxwell's Equations in concrete at their R & D center.

Having tried to edit on the Sony (40 characters) and Brother typewriters (16 characters), I think we should not make people suffer, but pay the extra price (say $500 selling price) for something that can be used.

The 8 line display be totally program transparent to a standard 24 line CRT by having two characters define the bottom of the window. On entry it would start at 8, go to 24, and stay there,

scrolling off the
top. At anytime the window bottom could be moved back, independent of
the cursor. Any action on the cursor would snap the window back to
24, displaying the bottom part of the "CRT".

KEYBOARD - I'd like a regular typewriter keyboard although the $200
Brother is acceptable. It should be quiet.

PRINTER - I now believe a printer of some sort is nearly always
required for the foreseeable future. Here, it would be nice to print
high quality so that personal notes and letters could be sent. It
would be possible to have this printer modular, but given the small
Brother portable, the typewriter doesn't seem to add much size or
cost.

The printer would be used to supplement editing, for personal
correspondence, forms, order confirmation, calculator, etc. I typed
on the big, office, Daisy Wheel Brother which had a 16 character
display and did most of the important functions of our WPS. It was
very impressive and especially nice to have no carriage motion until
the line was ready to be printed.

The $200 little, thermal, sub-portable Brother was most impressive!
It too had a 16 character display and includes a calculator mode.
It's the size of a Sony Typecorder, so it occupies about 1/4 briefcase
and is 1 1/2" - 2" x 8 1/2" x 11" - or "paper stack" size" or 1/2 the

size of a portable.

MASS STORAGE - Although it's too late to redo our decision, the Sony 31/2" Micro floppy looks to be ideal and could obviate the need for the 5 1/4". The project engineer gave one of the best presentations I've ever seen on why it will become the dominant drive. He started with goals and constraints and went into detail of all kinds. He believes they've got a technology base that can live for 10 years in terms of form factor and cartridge.

For this computer, it could be acceptable to limit response time to small tapes since they would only store files that would mostly be in memory.

APPROACHES

I don't think we can achieve the "ideal" within two years. Rather than waiting, we can take two, two-step approaches:

1. Build the right sized unit now and put in whatever is possible, giving up some level of functionality. Don't worry cost, but put in the most functions we can for the "Typecorder" size. The next incarnation would have more capability and approach the ideal.

2. Large size first with right functionality, then cost (and size) reduce.

I strongly prefer the first approach targetting small size to get our thinking down. The Nebula with VS100 and good copier

output
is what I want. Therefore, it's important to constrain size, not
function in our design! Such a product could be easily spec'd and
built either here or with one of the major Japanese vendors.

SUBJECT: LOCATION OF TERMINALS/SMALL SYS. ENG. F/U 3/14/80

I believe we need a general space strategy for T/SS along these lines:

0. Identity of a non-Mass site to accommodate the anticipated high growth by June 1, considering locations of people and manufacturing.

1. Space requirements in Maynard/Hudson would be at a reduced

growth plan. Growth would be at new site including a significant move.

This is based on the following goals and constraints:

0. Retaining our talented people.

1. No growth in Massachusetts. Watch out for overpopulating NH in light of high Commercial and other growth, and desirablility.

2. We are open to a Terminals division proposal, and independent of an actual division, we can have a virtual division by co-location.

3. Coupling process related parts of engineering and manufacturing to focus on cost, producibility, and support. This implies strong engineering presence in SW.

4. Coupling PM to systems and internal group customers for 50% sales. Coupling to systems groups for software and for protocols. This implies strong engineering presence in NE.

5. Terminals and small systems engineering should co-locate to build on common parts and technologies, and because the next generation terminals will become indistinguishable.

6. Co-locate a part of low end Mass Storage for responsiveness and competitiveness.

7. Current rack and stack systems are outside the new, very

high volume focus of small systems. Qbus options will be done everywhere.

Would you please prepare a plan?

Subject: **Naming, Identifying and Segmenting the 11- Based Terminals**

To: Al Dziejma, Len Halio,
Mike Wurster

CC: Distribution

Date: 10 MAY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

Follow up 5/22/78

Somehow the name and numbering for our 11-based terminals as the Programmable Data Terminal or PDT doesn't feel or sound quite right. These products have to be segmented and clearly identified with appropriate fan fare and whoopla. (This was the same issue as the VAX name.) (It is essential that it not be called or labeled as simply an Intelligent Terminal (IT) -- which connotes nothing!)

Also, I'm concerned that there be too many identifying model numbers for what are variations in systems configurations (e.g., with/without tape). Is it the 100 series where VAX is 700 series and 11's so far are 00-99?

The naming format should be:

0. Maybe let us grab an important generic name (e.g., Digital) or create a name (e.g., Frigidaire).

1. Give room to create future terminals and to grow.

2. Have a good pronounceable (feel) sound - preferably one syllable.

3. Build on any image we have, yet

4. Segment - show the world we have (or now endorse) a new computer (package).

5. Be a major part of 11 image.

6. The product should somehow also be segmented from the dumb, and fixed function video terminals (e.g., VT100, 105, 161). It also might have a visual clue (e.g. painting a gold strip around bezel) and permit other options (e.g., color monitor) and FONZ (different color).

Some options for names:

PDP-Series/Model #
identifies it by series # as a terminal and programmable

PT/Model # identifies it as a terminal and programmable

PDT-11/Model # ties it to an 11 (also rhymes with PDP)

PT-11/Model # ties it to an 11

IT-11/Model # People talk about IT's, the 11 is necessary to attach to an 11, I means nothing

DP-11/Model # Distributed Processor

PC-11/Model # Personal Computer (maybe we want to save this one)

T-11/Model # Terminal and 11 (easiest to pronounce)

DT-11/Model # Desk Terminal-11; also permits Lab Terminal (LT) too

Surely there are better identities. What was considered? This is important -- can't we be more creative?

SUBJECT: TERMINALS ARCHITECTURE AND COMPATIBILITY

It is clear that our highest priority is to have a terminals architect. I am really disgusted about our recent products in
this area. Clearly, these have to be dealt with right now as they are crisis level. I don't see anyway our software can support this hodge podge. Here are the problems I know of:

Gigi and VT125: 2 problems, compatibility with each other (it blows my mind that they are not subsets of one another); and their compatibility with the 100 so as to run the software
the way the CUSTOMER WOULD EXPECT IT TO WORK! Here, I would like to see a plan to address these two issues.

VT278 compatiblity with VT100. Here, we have to acknowledge that a VT100 is actually a VT100+VT52. There is no such a terminal as a VT100 mode only terminal. This is the same issue
with VAX, which includes an 11! When we ever put in a backward
compatibility mode, then all successsors are stuck with providing this, cause the software depends on this mode.

VT131 block mode terminals. Is there any expectation that these will work on or be supported on DEC systems? This one really bugs me, cause the control is totally different than any of our editing terminals. How we could build this is unintelligible to me. I want it clearly spelled out in the sales literature that it will not run, nor will it be supported on DEC systems!

What will EMS support? How about the 100 mode part of a 100?

Coping with the additional capabilities of CT terminal emulation.
Here, I would anticipate that CT should be able to behave precisely as a VT125... but since there is only a single display, then I don't see how it does all the stuff. While

the 125 is cute with the ability to run the two screens independently, it looks like it should not be used or supported
at all, cause it's not something we can perpetuate in follow-ons!

We seem to have built the messiest set of products I have ever
seen, and we are going to be spending several years cleaning this up. Before we introduce ONE more product, I want clear statements about how each of them are going to be fixed.

Please understand that a terminal is just as complex and has the same costs as supporting a given cpu architecture such as VAX or a 10. This means it really has to be nailed down precisely so that it can be used AND we can not have an arbitrarily large number of different terminals.

Please get together individually and then with me and give me an
indication of when we are going to have this problem under control. Sam, will you figure out how we are going to do this?

SUBJECT: TERMINALS BUSINESS LOCATION F/U 3/28/80

From: Stan Olsen, Jack Smith, Gordon Bell

Would you please prepare a proposal for the movement of terminals
and small systems engineering, marketing and manufacturing (headquarters) to some non-NE site. Given the growth in NE, and
the possibility of 15 thousand engineers here, both Ken and Win
believe we need to look at this as one such proposal.

Undoubtedly we will need other groups to leave NE to achieve the
Massachusetts cap constraints. We envision having a site that
might grow to near our current size by 1990. We all support making this proposal. In fact, two of us (SO, GB) have tentatively agreed to rent a house and spend significant time at
this new site.

All of us have favorite sites and want to input to your site evaluation process with names and criteria (proximity to other
manufacturing sites, universities, schools, engineering base, ability to grow engineering, culture, climate, etc.). The site
selection process should be open and criteria explicit (sites,
criteria).

The complete terminals business unit would co-locate: terminals
engineering, TPG and terminals manufacturing headquarters. In
addition, it is imperative that the non-cabinet based small
systems engineering co-locate because the next terminals behave
as small systems, providing user programmability. This would
provide excellent co-location possibilities with your main users,
such as standalone word processing and the retail products
group... but this is a detail.

Ken has declared that we are not going to consider the division
question at this time. Please work up the geographic proposal
and address the necessary organizational implications without
resorting to a division as the only solution. In fact, if the
site and breadth of markets is great enough a division probably
is less relevant.

What is an appropriate date for a proposal? Can we get together
with you and discuss this?

SUBJECT: RE: RE: MARKETING PLANS/TJ MEMO 3/13/81 ATTACHED

I strongly support widescale sales of these terminals and small systems using the approach of having the terminals product line take the lead in programming (hopefully in a hll) specific protocols (3270, tektronix graphics) and doing speciific block mode applications to make the smart terminals.

Could we take the vt101 etc and put the microsoft basic in it so as to be useable for programming these?

Let's start with the 101/131, 125, gigi, pdt, and 278 word processing terminal.

Could they also have programs, written in Fortran to support the terminals on ours and other systems? (In the case of the graphics terminals, visicalc, and plotting are really necessary to make them play.)

As an aside, I would like to get the support plans for the VT125 for our systems. I find NO ONE using them in our systems programming and this is crazy!

SUBJECT: CHANGE IN TERMINALS PRODUCT DIRECTION!

I am excited about the discussion that we have scheduled which I hope will be long enough to get into product details. It has been hard to hide my agenda that our terminals product direction is not adequate. Fundamentally, I want us to divide the problem up into evolution based on the vt100 and products that will be more revolutionary following it. The more revolutionary products though maybe should be constrained to be compatible with the options advocated below.

The premise is that vt100 has attracted many competitors and imitators and there will be piles of competitors ready to do us one better. Given the $'s being spent to tool the 100, we had better do something quick to make it be unique. Fundamentally though, it is unique because it has extra power and space that we must capitalize on. Thus, the VT100 will be the Kernel for much future terminal expansion. The following 1 board options seem essential:

1. vt132-editing option board with block mode and some ability to do specials (possibly this would also support a tu58)
2. vt 162 forms entry with block mode ddcmp. Do not release the 162 as we know it cause we can't support or get the 100 capability in it! WE MUST HAVE COMPATIBILITY IN AN UPWARD FASHION. ALSO, GIVEN THE 162 is Fonz based, then we can also do a limited set of programmable functions...even though I don't know specifically what they are right this minute.
3. VT125- Graphics board.
4. vt278 processor with connector for remote floppy. This would have a built in modem, and serial port to support lqp, la34 or la120, and also support 2 floppies in a PDT case. Note, by plugging in this board we get wps! (Also, there is an RSX version of wps that does remote wps processing so that many users can tie into a large 11 for the lowest cost.

Here, it is desirable that the 278 board be in the 100. 3 and 4 would work together.
5. vt103 as announced already follows the philosophy of being an option.

Imagine being able to market a terminal (cabinet) with these capabilities? By the time we get the products ready, we'll have an ad on base of at least 1/4 million...and if each of these will only buy 500 worth of ad on. No one has done this. Let's do it...it also solves the multiple terminal problem cause one terminal could be dumb ala 100, with graphics 125 module; and have the forms entry board als 162 doing some special function. With the 162 board we could let css or Art's engineering really go after the medium volume

1k-50k specials by merely writing 11 programs (in Pascal, I hope). Julius, I hope you'll support this approach versus the special 162. Note, with the 125 and the 162 together we can easily build the highly specialized multi-font typeset terminals with a program.

I want to define these board architectures so they play together and we can do all these things. Also, some of the boards could be used in the LA's to get us specials. We have most of the work done for the modules, now let's look at this slight eco to make them play together!

SUBJECT: THOUGHTS ON TERMINALS FOR DUMB, WPS AND TECHNICAL USE

Ken just sent a note around based on the Frost and Sullivan data that says the full page wps now is 23% of the market and will decline to 13% in 85. The current WPS market is 2GB and will grow at 28% (doubling every 3 years) to 5GB. Hard copy only
units will decline to a few percent based on 13% now. These numbers are ALL UNITS, not dollar volumes. We need to decide what we want to go after.

In general, I don't really trust these surveys. However, it's
clear there will be a lot of minimal systems sold (I assume these
will be the cheapest system). Here, we must use the 278 really
aggressively to go after the typewriter replacement market! I
hope it is cheap enough. It is also possible that someone will
make a really good system and capture the whole thing. Note that
Sony has a full page which I am still receiving parts of, and I
believe that this will tell us something as to how much we can
believe the numbers. Note, the IBM Selectric dominated the market not due to cost, but due to quality. They got the market
not on price and maybe not even in terms of units, but they got
the $ market. In short, I believe technology and quality could
blow any market data like this all to hell!

Note, a new company has announced a $2500 full page alpha display. I think we have to look at what it would provide, before we base our work on Market surveys. Similarly, there is
much fundamental work going on in raising the TV standards to higher quality. I trust we have one on order!

QUARTER (THIRD OF TEXT) VERSUS HALF PAGE

For starters, I am very confused as to what a half page would do for us in the alphanumeric market, versus our 1/3 page. Note we have been calling this 1/4 now (for 240 lines) and 1/2 (for 480 lines) to give something like 33 lines of text. For starters, this interim display would give us some higher quality letters, but it would also give us decent resolution for our technical users who operate remotely. As a buyer now (with VENUS) I would like to give every engineer a VT125 that would have 480 lines (versus 240) so he could see his prints at home! Right now, I'd like to have something we can experiment with so as to find out what these different page sizes would provide.

Another cut at this would be to make the screen flicker by using
it non-interlaced. This would give the resolution at the price
of flicker. Here, let me speculate a really low cost, but potentially useful display. Make it just a 240 or 480 (non interlaced) display. As an alphanumeric, it would be a VT100, or
when operated in 480, it would be called Rough View Mode. With
this, one could VIEW 53 lines using 9 lines per character (7+2
spaces). This still doesn't get to a page, since most are 55 lines of the possible 66 lines and ? for European pages. When
used as a graphic display, then View mode mode give a much bigger
picture.

This doesn't mean we should hold off any plans to get a VT200!
It is critical to get a VT200 emulator to every development group
NOW (which should be easy, given the VT103), since we need to start off loading terminal handling Yesterday.

WHY WAIT FOR THE VT200 CHIPS BEFORE WE GET FULL PAGE TERMINALS?
Somehow, I don't believe this is going to happen. It feels

like
the Semiconductor industry is going to have chips before we do.
In talking with the NEC semi folks, those guys are committed to
get this market! Somehow, I think we'd be ahead to take their
chips and use them for our full page work then to totally base
our VT200 on our own chips. If full page is going to happen,
let's drive to get it out there now and not wait on our chips.
Note there are only 200 chips in the Stanford Workstation! We
could have this out on the market within a year, if we adopted
their design.

GETTING A DECENT HIGH QUALITY TERMINAL FOR VAX
I'm really concerned that we are doing so many really interim,
low quality redos etc. versus getting a high quality terminal out
there for VAX. We just can't get the big Suvax display out
there and we have no alternative for a production display for the
professional for VAX. I thought that CSS was going to market
this impressive terminal.

We also need something of Xerox Star quality (1 page, 960 lines)
that can plug into a Unibus and be used to give say 3 to 8 high
quality workstations on a 730 or 750. Note this gives the best
professional station in the industry at competitive prices. This
just has to get factored into the funding this go around. It is
much higher priority than say CAT, and a lower cost VT100. VAX
is both directly funding and indirectly funding terminals by

providing the ports for all the low end money losing
projects!

As we allocate resources during this budget pass, the above
are
some thoughts. I'd sure like to see some protos to help
decide!

SUBJECT: GETTING THE ARCHITECTURE OF THESE TERMINALS
SPECIFIED

I believe there has been a suggestion around for several
years

as to how to specify terminal hardware architecture such as the
vt100 and 125. It may have trouble when the terminal gets more
complicated though.

Fundamentally, the specification has to be written in something
like ISP or the notation used in the SRM. It has to be organized
with the same kind of rigor:

State internal to the display
State that is visible Screen[0:23]<0:132> for example
The I/O ports and the sublety of any buffering in them, including
 the keyboard
The operations on the state when a character arrives in terms of
 what's displayed, the cursor, etc.

I don't see what is tough about this. I keep seeing these idiotic
tables of differences that assume an incredible knowledge about
the semantics of displays.

I haven't seen a decent manual yet on displays.

Bill Avery,
For months, I've requested that we really write a classic manual
that defines all our terminals and how they operate so we and our
users know what they are. Is there any chance we'll ever do this?

Since DECSIM has a really good way to describe systems like this,
what about using that language?

SUBJECT: GETTING VT'S,LA'S,ROBIN AND CT OUT FIRST, THEN WHAT?

I strongly support Bill and Si in this next product
direction.
We must have a terminal that can become a computing terminal.
The lineup now:

vt 1xx	500	should be cheaper and expandable to a ct
vt125	1000	
vt180	1450	
ct120	1450	
ct150	2500	

Desired:

vt	350	(expandable to a vt125 version cheaply and to a ct))
vt125'	500	
ctversion	800-1000	
ct120	,<1450	
ct150	2200	

If my hunch is correct, we are going to badly need a terminal
after the market responds with a very loud yawn with
the new vt 101,102, 131, 132. This has to be our famed, but
long awaited vt200. The question is whether we can
wait for a more expensive monitor.

We should proceed asap to get some data bout how to get
this next low cost vt/ct. The breadboards should include:
CAT

TRIAD as a way to get the expansion and 11 compatiblity
(by doing this designy, we have 2 options... it is the vt/ct we talk about above, or it can be a ROBIN type product that we put in a vt100
vt200 ... currently directed at being 1/2 page, but no monitor
and a very long schedule

At any rate, we ought to go like hell to get our current, very
full plate into production and into our customer's hands.
Recall, we are announcing or planning to deliver vt101...131,
la24, la12, vt125 (a hell of a task when you consider the
software), ROBIN (with the hope of it being an FA&T version
given that Xerox is delivering 7,000 per month!), ct120,
ct150. I
say we are crazy to be talking about introducing any more
products for the next year, if we want to do a quality
development, manufacturing and marketing job! Are we
committed
to quality????

Bottom line:
Get the products out. Get together and get several
breadboards going
that aim at the above (or you change it) target.

When can Si and I see the plan?

SUBJECT: RE: VT 180 FOLLOW ON/BILL AVERY 8-31-81

The follow on product must be a terminal that becomes a personal
computer. If we build a box that is independent of the terminal
then it is just another CP/M box and there are many of those. So
we loose every bit of pizzaz and end up just one of the crowd and
might even confuse the CT message.

SUBJECT: VT180 FOLLOW-ON

We need to establish a hard set of goals for the VT180 follow-on.
It looks like the FCC standards may force us to put the processor

in the box with the floppies; we will also have the T-11 and hence a DEC SW strategy. This product will have much more of a personal computer flavor then the VT180; I believe it will be a corporate product and will be marketed by numerous groups. There are a number of engineering groups in a position to contribute, including CT, Small Systems Software, and the Video group.

I would like you to put down a preliminary set of product goals that we can review at my staff meeting on 8 September; we can then start to set expectations as to what will happen and who will be responsible for what.

Subject: **Issues on Where Terminals are Heading**

Am glad you anticipated what would have just been this memo and allowed me a personal dump about the overall direction. There are 3 pages of comments with some appendices of earlier comments plus the Commercial Products Terminals request. I really care about terminals because they are what all our users see and interface to.

. I want to test all our Terminals at a time when they can be affected. Note, there is still something wrong in the Keyboard "feel" on our terminals. Mary Jane seems to think this problem is solved with the Hytek keyboard. Has it? (A. Note the attached comments on LA34.)

Architecture and Technical Direction

. Architectural control. Generally we have to have architectural control to avoid the plethora of point products we now have that are incompatible internally, and cannot be built on in an intelligent fashion. OR, in order to do the insanely large number of terminals we desire, we must have a common architecture. Let's get the combinatorial number of terminals x electrical interfaces x protocols x mass storage units x smart or intelligent part down to a arithmetic problem by having common interfaces. (C. Note the attached comments.)

.Graphics architecture, design and control. Graphics look like one essential mid-life kicker for VT100. I'm worried about when we are getting the 125 and how we are going to handle the

architectural evolution that is implicit in it. (D. Note my attached comments on graphics.) We also have to be able to print what we view. This terminal should fundamentally be considered to be a 2D Calculator (and it will evolve as such).

. Built-in modems and/or acoustic couplers. The physical interface plug and cable has to be right as noted about the WPS 200. Let's assume a telephone company will install cables for terminals. Can we assign one person to handle the cabling, plugs, modem and protocols work? Before the terminals group gets a marketing person to squelch it, let's consider the user and stockholder by building modems into all terminals! I fought this one several years ago. Hopefully, Ken will solve this one where I've failed.

Product Proliferation versus High Volume, Quality Products

. It seems like there are too many like crazy, given there is no architectural commonality. What new ones can we not have? How can we merge using common components such that we get all of them but by parts, not point products? I think that we have to change our direction as per the REDBOOK!

Evolution versus Revolution

. VT100 Evolution. Given that we have attracted a large competitor following with the 100, and given that it has extra power, cabinet and hooks for add ons, can we make lots of add-ons for it so as to drive the look-alikes bananas and get an even bigger market? (E. Note the attached comments on the VT100 mid-life kicker and EMS message of 1/15/80.)

. Revolutionary Gonzales' Modular Packaging. This has to be the way to go for all new terminals to give us the edge. Can we make all new terminals this way, and count on the above evolution of the 100 and the enhancements that Terminals group is doing to the hardcopy to hold us until we get the design under control.

Specific Product Issues

. Very Low Cost Hand Held Terminal (VLCHHT). How real is the very low cost terminal that R and D is doing, and why not do it rather than getting the evolutionary slight cost reductions (eg. 100L). Terminal costs are not the issue with a user...the terminal is a minor part of his total cost, functionality or reliability or speed wins every time when he looks at his costs. Let's also use VLCHHT for our computer and mass storage consoles. Should we get Sharp to build it to our specifications?

. Physical cable interconnects to terminals are inconsistent and need attention. Note comments to you and WPS on VT100/WPS200.

. Let's make the VT200, i.e. the VT100 follow-on 66 lines! If this is not the case, let me know immediately. Note: VT03 (12 lines); VT50 (12 lines, only upper case) and evolving rapidly under market pressure to VT52 (24 lines, both cases); VT100 (24 lines, better and both cases and foreign characters and 132 columns allowing 48 lines on a side by side basis); and VT200 (should be higher quality characters with a full page).

. Color. I suspect the best test will be with GIGI. Namely, color probably is only needed when video and pictures are used and that means graphics have to happen first. IBM has lead the way...will the customers follow? (Don't we have to be really prepared if they do?) (F. Note the attached comments on the color issue.)

. Noise is certainly an issue for most user environments.

Understanding and Advanced Development

. Understanding historical and depicting future of terminals by use of family trees. The Redbook usually has just the next few years with the various terminals plotted in a cost vs. time fashion. Given the plethora of new terminal products I think it would give us all a great deal of insight to have the family tree plotted clear back to the VT03 and LA30 (and ASR 33). These would be similar to those in Computer Engineering or the big DEC tree hanging in the museum. There's lots of information. Namely, when the project starts, the branch is put on the trunk and when it ships a node it is put on the branch and when we stop shipping, the branch is terminated. Enhancement models get extra nodes on the trunk. The insight I'd like is gestation period changes, width of the tree, what segments, etc.

Organizational and Interface Issues

. Poor connection especially with Campbell and Delagi re joint REALISTIC plans. Our projected revenues come from every segment of hard/soft copy, cheap/constant cost with increased capabiltiy, office environment/portable dumb/smart/intelligent, DEC/other vendor/custom, domestic/foreign combination. We can't design, build or support all these dreams. Besides the Terminals group doesn't have a coherent, documented plan.

. Better interface to commercial. (B. Note their attached comments on products requirements on terminals.)

. Better interface to WPS, Typeset.

. Better interface to MPG so we get saleable terminals there.

. Better interface to Small Systems (i.e. Shanzer) to let them use your extra cabinet space and power to make a complete system without a major redesign.

. Manager for Video? Let me know if I can help sell a recruit in this vital exciting job.

AVRAM MILLER
BILL PICOTT

DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: UURGENT PROBLEM: RESPONSIBILITY FOR LOW COST SYSTEMS

For our disussion at GVPC:

Independent of whether I have be able to help build better low end personal computing terminals, historically we have tried and generally have done poorly (market share, profitability,quality).

PRODUCT HISTORY

The products arena, over the past 6 years and currently:

VT8/E (Reuters), VT14(originally GM for PDP-14)
VT30, 31, etc. by CSS for weaving, mimic diagrams, tv
VT15,GT40, GT60, Megatek (lab and engineering graphics)
VSV11 (Graphics and Image) LDP, now CSS
VT20,21,71,171, etc. for Typeset also Tektronix based
LA36/BSR, LA36/TU60, LA120/TU58 (AT&T), LA44, VT134
PDT130, PDT150 (for ADP)
Minc, Mini-Minc, TLC
Gigi, Gigi 1.5
VT103 (TPG)
DS315

WHY IT HAPPENS

Our structure and the basic P/L Bill of Rights (which I do not advocate changing), created the problem. Some of the forces:

.Customers specialized need (Caused 6)
.Perceived specialized market need (caused about 20)
.Perceived general purpose, high volume opportunity (5)
.The components are available, and it's about the only piece of hardware that a P/L can afford to engineer
.They are fun to start. It is the one product that can be built according to the classic model: marketing specifies and engineering builds it
.The market is perceived to be sufficiently different that no gp system can be built (Apple disproved this!) ... hence no common system was able to be defined
.The engineering budget was not large enough to cover this evolving part ... for example, the whole WPS P/L had to be started up to start the eng. investment
.Poor engineering leadership to recognize need, and propose it

SOLUTION

Now that we have recognized the problem, let's solve it.
        .Technology is changing making engineering cost higher,
         product costs lower, and unprofitabity clearer
        .We are doing a system to cover many of these areas
        .Near term, Engineering is taking responsibility for 278
        .Engineering will operate "modified Golden Rule":
         .Will operate with Business Plan and Phase Review
         .Will get an outside assessment of product viability

        .Review the current terminal and PC's ... there are
         lots more lurking losers. Put the $'s in low end PC's!

SUBJECT: SOLID WIRE ON PEDESTAL 100'S AND THE WPS200

I can't believe that FS just connected a bunch of VT100's on movable pedestals to our WPS 200 system with solid wire. These are 20ma connections and they use a really poor connector. Why don't we use a standard modular jack such that standard phone cables, connectors and telephone installation procedures can be used?

What are the installation standards here? Who has this responsibility? Could you send me the standards we do use? I'd like your groups to get together and work out what we do use. The WPS200 wiring as demonstrated in our area is totally unacceptable as an office product in quality, wiring, reliablility, noise level and aesthetics. As a system, I think the WPS 200 system is fine, ignoring the fact that it is unsupported because it is a large 8. Will you convene and segment the problem and decide who's responsible for what? and what can be done?

For starters, switching the WPS200 to serial lines for both the Draft and LQP would help matters enormounsly. It would give us greater distance and get rid of the eyesore that can not be installed. It would also give us the needed increase in signal to noise ratio and help reliability...and even allow interchangeable use of fiber optics. In looking at the specs, I find that FS didn't need to use 20ma, but could have stayed with the EIA. This cost us in time and engineering at our floor site.   Here again, I want to get the number of configurations down a lot so that we can make what we do sell work! Having these infinite options and FS designs just complicates the already marginal software package...and in order for us to survive here we have to start limitin options on the 200!
Bob Gray it is clear you have the leadership here, and I'd like to know what and when we can expect simplification?

SUBJECT: RE: RE: WE REALLY DO NEED LOTS OF ARCHITECTURE IN TERMINALS

Great. I am busily rethinking the great terminal. I just visited Allen Newell and looked at his use... another atypical
user, but found in addition to calculator nearby (we would show it on the screen, plus the registers of it plus past results
(ie the tape)), I found a clock, and possilbly an alarm clock that should be built in. The way to do these is to have about 4 virtual terminals there with a nice, quick action, eg.
like a telephone extension switch to move among them and the ability to generally do virttual circuit switching so that they
could all be used in an independent way.

We would put a rom in the terminal that would get the user the
various capabilities which he'd pay for as options. Now, I see them as: the telephone management connection (with phone
dialer and ability to put in numbers to recall for dialling); the
calculator-timer-clock option; the BASIC option; the paper option-
where we store all the scraps of paper that a user needs as a reminder
to keep his terminal in operation. All these would be independent
of the host.

Is there anything patentable here? How do we keep it from getting out and getting in other terminals before weget to the
market ?

Can you get me a person to help define and write the software for

these (ie the VT100) so we can see how they work? (I only want
one person in and R (A/D) role. Note, we can use these as Midlife
Kickers to the 100 too.   How are we going to plug in the option
roms?   I would build them on a PDT first to really get them
refined. When can I get the help?

SUBJECT: WINNING COMPUTING TERMINALS AND TERMINAL STRATEGY

Avram has proposed how we should focus our product development in the
computing terminals and terminals effort. Given we have the strength
and creativity of the groups who have been doing product engineering
in RPG, and TPG together with a unifying product direction we should
be able to put together a product set that would ship in August 82.
The product set:

. Black and white monitors to be used across all products
. LA24 ro printer and possible LA12 ro if the cost is there
. modules for the ct100 that can be used in the lower cost

versions
     including: rom, floppy, telephone management, and modems.
   . ct-wini with >2K product cost
   . ct-floppy with 1.3K cost
   . vk gigi 1.5 with 600$ + Monitor product cost with the ability to
     use the ct modules
   . a really low cost dumb or small computing terminal in a VK, with
     a product cost target of 200. Hopefully it would take the
     modules, but its goal would be cost and the only important
     modules that it need use would be the modem.

I think this is the right product direction. We can and should do it.

How can we proceed?

Subject: **Why I Believe The Tewksbury Group Should Have the Highest Morale**

To: Bill Demmer, TW/D19

Date: 4/9/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

CC: OOD
Brian Croxon, TW/C04
Dave Cutler, TW/D08
Bill Heffner, TW/C10
Bernie Lacroute, TW/A08
George Plowman, ML5-5/E97
Dave Rodgers, TW/C04
Bill Strecker, TW/A08

At a meeting in Tewksbury with the Venus Developers, who I all hope will move to Marlboro to continue their work, a question came up in regard to morale and future work. The question was why is Tewksbury being persecuted by having projects (cpu's) killed (70 CIS, 68) or moved (Venus)? The answer is quite simple and must be communicated there:

1. We did not continue the 70 CIS and 68 because you were so successful in building VAX! This seems like a paradox, because it means the harder everyone there works on VAX, the less products (actually just basic systems) we'll have. I don't believe the group understands that at the same time, we are moving toward a much more diminishing role for the 36-bit line. In fact, the attached statement gives the direction for this product line. Note that by stopping Dolphin, we have redirected 2 years of work that would have otherwise gone ahead had VAX been less successful.

2. Venus was moved because it was in such good shape as a project team in terms of focus and definition. There is expertise for ECL-based systems in Marlboro and rather than closing down this engineering center, I want to see it work on mainline products in a lower price range.

3. Tewksbury must become the architectural center for the Homogeneous Distributed Systems as given in the strategy. The base software is done there now and it is the place where this total architecture, and much of the implementation will be carried out! I want you to take over this global interconnect/network function and establish the appropriate links and controls with the Small Systems/Terminals group, DECnet/Comm and to the relevant Product Lines so that

the Corporate Product Strategy is implemented in a much more focussed, timely fashion.

Although I and the rest of DEC have commended the 780 and VMS team many times for a great system just as our customers are now by buying them, the ultimate satisfaction must come from knowing that your product is the base for DEC's computers for the next 10 years! Now I want you to build the structure that interconnects these machines together and to other computers in a as yet undefined totally novel (and good) homogeneous environment.

From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Stan Olsen, MK1-2/C36
Bill Segal, ML3-5/E82
Tom Stockebrand, AB
Bob Travis, MK1-1/J14 follow up 12/11/78

Don Knuth's Tan Epsilon Chi (TEX) computer typesetting system is probably the major contribution to typesetting in this century. It may rank somewhere near the Guttenburg press in terms of importance. Don Knuth, as usual, has "put it all together" by understanding typesetting very, very deeply and has posited a system which:

a. understands typesetting and allows a user to prepare text on <u>any</u> typewriter, word processor or editing system, or directly;

b. as distributed with the current macros (and described in the manual AIM-317 or STAN CS-78-675 by the Computer Science Department) can typeset major books in science, engineering and mathematics;

c. can be tailored, by a set of simple macros to virtually all typesetting applications.

Fundamentally, I want us to get distribution rights for the program so that we can use it now and build all subsequent typesetting systems on it! Now it runs on the 10, is written in about 10K lines of SAIL, but will be re-written in PASCAL. As a high-quality typesetting machine, the 5,000 pts/inch laser scan Alphatype Corporation product, for $25K is the best.

<u>High Precision Alphanumeric Scope</u>

Forest Baskett wants to build a high precision alpha scope for high quality word processing (including typesetting) using the new Motorola $500, M4408, 50 Mhz monitor. It would have a 8 x 10-1/2 page-oriented viewing area and 768 x 1024 pixels each with two brightness levels. It would use 32-64 Kchips to give 256 Kbytes and the whole design would be about 100 chips. The power is 5V, 5A; 55 volts 1.2 A (I said use Fonz).

I want simply:

a. us to supply the parts and constraints;

b. him to consult on this (Forest is very impressive with experience, accomplishments and energy);

c. us to get it into manufacturing, making sure it's buildable; and

d. distribute Don Knuth's Tan Epsilon Chi typesetting software.

George Berry's memo sums it up. We need to make a strong commitment to T_EX.
Joe, get us together to decide.

If we get organized, we can have a most significant product very rapidly. My feelings about T_EX are covered in the attached draft of a foreward for Knuth's book to be published soon by Digital Press. The activities we need to engage in are:

0. Make a commitment to an overall program (like this one).

1. Move the 10/20 version (in SAIL) in-house now to get the experience of the use and of the language. Be prepared to sell 10/20 if people want them. Distribute T_EX through DECUS if Knuth wants us to.

2. Move T_EX to VAX as it becomes available in PASCAL. Help Stanford make the conversion. Get it to be strictly compatible so that the learning and text in the 10/20 version are transferrable.

3. Use it now in Educational Services, for publications including Digital Press. Publish Knuth's book ASAP.

4. Extend the use for SWS, SWE,

CIS, Hardware Manuals and Products Promotion Group.

5. Get the necessary training courses set up based on the first course that Stanford ran, and build on their material. Eventually extend them outside when we offer it as a product.

6. Proceed to make it a product now as the highest priority, first commercial typesetting product. Move to put front ends and back ends on it based on SCRIBE, making SCRIBE fit it, rather than visa versa. (T_EX was there first, and if it becomes a standard (which I hope it does) then we will have to make the compatibility later.)

SIMPLE COMPUTER SIMULATION

Memory capacity: 24 3-digit cells

The Computer's Working Registers:

IR Instruction Register - holds the instruction selected by the PC

PC Program Counter - selects the memory cell for the next instruction

AC Accumulator - arithmetic register where results are accumulated

Instruction repertoire:

INP - 7 - INPut a number from the keyboard to a memory cell

OUT - 8 - OUTput a number from a memory cell to the typewriter

LDA - 1 - LoaD a number from the memory cell to the Accumulator

ADD - 3 - ADD a number from a memory cell to the accumulator

STA - 2 - STore Accumulator in a memory cell

STP - 0 - SToP! Do not perform any more operations

THE PROGRAM TO ADD TWO, 3-DIGIT, TYPED NUMBERS AND PRINT THEM ON TYPEWRITER

MEMORY CELL		NUMERIC VALUE	MEANING
00	INP 12	712	INPut a number from the keyboard to memory cell 12
01	INP 13	713	INPut a number from the keyboard to memory cell 13
02	LDA 12	112	LoaD the number in memory cell 12 to Accumulator
03	ADD 13	313	ADD the number in memory cell 13 to accumulator
04	STA 14	214	STore the number in accumulator in memory cell 14
05	OUT 14	814	OUTput the number in memory cell 14 on the printer
06	STP	000	SToP! Perform no more operations.
07			
12			Memory cell to hold the first number to be added
13			Memory cell for the addend
14			Memory cell for the sum
23			last cell of the computer's memory

HOW TO OPERATE THIS PROGRAM

WHICH "SIMULATES" A SIMPLE COMPUTER PROGRAM

THAT RUNS A PROGRAM TO ADD TWO NUMBERS (FROM THE KEYBOARD) AND PRINTS THEM

ACTION KEYS:

SPACEBAR (the long key) - makes the "simulated" computer go from instruction to instruction

0-9 digits - allows a 3-digit number to be typed. Any number more than 3 digits will cause an error and the program has to be restarted.

RETURN - terminates the string of typed numbers

If the program is stoped, it can be restarted by typing:

```
    LOAD "*",8
RUN
```

Your Underwood Typewriter is a welcome addition to our collection. Sometime in the future we hope to have an exhibit of typewriters through the years--yours will be an important part of that exhibit.

In the short term, Mary Jane is putting together for the ML12 lobby showcase equipment the office used in the 1910 to 1930 era, and she plans to use this typewriter.

Thank you for contributing to this project.

2 June 1983

Mr. Bruce Delagi
60 Peter Coutts Circle
Stanford, CA 94305

Dear Bruce:

It was good to do my final recovery in Palo Alto. After 3 days in Colorado Springs last weekend, I think I've recovered from the recovery.

Given your involvement in writing a proposal to work on AI Architecture for 3 years, how does this fit in with your plan for spending one more year at Stanford? (I still believe CMU's doing the best system's level work on parallelism and AI.)

I don't understand your own role as student? researcher? or manager?

Is it in AI (architecture? analysis? applications? systems implementations? etc.) Japanese Scholar? or designer of VLSIable hardware? or manager of our total PPA program there to understand how one applies it to ALL applications?

Believe there are very interesting possibilities as the person who works across all areas using PPA. (This is much safer and useful to work on in terms of getting results versus what may be an insurmountable problem of non-parallelism given the commitment to LISP) LISP parallelism may not be expressable or implementable except at AGE, MRS and application levels.

I hope you'll take a quick look at implementing Titan in Trilogy technology. It might provide an opportunity to mend fences with WRL.

I plan to propose a Bay Area Engineering/Manufacturing group and facility that would do joint ventures with various concerns -- especially start-ups.

Sincerely,

Gordon

The public thanks were real. The presentations were great, and I look forward to viewing and interacting with the videotapes.

It feels like even more people could attend and still have it interactive. It may be worth keeping it down to only 3 days however. Stan Pearson has suggested Profession Based Systems as the topic for next year. I'm sure there will be other topics...eg. with all the focus on products, maybe we should just go after the development process and all the parts that support it. This seems like an interesting way of focusing on the importance of all that money we spend below the line.

Thanks again, and you too Dick for supporting the effort. Who's going to do it next year? Bill, are you volunteering?

Pete Jansen and Bob Trochi did a very credible job in putting the slide talk together which I presented at SIGUCC in Boston on Monday, October 16. Even though this is per our agreement, thanks anyway.

I hope the talk helps the Edu Image with SIGUCC. If I can ever help in selling, let me know.

Mr. Carver Mead
Department of Computer Science
California Institute of Technology
Pasadena, CA 91125

Dear Carver:

It was really a great pleasure to be in your course last week. On behalf of Digital, let me express my thanks for a stimulating experience. The talk on Friday to various people outside of engineering, including several of my peers was also very worthwhile.

As one who tries to understand the future out of the past, I appreciate the analogy with the mechanical industry. We're only just beginning to understand the vastness of the various forms the information processing industry will take and the mechanism is probably the broadest analogy. The effort at the museum is another way I try to get at this. Here, I'm firmly convinced that PMS is a good taxonomic framework to hold all past artifacts (including programs). It's unclear how well it will hold up in the future. About two years ago, I gave a talk at Stanford on the lessons (about 45 now) we've learned from generating the computer generations. The RCA example and need for free resources that Gordon Moore talked about are already in them in some form. Gwen and I are trying to get these into a book.

I was glad we were able to spend some time together on Friday afternoon and discuss our product/technology dilema. Given your teaching, it is more than ever clear that the design work has to be done via people versed in programming who can think creatively about the programs necessary to do the design automatically! Anytime you have ways on how we can provide more effective products, I'd sure like to talk about them... on the phone, here, there or wherever. I'd like to visit Cal Tech when there is another opportunity. Look forward to more on the chip compiler.

Again, thanks for spending the week with us.

Sincerely,

Gordon Bell
Vice President of Engineering

GB0003/55

In order to effectively identify, design, produce, and distribute products to what appears to be a nearly infinite marketplace, an effective segmentation scheme is needed. The marketplace is so large because the computer is fundamentally used as a supplement and substitute for human and other information processing systems.

Furthermore, most information processing can be done in various modes ranging from a totally distributed, decentralized fashion with small computers to a single centralized, shared, very general purpose computer. While conventional market segmentation schemes must apply, the dynamic range of the product (in terms of price, technology, and function) makes a simple product segmentation scheme (1 dimension) useless. The set of producers for a small segment of the market can be segmented using a product based scheme...and then within the set more conventional segmentation can be used.

This essay is fundamentally a taxonomy of marketplace segmentation dimensions. The dimensions are presented in three clusters: product and producer-based (e.g., function, price, size, technology, level-of-integration); the distribution channel (e.g., direct versus multiple suppliers) and consumer-based (e.g., location, organizational size, demographic). Table Marketplace gives all the dimensions according to the three clusters.

Application TEchnology
Time and
  Real Time
Shared vs. Distributed
  (# Applic./System)

Applications Problem Locality

One unique aspect of computing is that the consumer is very often the entity which writes the final application program...hence the consumer is also his own producer for a large fraction of the product. Also, the producers form opinions based on their own needs and consumers. Producers mistakenly dismiss the notion of applying a computer as simply "an application". "An application", is fundamentally "the product"...and this usually implies a significant amount of software. For example, a lawn mower is "applied" (or used) to cut grass. Producing motors, wheels, tubing for the frame and handles, some sort of blades that could be used to cut grass would hardly constitute being a lawn mower supplier...nor would consumers of these parts (without assembly plans) regard the parts as lawn mowers, ready for application even though occasionally the parts had been assembled into lawn mowers (also tractors, wagons and other motorized vehicles).

In a recent seminar held within DEC a number of sales, marketing and product development people were asked (in groups) to give various ways the computer marketplace is segmented. Table MS shows this segmentation in a form which has been rearranged into the three groups which will be used in the remainder of this essay.

Table MS: Market Segment Dimensions Listed by Group

Dimension	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**

The basic computer hardware, an operating system specialized to a specific task (or highly general), an applications subprogram library, and the specific application based in part or wholly from the library, all determine the end use of a computer system within an organization. This network of parts is shown in Fig. Net as a flow, it corresponds to the original model and to the levels of integration. There are a large number of hardware models, h, each of which provide a certain range of performance at varying prices, on which, b, basic operating systems, and language-sets operate...giving what might be a large as h x b basic systems. By having a set of applications programs, a, each of which can operate on all of the systems (which is a desirable, optimistic, though unrealistic assumption), at "n" at a time, the number of unique systems is so large that all systems, are essentially unique. The number of unique systems increases since many of the systems will be used for more than 1 application over the machine's lifetime, or at a given time. A given application will usually find widest use based on fundamental activities within the organization, although it may be necessary to specialize the application to the particular organization. These applications correspond roughly to certain professional and intellectual discipline needs (e.g., electrical engineering--filter design, patent searching, statistical analysis of sales, inventory control) or across a set of more basic generic activities (e.g., word processing/typing, filing, message switching, plant security).

Distributed Product Design and Marketing

To further obscure the definition and responsibility for a system, a set of third party suppliers often participate in the design and manufacture by selling direct to the end user, or to the manufacturer for resale; assisting in the sale, application, installation, education and ultimately modification of the system. In the case of communications-based equipment, a common carrier is also involved. Alternatively, the end user may choose to apply the system at any of the multiple levels-of-integration.

Figure Mkt. shows the size of the market to be proportional to the amount each supplier is willing to participate in the definition and solution of the user's problem. Furthermore, the market often appears to be completely elastic with price, for a given application. Here we measure the cumulative degree of participation as being a 100% on the outer periphery of the onion (when a final application is supplied), and nearly 0% when only supplying the core (only the hardware). Whether a supplier can simultaneously sell at multiple levels-of-integration is a separate issue. Hence, it is possible that part of the market is unavailable because a seller only sells final solutions...and doesn't sell components on an ala carte basis. Very often, the degree of participation is highly correlated with the users sophistication in computing. A highly sophisticated user can indeed work with a only computer hardware, and proceed to write operating systems, languages, and applications programs with no further support. Also note that the price of the system increases rapidly as one supplies more of the system.

The metric for measuring market maturity is somewhat elusive, because it's so highly variable among markets and applications. Within a university the researcher is the first to use a computer for experiment control...yet the controller is last to use a computer for payroll or for inventory control. The application of a computer to a particular discipline follows the basic model shown in the first figure of the first essay...here, the computer or a particular program represents the basic research to be injected in the pipeline process. Just as we measure a given technology in terms of shipments of the product to a user, critical events (times) measure the market maturity.

THE THIRD PARTY MARKETPLACE SUPPLY

This marketplace has grown up around several activities:

1. Hardware is supplied initially to computer manufacturers for incorporation in systems, and as the user's understanding increases, these suppliers sell direct (as indicated in Fig. Mkt. in an add-on fashion). A separate,

independent add-on market not predicated on selling to computer manufacturers develops some time after initial sales and depends on knowledgeable users who are willing to take the risks commensurate with the lower costs.

2.Basic Operating Systems and Languages is by comparison quite a small market, and almost limited to special products (e.g., languages for simulation, data base management) on an add-on basis. These occasionally provide a degree of standardization among computer manufacturers. They take advantage of functional or performance limitations in the general, manufacturer supplied software.

3.Applications libraries have been the domain of the third party software suppliers. By becoming expert in an applications domain, written in a given language and operating on either a very specific configuration or a wide range of computer systems, a supplier is able to become expert in a marketplace, and hence dominate it. This is based on the fact that a computer manufacturer can not develop all applications, or the fact that a user is not in a business of applying and then selling back his application to other users.

Although this software is one of the purposes of a given manufacturer's users organization, it's voluntary, and usually non-profit, hence a limited supplier. The lack of protection (e.g., patents, copyrights) further deters there being a more well-defined marketplace surrounding user-supplied software. Ultimately, this will exist as programming cost continues to dominate hardware ownership costs. Such a marketplace will exist and be most similar to today's publishers; in fact, the publication of programs (algorithms) could ultimately supplant static text publication.

4.Applying/Installing/Training are also activities of third party suppliers. The final application, given a basic application library is a significant activity which implies a deep understanding of the organization which is to use the computer. For most cases this implies changing the program to fit the organization...or conversely changing the habits of an organization. There is still significant training involved to use a computer since it has a low tolerance for ambiguity, is generally inflexible, only adaptable up to a point, and can't learn. It should also be noted that a computer program in an organization is fundamentally a non-static entity and must constantly be changed and adapted to the organizational needs.

Figure Ch1. shows a complete diagram of the product flow via numerous channels based on one or more third parties which supply: complete systems, for which the computer is a minor part; an "added-on" part at any one of the levels-of-integration (including application, training, installation and service); or the final levels-of-integration based on taking lower level-of-integration parts from the manufacturer. In this diagram, there is a further separation between being a basic supplier as a main channel of flow (bottom to top of a box in the diagram) for the product (i.e., the channel handles the product), and being an "add-on" vendor (flow from the right in the diagram) to an existing product base with no handling of products. The diagram also shows the hardware, operating system and languages are further refined to the application even within the manufacturer's organization...rather than being totally general. For example, a factory data collection system has terminals that are specialized to the environment.

Often six organizations can be involved in a system: a third party supplier can supply disks to a manufacturer (and to the ultimate users on an "add-on" basis); the original manufacturer supplies hardware and software; a common carrier provides communications services; a third party develops basic applications library; another supplier installs, applies and trains the end user to operate the system; and finally the end user is provided a system which is ready to be operated, serviced and used.

The final user can also take on many of the roles of the third party or manufacturer by buying the system at a low level-of-integration and then adding appropriate applications knowledge, finally applying and using the computer.

Figure Ch2. shows a slightly more complete picture of the flow, yet simplifies the fact that multiple vendors can supply parts as third, fourth, etc. party vendors. In this figure, the extra boxes, of operating, servicing, and using the computer are added. Here, we have cases of both third party service and operations, (i.e., service bureaus or timesharing computer supply companies). In some instances, the manufacturer is also a supplier of a complete computation service (e.g., CDC). The original manufacturer supplies most service, and the end user organization operates the machine for his own use in most cases.

Figure Degree shows the product amount supplied for each of the three classes of organizations as a function of level-of-integration. The amount of basic supply varies for each manufacturer. In general, the larger the manufacturer, the more they supply directly without buying hardware from other vendors. (Also, the largest manufacturers attract the largest independent suppliers for add-on.) Operating systems and languages are mostly supplied by the manufacturer. The domain of application programs (i.e., the product) varies with the marketplace, customer size, etc. but has traditionally been handled by the (knowledgeable) user.

Basic Computer Function Dimensions

Each computer system carries out one or more information processing functions in a given environment. The section on the organization using the computer discusses the various intellectual disciplines as a way of segmenting use - although it doesn't specifically segment (list) them. These disciplines, rather than the associated environment, determine a computer's function more than any other factor since computers assist existing organizations in their information processing tasks. Alternatively, as computer designers, we feel that the structure (or form) determines the use. Thus, we can analyze the function or the form just as architects claim that "form follows function" or function follows form in some structures.

The second comment (warning) about function is that systems often take on multiple functions due to their inherent generality. In the section on operating systems we noted that all systems evolve to provide the same, general capabilities given enough evolutionary time. Thus we must also warn here of another rule of generality:

> All computer systems can be programmed to carry out the function of any other function...provided there is enough memory in the system, and that users will wait long enough for response and will spend the time to write the program.
>
> A consequence:
>
> Most computer systems carry out multiple functions, despite the fact that they were not originally installed for the secondary functions.
>
> A second consequence:
>
> Minicomputers (and other small computers including hand-held fixed and programmable calculators) are installed to handle limited functions that grow up around the highly general use of larger computers. (They are especially effective since the problem is now well defined.) The programmable, small computers begin to evolve at constant price and increasing generality. The well established, useful functions for a given discipline are placed in read only memory and become fixed functions. For example, the early scientific calculators evolved from just having logs, exponentials and transcendental functions to include statistical analysis, curve fitting, vectors and matrices.

The number of functions (i.e., applications) has increased significantly over the few decades of the computer's existence with the technology providing improved performance, cost/performance and cost for computation. Therefore, the classical functional segmentation used in the early days of computing are hardly applicable today. Table Fun1 gives two segmentation schemes: the classical one, and one which seemed adequate in 1971 (Bell and Newell, 1971). The classical (and IBM) segmentation divides the world up into three functional parts: Commercial--which is primarily record processing oriented and appears to be an extension of the card systems of the early 1900's; Scientific--which is predominately computation oriented using algorithms for processing numbers, symbols, graphs and consisting of scientists, mathematicians, engineers, and designers; and finally Industrial control (IBMeze for sensor based) is for real time control of mechanical processes which are directly connected to a computer.

The Bell and Newell (1971) scheme (column 2) added communications, file control, terminal and timesharing computers as functional categorizes.

Communications computers are special cases of real time control where the input-output interfaces are communications lines to terminals and to other computers. These have come into existence as: pre-processors to time multiplex a number of low speed lines onto a single line (the front end computer); message switching computers - replacing torn-tape telegraph; telephone switching control; and store and forward switches for computer networks. Computers are scheduled as in demand to the characters and messages on the various communications lines - hence are not real time. They differ from the highly general computers by not having general purpose peripheral equipment such as printers and substantial secondary memory. They usually operate with only a single program as opposed to being multiprogrammed.

File control computers were used in the control of disk memories and we expected them to evolve to become complete file and data base management systems (the so-called back end computer)...these are still yet to materialize as separate functional entities.

Terminal computers have evolved to a much higher degree than we expected.

These have materialized because the control for terminals (e.g., calculators) are done with microprocessors (i.e., processor-on-a-chip) and every terminal includes a stored program computer. Given this generality, it is a small matter to provide the terminal user with facilities to write programs.

Timeshared computers were shown as separate functional entities. These are probably a misnomer, but simply represent the ultimate generality for a computer.

Table Fun1: Simple Functional Segmentation Schemes

Classical Functions	**Bell-Newell Functions**
EDP (batch and rje oriented)	Business

Scientific (batch, timesharing for computation)	Scientific
Industrial control=sensor-based (real time discrete and continuous control)	Control
	Communications
	File Control
	Terminal
	Timesharing

Discipline-Environment Based Functional Segmentation

Table FunDisc gives a detailed segmentation scheme based on the intellectual disciplines and generic environment (e.g., home based) using and developing the computer systems. This scheme is given in substantially more detail than the two previous schemes, but is quite similar to the classical segmentation scheme. It also shows the evolving structures in each of the disciplines...hence, one can see that nearly all the environments evolve to provide some form of direct, interactive use in a multiprogrammed environment. The structures that interconnect to mechanical processes are predominately for manufacturing control. Other environments, such as transportation, are also basically real time control. Another feature of discipline-based functional segmentation is the fact that each of the disciplines operate on different symbols.

Commercial (or financial control) based environments hold records of identifier names for entities (e.g., part number) and numbers which are values for the entity (e.g., cost, number in inventory).

Table FunDisc: Discipline/Environment Based Functional Segmentation Scheme

Commercial environment [financial control for all
industry, retail/wholesale
distribution=BICARS]
=records storage and processing
traditional batch transaction
processing against data base business

analysis (includes calculators)*

Scientific*, engineering and design based environment
=numbers, algorithms, symbols, text, graphs storage and processing
traditional batch computation*
data acquisition*
interactive problem solving*
real time (includes calculators and text processing)
signal and image processing*
data base [notebooks and records]

Manufacturing environment
=record storage and processing
batch*
data logging and alarm checking
continuous real time control
discrete real time control
machine based
people/parts flow

Communications and Message Based
(Message/Text transmission switching, storage and processing)
message switching
front end processing
store and forward
networks
speech input/output
word processing
terminals and systems

Network (e.g., highway)
network flow control (excludes comm. nets)
on-board control

Education-based (Computer Assisted Instruction)
=algorithms, symbols, text storage and processing
drill and practice
library storage

Home-based using TV set
(entertainment, record keepint, instruction)

*Implies continuous program development

The scientific, engineering and design based disciplines use various algorithms for deriving symbols or evaluating values. Text, graphs, and diagrams are the major ways of representing objects, and have to be processed. For these environments, we have seen the computer change from a calculator (as it was initially funded to do calculations for ballistic weapons) to a sophisticated notebook for keeping specifications, designs and scientific records. It has also evolved for direct recording and analysis of time varying signals and images. Initially the computer was only used as a transducer to collect data from physical phenomena to be analyzed later on larger machines with some preprocessing (encoding). Eventually, the computer was used in direct analysis and control. Now, many transducers have (or will have) computers embedded in them in order to encode information at a high level so that its output does not have to be processed by another computer. These will invariably be connected to other larger computers in a network fashion to handle notebook graphical display and control functions. This corresponds to the intelligent terminal that is prevalent in the human interactive systems where processing is done at the lowest possible level and only the meaning of symbol is transmitted not the values of individual, time varying samples.

Manufacturing environment computers have evolved from a simple record keeping function which is quite similar to records in the commercial environment to direct on-line human control in a way identical to the other financial control-based disciplines.

Process-control computers have evolved from their initial use as assisting human operators (controllers) with data logging and alarm condition monitoring to full control of processes with either human or a second computer backup. The structure of the computer and the control task varies widely depending on whether it be a continuous process (e.g., refinery, rolling mill) or a discrete process (e.g., warehouse, automotive, appliance manufacturing).

Transportation for aircraft, trains, and eventually automotive vehicles is a form of real time control that uses both discrete and continuous control. Control is carried out in two parts: on board the vehicle and the network (e.g., airspace, highway) that carries the vehicles. The transportation control function dictates three unique characteristics for the computer structure:

1. very high reliability. Society has placed such a high value on a single human life that all computers in this environment can not appreciably lower the likelihood of fatality.

2. very small size for on-board computers.

3.extreme operating and storage temperature range for on-board computers - especially for automotive vehicles.

Communications and message based computers have evolved from telephone switching control, message switching, and front ends to other computers to be the dominant part of a communications system. With these evolving systems, the communications links have changed from analog-based modulation representation and transmission to sampled-data, digital transmission. By using all-digital transmission, data and voice (and video) can ultimately be used in the same system. Voice transducers enable speech communications with the computer.

Word processing (i.e., creation, editing, and reproduction) together with the long term storage and retrieval, and transmission to other sites (i.e., electronic mail) have evolved from several systems:

1. Conventional torn-tape message switching (e.g., TWX, Western Union, Telex).

2. Terminals with local storage and editing (i.e., flexowriters, teletype ASR's, magnetic card/magnetic tape automatic typewriters, and the evolving standalone word processing terminals.

3. Large, shared text preparation systems for centralized documentation preparation, newspaper publication, etc.

4. Large, systems with central filing and transmission (distribution). These will negate need for substantial hard copy. With these systems, text can be prepared either centrally with the system,, or with local intelligent word processing systems.

The education-based environment implies a system which is a combination of transaction processing (for the human interaction part), scientific computation as the computer is required to simulate real world conditions (i.e., physical/natural phenonmena) and information retrieval from a data base. These systems are evolving from the simple drill and practice systems which can be represented by a small, simple algorithm; through simulation of particular real world phenomena; to knowledge-based systems which have a limited but useful natural language communications capability.

Home based computers are beginning to emerge. The dominant use to date is in providing entertainment in the form of games that model simple real world phenomena (e.g., ping-pong). Appliances are beginning to have embedded computers that have particular knowledge for their environments. For example, computer-controlled ranges can cook particular food in fairly standard ways. Alternatively, cooking can be controlled by embedded temperature sensors.

Simple calculators to record checkbooks have existed for quite some time. These will soon evolve to provide written transactions for recording and control purpose. Many domestic activities are in essence scaled-down versions of commercial, scientific, education, and message environments.

PMS Structure Based Functional Segmentation

Table FunPMS presents a segmentation scheme that is based first, on the function the information processing system components are carrying out and second, on the disciplines and environments. Thus function follows form.

It should be noted that on evolution, each computer ultimately has a significant amount of computation, memory for data-base storage, transducers to connect with people, mechanical processes, and connects to other computers. Initially, one can characterize use by a simple information processing component. For example, the early card based equipment included only transducers, simple data-operators (+, -) a few words of memory, and plugboard switches. The evolution:

1. Keypunches: transducing alphanumeric records to a card deck record.

2. Verifiers: transducer/data-operator to transduce same record and to compare for identity.

3. Card interpretter: transducer to print characters on card for each column of holes.

4. Card reproducer: transducer to reproduce an identical, or column transposed copy of card deck.

5. Card lister: transducer to list each card as a line on paper.

6. Card sorter: data-operator to rearrange card deck in ascending/descending order according to column record values.

7. Printing calculator: transducer/data-operator to read and

store (in limited internal memory) values from a set of cards, to carry out simple operations on the stored values, and listing read, stored, and calculated values. Processing is fundamentally on a one pass basis.

Table FunPMS: PMS Structure Based Functional Segmentation Scheme

C:=Computers S:=Switching

- Business control (records)
  - batch
  - transaction processing
  - timesharing for development
    - modellings analysis*
- Scientific*, engineering, design (numbers, text, algorithms, and graphics)
  - batch
  - data acq.
  - interaction problem solving
  - real time signal and image processing
- Manufacturing control (people based - records)
  - batch
  - transaction processing
  - timesharing for development, modelling, analysis*
- Manufacturing Real Time Control
  - data acquisition and sensing (mechanical process variables and control algorithms)
  - discrete control

- Control for comm. nets
  - front end multiplexors
  - store and forward
    - torn tape message
    - computer-computer

T:=Terminal/Transducer

- personal standalone
  - fixed function arithmetic
    - calcualtors
  - discipline-oriented, fixed
    - function calculators
  - small, programmable
    - calculators*
- personal computer-based
  - dumb
    - text
    - graphics
  - text/word processing
  - fixed function (e.g., data
    - entry)
  - programmable
    - single, remote load
- personal rje station*

continuous control independent with single
discrete/continuous testing language*
general purpose - see C*
Transportation control shared
remote job entry stations
Home (records and entertainment) special printers
COM
Education (algorithms, symbols) speech i/o
sensor based front end

M:=Memory

Back end data base

*implies continuous program development

In this scheme, nearly all the environments of the previous scheme have been classified as computers (with full generality). Most of the functions for the communications category of the previous scheme are characterized as switching. Terminals occupy a significant segment reflecting both the cost and the perception that the terminal is now the computation facility (with embedded processing and memory). For very small systems, such as calculators, the keyboard, lights, housing and power supply (i.e., those parts that appear to be the terminal) dominate the cost and size. Here we have included the calculator as the most elementary terminal. The complete set of terminals is given in order of increasing size (and cost) and intelligence (i.e., amount of processing and memory).

Terminals, like computers, evolve to be fully general purpose with the capability to represent most of the information forms users need including text, graphs and figures. The terminal entitled the personal remote job entry station is such a terminal--it would have substantial secondary memory to store a user's personal files, processing to attend to a fairly large number of tasks, and programs to carry out text and program preparation functions in a standalone fashion.

Although the last two schemes appear to be different, they are fundamentally about the same. The first is organized basically on the discipline, and then by the evolutionary values correspond to the features of the structure (form) which provide the function. The second segmentation includes the discipline segmentation (function) as a secondary segmentation for each structural (form) given -- hence is a more detailed segmentation variant of the first scheme.

BASIC COMPUTER STRUCTURE PERFORMANCE DIMENSIONS

The simplest, yet still effective product segmentation is on the structure and performance of the basic computer hardware. There is a tacit assumption that sufficient software exists to exploit the structure, and that the transformation from this basic, lowest level hardware machine (here the macro machine) to the user machine (as provided by a language such as COBOL or FORTRAN) is relatively constant across various hardware (architecture). As each level is crossed, a transformation takes place requiring computational work. The form of the work with compiled languages is via the computer and run time support and with interpreted languages is via constant interpretation of the program. At the lowest level, the internal micro machine provides the architectural facade, the ISP, for the macro machine and operates at roughly 10 times the later's speed. Thus a machine executing 1 million instructions per second may have an effective microcycle time of 100 nanoseconds, permitting 10 million micro instructions/sec. execution. In turn, this implies that a conventional macro machine (ISP) executing 1 million instructions per second, is capable of perhaps 250,000 higher level FORTRAN language statements (instructions) per second depending on the mix of built-in functions and external functions called. To give constant ratios across levels of integration is a poor simplifying assumption when comparing machines of differing classes (e.g., micro to super) because there is not a consistency of data-types (i.e., micros currently have no built-in real arithmetic, whereas minis do). However, for machines within a class (e.g., mini) it's probably all right, provided the two machines have about the same data-types. Hence a count of the data-type is one of the more significant performance indicators, whether it be for a micro machine, macro machine or a language machine. This count must reflect the utilization of built-in operators for the data-type.

In a subsequent section we will show the transformation on performance starting with the highest level machine (language) requirements, down through the operating systems (which absorbs processing capability) and on to the basic hardware macro level machine.

The PMS structure, with the corresponding performance attributes for various components provides the basis for understanding machines and comparing them with each other. Figure BPMS gives a PMS diagram of a basic computer, with the parameters that are relevant to model computing structures adequately for this first set of essays. The diagram shows the key structural and corresponding performance parameters of each component as they provide a total computing environment. Alternatively, one might use a more descriptive, or tabular form, but the goal here is to provide a structural/performance basis for parameterization, comparison, and specifying the finite resources of the computer.

It's imperative to consider the resource constraints, and the effect of their interaction as each next layer of a machine is designed. For example, a certain line printer requires buffer space (Mp. size) and processing time (Pc. speed) which is then unavailable at the next machine level (e.g., FORTRAN).

In fact, Allen Newell and I once argued that we could describe a machine (at any level) with any number of parameters. Recall the first essay postulated a single performance indicator, the product of memory size x processor-access/second was adequate. Newell and I carried out the exercise for up to 5 parameters:

Number of parameters allowed:	1	2	3	4	5
1	Pc(i.rate)	-	-	Pc(op.rate)	
2		Mp(size)	-		-
3			Ms(size)	-	-
4				Pc(i.width)	-
5					No. of terminals

We did not allow ourselves any product indicators such as the product term of processor speed x memory size to indicate basic computational performance which we used in the first essay.

The first parameter Newell and I used was information.rate between the processor and memory, instead of the more conventional instructions per second. The following example of 3 different architectures (with 2 implementations of a stack architecture; one with the stack in the primary memory, Mp, and the other with the stack in the processor, Pc, using fast registers) show the difference in the various measures in what should fundamentally be about the same performance for a given problem.

The simple expression with the two operations, + and := A := B + C.

	Stack <u>(top in Mp)</u>	Stack <u>(top in Pc)</u>	1-address or <u>general reg.</u>	<u>3-</u> <u>address</u>
Program B,C,A	push B push C add pop A	push B push C add pop A	load B add C store A	add
No. of Instns.	4	4	3	1
Accesses	4op'+3a+6d 1op"+3a+3d	4op'+3a+3d	3op+3a+3d	
Program size (bits*)	64	64	72	60
Bits accessed	16+48+192 12+48+96 =266	16+48+96 =160	24+48+96 =168	 =156
Time to execute** (microseconds)	0.5+1.5+6 .37+1.5+3 =8 =4.87	0.5+1.5+3 =5	.75+1.5+3 =5.25	
Statement exec. rate(actual performance)	1/8 = .125m 1/4.87 =.21m	1/5 = .2m	1/5.25	=.19m
Oper.rate	2/8 = .25m 2/4.87 =.42m	2/5 = .4m	2/5.25 =	.38m
Inst. rate	4/8 = .5m 1/4.87 = .21m	4/5 = .8m	3/5.25 =	.57m
Pc(i.rate)/ = 1m word length	32m = 1m	32m = 1m	32m = 1m	32m

*assumes: address/a = 16b; data/d = 32b; op = 8b; op' = 4b; op" = 12b

**assumes a memory limited processor which can access 32b/microsecond

We have constrained the information rate between Pc and Mp to be the same in all cases, indicating roughly the same technology. The statement execution rate (the actual performance) is the highest for the 3-address machine, reflecting the highest performance whereas the conventional measure (instns/sec) shows it to have the lowest performance (by a factor of 4) over the fastest machine. A more subtle measure, operation-rate, is correlated with the true benchmark statement execution rate. It should be noted, (ignoring the first machine, a stack machine with stack in Mp) that the information-rate is a good performance indicator - versus the conventional, but poor, instruction-rate measure. For more unconventional machines, instructions/sec. tends to become a significantly poorer measure. The various vector/array machines (e.g., ILLIAC IV, CDC STAR, CRAY-1) have single instructions to operate on at least 64 operands per instruction.

Alternatively various programmable calculators have single instructions such as Sin, Polar to Cartesian co-ordinate conversion. Accesses/sec. will be used as a Pc performance measure.

For multi-processors the number of processors x the memory accesses/sec. roughly gives the total Pc.rate. Pc.rate can be computed more precisely by using the number of primary memory modules, Mp, and their data-rate. For a system where the memory access time, and the memory rewrite time equal the time for a Pc to operate on a word, the performance (Strecker, 1970) is roughly:

$$\text{Pc.speed (in accesses/sec.)} = (m/t.\text{access}) \times (1 - (1 - 1/m)^{p})$$

where m = # of Mp modules, and p = # of Pc's

Note that when p = m = large, the performance reaches an assymtope:

$$= m/tc \times (1/e)$$

In the case of multiprogramming systems (e.g., real time, transaction, and timesharing), the time to switch from job to job is critical. This measure, process context switching rate is one of the main attributes since most computer systems operate with some form of multiprogramming.

The number of data-types in the Pc, or preferably data-types compatability give the performance measure when operated with a particular language.

The memory sizes (in bytes) for both primary and secondary memory gives memory capability. The memory transfer rates are needed as secondary measures, especially to compute memory interference when multiple processors are used. This measure also permits system performance to be computed by subtracting the secondary memory transfers and external interface transfers. For file systems which require multiple accesses to secondary memory for single items, the file access rate capability is needed in order to compute performance. Similarly, for multiprogrammed systems which use secondary memory to hold programs, the access rate is needed.

Communications capability with humans, other computers, and other electronic encoded processes are equally important structure and performance attributes. Each channel (e.g., a typewriter) has a certain data rate and direction (full duplex for simultaneous two way communication). Collectively, the data rates and the number of channels connected to each of the 3 different environments (people, computers, other electronically encoded processes) signify quite different styles of computing capability, structure and ultimately use. For example, having no communications connection to other computers implies a standalone system. Having only interconnection to mechanical processes via electronically encoded links implies a real time structure. Similarly only human intercommunication with multiple terminals denotes a timesharing or transaction-processing orientation. Figure PLOT uses a Kiviat graph to display the six main dimensions of processing, primary and secondary memory capacity, and the three communication channels in a single 6-d graph, with 3 additional dimensions. Each dimension is logarithmic over a factor of 1,000,000 with the value 0, denoting the absence of an attribute (e.g., there is not communication with external systems beyond human and standard comm.). Various secondary measures and unit quantities are denoted by separate numbers by each dimension. Unit quantities can either be multipliers, x (denoting the measure is for 1 unit such as a disk) or divisors, /, (denoting the measure is for all the combined units of the system). A number-sign, #, is equivalent to a multiplier, x, denoting the graph value is for just one unit. Additional attribute: values are plotted parallel to or as marks on a given dimensional scale. Occasionally dimensions are further specified (e.g., audio, video). Arrows denote directionality of information flow. Note that if the Pc speed is "balanced" with Mp size according to Amdahl's constant, then the value of the two should be about the same. (Here Pc is accessing 300,000 bytes/sec. corresponding to say 100,000 instructions/sec., with Mp of 100,000 bytes). The graph conventions include subtleties of showing fixed points (i.e., ROM or hardwired), and averages, range and overhead due to other resources.

The arrangement of the six dimensions allows easy recognition of a structure in terms of the relative mix of the resource/performance attributes. Figure BPMSR gives a diagram of a computer system in the same order as the graph's dimensions.

Figure EXAMPLES shows how the 6-d plot can be used to represent and differentiate various computing structures in which we're interested. The first two structures are keyboard i/o, i.e., a single information transducer we know as the typewriter which has half-duplex i/o at 10 characters (or bytes) per second. A 10 char./sec. teletype is formed by adding a line interface.

The simple, early fixed function hand-held calculator, e.g., the HP35, which has a fixed processing/memory structure with about 4 x 10 digits (or 20 bytes to be more precise, of primary memory and store, limited keyboard input and 10 light LED output at about 10 char/sec. The internal fixed program is stored in about 2,000 ROM bytes--hence there is a single, fixed point; and the operation-rate of the unit is fixed at about 100 accesses/sec. of the HP35's powerful data-types. The HP65 programmable calculator is shown next with various fixed functions being replaced by programs, and Mp and Ms are each 500 bytes. The functions in ROM, though still present are not apparent to the user, hence are removed.

The second line gives graphs of various terminal structures beginning with a fixed function operating at 10,000 accesses/sec. (or 100 usec) with about 1,000 bytes of local memory and 2400 bits/sec. or 300 bytes/sec. access to a computer. The unit can be made programmable at 20,000 accesses/sec. by proving processing on a 4,000 byte primary memory. Mass storage, here a floppy disk, is also added in the second case--which also serves as a communication link. Communication to the external world is at 2,400 baud, or 300 bytes/sec. Output to the screen is at 2,400 bytes/sec. or 19,200 bits/sec. with input at 10 char/sec.

The next two systems are remote job entry stations, the first is fixed function and the second programmable. There are two i/o channels, one of 2,400 baud (i.e., 300 8-bit bytes/sec.) for the card reader and 4,800 baud (or 300 lines/min. = 5 lines/sec. at 120 bytes/line = 600 bytes/sec.) for the line printer connected via a 4,800 baud full duplex link. The second RJE terminal also includes a Pc at 50,000 accesses/sec. and an Mp of 16Kbytes. A tape unit of 50Kbytes/sec. which holds 300 Mbytes.

The next system is a programmable, store and forward system with 16 Kbytes, with a Pc which has an access rate of 100,000, with a context switching time of 1 millisecond. There are 32 lines of 10 to 150 bytes/sec. The four communication links to other computers operate at 600 or 1,200 bytes/sec. (or 4,800 or 9,600 baud). The next system is a fixed function, remote full duplex analog multiplexor with 16 channels operating at 16 x 100 bytes/sec. and multiplexed into a 1,200 byte/sec. (9,600 baud) line--hence the line limits the maximum sampling rate.

The next system is a programmable, remote, standalone process control system. Note the absence of any lines to communicate with other machines. A secondary memory system of 10 million bytes is used for communication with other
computers. Both gross and net Pc (2,000 accesses/sec.) (2,000 bytes) resources are given. Net capabilities are after the other resources are managed. One-hundred transducers are sampled each 10 milliseconds with 3 transducers connected to humans at a data-rate of 30 bytes/sec.

The last series of systems are, general purpose, multiprogrammed computers. The first is a batch system with card and line printer. The next is an 11/70 with 100 real time inputs, 60 terminals, and 2 connections to other computers. The KL10 is a large, multi-user (100) timesharing system. Finally the largest computer, the CRAY-1 is given, showing the dependence on external computers for Ms, and terminals.

Some comments can also be made about virtual machines!

OPERATING SYSTEM/LANGUAGE/APPLICATIONS DIMENSIONS

The outer three levels-of-integration operating system, language, and application structure dimensions determine the performance of a given computer. We know there is a fixed set of hardware resources--the basic hardware machine to which the various layers of software are applied...forming intermediate machines. At each level (machine), resources are used (taken away) to provide the next higher level (machine).

At the lowest level, the operating system provides control and management of the hardware, and permits it to be allocated to the multiple competing use requests. The multiple use requests may take the form of:

1. Single stream batch usually with overlapped input, compute, and output (i.e., spooling of input/output).

2. Multiple, concurrent batch streams.

3. Timesharing with independent user virtual machines.

4. Timesharing with shared concurrent processes for a single user.

5. Partitioned system with various batch and timesharing environments, each of which may have independent or shared tasks.

6. Real time with independent and/or shared processes.

7. Transaction processing with independent and/or shared processes for each terminal.

Although it's difficult to be completely precise about an operating system type, we will proceed to classify them simply along what appears to be the scheduling urgency dimension as: batch, timeshared, real time, or a hybrid combination of the three. The classification difficulty comes about because a computer is so general purpose and because:

"Every computer evolves to be fully general purpose, given enough time".

In batch mode, there is little urgency; the machine is scheduling its workload. The utilization of a batch oriented computer should be highest, since all the jobs are available to schedule, and there is no urgency to expedite particular jobs. One puts in a batch of work and then gets out reports for "management". (For management, these reports seem to have a problem due to their size, error prone, totally numeric, and uninteractable character. They are a way of presenting everybody with all the data and the user has to search through it, so it is putting all the onus on the user. Batch mode is straightforward in terms of urgency; you do not care when things come out. There is one exception, payroll, which everyone cares about...but it requires little new information to run for most environments since everyone is paid at about the same rate each week or month.)

Interactive mode, in the form of timesharing as we have known it, is essentially stochastically scheduled. People sit at terminals making demands on the system at random intervals. We know that a system must meet certain response time constraints in the order of 2 to 10 seconds, for very simple requests and can take longer--depending on the users' perception of how complex the job is. If one doesn't get the information back within the right time, they walk away--and the system is declared unusable.

The difference between batch and direct-interactive use is shown in Fig.___. With the batch system there is a long, error-prone set of links between the user and the computer which require several days. With a direct, interactive system of the form: timeshared or transaction-process based, the link is direct...or at the most human-human, with direct feedback to correct errors. It's important to differentiate between timesharing and transaction processing computers. In timesharing, each terminal (or possibly small set of users at terminals) has a single job (or virtual machine) assigned to them. The interaction takes the form of running that single job, with multiple implied phases in respone to the user's terminal request. The system is designed to permit all users to operate completely independent of one another. One (or a few) basic programs, and all users are constrained to operate within the set. The program is actually a set of interconnected processes, and information is passed from process to process depending on the requests (control) from a terminal. The structure is quite analogous to a job shop with multiple, specific machines (i.e., the process) and the work is passed from machine to machine. Figures __ and __ attempt to illustrate the difference between these two structures.

Real time implies an even more stringent scheduling function, typically in the range of 100 microseconds, up to about a second for a request. We will now use scheduling urgency as the basic criterion for deciding the basic function of a machine and to generate a taxonomy for all machines. From the model shown in the figures, it is easy to see that process structured operating system provides greater performance than a general purpose timesharing system when used for a single transaction processing application.

The next level above the operating system is the language level. This level gives rise to machine support of the language or multiple languages...language variability. That is, is there just one language or are there several? Are the languages fixed or is there a machine language and the ability to add more? That indicates the language generality of use for the particular machine.

The effect of multiple languages is to require larger memories to hold common compilers or interpretters and run time support software; hence either a single larger primary memory or high data transmission rates between primary and secondary memories. Similarly more generality is required to provide for the multiple user machine environments implicit in multiple higher level machines (i.e., the languages). The effect of being able to add languages is the need for protection/sharing mechanisms.

The final level is the application level. Here we must ask how many jobs are performing that function? One,...N different jobs? How many terminals? Is there sub-job structure within the job structure? Another criterion, which is particularly relevant to the notion of minicomputers vis a vis mainframes, is the degree of dedicatedness. Is the program fixed or is it variable? Then, within what timescale is the program fixed or variable; for example, is the program changed daily? The greater the variability, the greater the uncertainty as to the system's performance and the need for idle capacity to provide acceptable response.

Of course, this is a grossly simplified model of a computer system in that it predicts the lower bound on performance. By having a number of "compatible" jobs, which do not compete for the same resources at a given instant, more performance is possible.

The critical dimensions which are traded off against the fixed resources of a computer:

1. <u>Operating System Level</u>

Function = Scheduling Urgency:

Batch	Don't care	0 - hours
Timesharing	Stochastic	2 - 10 sec
Real Time/ Transaction Processing	Demand	0.1 ms. - 1 sec.

2. Language Level (number)

One, fixed
Multiple, fixed
Multiple with machine language access ability to add more

3. Application Level

Dedicatedness = fixed or variable (programmable)

4. Number of Jobs (dependent variable)

A given computer has a fixed set of resources which may be traded-off in varying ways to provide performance to its ultimate users. In essence--"you pay your money and take your choice" by trade-offs among scheduling urgency, whether the machine is dedicated to one or more tasks, using one or more languages, and the responsiveness for a given set of users.

Figure 4 shows these trade-offs. The surface of the triangle represents fixed resources, and as scheduling urgency increases, less resources are available for use (or conversely, increased scheduling urgency requires greater resources. If one wants to put more work on the system, the scheduling urgency must be decreased because you do not care when the work comes out. If one requires more variability in terms of different applications, one must pay the price in terms of decreased load (less jobs). One can trade off languages along the generality axis and applications along the variability axis; and applications for a larger number of jobs. In essence, if one knows what work has to be done, a system can be dedicated. Minicomputers are predicated on doing dedicated tasks which are usually specified at the time the system is ordered (and delivered); we do not try to do something for everybody.

OPERATING SYSTEM TAXONOMY BASED ON SCHEDULING URGENCY

We can also use the previous dimensions as attributes to form a taxonomy of the systems. Figure 5 shows a family tree of systems, with the first branch, operating system scheduling urgency: batch, interactive, real time. The next attribute is whether there is one or N basic streams (or tasks). The third discriminating attribute is whether tasks are fixed or variable (programmed).

All machines seem to start out as being "purely" designed for a particular function, in that they follow just one of the alternatives from the set of possibilities. For example, in the case of batch, one can see adding generality, moving from a constant work, fixed single stream batch system for purely production, through a programmer serviced batch system, then adding multiple batch streams. From there we go into multiprogramming; multiprogramming to do fixed work and multiprogramming for variable work. Then it is interesting to note that hybrid systems start evolving to give the benefits of both interaction and batch. A system is used for programming with N jobs, a number of batch streams, and somehow all jobs have to be done in that environment. We notice a whole class of remote job entry systems (or interactive) forming from batch systems but a way of varying the scheduling urgency while living within the batch mode. That is in fact an interactive, N job stream, fixed system: a hybrid of a pure, interactive system and a batch system. The hybridization is tacked on to get the programming work done at the location of the programmer. The hybrid systems are supported by partitioning the operating system into a number of separate machines but this is an indirect way of providing an interactive environment.

The second major branch (Fig. 5) is for "interactive" computing where humans have direct communication with the computer. In the early days of computing, before there were significant operating systems, one simply permitted a number of users to sign up for a given machine and directly interact with it, at its console in a solo fashion. That was a pleasant environment but it was inefficient in terms of machine utilization; it was desired to have a larger number of users for the machine and one knew we could do it if we simply put them in via a batch job stream. It should be noted that modern, programmable (e.g.,TI, HP, WANG, IBM 5100, DEC Classic/310) calculators are in essence a return to this style of direct, interactive use.

Timesharing grew up by providing virtual machines, by sharing a single physical machine for each user with control via a terminal--hence N users were involved, each given a capability to run any type (a variable) of job.

Transaction processing originated from batch and timesharing use with an attempt to fix the job mix in order to gain and predict efficiency. In fact, timesharing and transaction processing systems tend to evolve to look rather similar. It's most closely related to a real time system as we noted before.

With a transaction processing system, one might start with a fixed load and some idle capacity, to guarantee service. Batch is run in the background to utilize the idle capacity. Then one finds that the fixed load was not fixed anyway. For example, we might have a program doing a data entry application but the applications programmer starts on the next application and hence is doing program development on that same machine. In timesharing one starts with a variable load and then evolves to bind applications to have a fixed base load so that the stochastic load doesn't have to be provided for--hence efficiency is gained. Eventually variable batch load and possibly some real time capabilities are added.

The real time based system also ultimately provides a similar capability to that of transaction processing. A process monitoring application is designed and scheduled on the basis of knowledge of a particular processing structure and load. Message switching is an example of an application which can be designed as a fixed, single task. Laboratory environment where events are highly structured and the processing task is relatively simple, but highly variable from experiment to experiment is another real time based system. One can understand the interaction of events and begin to know how well the system will perform. Alternatively, we may start with a variable load; with, say, an experimenter who is working to create his system to carry out an experiment. When he has finalized his system, the variable load evolves to become fixed; the machine is sitting there, running 24 hours a day, collecting data and assisting in the laboratory. Whichever origin, an environment evolves to one of being able to develop the next program while that fixed program is running. This created a mode, we call foreground/background (to utilize the idle capacity and get work done) with a simple machine.

I hope it is clear that a system starts with basic hardware and then is applied (be it somewhat modified) in different ways; these different ways provide batch, interactive and real time utilization. Small computers have traditionally been applied in real time and interactive mode...but they are impressive with batch mode too.

The other way of looking at these structures is by their interface to the outside world. Even batch mode is really coupling computers to people, but through a key punch and it's associated human links (see Fig. __). For a non-human, real-time process the structure is quite similar to transaction processing--but with more demanding time constraints because the process can generally not be slowed down (i.e., there is inertia). I believe in the limit, all systems take on all functions given enough time. The market causes the evolution. Once one produces a system, the pressure is to evolve every machine to do everything and we tend to succumb to that, either in marketing machines or in doing applications. With the evolution, the supporting costs (service people) start climbing. If one doesn't succumb, there are many highly tailored machines...the origin of minis and now micros.

Price and the Range of Price (and Performance)

Price is the critical attribute of the system as it directly determines the applicability (buyers) for a system or set of systems. With the very first computers, each advance in technology caused a new computer to be designed to match its inehrent capabilities. For example, as the early vacuum tube computer packaging improved, resulting in the fabrication of larger computers, registers were added together with additional data types (e.g., floating point data). By the mid to late second generation it became clear that computers could not be changed rapidly to precisely track the technology because users wanted to preserve previously written software to run on the new computer (of higher performance or of lower price). Similarly, as users applied a given computer to a task and then outgrew the computer as the task expanded, they also wanted a range of compatible computers to choose from in order to migrate tasks among them. (While programming languages attempt to permit a substantial amount of machine independence, they don't entirely. Similarly the manufacturer who exploits the idiosyncrasies of the machine language level also requires compatible machines in order to build on a base software investment.)

Thus, as we build machines from new technology, there is always a constraint of past machine compatibility, and to provide machines across the widest price (and performance) range. The IBM System 360 utilized this principle more effectively than any other computer.

It is completely described in the literature (e.g., Bell and Newell, 1971) and by IBM. However, let's look at what the models provide in terms of price and performance.

According to the Telex papers IBM tried to provide model separation of a factor of 2 in price and 3 in performance. Hence, the relationship between performance and price should be:

$$\text{Performance} = K \times \text{Price}^{3/2}$$

which is not what Grosch's law calls for. Looking at the models range:

Models	**Price**	**Performance**
20 - 91	1 - 105 (mins)	1 - 300
	1 - 65 (arg)	
	1 - 125? (min of min to max of max)	

Here, the initial 7 models included: 20, 30, 40, 50, 65, 75, and 91.

And models: 25, 44, 85, and (a few) 95 were added.

Thus the original plan called for each machine to cover roughly a factor of 2 in price:

$$125 = 1.99^{7} ;$$

whereas, adding 3 models caused each machine to cover 1.6

$$125 = 1.6^{10}$$

Performance becomes:

$$65^{1.36} = 300$$

Gene Amdahl, head of Amdahl Computer Corporation, has pointed out (from the Telex papers) that the number of machines sold follows a completely elastic market. Also this corresponds identically to the revenue distribution of the world's corporations. Figure IBM shows the distribution function for the 360 (less model 91). Profitability is distributed differently with the smaller (and higher volume) machines having constant profitability versus lower profitability for the 168 which incurs greater development costs. (Amdahl also points out that the larger machines are at least as profitable as small machines when considering the lower support costs of the experienced user.)

For the current DEC PDP-11 family of machines:

Model(s)	Price Range (in K$)	[mid]	Performance (Scientific)
03	10 - 30	[15]	3
04	20 - 40		1
34	30 - 80		10?
45	45 - 150		40
55	60 - 200		70
70	95 - 300	[250]	65

Thus, the range 300/10 = 30 is covered on a per model basis of:

$$1.76^{6} = 30$$

or if we assume 04/34 and 45/55 as a single model then:

$$2.34^{4} = 30$$

The economy of scale factor performance using midpoint prices over the price range of 250/15 (16.67) is 1.51. I.e.,

$$70 = 16.67^{1.51}$$

Range Metrics

From the above discussion we can assess a set of computers in terms of the various price and performance metrics for each of the models (i.e., the range). Figure RM shows three hypothetical systems which are introduced at various times. The first 2 are introduced at a price range of 2 and then given enhancements to increase and decrease their price ranges to a factor of 4 and 8, respectively. The third system has a constant price range of 2 (between 32 and 64). The third graph shows the price range factor of 645 for the three systems and the fourth graph shows the effective price range factor of 32 for all three--reflecting the hole between 16 and 32. The fifth graph plots the % of holes and overlaps. The value of the effective price is used to compute the effective price range per system. (Note this is the metric that was used to evaluate the models of the 360 and PDP-11 above.

These metrics can be similarly applied to performance, memory size and other system attributes.

The goals for a complete, compatibile produce line (i.e., set of products) is to have:

1. the widest range of products in terms of price offering.

2. the largest economy of scale factor for performance that separates the models.

3. the smallest number of models to minimize costs of design, manufacture, selling and spares inventory.

4. the most cost-effective/competitive solutions for each price in the space.

Size (and Form Factor, i.e., Shape) Segmentation

Although computers have evolved to have a particular set of sizes and form factors (shapes), many computers are embedded in other systems--hence these take on the shape of the native system. The system price is roughly correlated with size and weight for most computers--although aerospace computers were initially priced inversely with size and weight.

For example, the very first hand-held calculators were implemented with small, stored program computers - hence the size and shape was that for personal convenience (e.g., portability). Now it's clear as hand-held calculators are made to be programmable that they are indeed stored program computers. Traditional minicomputers were successful in part because they were mounted in standard (9" equipment racks and as such "fit in" with other electronic control equipment.

Memory Size as Single System Size Metric

We have spent considerable effort describing the complexity of computer structures and why there are so many important dimensions in which to characterize a computer. Alternatively we now describe primary memory size as a single metric to characterize a computer system. This has arisen because: according to Amdahl's constant, processor speed, memory size and i/o bandwidth are all correlated; memory size is the dominate system price determinant; and with memory hierarchies, the total memory size is known given the primary memory size and processor speed. Alternatively by knowing the primary memory size, one can impute the type of use for the system...given a knowledge of the user environment. In this way, the cost for various systems can be projected (into the future).

The amount of memory for a given environment may also follow the distribution of organizational sizes.

Figure MemDis shows a wild guess at the memory distribution of various entities. The largest consentration of memory is centered around 7 digit numbers (e.g., phone #, the price of some object, street address, social security, a small number of time events). The next ditribution is based on a page of text. Note, the memory size is calibrated both in bytes and in terms of various physical memories that are worthwhile.

Examples of Segmentation Schemes

Authors, market surveyors, students of computer engineering, buyers and sellers must have some specific scheme for market segmenting. In this section, several of these schemes will be described.

Phister (Functional) Segmentation

Phister (1976) segments the use of machines by application area and then tracks this use for various sized systems. Figure Phister shows the use of minicomputers for:

Engineering and Scientific Computation
Process Control
Data Acquisition
Testing
Business

Note the middle three applications would have been characterized earlier as real time because they all interface to non-human, non-computer, external processes.

A Market Survey Functional Segmentation

One of the numerous market surveys also segmented computing in terms of functions performed. Then within each function, an estimate was given of market size and maturity. This functional segmentation (and corresponding PMS Computer Structure Components):

1. Communication - S, K, M

2. EDP Support - T

3. Business Data Processing - D, TD, TDM, TPM

4. Specialized Data and Word Processing - TM, TPM

5. Industrial Automation - T, TK, TPM

6. Specialized Data Acquisition - TM

7. Laboratory and Computation - DM, PM, TPM

8. Instructional - T, TM, TPM

The fine structural segmentation within the communications was:

1. Front end - S

2. Concentrator - S

3. Message Switch - S, SM

4. PABX - K, KM

5. Monitoring/control of central office - KPM

All the other segments are similarly broken up. Each subsegmented is also further segmented by price. The goal of this segmentation scheme was to have orthogonality among the segments (i.e., no overlap).

Size Based Market Survey Segmentation

One of the poorest segmentation schemes is a pure size based scheme because, at each size level, all applications are available. The values of the size basis:

1. Microprocessor (integrated into peripherals)

2. Modules destined for OEMs

3. Micro or mini capability for networks

4. Micro or mini specialized processing

5. Mini specialized packaging

6. Mini complex network computer

7. Mini used by novice

8. Mini top of range

9. Mini top of range, but integrated into nets

These 9 segments were then reduced to 4:

1. Micro - weak perf., variable complexity, functionally specialized

2. Micro + specialized average perf., weak computation, multi-Pc

3. Mini -, good perf., compatible, complex

4. Mini +, high perf., weak compatibility, multi-Pc, general purpose

DEC Segmentation

USER SEGMENTATION DIMENSIONS

The user-based segmentation dimensions of Table MARKETPLACE will be discussed in this section. The premise that a given application (product) is independent of the organization-based segmentation dimensions turns out to be totally false. There is a high degree of correlation between the product and the organization. The conventional, simple dimensions of location (geography), Standard Industry Classification code (what an organization does), the intellectual disciplines within the organization (e.g., accounting, engineering), and the size all dramatically affect the product (application) design. This section goes through the segmentation dimensions one at a time and discusses their effect on the product.

Geography (or location) is the simplest segmentation dimension because computers are complex enough to require salespersons. A given producer can only employ finite resources, and the rate of change of sales resources is fundamentally small. It's not necessary that geography be the dominate segmentation it is now. By drastically changing the intelligence of the computer, one could affect the dependence on personal selling. For example, the hand-held, desk, and small-programmable calculators have very little fixed intelligence...hence are understandable (and can be sold via mail and other non-people intensive channels). Similarly one could postulate a computer system with sufficient intelligence (not requiring the highly stylistic programming of today's computers) that could adapt to and provide information processing in a highly limited intellectual discipline (e.g., inventory control, message switching).

A further factor to complicate geography-based segmentation is that an organization (e.g., federal or state government, a state university, large corporation) is distributed over a large area...hence is unattended to by a single salesperson or area. Very often geography clearly impacts product design since various countries, states, and cities have differing regulations that affect information processing structures.

Although we currently poorly segment computer use by geography, it is reasonable to do so since areas vary widely in their willingness to take risk, spending for computation, and educational capability.

Standard Industry Classification (SIC) Code was devised in the 1930's by the Department of Commerce to classify the activity of an organization (see Table SIC).

Table SIC: Standard Industrial Classification Codes (first level)

A.	Agriculture, Forestry, Fishing
B.	Mining
C.	Construction
D.	Manufacturing
E.	Transportation, communications, electric, gas and sanitary services
F.	Wholesale trade
G.	Retail trade
H.	Finance, insurance and real estate
I.	Services
J.	Public administration

This segmentation dimension is probably the most widely used today even though a second level of refinement, the Intellectual Discipline, is necessary for products (i.e., to provide particular applications programs). The SIC code does not have a category which classifies various forms of consumers (e.g., personal, family). For example, all the categories have a set of activities that are independent of SIC code, reflecting the nature of an economy based/coontrolled organization. Some of these are shown below:

SIC Code Independent Generic Information Processing Activities

interpersonal communication
phone communication

text creation, copying, transmission and filing (includes TWX, message switching, intra/inter-office mail)

personnel record keeping (e.g., payroll, insurance)

legal

selling

general business
income management (billing, accounts receivable)
asset management (inventory, plant and facilities)
outgo management (orders, accounts payable)

These activities are really not totally independent of the SIC code, but rather depend on both the code and the intellectual discipline within the organization. For example, a payroll program which pays on the basis of skills for a hospital (e.g., various-typed doctors, nurses, administration, maintenance workers) would be considerably different than a payroll program for a construction company with different skills and control rules (e.g., unions, overtime).

Intellectual Disciplines (and Homogeneity)

A more fundamental, and more useful segmentation dimension that determines the product is the intellectual discipline (or activity) within an organization. since a computer is often supplementing these disciplines by helping with processing, holding information, capturing input data, presenting output, or doing control that would otherwise not be possible, it's natural the applications totally coincide with well established human, intellectual disciplines. Society (and universities) have segmented and codified this knowledge (often with algorithms) such that it can be applied by human information processors...and machines capable of interpretting the algorithms.

Demographic Factors

It's not clear that the use of a computer system within an organization is correlated with any of the standard, simple demographic factors (e.g., age, sex, nationality, eye color, education). Formal education in secondary schools and colleges, to the notion of algorithms, and computation probably aids in getting potential users to consider applying computers. Hence, use may be more highly correlated with recent education and therefore inversely proportional to age.

The more general intellectual capability measures (e.g., IQ) that transcends computer systems must also be considered as a segmentation dimension.

Organizational Structure

Many separate dimensions are needed to adequately characterize an organization structure as it relates to computers and information processing. It has been hypothesized that the structure of computers within an organization reflects the structure of the human organization. This should, in fact, be true if one accepts the conjectures that computers supplement/substitute for information processing of other forms (e.g., humans).

The simple metrics of size (measured by people, area, net worth, income profit, etc.) are often correlated with spending power - whether it be for buildings or computers. These metrics assume all organizations are identical, hence spend the same fraction for computing independent of what it does, where it is, or how its organized.

Clearly organizational ownership is also important, not as it affects products but by the way it buys machines. The alternatives range from the individual, through partnerships, co-operatives, corporations, non-profit corporations and the various levels of government. For example, in the case of the U. S. Federal Government, a strict centralized, approval mechanism is employed to insure that obsolete, low risk/lower benefit equipment is used. A small, privately owned organization can often make decisions rapidly since only one or two people are involved in the decision.

For large organizations, the geographical location of control (central versus decentral) is important. A geographically remote (decentralized) part of an organization may be completely centrally controlled, hence is merely a satellite subject to a central organization. In larger, strong centrally controlled organizations which use computers, IBM is the usual vendor. This phenomenon is fairly predictable because:

1. IBM was there first...10-20 years ago.

2. There is one main place to sell to, plus any general corporate selling. (IBM excels in this role.) There is no other way to enter the site.

3. There is the belief in Grosch's law...hence it's better to have one large computer than n smaller ones of 1/n power. Furthermore IBM doesn't provide small computers for distributed use.

4. A single computer is easier to control, hence easier on the organization.

Another organizational notion is the location of intellectual disciplines; the two extremes are the autonomous divisional organization and the functional organization. In the former, each division has its own intellectual disciplines...hence can be treated as independent, small entities.

The functional organization is based to independent skills centers; i.e., the intellectual disciplines, hence is easier to "sell to". Alternatively, unless a division is quite large, the functional organization will have a larger critical mass of skills to apply the computer (i.e., develop the product).

Conversely in a divisional organization, (unless there is some sort of mechanism for inter-group communications, and since divisions by their nature are set up to compete with one another) each division will tend to purchase and develop its own system! The matrix organization attempts to solve the problems inherent in the above two organizations by making each person part of two independent organizations: the function and the division (or project/product group). In this way the professional identity/management is retained; and the motivation associated with a product or project is added by assignment.

The locus of decision making (or theory X versus theory Y organization) is clearly important in both purchase and development of systems.

Each organization has a unique way in which systems are identified, proposed, approved, and implemented. It's essential that the people responsible for implementing a system recommend the system...otherwise there is a high likelihood it will fail to be applied properly. Unlike any other entity (including a new co-worker) entering an organization, a computer is fundamentally a part of an organization hence must have the approval of its co-workers.

User (Consumer) Capability as Computer System Producer - Applications

As we saw in the original diagram (Fig. Ch1) showing the network flow of products to use, any organization can serve as a producer. Most often, the final user (consumer) organization is also the developer (producer) for the applications programming, installation and training. This incestuous relationship does have a fundamental problem because there is not the normal check and balance relationship that exists in a producer-consumer (seller-buyer) pairing. Even though a clean interface exists in the form of a given language, there are a large set of non-orthogonal performance dimensions so as to thoroughly obscure fully characterizing the performance of a given computer system. Furthermore, in the initial design stage, a problem is very difficult to characterize in terms of the systems' performance dimensions.

A given organization may attempt a more complete design than it's capable of. For example, it may predicate a design on multiple third party hardware and software vendors, communications links from a common carrier, and have significant applications programming. Such an undertaking requires deep understanding at every level-of-integration.

A user organization then can be characterized by the following breadth and depth measures:

1. Participating levels-of-integration

2. Understanding, i.e., the capability at each level-of-integration (including the application)

Experience with other vendors is another important attribute-value pair. The most predominate value is the degree to which IBM supplies serviced equipment, software and other services. In fact, most IBM customers do not participate in a system design at the hardware, operating system and language levels-of-integration. Purchasing third party hardware is regarded as a high degree of participation in system design; and a user may still not have much understanding/capability at this level-of-integration.

Cost (and Risk)/Benefit

Ultimately, within our economy-based societies, all use of resources is tested with some sort of cost-benefit analysis.

Perhaps the easiest segmentation scheme is then a combined analysis of the cost, risk and benefit of applying computers to a given task. Presumably the producer has already done a preliminary benefit analysis for a given application before attempting to market his product. Since many applications are user originated (versus manufacturer originated) the cost-benefit analysis techniques are predominately done by the user. Note, a given new computer application may turn out to be economically infeasible after it's installation because the analysis techniques are not widely used by manufacturers or by many users.

The concept of computer equipment renting and leasing permits the cost and financial risk of a new application to be decreased. By this averaging process, each application is more expensive because it's paying for a share of the new applications.

Various characterizations of people can be used to further segment risk attitudes. Haley (1969) used these for a study on consumer marketing:

worriers
sociables
swingers/sensory-oriented/ego-centered
price-oriented (idependent)

If we characterize benefit and risk for a given application:

```
          benefit

risk          low               high
          -------------------------------
              !
low           !                     (easy decision)
              !     price -->  <-- worriers
              !
              !
              !
              !     (may be non-   (may involve
              !      existent)     research)
              !
              !                <-- swingers
high          ! ego-centered-->
              !
```

An organization's attitude toward risk taking is an essential ingredient, especially in the less mature application of computers. Nearly all computer installations have risk associated with them. For mature applications, there is even a risk that the biasses and mind set of an organization will cripple a computer and insure its failure. For new applications where there is clear benefit, the application development may not be possible at the required performance level and hence the cost will be too high.

An organization which does not have an R and D function, for example, is probably not familiar with the concept of risk...hence is likely to be either extremely early or late to use computers.

The simplest measure of risk is the cost of the application hardware and software measured in calendar time and human effort. It has been observed that cost and time increase exponentially with system size and that there is a maximum system size which can be built at a given technology time. Therefore risk increases with the system size.

Application Technology Time and Calendar Time

One might consider the timeliness (feasibility) of a given application to be part of the cost-benefit analysis. Alternatively, we should recall the time-evolution process model described in the first essay for all products (including the given application of a computer to a task). Here, an application product may go from basic research, to applied research, advanced development, development, production, product enhancement, maturity and ultimately die.

We must be careful to measure and separate the application time from the real time. At a given real time underlying technology or understanding may be such that basic research in a given area can not be conceived or even considered. Later, when the carrier technology has progressed, the necessary basic research may be carried out quite rapidly and progress to a production stage in only a few years. Figure Mat1 shows two hypothetical application base products that are increasing in use at different rates until they achieve saturation and then grow at a constant, slow rate. One application, the computer to understand speech, has been in the research phase from 1955 till 1975. Certain limited production use occurred in the mid '70's and as technology improves, we would expect this use to increase significantly. On the same figure, the number of hand held programmable calculators is plotted. Note that there is not a substantial front end phase with research, but rather the use occurs much earlier and lasts a shorter time before it saturates (at the number of people who are capable of programming or using a pre-programmed program.

Alternatively there is an effect which reflects the combined knowledge about the application as shown in Fig. Mat2. Here, by increasing the degree of participation a supplier can provide more systems than if the application (product) is developed by the user. Since many users are doing development at the same time there is no combined learning--hence the market matures more slowly than if there is development by the producer.

A secondary effect of technology time is to limit the maximum size system which can be build. Furthermore the time (and cost) vary exponentially with size times a technology building constant.
I believe we're at least starting to get some NI Servers/Stations started, which are predicated on Seaboard I and II unbounded Qbus based products, and then moving to bounded MicroVAX chip based products. The potential is just incredible, and certainly much greater than we had with the

original 11 with it's Unibus.

But alas, I fear we'll do what we did with CI clusters, making no one in charge of the overall structure to do the nurturing and pushing, followed by the ultimate product introduction of the concept and supporting the specific product intros. The result will be that the structure, as described below will take FIVE years to achieve, and by then, when we achieve it's full potential, it will be greeted by a chorous of yans.

I'd like to see this be a major product/project, even though the specific server projects are being done across all engineering.

The status (and Product Vision) I see as the current Project Engineer:

1. Seaboard/Seahorse IS the base for building the servers. MicroVMS will be the system in the Person Server.

2. The Person Server is moving a bit. (Andy, does this correspond to the Workstations program you're working on?)

Hardware. The video board, QVSS, for doing graphics is defined and will be delivered shortly. Just as soon as we understand the performance issues, we should move rapidly to firm up a low cost color version spec. The VS300 looks good, but at a cost of 5K plus VAX isn't what we want for the mass market computing terminal. The group to DO the VC100/PC32 should be assigned. I'd like to see several proposals, and possibly breadboards, then we build the best one. In no case, should we charter a group, give them carte blanche, and proceed without seeing a plausible design and a plan. The overall direction is: build the QVSS now for the undbounded first product on Qbus-Seahorse to gain experience, and follow it with a bounded version at low cost. We still need a color version to be competitive according to Roger Cady, and I'm inclined to agree. This is in Jim's court, and we are already VERY late in getting started, given the MicroVAX chip progress. Two versions will exist with and without mass storage. The large volume of computing terminals shouldn't have Mass storage.

Software. Dick's doing it. I think we need to tie the relationship to what the VS100 based workstations and software is.

3. The print server direction isn't firmed up yet, but has the potential to be done because there's lots of experience around, even though there's too many people working on it to ever get the job done. I've made a proposal about its redirection. I'd like to start the project on a much less roccocco design base. As Alan Perlis said: "software goes from roccocco to ruble".

We must be able to print what we display, and we currently can't.

Hardware. I've asked John Ring to adopt Forest Baskett's Unibus design for the Qbus, and take the responsiblity to build the 2 designs and introduce them into production. The software group's design intuitively feels better to me (I may not be close enough to this area) and I'd like to resolve whether the run length encoding and transformation hardware can be put into Forest's design. (Sam, can you help?) Since Rich's design works, we should be able to measure and analyze both designs to see exactly whether it's worth persuing both designs. The ideal would be to have the simple instruction Rich needs put into the Reid/Baskett design.

Software. There are four groups involved (printer, software printing under Hassett, distributed systems, and workstations), and I have no idea who's doing what. I think we want to have software folks do the design, because they know about software engineering, and they've built a printer.

4. Communication server. I don't know what this is, nor who's going to do it, but I know we need it to save the world from what is probably our worst design of this decade, Pluto, the dog. (At least I hope we don't do anything worse.) There are breadboards for comm servers all over the place, and we should pick one and the corresponding group and productize it.

Hardware. It would seem that the current package is inadequate for the connection. Ken's asking for Qbus communication modules, and if we can define what's needed, then we could get the appropriate modules and packaging. It would be ideally a mod on the Qbox.

It's a non-trivial design, but Seaboard looks like the ideal environment for it. I'd like to see this one done at DECwest, because it's a product we can no longer afford to play with.

5. File/Database Server. Supposedly this is being done in Colorado. There may be a slip on this while the team is taken back to finish HSC. Also, we do need a Qbus adapter for SI disks. The specs, like those of HSC (when it gets done), sound great.

6. Real Time Server. LDP has a fabulous opportunity to make a great product. How can we get them focussed on it?

7. Factory Conrol Server. MDC ought to flush it's plans for controllers and build from this excellent base! I don't see any hope here. The best approach is to go find several really good OEMs to do the various interface hardwares and software.

8. Commercial server. If we decide to enter this market somehow with Bob Daley's products, then we have a great base to make some interesting products.

9. OEM Servers and third party software builder servers. We should recognize that there's going to be tremendous opportunities to build all kinds of services (eg. pabx, image processing, teleconferencing, etc.) on this excellent base. It would be great if we figured out how to manage these potential opportunities.

10. Gateways to other vendor equipment on Ethernet, such as Xerox, and gateways to other networks such as Omninet. We need an approach to this. DECwest may be the place to do this.

I'D LIKE SOME HELP NOW
DECwest and the VMS groups have given us an excellent base for building these specific products.

I don't see the "buy in" from the critical groups that are needed to go after some of the servers, nor the commitment to pull the whole system off.

I want someone to take this overall resposiblity and to proceed to get the resources from the collection of junque we're doing it and then redirect it so that these critical projects are put in place to achieve the above distributed system dream.

What you say? Is there any chance we can go this way, or do you not want to disturb the sleeping?
.

I would like to go all out and buy a signficant fraction of the folks we met on Friday, Symmetric Computer Systems for the following reasons:

0. We need a product that could ship within 6 months.

1. They have a basic product and very constrained architecture that lets us get BELOW the Multibus and Qbus based systems, yet is expandable enough to handle a reaonsable range. It is a factor of 2 or more below the HYDRA structure in cost with about the same performance for a minimal system. Apparently the product can be expanded to handle the Workstations case. Whether they could ever do portable or ECL or large servers is probably incidental. If the general bus is good, then they have a chance of making a very interesting low end product family (including our servers and gateways).

2. They have UNIX 4.1 running and are moving on to 4.2. They have Mr. 4.2 as part of the team. We need to have this expertise in order to reduce the risk and time to market for HYDRA to a reasonable level.

3. They are young, naive, enthusiastic, poorly led and don't understand the market. Furthermore they don't know how to get a product like this into high volume production. Hopefully, they are going to have a little trouble getting VC financing... and hence **may** be available to us.

THOUGHTS ON GETTING COMPANIES
I am quite distressed about our ability to find interesting companies to buy, buy product from or that approach us in startup mode.

BUYING PRODUCT
Traditional computer company metrics forces a make (not buy) mentality even though the ROI may be quite high. Virtually all of the discussions on buying products seem to start and end with conflict.

The DDE product was quite close and could have been quite profitable. Here, the compatibility, lack of UNIX commitement and understanding and conflict with HYDRA were the stumbling block.

Maybe a geographical distribution is the key. I know folks in Japan and the UK, but UNIX understanding and availability on the xxx32 is probably the bottleneck again.

BUYING A SHINY ON-GOING COMPANY
I don't think there are any that want to relinquish any form of control that would make them part of us. The only condition would be that they would relinquish equity or control seems to be unacceptable to us.

BUYING A TROUBLED COMPANY
These look poor ala Codata and Momentum.

START-UPS WHO COME TO US
I don't think we're going to get any start-ups who come to us unsollicited. Our standards are probably those of the VCs, and as such we simply are unattractive. I think start-ups want the independence and chance for the reward that they perceive we do not offer.

For the naive startups we have been unable to attract or hold them.

START-UPS WE FIND AND CREATE
This avenue ala lamP, Charle and what we may have to do in networks is going to take along time. The team has to form and we have to do a substantial part of the work. Also, we interfere with the natural selection process.

BOTTOM LINE
It would be wise to peg HYDRA somewhere around what Apollo and Masscomp did (start: 10/81; FCS: Nov. 82; Rev.83: 2.5M; Rev.84: 24M). Apollo was first, Masscomp followed 18 months later and HYDRA's 2 years behind Masscomp. This is significantly more aggressive than Sequent who will ship after 21 months, which is probably more realistic for a more complex (than Masscomp) product.

I don't see anything like a 30M year in our second year of operation UNLESS we get a company that would have product within 6 months, and that could deliver on the order of 20M next year. This could be obtained if the financial window opens for us and closes for the public offerings, which let the VC world dump their misFortunes and Wildcats on the public and replenish their money supply.

WHY SLUMBERGER SHOULD TAKE A SIGNIFICANT POSITION IN ECC

AS AN INVESTEMENT Clearly ...it passes their hurdles. But, they are used to buying bargains and we may not be perceived this way.

ECC AS THE CENTER OF THEIR INFORMATION PROCESSING BUSINESS. Ideally, they would some day own all of us. They really need ALL of ECC, to be a significant force in information processing because of our scope as a complete supplier. Currently they have semis, a plotter company and a CAD/CAM software company spotted across levels-of-integration. The paper on the structure of the industry shows how this CAD/CAM company is going to be evolved out of existence because of the migration to software only companies. Having us as a hardware, sales and service supplier would let them migrate these field people to our field company and let CAD/CAM company concentrate on software. Having a Systems company would also have a major-effect on the product direction of Fairchild. (It's important that they really understand the notion of the levels of integration model.)

Their size and structure inhibits doing this. Ideally, we'd do this and then effect a merger at about the 1 billion level. (Here, we have to be a bit careful in describing this, because it could help them tune and build their empire.)

We give them the critical mass through our field marketing organization where the only economy of scale exists. AND we give them a wonderful product line on which to base all their Fairchild, CAD/CAM and drilling work on.

SYNERGY WITH THE MAINLINE LOGGING BUSINESS Maybe they could just be a buyer, but it would be great if they had a much better source of supply than DEC... who they are worried about.

Our emphasis is on performance, moving into AI when appropriate and hence the synergy. In addition to the focus on parallelism, we want to build on the work of HT Kung at CMU which is completely targeted at signal processing, the mainstay of logging analysis. Kung has a real edge and we are talking now about how to establish and exploit this.

SYNERGY WITH FAIRCHILD AS A CUSTOMER
They are trying to be a source to the National 32032; this is critical. We certainly can help them focus on being a customer. We also use the Fast logic in our work.

SYNERGY WITH FAIRCHILD AS A SUPPLIER
Getting serious on the National part means having a source of software for the OEM we could be this!

Their tester needs HYDRA and perhaps Kung's machine since it processes data (signatures) at such a high speed.

Their AI effort clearly needs a host. Hydra is it.

SYNERGY WITH FAIRCHILD AS A JOINT PARTNER IN ESTABLISHING COMPANIES
Their AI effort is not spectacular due to lack of focus and their misunderstanding of the traditional model of research. The current behavior of researchers is to "use" a research environment to build a product or establish a set of customers (eg military) and then to break away and exploit this at your own company. Even if there was a product, there is no vechicle to sell an AI product. Their only rationale is for internal use, and this is nonsense because their problems are too hard for AI. Furthermore the people they have working for them are AI scientists NOT engineers; hence there won't be a product anyway.

AI COMPANY could be established asap. I might instead want to buy one jointly with them. My favorite would be Smart Systems Technology.

A SIGNFICANT ARCHITECTURE TO GET THEM INTO THE MICRO BUSINESS. We need a partner to fabricate and distribute MIPS! We supply the architecture, software and strategy. They sell the chip and possibly board products through the traditional channels. We're ready to move on this! There is an effort inside of Fairchild that should probably be scrapped!!!!! They have been a total failure in this area, but need to succeed to be a significant semicomptuter company.

A HIGH PERFORMANCE COMPUTER WHICH WOULD PUT PRODUCT FOCUS ON THEIR HIGH END TECHNOLOGY. My feeling is that Fairchild shoud get out of one of their businesses and concentrate say just on ECL and CMOS, but don't know. A joint development effort implementing either MIPS or the 32032 in ECL would be a winning product.

A WINDOW ON PEOPLE VIA ENTREPRENEURIAL ENERGY.
ECC CAN DO THIS. SCHLUMBERGER CAN'T.

BOTTOM LINE:
WE COULD OFFER THEM A BETTER VIEW OF THE FUTURE COULPLED WITH INTERESTING ALTERNATIVES FOR BUILDING NEW BUSINESSES
... IF THEY'RE INTERESTED IN PLAYING IN THE INFORMATION

PROCESSING

A NUMBER OF PROCESSORS SHARING A COMMON PRIMARY MEMORY

PARALLELISM   RELIABILITY   PERFORMANCE
I believe we're at least starting to get some NI

Servers/Stations started, which are predicated on Seaboard I and II unbounded Qbus based products, and then moving to bounded MicroVAX chip based products. The potential is just incredible, and certainly much greater than we had with the original 11 with it's Unibus.

But alas, I fear we'll do what we did with CI clusters, making no one in charge of the overall structure to do the nurturing and pushing, followed by the ultimate product introduction of the concept and supporting the specific product intros. The result will be that the structure, as described below will take FIVE years to achieve, and by then, when we achieve it's full potential, it will be greeted by a chorous of yans.

I'd like to see this be a major product/project, even though the specific server projects are being done across all engineering.

The status (and Product Vision) I see as the current Project Engineer:

1. Seaboard/Seahorse IS the base for building the servers. MicroVMS will be the system in the Person Server.

2. The Person Server is moving a bit. (Andy, does this correspond to the Workstations program you're working on?)

Hardware. The video board, QVSS, for doing graphics is defined and will be delivered shortly. Just as soon as we understand the performance issues, we should move rapidly to firm up a low cost color version spec. The VS300 looks good, but at a cost of 5K plus VAX isn't what we want for the mass market computing terminal. The group to DO the VC100/PC32 should be assigned. I'd like to see several proposals, and possibly breadboards, then we build the best one. In no case, should we charter a group, give them carte blanche, and proceed without seeing a plausible design and a plan. The overall direction is: build the QVSS now for the undbounded first product on Qbus-Seahorse to gain experience, and follow it with a bounded version at low cost.   We still need a color version to be competitive according to Roger Cady, and

I'm inclined to agree. This is in Jim's court, and we are already VERY late in getting started, given the MicroVAX chip progress. Two versions will exist with and without mass storage. The large volume of computing terminals shouldn't have Mass storage.

Software. Dick's doing it. I think we need to tie the relationship to what the VS100 based workstations and software is.

SUBJECT: THE 3 RIVERS PER Q - A THREAT, TREND? FOLLOW UP:
2/1/80

Every university I've talked to recently (Newcastle, CMU, Purdue, U. of Washington) have commented that they intend to get a number of PER Q's. Also MIT's building their own.

Why haven't the folks in marketing asked about this?

When will we have a Nebula mock-up or a breadboard, working software for this product? When could we get it to the market?

I got these points at a conference in France from their applications engineer.

4/74	Process technology begins
7/74	Initial 16K design
10/74	Layout
2/75	First functioning unit
6/75	64 devices operating in 1Mb memory
9/75	Compatible TTL version
12/75	Customer sampling of 2116

His data present in terms of # elements/chip = 2**(t-1959) versus my # bits/chip = 2**(t-1962) give a 3 year delay...or x8 elements/bit.

SUBJECT: SELLING TINY--ESPECIALLY WITHIN DEC

It feels like we need an aggressive internal campaign to sell and use Tiny. I see systems being built around the 8085 that should be Tiny. I also see work not being done that should be based on Tiny. Can we get this moving somehow? Some of the recent applications: getting all our line printers to have serial interfaces by using a Tiny in them, building a generalized protocol converter that converts SNA, etc. to DNA, consoles for our large systems. Your demo system is fine, but we need a bigger effort and we need more of them.

It seems like we need two kinds of systems: the 64Kbyte system you are demoing; and the 2 x 65Kbyte one where there is a controller space, leaving the 65Kbytes for an application (eg. communications). Let's have demos (build more Crickets) for each of the groups.

On the second type, can't we take the control algorithm out of the TU58 and put it in Tiny? Then we can use just the TU58 mechanism and get the cost down for what is essentially a ROM cartridge in the low volume applications where the code is likely to change or there are likely to be lots of variants (eg. the protocol converters).

Also, it has to be clear what the software alternatives that we
recommend using to write applications. Here, I would hope we could start pushing Pascal as a HLL, along with the various alternatives for the Operating System: S, RT, SSC, etc. It is
important that the users don't have to write their own, as we found out in using S as the basis for the VT200 controller! However, when we start using the TU58 or a comm. line for down
line loading of the system, the whole thing has to hang together
and be supported.

What systems are we planning to sell and support?

Who is responsible for the various systems (hardware and software)?

You are probably right: Associate Head, Vice President of Engineering isn't right.

Note Dick's title is:

Vice President, Computer Systems Development

Puffer's old title was:

Vice President, Engineering Operations

my title is:

Vice President, Engineering

In the organization chart, I simply put (Associate head or Associate) when both of us were in a box. It could be used like this if were simply always confined to the writing down on an organzation chart. Some alternatives:

Vice President, Engineering

Vice President (Associate), Engineering

Vice President, Engineering Operations

Vice President, Engineering (Associate)

Other possibilites, but maybe incompatible with other DEC titles:

Associate Vice President, Engineering

Assistant Vice President, Engineering

SUBJECT: TLC DEMO MAR 9

I was delighted to get the information on the TLC.
It is a very impressive terminal, and looks like a good way to shake down the definition of the VT200. Here, I'd hope the 200 would do virtually all that TLC is going to do, but be low cost... and hence further out in time. TLC looks to me to be essential to hold our technical base. Frankly, at 5K it looks like a bargain! (Also, I see it as backup for the
VT200 approach.) Also, it's the first terminal that I think I could be very happy with as a user.

If you are prepared, could it be a real dog and pony show for some of the other people working on terminals?
VT12200-Picott, forrester, james, don haney
Suvax-nat parke and don north
gigi 2 graphics-stony ballard
terminals architectur- tom McIntire

It would seem that this might be an alternative to doing the Suvax display if we make any reasonable number of suvax's forrr
Nebula. Also, it would be a clear winner as a typeset terminal

given the page size (I assume the way to program other
character
sets really works... which technical users thrive on). The
high
baud rate also looks good.

All in all, the specs made by day. Now, assuming you can
deliver on the terminal, it can really help keep us in the
terminal market. Am looking forward to the demo! (I hope
you are really pushing on the terminals engineering group
to get a high resolution monitor.)

SUBJECT: TMS

Let's get together and talk about where TMS is headed. I'm
certainly excited about it and especially the many types of
software that it'll spawn. I'd like to get Walt Tetschner
into
the discussion too because he's off doing a voice interface
to a synthesizer, so large systems can build things like
EMS voice mail systems that read memos to you. Also, the
Klatt algorithm should be put in TMS. There is room for
all kinds fo products and misunderstanding and I don't want
to contribute to them.

Also, assuming the TMS is all it was spec'd, the reward
should be to keep the team together to do it again.

Can you get with Walt first and find out what's going on

there
and then let's get together?

(My part in getting the speech thing going under Walt was that we'd spent lots and got nothing. I wanted them to build what amounted to a type and talk that all sorts of systems could use to start building products.)

Bruce Delagi and I also speculated about a party line or group
kind of conference facility under the control of 2 CT's. It would also be nice to have a cheap, low resolution ccd camera for sending snapshots of the meeting. The voice could either go over the line encoded or on a seperate line. The ct's would
control what was put on the screen (ie the slides that would have been sent ahead of time and that would exist in every ct).

Subject: **Enhance the Q-bus Modules and Build the Commercial Terminal--Don't build Toby**

To: Dick Clayton, ML12-2/E71

Date: 12/9/78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

CC:	Buzz Brooks	MK1-2/H32	Ed Kramer	MR2-2/A67
	Steve Coleman	ML12-1/F41	Jack MacKeen	MR2-2/M65
	Bruce Delagi	MR2-1/M64	Roy Moffa	ML5-

2/E93

Ed Fauvre	MK1-2/E06	Stan Pearson	ML12-2/E71
Don Gaubatz	ML3-2/E41	Mike Titelbaum	ML1-2/E65
Bob Glorioso	ML3-2/E41	Mike Tomasic	ML12-2/E71
Andy Knowles	ML10-2/A52		

<u>WHAT</u>

Since I am the culprit in suggesting no TOBY, I want to be constructive and say what I think we should do:

1. Build the appropriate Commercial Processor module with CIS, putting as much as possible on a Quad to connect to Q-bus.

2. Configure a system out of the Q-bussed modules to be functionally equivalent to the Commercial VT-100 terminal that was being built to hold TOBY. Do the documentation so as to see that it is not FA and T'd. (There is no way you can convince me that by building a new set of 5 modules that plug together without a green block versus using a few other modules that use a green block, we have to have no FA and T or not.) We might call this phenomenon the Green Block's Disease, if true.

3. Configure the modules and build a really great bounded system based on the RL02 that is suitable for TRAX, using the VT162 et al so that we have something that is functionally equivalent to the 8100 for transaction processing, but is 1/2 the 8100 cost. It would also run SCS and be used with a configuration to give HP 45 and HP 300 functionality. Stylistically, it ought to be designed for a terminal user/operator too.

4. Use the VT162 (Fonz-based system) as the true low-end 11 bounded system by running an applications there too by basing the design on SCS (with the terminal running in the foreground) just as the Advanced

Development program that Sebern carried out for you indicated. Do the packaging to get clean ROM pluggable options so that we can make many different terminals in a fixed fashion. This gets us a really low cost system.

WHY

We can carry out these designs for the cost of the TOBY terminal and the VT162 (which we are already doing) projects, yet we have a better base. The reasons for this approach are:

0. We get the RL02-based and low-cost 11-terminals products too.

1. Let's invest in a base (Q-bus) which can be used to track any changes that we may encounter in the marketplace. This gets us volume and cost. Furthermore it gives us a base for putting all future systems together. (Observe that the micros are even standardizing on the Intel Multibus!)

2. We will have to have hardware and software for SDLC, X25, DDCMP and our new high speed multidrop interconnect network. Although TOBY can be modified to track these changes, I ask why bother, when they must be done on the Q-bus 11 base already.

3. The system must surely interface to RL02, and I don't see making another interconnect structure which this will imply when using a bounded system.

4. Although the cost differential of 20% (as an outside high) sounds like a lot, I think it is small compared with our ability to get volume quicker (i.e., a short time to market), the ability to have different, unique systems if and when necessary, enhancing the modules base so that we can build a cabinet based RL02 system which we badly need to compete with IBM and HP. I can't get anyone to say that this market is that price senisitive, or they are that sure of the configurations.

5. I really can't stand the idea of starting a new, distributed bus (MUSH BUS) around those 5 modules for what is a negligible cost difference!

OTHER THINGS TO INVEST IN

Overall, it seems like there are more important basic options and software to invest in that will give us a bigger bang for the same buck that I believe will be deadended. Some ideas and significantly higher priority than a 20% cost reduction effort:

1. Communications/Interconnect- see above plus modem, acoustic coupler, IEEE bus, speech output

2. Hard copy- FAX and connection to LAs for hard copy. We also need graphics output, Letter-like quality, and Letter Quality. Communicating LAs.

3. Basic Q-bus Options- more LSI for lower cost (eg SQUID), PUSART, Tiny, the packaging for a good solid state memory for program distribution.

4. Basic, new Processors- Here, we have to get >256KB quick...note what all the other 16-bit micros can do.

5. LSI VAX, though low in expenditures to explore now, takes talent.

6. CRTs- high resolution for WP and Typeset. Graphics. Color. Hard copy output is needed with them all.

7. Special Transducers-- Speech output, Wand input, BADGE/Turn-around document input, ability to have special consoles (ie. keyboards) for different applications. Card reader, enabling an RJE to be configured and built.

8. Low cost terminals, especially if we go after mass market doing transaction processing on this kind of system where the goal is A TERMINAL FOR EVERYONE (sound familiar?). This includes the CRT and the small alphanumeric that Savell's group has breadboarded.

9. Other systems. Getting above 256KB is essential in light of 16-bit micro. Jack MacKeen and Ed certainly support the multiprocessor (see attached). We have a lot of understanding here on it and we can build on this or we can wait for the competition which we see coming.

10. Software systems. Communications support to the various other systems. RJE station emulation. 3270...et al emulation for various use as a general terminal. Concentrators for clustering and emulating VT162's with multiple VT100s. MINI-TRAX that will support more users on 256KB. Graphics support, given we get some hardware.

Overall, I think TOBY is dull and dead end, but given the customer interest in PDT, we'll probably sell some. However, given the same resources, I believe the products I have outlined in the first section will get us more product and functionality, a hell of a lot more revenue and a better product base.

Are we doing all the above now which I consider higher priority?

Tom McWilliams is graduating finally. What's the chance of getting him to come here and work on the VAX-on-a-chip? Also, I've asked him to look at making an emulation mode of VAX on the next version of the S-1. I'm trying to get Forest Baskett to try to build a VAX-on-a-chip at Stanford as a chip to test their capability. He might want to do this if we can get him interested in extending the VAX architecture.

Can we import the Widdoes/McWilliams CAD system? What part of it can we use as is?

Dear Tony:

I enjoyed the discussion with you and your team last Tuesday. Enclosed is a non-disclosure agreement which I promised.

After the meeting, I talked with John McCarthy's group regarding a Queue-based Lisp. I hope that we can satisfy the group that we have the right approach. John is intending to visit us soon.

I have already asked John Payne of National to contact you regarding their support in a Common Lisp. Also, I will call both Larry Walker at Sperry and Joe Watson at TI to enquire of their interest.

We would like to get an idea of the cost of implementing a compiler.

Sincerely,

Gordon Bell
Chief Technical Officer

Here's what we said:

GB: I'm calling because our marketing people told me what a mess
they'd made of describing VAx. We had the wrong group talking to
you and didn't get into the critical product areas.

DT: Last week we decided to go to IBM for their cad/cam. We need IBM
net interfacing and hi performance color and B/W graphics. We
visited you in December and didn't think you were in this area.

GB: What about having a smaller parallel path using VAX?

Could you
come visit us and look at our very impressive workstation plans?
Or can we start by visiting you and describing this?

DT: Come here immediately! I'll be at DEC within 2 weeks to sell you
a Silicon foundry and could see the demos then.

You're at the 11th hour.

GB: I though you were at the 25th hour.

DT: No, it's 11:59 and the window's closing. Come sell.

GB: Ok. we'll be there asap.

Can you guys not make a liar of me? Why do we do such crappy selling/marketing vis a vis charters?

Forest Baskett suggests that the most cost effective way to use the 30-bit address on the 20 is to put in the pipes mechanism of UNIX and to keep the individual process less than 256 Kwords. The operating system would manage a set of processes in a 30-bit environment together and the switching among them would be almost instantaneous and by mapping. This would allow nearly all the problems to be solved that a large address environment would provide except a single large array access. By going to 30-bits everywhere I fear not only the massive development cost, but more likely that the machine will not perform well. Hence, a simple explicit mechanism may be better than having 30-bits everywhere.

What do you think?

I ran onto a system where programming is really taught effectively and cheaply. You might do it/sell it other places. They use their language SP/k, a subset of PL/1, and the students use mark sense cards with the SP/k language. The system is wheeled into class and programs are run. For cost/job you probably can't beat it.

They'd be happy to have you use it, sell it, see it, etc.

SUBJ: Over 40 Engineers

I got this message from one of our "over 40 engineers."

"During the last six(6) months, I've had the experience of bringing a bunch of fresh college grads & Senior people into a group simultaneously. The contrast between the recent grads & the senior people was really striking to me.

The recent college grads:

Have an abundance of common sense & maturity.

Are optimistic & enthusiastic- don't know that it can't be done.

Are positive & constructive.

Are creative.

Are disciplined, smart workers.

Are flexible & adaptable.

Are crisp, clean, ego-less communicators.

In contrast, the senior people I've found to be lacking in each of the categories. The junior people are an absolute delight to manage & the senior people require the most help. The senior people also happen to be highly educated & have a strong pattern of formal re-training.

I'm certainly for making it easier for our engineers to obtain formal training but I do believe that it's a minor part of the problem & thinking that it's anything more is a cop-out.

Note that none of the areas that were identified above would be effected by technical training programs & yet they are essential ingrediants for having a first-class engineering function.

The problem of "Engineer deterioration" is created by a set of industrial managing priorities that simply don't have the technologist high on the list. The fresh engineer isn't aware of this situation. As they see the lack of appreciation/importance that we place on their work, they start the deterioration process."

We must break the viscious cycle: poor education causes poor products and longer schedules, with no time for education!

Very long projects don't allow for education, nor is Continuing Education part of our Individual Development Program evaluation. Close in projects (mid-life kickers) teach nothing!

A continuing education program is vital, given our demographics and lower growth which filters out young (teaching) engineers.

MESSAGE ID: 5202828273

SUBJECT: ENGINEERING SKILLS=PROJECT/PRODUCT PERFORMANCE

GB6.2

In this year's strategy update, I identified developing our skills as #2 in the top 10 list, just below sorting out what work we have to do and who does it.

During the last few weeks I've been exposed to several projects which are mainstays of the product strategy, and find:

THERE'S NO WAY WE CAN IMPLEMENT CRITICAL PRODUCTS IN THE PRODUCT STRATEGY WITHOUT SIGNIFICANT ON-THE-FLY TRAINING OF ENGINEERS AND THEIR MANAGERS!

Frankly, I'm stumped, and think we have a stalemate and are not addressing training. EMC members seem to want no part of education for two reasons:

- your people are adequately trained for the current work, and your particular work environments are actually quite nice. Hudson and Marlboro fall in this category. Littleton's improving. I don't know of other acceptable environments.
- the situation is hopeless, and you're hoping the problem will go away. Pockets of the mill, some A/D, and Tewksbury are typical

WHAT IBM DOES
Erich Bloch, VP who built and operated Fishkill for many years, is in charge of their education. They just have to have an edge because:

- technical people take about 4 weeks per year in new courses
- managers take 3 weeks per year including one week of required technical education

EMC AGENDA ITEM
I'd like to discuss this critical item for a few minutes at EMC because the number of poor projects has reached epidemic

proportions
as measured by our performance against schedules (measured in being
1-2 years late) and simply by looking at the projects (and feeling my
gut).

A long awaited task force report is in process, but it is not aggressive enough in time, effort or direction.

Mostly, I want several projects very badly, but I don't believe they
are possible with the current people as trained and managed.

25 October 1982

Mr. Edward A. Reynolds
Quality Assurance Consultant
Mattituck, Long Island, N.Y.11952

Dear Mr. Reynolds:

Thank you for your letter and your concern about DIGITAL and the issue of Engineering Obsolescence. I appreciate your candid assessment of one sample of our Quality and Reliability Engineering. Since I don't know the plant or discipline, I won't comment except to say that Digital has grown more rapidly than any other company in history. The emphasis may have been on getting an organization in place rapidly, and perhaps less on technical skills. Therefore, you might find that we have an exceptional personnel department in our plant; we do have very good employee relations. As you properly point out, high technology is based on technical skills.

If you look at the officers of Digital, the majority come from an engineering background and a few have additional MBAs. Ken Olsen, our president, practiced engineering for many years and is still active in product design. There are a few companies who have a stronger engineering foundation in the officers than Digital. NEC has an amazingly large collection of engineers who have made contributions as officers. IBM appears to be an anomoly; it is strongly supportive of science, engineering and education, (and even the arts) yet it's top managers are from the field and marketing organization who have become professional managers. Watson has commented that he never understood why their great engineers never became the company's top managers. (I believe I understand why, but that's another topic.)

The problem of Continuing Education has become acute for us for many reasons, which I won't describe here. For example, the performance ratings of engineers entering their 40's shows a drop. We need a whole range of educational activities:

all forms of education within our research and advanced development organizations where industry (and I) expect new ideas and the assimilation of scientific knowledge necessary for high technology products;
continuing education aimed at the M.S. for all engineers who intend to practice engineering on a lifelong basis;
continuing education to update the skills of all engineers simply to track engineering knowledge;
updating our technical managers with technical courses at least on a two weeks per year basis so they are literate in the technologies they manage; and
degree programs for technicians.

Technical managers represent a special problem since there's a growing body of management knowledge. Therefore, those who practice it must also go through continuing management education instead of regarding management as a static field or "art". I often think that some engineering managers went there because they got tired of engineering and having to keep up technically. We simply can't have managers who are there because they are not good enough to engineer.

Right now, we have many courses and degree programs (including the popular MBA, unfortunately) within Digital, yet I'm uncomfortable that we are doing enough. The discomfort comes from visiting engineering sites only feet or minutes away from one another and finding a range of: bright young and older engineers who are stimulating and productive; and rapidly obsolescing young and obsolete older engineers. This leads me to think it's solely management and projects that most determine the excellence and mental age of its engineering and its products. We're trying to understand these factors in order to change.

Thanks for asking: What is DEC doing to improve this? The short answer is not enough. We're leaving too much to the individual, while at the same time pushing for short schedules and excellent projects based on no new skills. Clearly we have to change.

Sincerely,

Gordon Bell
Vice President, Engineering

SUBJECT: ENROLLMENT IN THE VLSI COURSE, HUDSON

It is absolutely crucial that this course be attended by our designers outside of the Hudson group. Based on some cursory figures, our VLSI content in products is nil. We must upgrade our skills, by getting our consulting engineers taking these.

I would hope to see people like Kotok and Stewart in these courses, for example.

It is difficult to imagine that any of our projects would slip perceptibly by having one designer in these courses. On the other hand, it is difficult to believe that we can build decent products without using this technology. Also,

based on our long lead times for PWB's, it would seem possible
that VLSI is a way to get reduced design times while also getting lower costs.

Therefore, I would like each of the engineering staff to get a plan together to attend this next, and subsequent courses.

SUBJECT: VLSI COURSES

We probably have to have a goal that states EVERY hardware engineer and manager takes this course within the next two years!

Gordon

GB2.S6.6

TRANSISTOR GENERATION

"What is a Transistor?

Transistors are made from silicon by the introduction of minute quantities of impurities that determine the electrical properties of the host material. By precisely controlling both the location and the concentration of impurities (called dopants), engineers can build up the transistor structure.

Doping impurities come in two types. The first adds free electrons to the silicon, coverting it from a near insulator to a conductor of electricity (although the conductivity is much less than that of a metal). The second type removes electrons from the bonds keeping the silicon atoms in the solid, leaving behind electron vacancies or 'holes'. The holes behave like positively charged carriers of electricity and thus the second type of dopant also raises silicon's electrical conductivity. Silicon that conducts electricity by way of free electrons is called n-type, whereas material that conducts by the way of holes is called p-type.

Transistors consist of three segments of doped silicon back to back, as it were. The sequence of segments is important; the allowed orders are n-type-p-type-n-type and p-type-n-type-p-type. There are two general classes of transistors, but both can have either the n-p-n or p-n-p sequence of doped silicon segments. The historic first transistor built at Bell Laboratories in 1948 is called a bipolar transistor because electrical current flowing through the device from one end to the other passes through both n- and p-type silicon and both electrons and holes contribute to the current. Bipolar transistors are also called current controlled because a small electrical current entering the device through the center segment controls whether the device as a whole conducts electricity. A voltage applied only to the two end segments will not cause the transistor to conduct electricity. Viewing the transistor as a switch, one says that the current into the center segment turns the switch on or off.

The second class of transistor is the insulated gate field effect transistor. In this type of device, a thin insulating layer (usually silicon dioxide) is placed between the central segment and its electrode. A voltage applied to the electrode creates an electric field which converts the region of the central segment just under the electrode from one conductivity type to the other (n- to p-type of vice versa). Thus, field effect transistors differ from bipolar devices in two ways: they are actuated by a voltage applied to the central segment rather than by a current, and all the current is carried by one type of carrier in three segments of the same conductivity type.

With the invention of the integrated circuit in the late 1950s, it became clear that the field effect transistor offered distinct advantages because fewer processing steps were needed to make this type of device and because it took up less space in the silicon. The type of field effect transistor called metal-oxide-semiconductor (MOS) has become the dominant form of commercial integrated circuit. The biggest advantage of the bipolar device is switching speed. Thus, for those applications requiring this capability, such as high-speed logic circuits in computers, bipolar is widely used. Moreover, new forms of bipolar circuits that are more amenable to miniaturization than the older types are being investigated and may well turn out to be important as MOS microcircuits in the next generation of microelectronics, the VLSI era." (Robinson, 1980)

By 1960 transistors had replaced tubes as the technological base for computers. Their properties, lending themselves to automated design and manufacture no longer meant that the innovative machines would come from handcrafted projects in laboratories and universities, but from industrial research and development. The end of the fifties saw the last spurt of laboratory built machines: Lincoln Lab's TX-0 (Transistor Experimental project), MANIAC 2, Bell Labs Leprachaun and ILLIAC II. In 1959, a Siemens 2002 was delivered to the Technical University of Aachen. The same year IBM introduced their fully-transistorized 7030, the 7090, and the 1401. In 1960,the CDC 1604 and 160, and Digital Equipment Corporation's PDP-1, the IBM 1620, and the UNIVAC 1105 were announced. The full range of computers were then available for purchase: ranging from business to scientific, and from small to super, i.e., from $100,000 to $10,000,000.

The early sixties brought the space race creating new computing needs in science and education. This generated new demands for computing power that, once available, led the first generation of "hackers" to enhance the machines into super toys. The Gemini flight inspired a group in Cambridge to use the computer scope to simulate space flight and space wars. Active communication between users from coast to coast rapidly developed into a computer game culture. The children of the first hackers started to college in the eighties and are as distinctive as the so-called tv generation since they grew up with computers as playmates.

Simultaneously, business was beginning to define a need based on computing versus tabulating and sorting. Champine (80) has listed the phases that characterize the development of commercial applications. As early as 1955, the full range of business uses were envisioned that are continuing to create a need for larger and faster business computers. But he notes that only the leading edge users were implementing the intermediate level functions in the late fifties. Thus, business data processing only began to drive the development of computers with second generation machines.

CDC 6600

Word Length: 60 bits for the Main Processor and 12 bits for the 10 Peripheral and Control Processors (PCP)

Memory Size: 131,072 words in 32 banks of 5 4096 12-bit word modules and 4096 12-bit words for the PCPs.

Speed: 250 million bits per second; 2 million instructions per second for the Main Processor and .5 million instructions per second for each of the PCPs.

Clock Rate: 10mhz (4 25 nanosecond phases)

Arithmetic element: Main cpu contained 10 functional units that could operate in parallel on the 16 word general register array.

Instruction format: 15 bit (operations on registers) and 30-bit (memory access)

Technology: All transistor logic; 6700 modules with 64 transistors in a 2.5 x 2.5 x 0.8 inch module, "cordwood package"

Number produced: 10 by the engineering group at Chippewa Falls

Price: approximately $3 Million.

Project start: Summer 1960

First delivery: September 1964 to Lawrence Livermore Laboratory

Software: COS (Chippewa Operating System) and FORTRAN

Project leaders: Seymour Cray with James Thronton

Predescessor: CDC 1604 and 3600

Successor: CDC 6400, 6500 and 7600

Use: Batch processing and shared use in large scientific computing centers

Achievements:

* 6600 and 7600 were the fastest supercomputers until the Cray I was introduced.

* Development of freon-cooled, "cordwood" packages proving a ten-fold increase in logic density.

* Fine multiplexed control for Peripheral and Control Processors.

* Independent parallel, functional units for high speed with tag control.

<u>IBM 7030 "THE STRETCH"</u> IBM, 1961, Gift of Computer Service, Brigham Young University (D250.81).

Word Length: 64 bits plus 8 bits for parity and error checking

Memory Size: 1 to 8 16k core memory stacks, self-contained each with its own clock, addressing circuits, data registers and checking circuits, addressing of up to 256k word locations.

Data Transfer Rate: Addressing of memories and transfer of information from and to memories by a memory bus permits new addresses, information, or both to pass through the bus every 220 musec.

Central Processor: The processor consists of the instruction unit, the look-ahead unit, a parallel arithmetic unit and a serial arithmetic unit.

Multi-programming through program interruption and address monitoring, and overlapped or parallel execution of instructions is possible.

Instruction Format: Halfword formats accommodate indexing and floating-point instructions. Fullword formats are usedby variable-field-length instructions. Five instruction sets and 765 different types of instructions are used.

Technology: Standard Modular System Transistor Cards. Used 150,000 high speed drift transistors, and provided interleaved magnetic core memory with 2.18 usec access cycle.

Number Produced: 9

Price: $6-8 Million

Project Start: 1954

Project Leaders: S.W. Dunwell; Gene Amdahl, John Backus, Werner Buchholz, B. O. Evans, Jerrier Haddad, Lloyd Hunter, Ralph Palmer, and John Sheldon

First Delivery: April 1961 to the Los Alamos Scientific Laboratory

Software: Algebraic and Fortran compiler

Use: Large scale scientific research, for example: nuclear reactor design, hydrodynamic problems, problems in nuclear physics.

Innovations (Adapted from Hurd, 1981)

* The drift transistor, a fast, diffused-base, alloyed-emitter transistor, improving quality, consistency, and speed.

* A

logic circuit design called transistor current switching permitting faster operation.

*

Two microsecond memory access time (compared with 6 microseconds).

*

Memory interleaving of up to four 2-microsecond memories, permitting average memory access time of one-half microsecond.

*

"Lookahead" reading instructions three levels ahead of the one being performed, determining memory references and allocations for instructions.

*

Advanced interrupt system.

*

Multiprogramming incorporating a system of memory protection.

*

Disk drive with a set of parallel read/write arms contained in a single mechanism with access ability of more than one-two million word disks with a data rate of several million bits per second per channel.

*

TRACTOR, a mass storage device using tape cartridges with exceptionally high speeds.

*

Error-correcting codes for memory.

*

Computer-aided design.

*

Automated assembly and testing of printed circuit boards.

*

Elimination of distinction between character, decimal and binary machines, fixed and variable word length machines, and fixed and variable record machines. Werner Bucholz coined the word "byte" to define variable-sized parts of words.

"Stretch: The Technological Link Between Yesterday AndTomorrow", Brigham Young University, 1981, Color, 3/4" videotape, 15 min. running time (V16.81).

The "Stretch", IBM's 7030, was the supercomputer of 1961. The system's innovations, including lookahead, array processing, and error correction codes, are highlighted in interviews with former users and footage of the machine in operation.

<u>LINC Computer</u>, Lincoln Lab, 1961, (D118.79)

Word Length: 12 bits

Memory Size: 2048 words

Speed: Approximately 125,00 single address instructions per second

Clock Rate: 500 khz using dec 4000 series modules

Arithmetic Element: Six 12-bit registers

Instruction Format: single and double operand, multi-mode

Technology: Discrete transistor using dec 4000 series modules

Power Consumption: 1000 watts

Size: 69"x32"x32", plus separate tape, keyboard, console, and interconnection boxes.

Price: $43,600

Project Leaders: Wesley Clark and Charles Molnar

Project Start: 1961

First

Shipment: March, 1962

Withdrawn: December, 1969

Number Built: 50 total, 21 by DEC

Successors: DEC LINC, LINC-8, PDP-12

Achievements:

*

Laboratory system to accept analog and digital inputs directly from experiments and to provide signals for control.

*

First truly personal computer with automatic file system via two LINC tapes, interactive program editing, development and control via crt.

LINC-8, Digital Equipment Corp, 1965, (D119.80).

Word Length: 12 bits

Speed: Approximatley 667,000 memory accesses per second

Clock Rate: 1 Mhz (same as PDP-8)

Instruction Set Processor: Both LINC and PDP-8

Arithmetic Element: Four PDP-8, six LINC 12-bit registers

Instruction Format: Single and double operand, multi-mode, 12 bit instructions

Technology: DEC "Flip Chip" R-series general purpose modules. (Discrete components)

Power consumption: 2,000 watts

Size: 69"x32"x33"

Price: $38,500

Project start: 1965

First shipment: August, 1966

Withdrawn: December, 1969

Predecessor: LINC

Successor: PDP-12

Achievements:

* System where both processors could operate in parallel.

* Utilized either LINC or PDP-8 software.

PDP-1, Digital Equipment Corp, 1960, Gift of Inforonics Corp (D116.79).

Word length: 18 bits

Speed: 100,000 single address instructions per second

Clock rate: 5 Mhz and 500 Khz for input-output

Arithmetic element: Accummulator and input-output

Instruction format: Single address 5 bit op code, 1 indirect bit, 12 address bits. Extended field with 15 address bits.

Technology: Early second generation Digital 1000 series 5 Mhz and 4000 series 500 Khz systems modules

Power consumption: 2160 watts

Size: 69"x88"x28"

Price:

$120,000

Project leader: Benjamin Gurley

Project Start: Summer 1959

First Shipment: Bolt, Beranek and Newman, November 1960

Number built: 50

Achievements:

* First commercial computer with graphics display.
* Operation as time shared computer, BBN, September 1962.
* Original space war program by Steve Russell at MIT.

PDP-7, Digital Equipment Corp, 1964, Gift of Computer Science Department, Worcester Polytechnic (D143.80).

PDP-8, Digital Equipment Corp,

Word lenght: 12 bits;

Memory Size: 4096 words (expandable to 32,768 words);

Speed: 333,333 signle address instructions/second; 1.5 microsecond memory cycle time;

Clock rate: 1 Mhz;

Arithmetic element: accomulator and 8 auto-index registers in memory;

Instruction format: Sincle address 3 bit op code, indirect bit, 1 page bit and 7 page address; 32,768 word addressable memory;

Technology: Digital R-series logic;

Power consumption: 780 watts;

Size: 8 cubic feet;

Number poduced: approximately 5,000;

Price: $18,000 with 4096 word memory and teletype type 33ASR;

Project start: 1964;

First delivery: April 1965;

Predecessor: PDP-5;

Successors: PDP-8S, LINC-8, 8-I, 8-L, 8-F, 8/M, 8/A, VT78;

Software: PAL-8 assembler, Macro 8 assembler, Fortran II, DDT (Symbolic debugger), Editor, RT-8 and OS-8 operating stand-alone operation systems using Dectape and diskpaks;

Use: Real time control and data collection. First "OEM" computer. Data commmunication. Small business data processing. Timeshared computation for very low cost/terminal;

Achievements:

* Originated concept of minicomputer.

* Provided the lowest cost computation and performance/cost at the time.

* Producible in high volume manufactured using wire-wrap technology.

* Improved ease of interfacint (first DEC computer to use I/O bus structure).

* By

packaging, price and supply established the two tier supplier/OEM structure.

*

Lowest cost per terminal with TSS/8 (smallest scale timesharing system).

PDP-12, Digital Equipment Corp, 1967, (D156.80).

Word length: 12 bits

Speed: Approximately 667,000 memory-processor accesses per second

Clock rate: 1 Mhz (same as PDP-8)

Instruction Set Processor: Both LINC and PDP-8

Arithmetic element: Four PDP-8, six LINC 12-bit registers

Instruction Format: Single and double operand, multi-mode 12-bit instructions

Technology: DEC "Flip-Chip" general purpose modules. Discrete components.

Power Consumption: Less than 2000 watts

Size: 76"x35"x33"

Price: $28,000

Project Start: June, 1967

First Shipment: June, 1969

Withdrawn: June, 1975

Number built: 1,000

Predecessors: LINC, LINC-8

Achievements:
*
Improved price, price per performance and larger display.
*
Lowered LINC-8 cost by building a single physical processor to execute either LINC or PDP-8 instruction set.

Siemens 2002

TX-0 Computer, Lincoln Lab, 1956, (D154.75).
Word
Length: 18 bits
Memory
Size: 8192 words
Speed:
80,000 single address instructions per second
Clock
Rate: Variable, controlled by delay-line (max rate = 5 Mhz)

Arithmetic Element: Accumulator; In-Out Register for program-controlled Input-Output; Index Register

Instruction Format: Five bit op code, (2 bits initially used) + 13 bit address (16 bits for initial 65,536 word memory)

Technology: Discrete transistor circuits and core memory
Power
consumption: Approximately 5,400 watts
Air
Conditioning: 15 tons
Size:
Built into 9000 square foot room at MIT

Component Count: 3,600 surface-barrier transistors (SBT) of Philco type 2N240
Total
Hours: Approximately 50,000 hours with 12

transistor failures

Project Staffing: Lincoln Laboratory Division 6, Group 63; William Papian, head; Wesley Clark, logical design; Kenneth Olsen, circuit design and construction (followed by Benjamin Gurley) Richard Best and Jack Mitchell, memory design. John Clarke supervised construction.

Project start: Late 1955

Use: Research on electro-physiological signal processing; speech analysis and synthesis; picture processing; simulation of sensory aids for the blind; bubble chamber photograph analysis; handwriting analysis; interactive programming; symbolic program tracing and debugging.

Achievements:

* Tested transistorized circuitry for use in computers.
* Tested a large, 65,536 word (18 bit+ parity bit per word) vacuum tube driven core memory.
* Improved real-time interfacing.

"Tomorrow: The Thinking Machine", CBS, 1961, B&W, 3/4" videotape, Running time: 1 hr. (V6.81)

Artificial intelligence is the topic of "The Thinking Machine," a 1961 episode of the CBS News <u>Tomorrow</u> show, narrated by Jerome Weisner and David Wayne. Machine "learning" is compared with human and animal behavior. Highlights include an interview with Claude Shannon, a robot-sequence clip from the silent film classic "Metropolis", and three versions of a TV western written on MIT's TX-0 computer.

<u>WRITABLE AND READABLE MEMORY</u>

WAVE STORAGE

CYCLIC

Magneto-strictive

Delay-line stores hold information as a series of impulses circulating continuously along a closed path. In a magnetostrictive delay-line electrical impulses signifying data are converted into stress waves which travel the length of the nickel wire. The application of a magnetic field to the wire causes it to change dimension thus converting electrical impulses to stress waves, or vice versa. Coils similar to those found in an electro-magnet are used for inserting and recovering digital information from the delay-line. The Elliott Brothers' Computers in England were the first to use the magnetostrictive principle for storage of data. (Lavington, 1980)

<u>Magneto-strictive Delay-line</u>, Ferranti, 1958, Gift of Oliver Strimple (D230.80).

ICT Sirius Computer had 10 decimal digits per word, with 1000-10,000 words stored on delay-lines. Compile-add time cycle of

250 usec, and storage cycle time of 4000 usec.

MAGNETIC FLUX

RANDOM

CORE

Cores are made of ferromagnetic material that is able to become strongly magnetic when subjected to relatively weak magnetic forces. A magnetic field is generated in the vicinity of any conductor that is carrying a current. The direction of the magnetic field is related to the direction of the current flow in such a way that reversing the direction of the current results in a reversal of the direction of the induced magnetic forces. Each core has four wires: two which write selecting the proper one in a co-incident (x-y) axis. A third wire reads and a fourth wire inhibits a build up of energy. A number of core planes are then piled into a core stack or cube and in the transistor and integrated circuit computer generations were the most prevalent type of primary memory.

Digital **Interoffice Memo**

Subject: **Translation Between Standard 11 Macro Code, and VAX Macro Code (non-native)**

To: Bill Demmer
Date: 4 OCT 76
From: Gordon Bell
CC: Jim Bell, Peter Christy, Pete Conklin, Roger Gourd, Ron Ham, Bernie Lacroute, George Poonen, Larry Portner, Bill Strecker
Dept: OOD
Loc.: ML12-1
Ext.: 2236

F/U 10/11

The above product is probably absolutely mandatory when our users see VAX. It will also diffuse the compatibility issue. This translator would enable them to take standard 11 code and run on the VAX (not just the 11 environment). Honeywell did this for 1401 code for their 200 series.

Will you please get some of the relevant people together (or have someone else) to brainstorm the cost/performance of the above translator after we've disseminated some information so they can think about it?

The issue is not can it be done, but rather whether it is good enough to use and how much the human gets involved.

GB:ljp

May 2, 1978

Drs. Joe Traub and Allen Newell
Carnegie-Mellon University
Department of Computer Science
Schenley Park
Pittsburgh, PA 15213

Dear Joe and Allen:

As usual I enjoyed the interaction with you and the CMU faculty last week, although it was strained. Since I have been spending my spare time this year writing the Computer Engineering book, I have gotten into a habit of poor communication, unlike the other five years since I returned to DEC (this was the first time I visited since last Spring). Although there is quite a lot of interaction among individual members of the faculty and people at DEC, there is little visibility with you and I think it would be useful if Jim Bell met with you so that we are all aware of the exchanges that are taking place. Lloyd Dickman of our R&D group who works for Jim is the official liaison. (For example, last week he supplied the computer module project with soldered backplanes from our manufacturing plant, that was not accounted for or even seen in any of our discussions.) At the same visit I discussed the use of our semiconductor programs and facilities with several CS and EE faculty members. Already, some of these programs are in use there and we exchange information routinely -- unlike any organizations I'm aware of.

We have been careless in our hiring protocol. I have asked that we call CMU before an offer is extended to a CMU faculty or staff member. In the case of Mario, we offered him a job (in line with IBM, Xerox and BTL offers) when it was unclear as to whether he wanted to return to CMU because of his salary and status there. I agree that CMU should follow the same protocol with us.

I'm sorry that we went through a hassle as to CMU's use of APL, but am delighted that the local office did the right thing in making it available to you.

Our performance in getting the KL10 operational was really poor. I'm sorry about this, however I can understand how our own service personnel are less motivated about installing machines that they ultimately won't be responsible for. When there are future problems, I think we have to get the problems addressed more quickly. It's almost inconceivable that we went six months without getting simple problems like lost cables and the right diagnostics solved.

I am asking Baird to see that our Regional Field Service Manager visits Howard to see if we can't improve what still seems like an antagonistic relationship.

Although it may seem like we have a significant potential product edge by having the CM* work done on LSI-11s, a major effort is still required for it to flow to us as advanced development or as a product because of the operating system differences. Almost any company hiring a person from the CM* project would be in a better product position, even though we follow the research more closely.

I've asked Jim and Sam to try to improve this coupling with Richard Swan. Also, I still believe that our standard operating system, RSX-11/M is a reasonable base on which to build the research. (This has turned out to be true in the case of our own internal multiprocessor work.)

I'm truly sad that we have a much poorer relationship with Bill Wulf, for numerous reasons (the latest being our inability to help in the DOD language effort). I've enjoyed the interaction with him and hope this will return some day. Ron Brender will be spending next year there and this might start to re-establish the link.

Bill Strecker enjoyed the interaction with the faculty and students last week and sends his regards.

I am sorry that there is a feeling that we are taking CMU for granted. We certainly don't mean to be. We intend to help CMU remain at the forefront in hardware and systems research.

Sincerely,

Gordon Bell

follow up 7/12/78

Although I see the need for communications with Colorado, it feels like there's too much travel -- taking time and wearing people down. Can you get a handle on how many trips we're taking and figure out how we might be more effective and travel less?

We still must have computer teleconferencing as per the attached proposal. I'd like to get a project started immediately with phone units! Let's get conference phones, fax, word processing, and electronic blackboards in dedicated rooms at both sites.

As a separate issue we need really good electronic mail so as to avoid the memos and enhance written communication! (Note that CMS should, but doesn't solve this problem because it is not widely available outside sales.)

Who's responsibility is it to propose such a plan?

SUBJECT: TRAX 1.5 PROPOSED DIRECTOR

GB0005/46/EMS

I want us (Engineering Management) to be very, very positive in managing Release 1.5 on TRAX. You have the responsibility! Larry and I will help and would like to talk with the development team ASAP to answer questions. Also, I believe Roger should come with us. We must go and build a great, reliable product in 1.5.

Our decision to not aggressively market TRAX now feels good to me.

If we do well in 1.5 I'm sure the market will materialize - and as a developer, I'm happy for us to take the risk and not push it to marketing by asking for a guarantee, independent of whether we produce a good product or not. My scenario would be to let demand build and have our customers tell us to put TRAX on 11/74 mP and M+_ but we shouldn't plan it, nor do we deserve this guarantee.

follow up 12/5/78

I just saw that Bruce presented data on TRAX measurement to the performance measurement workshop. Could I have a copy? More importantly, I keep getting static from the field on TRAX in terms of its performance and what it is.

TRAX is a very key, important product (selling more than RSTS, I would hope). Getting the field behind it now is essential, and I'll try to help here all I can, but the information has to be available.

The TRAX team is certainly to be congratulated in getting the product into the library last Thursday!

Our credibility is certainly blown on this one. Julius is conveying his hurts rightfully. This one bothers me because in my gut I knew it wouldn't work and said so. The group got me in and sold me based on some experiments; however, the sickly feeling persisted...mainly because of Hopey, who I really didn't trust. I should have gotten back to you. Things like this will happen, and we'll have to learn, but it seems like right now we might:

1. Announce only after real field test.

2. Have your developers buy performance testing from the right group, rather than having the analyst be a single report into the organization. Bruce Horowitz was (is?) good, but he seemed to be totally under control of the group. Hence, wasn't objective.

3. Have a separate QA that reports through a different function.

4. Limit Hopey's future activities.

The rumour is that TRAX can't be fixed due to an M problem. Can't we fix it?

You're invited to Marketing Committee to educate us.

I believe the TS04 will turn out to be a good investment. We should note that the recently announced System 38 and 8100's have fixed disks and they use low cost Mag tapes and floppies for interchange, etc.

Ivan Sutherland relates the Xerox Park bad experience where a large system is used for filing and each personal computer has a 10 Mbyte removable disk. Namely, there are multiple copies of software that can't be updated. He says build systems (like Minnow and Nebula that are intended to interface to other computers) with fixed disks.

Comments on Tsongas Editorial and Speech

The Editorial of March 27, 1982 in the Boston Globe showed more thought and clarity than anyone else from government, with the possible exception of a report on the Japanese trade problem by the Comptroller General several years ago. A letter, commenting and correcting his report is enclosed. Please allow me to add to your position:

. Our high military expenditures versus Japan's give us ZERO productivity for a large segment of the economy; hence the more spending, the lower the productivity. Since the industrial economy pays for the military, how can we have this spending by importing everything?

. Independent of whether military spending is good or bad, it simply takes a large portion of our small engineering workforce out of circulation where we could be building products to compete with Japan, plus raises the demand and causes churning of the workforce. This is why I shudder each time Raytheon or GTE receive military contracts. Arguments that the side-effects of military spending aid the consumer economy are basically hollow.

. Military programs such as the VHSIC program are at most, 25% effective, say versus the Japanese MITI programs, because the recipients such as Westinghouse or Hughes are military body shops that do cost plus work. There is no one to transfer the results to for helping the commercial sector.

. Labor is not the problem in high technology, except that it isn't especially well managed and we have too much overhead and too little technical support. The keys to high technology are the product and how it is made! I suspect this is true of automobiles too.

. The Semiconductor Industry is probably lost forever because it went off shore for low labor cost instead of investing in automatic bonders as did Hitachi, et al so as to be able to keep their work nearby, thereby reducing work in process, having better control and producing more cheaply.

. Management is the key to American Industry whether it be low or high technology. Ken Olsen, our President, sent around an excellent editorial (Kenneth Eskey, 6/4/82) on this, say as compared to the Japanese which I've attached.

. American Managers are very poor when compared with Japanese Managers, whether they be in Government, Industry or Universities! Many factors have caused this situation, including having Business and Managment Schools where there is probably NOT a discipline. The Japanese Managers know every aspect of their business from the electrons up to the people who make products. Invariably, they have come up through the engineering ranks, and many have PhDs. The American Managers are superficial and rarely know the products, how they are designed, or even have a really good understanding of investments and return covering the gamut from research to "cash cow" products. American Managers can't derive or explain the notion of quality or how it relates to productivity! Usually the American Manager demands both without understanding either. The most important thing that could be done here is to eliminate all Business and Management Schools who only teach personnel, politics and how to bullshit a case study!

. Government is now nil and seems to have withdrawn under the Reagan administration. It still requires feeding and, like the military, is zero productivity ($ in, 0 out), but at least it doesn't compete for engineers. As one of the world's largest bureuacracies it is totally consumed arguing with itself.

. Your numbers on R and D spending are missleading because the Military R and D is so miss-directed. In one program, the Military will end up spending several billion dollars for their own computer when ANY commercial one would be better. Furthermore the Russians will use our computers and get the work done earlier, cheaper and better! Thus we lose two ways. (enclosure)

. The problem of not enough engineers is quite serious. While Digital can recruit engineers for product design, I think we need many more so that we have people with engineering training in many parts of the company just like the Japanese. We simply have too many people involved in designing, building, selling and helping the organization who know NOTHING about computers or how to build them.

. On the lack of engineers, make sure we do not cut off our supply of foreign engineers who come here for an undergraduate and graduate education and stay. While there is a real cost to educate engineers who may not stay in the U.S., it seems far cheaper than fixing the basic fabric of the U.S. which supplies people who have the understanding of science and mathematics and who love to create.

. Our primary and secondary education system, are exactly like the Business and Managment Schools. Teachers are trained to operate the education process, rather than to understand the subject matter. The incredibly low quality of the people who enter teaching, especially via the teacher's colleges, is the problem. Learning via computers may be the answer to circumvent the system.

Here are some comments on your speech on Meeting the Japanese Challenge, given on May 21, 1982 to the International Business Center of New England:

. The Japanese companies now HAVE the 256K RAM market. We have these chips from Japan at present.

. I think we have lost a substantial part of the computer market already:

.

NEC is now number 2 in Letter Quality Printers and I saw their first printers come off the line 4 years ago;

.

Japanese manufacturers supply most of the dot matrix printers;

.

Video components and video display units are now on the threshold of taking over in the U.S. They have the dominant technogy;

.

70% of the memories, as you point out, are Japanese;

.

The basic, lower level technologies (magnetics, optics, ceramic materials, video, silicon) are disappearing, given that we have lost the consumer market drive.

.

the large mainframe business is now totally IBM architecture based, with Fujitsu and Hitachi increasing their shipments into the U.S. base THROUGH U.S. MARKETING COMPANIES! (The same is true in the U.K., Germany, Australia, etc.);

.

robotics; we had a lead, but have given much of this up. They are effectively coupled into our research programs at MIT and CMU.

. We all believe reciprocity is distasteful! Japan got to it's current status by managing reciprocity and flow of technology to Japan! I believe we'll end up here in several more years of industrial decay.

. Something is wrong with our measures if you believe that our per capita productivity is greater! RECHECK!

. Comments on your proposals to meet the challenge:

Labor/management cooperation of all kinds might help a few percent. Greater ownership might get labor to more savings and hence a gut reason to "buy American".

2

I completely agree with you that far more is needed in research. This is a misunderstood and poorly managed segment of industry. In trying to stimulate R&D so far, the effects to date have been mostly negative because Venture Capital firms have started up Low Risk, mundane companies who offer nothing to society. (There are a couple exceptions, but not many; mostly this money simply churns the engineering workforce.) The Fifth Generation Research project of Japan, if successful, will give them an even bigger edge.

3

Agreed. We have a major engineering workforce problem. It is mandatory to get the universities to change too as they are forcing talented engineering professors into industry with their tenure policies, teaching loads and inability to allocate resources on the basis of demand and need!

4

Fortunately we don't get argue with the government much. A recent Federal Standard on I/O Equipment was designed to help the Japanese while penalyzing various U.S. vendors such as Honeywell, Burroughs, and Univac. The net effect of this standard will be very bad.

5

Agreed. More is needed to encourage investment. The problem I have is what would you recommend to an investor? U.S. Steel, GM, Kodak, Honeywell or Mitsubishi, Honda, Canon, NEC, Fujitsu, Sony?

6

Yes, expand exports. We're barely in Japan and it's been a struggle to get anywhere. To really make it there we have to give up control and get a Japanese partner who we know may take our products and ultimately incorporate the ideas into their products. The leader of the design of the high performance NEC machine has been in their Lexington sales office for the last three years. Our

Japanese office is headed by a marketing person with
minimal technical training.

SUBJECT: RE: TU58

Bad products cost money to sell. We don't have a large number
of salesmen to waste here, so let's get rid of it. We do need
to talk cause I don't understand why it isn't obvious we
don't get rid of it. Have you looked at the inventory lately?
If we force the product lines and salesmen they can obviously
sell it to someone. But why? Let's just use it internally and
not propogate it on the world.
g

GB1.S7.44

GB1.S5.67

Rather than spending our precious sales efforts trying to
sell TU58's at high sales costs and requiring us to remain in
the business for a long time, thereby increasing the product
array, it has been recommended we remove it from the market!
Since only ASG and Micros sell them (unsuccessfully) this
should be easy to do, given that there are 9,000 in
inventory. Here, we can put them into future products

(11/44, COMET, NEBULA, etc.).

Could you please look at this plan in conjunction with the user P/L's? Also, could you look at how we're doing versus the business plan?

SUBJ: Initial frustrations on the reliability and engineering of the typesetting (8000-type) and word processing interface

TO: Heidi Baldus, Ed Fauvre, Jack Gilmore, Bill Keating, Marcie Kenah, Bob Lane, Del Lippert, Larry Portner, Jack Shields

Date: 5 JULY 78
From: Gordon Bell
Dept: Office of Development
MS: ML12/A51 Ext: 2236

Although I'm really happy with the WT/78 (especially when we get a more cost effective solution to the communications among systems problem), I am frustrated by the interface between the Typeset 8000 and the word processing system. I would think we would have a unique and very large market in being able to offer both typesetting and word processing for in-house publications and for the publishing of manuscripts. Although we have a large book that would tax most systems, I don't think the demands are out of line compared with a reasonable system.

Six years ago we published a book that was completely typeset, laid out, indexed, and table of contents cross-referenced using a PDP-10 at Carnegie-Mellon. It was a joy to use, and we made changes right up to the last minute. By contrast, our internal systems don't have any of these capabilities and the human interface is abominable, plus many principles of good design are violated. For example, in order to get the many character codes that the word processor doesn't know that the typesetting system needs (like mu), one has to type an escape sequence of 5 characters which get printed...almost destroying any readability for the document. The coding isn't compatible with the printer codes that are used intermediately with the typeset 8000. There are many intermediate files in the whole process that are generated sequentially, so that when an error is corrected late in the production, it is down stream and not reflected in earlier files...which then become obsolete.

Last night I had to write a program to build an index because none exist. Ironically, in using the BASIC manual I spent five minutes searching because there was a poor index. It is inconceivable that a company which has so many writers, wouldn't have an indexing program. (I would have thought the writers would have written one.) Given the program, on the 10, there's no way to get the information back into the word processing or typesetting system. (Since the program's in BASIC, it doesn't have the right character set either).

The reliability of the 8000 in Tech. Doc. sure has been bad, and that also influences my attitude because it is necessary to have, given all the steps in the process. Are we selling those large systems without having better systems
diagnostics?

Somehow we have the potential of having a really great system. How can we turn it into one instead of a collection of components that some dedicated people have to suffer with to make compatible and move data at great pain?

Dr. Andy Herbert
Dr. Andy Hopper
Computer Laboratory
University of Cambridge
Corn Exchange Street
Cambridge CB2 3QG
ENGLAND

Dear Andy and Andy:

I thoroughly enjoyed the visit to Cambridge, seeing CAP, the Ring Computer, its distributed switch, the gate array design system and learning about the next high speed switch. It was interesting to see that a single computing system could be implemented reliably with such a large number of diverse computers and such a relatively slow switch. I understand the need for the bridge to increase the bandwidth. I'm interested in the new 100 Mbit switch because we have a need for a high speed, low latency switch. As you get results on it, please keep us informed. The CAD work based on MODULA extensions seemed very nice and again, we'd appreciate hearing more about it as results become available. In particular, when your staff is in the vicinity, we'd like to have them visit and give a seminar.

I so regret that we hadn't more time to discuss the fast ring and Mayflower. I'm delighted that Cambridge is getting interested in parallel computing. If you have a research plan on this, I'd enjoy reading it and commenting on it if you'd like, because we need fundamental work in this area. Also, I'd like to read books or papers on the current computer.

Thanks for the hospitality. I hope we (Cambridge, DEC and myself) can have more interaction.

Peter W. McFadden
Dean of Engineering
University of Connecticut
Storrs, Connecticut 06268

Dear Dean McFadden:

I certainly understand and appreciate the dilemma and need for computer science and engineering faculty. Basically I'm sympathetic and would like to recommend to our Corporate Contribution Committee that they contribute to your university.

While I certainly support this, I'm very concerned with the behavior and policies of universities, including yours, that discourages computer science and engineering faculty and teaching. We have hired faculty members <u>after</u> they have made a decision to leave academia because of: high teaching loads; poor resource allocation in line with need, market and external income; tenure bias against experimental work in favor of theory; and general miss-treatment as compared with other professions (eg. law, medicine), self-proclaimed professions (eg. business), the established sciences (eg. chemistry, physics) and even dried-up parts of traditional engineering.

I have forwarded your request to George Chamberlain, our Treasurer, who heads the Corporate Contribution Committee in hopes that we can help.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

<u>Customer Segment Letter</u> - <u>Sample Only</u>

Professor Peter Warter
Head, Department of Electrical Engineering

University of Delaware
Newark, Delaware 19711

Dear Pete,

I was glad to talk with you again in regard to the possibility of getting DEC computers for the University. The situation there with a large, but relatively ineffective, central computer and several distributed minis (including the two you have running UNIX, and the Series 1's) presents an interesting challenge. The dilemma now is whether to distribute completely, getting rid of the high rental burden or whether to switch to us and/or to IBM. Furthermore, you believe that the bulk of our subsequent development will be in the VAX and 11 areas, hence you are reluctant to be stuck with another non-IBM mainframe in the 10/20 that lacks the critical mass to survive into the 1990's.

First off, we are committed to supplying high end 10 and 20 system hardware and we are spending a great deal maintaining and evolving these systems. I should also point out that there are more 10's/20's than any of the other so called mainframe suppliers (Burroughs, CDC, Honeywell, Univac) and since there is a larger number of terminals and user base, we believe the invested software base is quite large.

My recommendation is simple:

1. Flush the large machine you have, its a drain and the software is pretty unimpressive for anything but the targetted commercial enivironment that it has led its sheltered life in.

2. Establish a network interconnection machine (something like the 11/34) so that the numerous machines you have and that I am recommending can be used in the most cost-effective configurations.

3. Start with a 2040 to handle the bulk of the esoteric languages and general purpose load. Alternatively, if this load turns out to be small, then several 2020's might be a better solution. (For example, give the CS Department

their own and let them run it...it'll teach them about real computers.)

4. Buy as many VAXs as the budget will allow, although I believe that two will give you much more computing than you have now with the central computer. Furthermore, this will save money. One would be used for the administrative part, running Cobol. The other one would be for general computing.

At any rate, these are the comments you asked for. They are clearly biassed, but I think they are right.

Sincerely,

Gordon Bell
Vice President,
Engineering

GB:ljp
GB0001/14

Brian Randall believes they have a fundamental idea or mechanism that can be implemented on any operating system that will allow the simplified construction of secure and/or highly reliable distributed systems. He claims the idea is very simple, say like paging, yet so far has not been discovered. It can be described in only a few sentences to someone who's been working in this area. It has been implemented on their Unix based distributed system in a short time and the resultant systems indeed do work as advertised. It doesn't require Unix.

They would like to offer it to us, on a non-disclosure basis. It has been disclosed to several companies. The National Research Development Corporation technically owns the rights, but Brian thinks they will revert to the university. They want the idea exploited. Their interests are therefore: 1. we would have an intellectual connection of co-operation with them; and 2. we would support the university financially.

I have a simple one page write-up urging us to go look. He says come ahead, but bring your non-disclosure. Could you guys get together and see who should go look and then contact Brian about a visit?

PS.
Brian just called and stated that he talked with Peter Lee, just arrived from Newcastle and working on Distributed Software, and found that it would be very advantageous to use their technique in building our new system.

College of Engineering
Cockrell Hall 10.310
University of Texas at Austin
Austin, TX 78712

Dear Herb and Dean Gloyna:

I just visited Austin again for an architecture conference and heard of your efforts to make the school of engineering a professional school. By implication, engineers would then be professionals along with doctors, lawyers and business-persons(?)

If you could accomplish this important recognition, it might help to address the salary imbalance in universities and gain the popular recognition that would attract more people to the profession. The reason for all this is to improve the quantity and quality of our scientific and engineering talent so that we can effectively compete in the world marketplace. Our international competitors apear to be well ahead in both raw brain power and in pure numbers. We have to address this.

While this movement may be a little like the equal rights amendment, it would seem that Texas has a real opportunity to lead and I, therefore, applaud and support your effort. Let me know how I can help.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Mr. Robert W. Ritchie
University of Washington
Department of Computer Science, FR-35
Seattle, Washington 98195

Dear Bob:

It was good to get your letter of May 10th. But first, let me congratulate you on what is appearing to be a first class Pascal.

I have forwarded your letter to Jerry Witmore, who heads the Education Products Group. However, it wasn't clear to me just what you had in mind with respect to getting our help.

The high quality printer is of concern to me and I'd be anxious to hear of work you are doing there. This interaction would be directly with Bob Glorioso who handles our Advanced Development of terminals and small systems, or it could be with Art Williams, head of Printer Development. We would, no doubt, be willing to discuss our direction and timing when you visit here next. This should be under the non-disclosure arrangement.

Again, I hope we can continue to work together.

Sincerely,

Gordon Bell
Vice President,
Engineering

Dr. Murray A. Thompson
Director, Physical Sciences Laboratory
University of Wisconsin-Madison
3725 Schneider Drive, Route 4
Stoughton, Wisconsin, 53589

Dear Murray,

Having received your letter summarizing our decision to stop the funding of PSL1, let me make some comments about the decision.
The PSL1 was completely successful as an advanced development program in that it led to a development program which we believe will be a successful product. I believe I can truthfully say that until your project was started there was little or no interest in building smaller VAX systems. Several ideas generated in your program have been used in our work and PSL1 was used as the benchmark for the cost and performance. Unfortunately, research and advanced development programs only lead to development, and successful ones, by definition, generally mean termination.

It is essential that we terminate the program in a professional manner. I hope that we can have a briefing here which presents the results of the work to date. We believe it is not useful to continue building the hardware, but the microcode should be simulated in order to verify that the cache works as predicted.

We would like to encourage you to publish this work within the next year, and if possible, concurrent with our product announcement. You may have access to our product data for your publication. Hopefully you and Bill might write something up jointly.

It is important that the team regard their work as completely successful, even though the physical machine is not being built.

Sincerely,

Gordon Bell
Vice President,
Engineering

As we have been discussing for two months, we have to decide whether to stop or continue in our relationship with the University of Wisconsin. It is grossly unfair to them and it will ultimately damage our reputation -- especially as we prolong an unfavorable decision.

The responsibility is yours. When are you going to exercise it?

We'll help, but you must lead now.

September 15, 1980

Dear Brian,

Things got changed around due to commitments in Maynard.

Will Monday, December 1 be okay?

Gwen and I would plan to fly to Newcastle on Sunday and would be
delighted to stay at your house. We are scheduled to leave on Monday,
at 5 PM.

Any ideas of where to hunt for calculators and automata in London?

Looking forward to seeing you.

Gordon

CC: Mary Jane Forbes
From: Gordon Bell
Date: FRI 2-MAR-79 14:24:58 EDT
Subject: Treating Wisconsin in a Human way

MJ: Pls send copy to John Leng, Joel Schwartz, John Mucci and Bill McBride.

Also send a copy to the Madison or Milwaukee office handling the account.

We have treated this customer absolutely shabbily. The deal was most likely
to be shut off in December, pending a review.   I got a letter of his dated
2/23 where he still has no hint that we might possibly want to stop it.

John Mucci has been handling this part of the interface and we can't go on!
Engineering is not going to put any more into the project unless you believe
now that we should.

I fail to understand why an organization such as LDP is totally incapable of
making a decision and getting a job done.

Unless you hear from John and LDP within a week, plese call Murray at
Wisconsin and tell him that we aren't going to continue support from an
engineering viewpoint, and you don't know about LDP. It isn't fair to treat
customers (in this case a future former one, no doubt) like do-dos.

Don't let us continue to go on in this destructive fashion.

You guys have to push Murray for a review. Given that you want to turn him off, we must do it NOW!

Could we get him to build a Nebula copy and work on microprogramming it and systems issues?

Command:

GB4.S1.23

On occasion some of you may have dealings with citizens of the People's Republic of China (PRC) or East Bloc countries (USSR, Poland, Romania, etc.). I want to advise and caution all of you that your dealings with such people may be subject to requirements under the U.S. Export Laws.

Those laws require the company to get an export license from the U.S. Department of Commerce before any technical data, as defined below, is furnished to a citizen of the above-mentioned countries. A license is required not only if the technical data were actually being sent to the East Bloc or PRC, but also if it is provided here in the United States to a citizen of the PRC or an East Bloc country.

Technical data is defined under the law as "information of any kind that can be used, or adapted for use, in the design, production, manufacture, utilization, or reconstruction of articles or materials. The data may take a tangible form, such as a model, prototype, blueprint, or an operating manual; or they may take an intangible form such as technical service." In addition to the obvious forms of technical data - engineering diagrams, process designs, etc. - this definition includes software and seminars, university lectures, training courses, plant tours and meetings at which technical data may be disclosed.

I am cautioning you about this at this time because the Reagan Administration in its concern for national security is putting an increased emphasis on the improper export of such technical data. A violation of these laws could result in harsh consequences for Digital and for any individuals involved.

In the event you wish to engage in an information exchange with a citizen of the PRC or an East Bloc country, or if you want advice on what is technical data, you should contact Tom Moran of our Export Services Group well in advance of the intended exchange, DTN 223-3102. Bob Steinbach in the Law Department is also available if you have questions, DTN 223-5523. In addition, you should contact GIA before having any discussions with PRC people because our marketing strategies for that country are still evolving.

Attached to this memo is a somewhat lengthier memo which more specifically spells out requirements which you, as an engineer at Digital, have under the U.S. Export Laws regarding the handling and communication of technical data. Please be sure to distribute this memo to your staff.

TO: All Engineers

DATE: 1 JAN 1983
FROM: Tom Moran
DEPT: Export
Services
EXT: 223-3102
LOC/MAIL STOP: PKO3-
1/K77

SUBJECT: U.S. GOVERNMENT REGULATIONS ON RELEASE OF
TECHNICAL
DATA

The U.S. Government regulates the export and reexport of
U.S.
goods and technology. Since Digital Equipment Corporation
is a
U.S. based company, most Digital products, including
technical
data, software, quotes, specifications, training and
service are
subject to these regulations. The Export Services Group is
the
sole Digital interface in all export licensing matters with
the
U.S. Department of Commerce, which maintains jurisdiction
for
most exports.

The U.S. government needs the cooperation of all high
technology
companies in its efforts to limit the unauthorized flow of
equipment and technology. It is in the interest of Digital
to
ensure that our business activities are carried out within
the
law and thus to minimize the possibility of being saddled

with time-consuming and costly investigations, to say nothing of running the risk of lawsuits, fines, possible loss of the ability to export, and even imprisonment.

The Reagan administration is sensitive to the fact that the uncontrolled disclosure of such technical data to "restricted countries" (Warsaw Pact and People's Republic of China) can put our country at a military disadvantage. The Administration has recently taken a number of steps to limit such illegal activities, for example:

- The U.S. Customs Service has fielded some 200 additional inspectors in an effort, called "Operation Exodus", to monitor U.S. exports more closely.

- The U.S. Department of Commerce is strengthening its compliance activities by placing a Deputy Assistant Secretary in charge, adding personnel in Washington, D.C., and establishing two new branch compliance offices, one in San Francisco and the other in Los

Angeles.

- The FBI and CIA have increased their efforts to monitor the activities of nationals of unauthorized countries in the United States and to detect and prevent the clandestine acquisition or diversion of sensitive U.S. goods and technology.

- The U.S. State Department and other agencies of the U.S. Government are seeking to strengthen and enlarge the activities of COCOM, the international body coordinating the strategic control efforts of the NATO countries and Japan.

- The U.S. Department of Defense is concluding a massive effort to identify equipment and technologies in the civil sector which they deem to be militarily critical and, along with other U.S. government agencies, is using this information to evaluate export license applications.

The engineering community of Digital can be of assistance by making certain that all engineering personnel - whether they live abroad, travel abroad, transmit information abroad, or merely come in contact with foreign nationals visiting the United States - fully understand that the U.S. Government restricts the flow of technical data and know-how, whether it be written, oral or visual.

The U.S. technical data regulations are complex but, briefly stated, technical data is classified into two basic categories; restricted technical data and data generally available to the public. Under these regulations technical data that is generally available to the public in the United States can be exported or released freely abroad. "Generally available" means data released orally or visually at open conferences, lectures, or trade shows, and publications which are available at libraries open to the public or available without restriction by subscription or other means.

Other technical data requires either a validated export license (for "restricted countries" and their nationals) or a written assurance from the recipient stipulating that neither the U.S. technical data nor the direct product thereof will be shipped directly or indirectly to "unauthorized" destinations without first having received written authorization from the U.S. Department of Commerce. Such a written agreement allows U.S. firms to conduct commercial business in countries other than the "unauthorized" ones, including training people, transferring software and controlled technology, etc. This applies to foreign nationals from these countries who are covered by such a written agreement with a U.S. employer.

This does not apply to nationals from "restricted countries" who may only be shown commercial equipment and facilities which are freely and generally accessible in the United States. Only published and freely available commercial information may be disclosed - neither proprietary or not generally available.

If you have questions about whether certain information is technical data, whether it is generally available and whether a license is required, you should call Tom Moran of the Export Services Group at DTN 223-3102.

The Training & Education Department of Export Services Group provides a presentation on:

The U.S. Export Laws and Their Influences on Digital Business

Presentation topics include:

o Overview of U.S. export controls
o Types of licenses used to export DEC products
o Responsibilities for compliance with export laws
o The Export Hold

Each presentation offers attendees the opportunity to ask questions and discuss specific issues.

Since forty percent of Digital's business is international, knowledge of the export laws and the means for legal compliance are vital to many groups.

Please contact Export Services (DTN 223-3113) if you would like to arrange for a presentation for your group or attend one of the scheduled presentations.

DAVE RODGERS FROM: GORDON BELL
BOB SAVELL DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-
1/A51

SUBJECT: UNA IN A REASONABLE TIME

Want to get the list and then review. These come to mind:
The current one used in the demo, backed up by a DMR NIFE
based one...
has an unblemished record of no output. Switching to 1 Mhz
until we
get chips... blows it as a very good Ethernet standard with
Xerox, Intel MULTIBUS BOARD VESION, and build converters to
Unibus and Qbus
Start from scratch... hits market at same time as chips
(really don't
see this). Let the outside market supply the boards...if a
source. Use the Multibus or a Xerox design. Go to Japan to
someone like Fujitsu to get it fast Just wait, but use an
interim to do the software. (This would essentially give up
on NI as a std.)

It is really discouraging to find that we have nothing
compared
to Xerox and Intel. What is being done to improve our design
capability here?

Can we get the complete list of possiblities via EMS, then
get the first looks at the ones we think might have gold as
to feasibility? and then meet to brainstorm?

Something around the Multibus looks most promising as of this
second. Am meeting with Intel folks this week re other
topics, so would like to know how much to enquire or push?

Clearly, we should minimize our development resources as this
is interim. I would really like to see a measure within this

hardware
group as to quality, and productivity (which, aside from the Pluto design is virtually zero as far as I can see.) Here, at some time, I'd sure like to meet with the engineers to discuss the importance of getting a product.

With the National suit and all the plug compatibles coming on stronger, it would probably be worth while to make it clear and get a policy that we are only selling operating systems for hardware we sell. This would mean that we would charge for handlers and diagnostics, and also we might reserve the right to not sell them. I don't understand the legality of this, but we might include this software in the hardware cost so it is clear that we won't sell them separately.

As a separate isssue, we can probably build hardware that is more secure to DEC made peripherals. (This will be a by-product of some of the security work.) This would allow us to enforce the separate component sales.

Given that the government is successful at getting an IO Channel or Device standard, it is clear that the plug-compatible people must pay for some of the expenses of the system. Charging back where the costs are incurred would be a good start.

F/U 12/14

I'm writing some essays on computer structures. One part has four essays on overview, technology, organization, and marketplace. The essay I'm writing now is on the marketplace (especially segmentation schemes).

This section is on the distribution channel. Four figures (attached) might be of use to help specify the structure of the marketplace, and then begin to get measurements on the product flow. I feel we must ultimately understand this flow and the associated implicit model to use as an investment strategy.

The figures are:

1. Basic pieces of hardware taking on entirely different machine characteristics by various operating systems. One or more applications are added to match the ultimate single or multiple use in an organization.

2. At each level-of-integration and also for application & installation/train and service (including applications) DEC, a 3rd
3. party, or the ultimate user can be the supplier. Also multiple 3rd parties can participate. To really track, understand we must know something about the channel...i.e., what is ultimate use?

4. Shows data (hypothetical) for what the various groups do/supply. This particular data and the consequential understanding might be the basis of our market investment strategy. The particular plot should be done for: size
product lines

5. Shows market size (availability) with level-of-integration.

Overall, shouldn't we try to get a more proprietary position with a basic applications library such that we, franchise as OEMs or end users can get to the applications quicker?

Dear Roger:

Thank you for your request for funding the 11/55 front end computer for Real Time Computer Music Research at CME. I'm really impressed that you and Dick Moore have made so much progress with the VAX.

There are three methods we might have of funding the proposal, and I have sent your letter and proposal to each of them. They are:

1. A corporate contribution - George Chamberlain our treasurer, has this responsibility.

2. A product line contribution - Joel Schwartz, head of the Laboratory Data Products Group has this responsibility.

3. A joint DEC-UC/SO research proposed - Dick Eckhouse of our Corporate Research group has this responsibility. This requires that someone inside DEC jointly sponsor and monitor the work.

I hope your salesperson, Les Conklin, will help sponsor this work. Meanwhile, I'll collect their inputs and reply to you as soon as possible.

Dear Arthur:

Thanks for your letter and materials sent in July. We've put you on the Museum mailing list and do hope you'll be able to see it some day.

Our concentration at the Museum and Digital Press has been directed to the existing market--the computer buff's bag - not an expanding market.

Intuitively I feel that the major breakthrough on computer literacy will be "subversive" via word-processing and not directly via learning programming. Users of word processing systems begin programming without knowing what they are engaging in such a mystical skill. I am in fact more optimistic than you about computer literacy approached in this way.

Thanks for letting us see your proposal.

Sincerely yours,

Gordon Bell

June 30, 1980

Professor Maurice Wilkes
University of Cambridge
Head of Computer Lab.

Corn Exchange Street
Cambridge CB2 3QG
ENGLAND

Dear Maurice,

I am glad we could get together on Friday and discuss various issues surrounding your coming to DEC. Anxiously await being able to interact with you on all the problems we have about future directions and research. I have asked Dave Rodgers to forward the Ethernet Specification to you and Bob Swarz to send the floating point information.

Enclosed is a copy of a Consumer Reports Magazine which gives information on automobiles in the U.S. Personally, I am not fond of the Chrysler products because of their designs and service. The GM small cars that are now emerging (the so called X-Car design) really don't suit me because they feel always on the verge of being out of control due to size and stiffness of steering. If you really want to become American, then these or something much bigger is the way to do it. You also might look at the American designed Fords.

We have a Ford Fiesta which we really like, but it is not clear whether Ford is going to continue it. If they don't, replacing it by a new American design, then the price may go down to unload the Fiestas. But on the other hand, the service may not be as good. Given the quality, however, I may get a second one if this happens, just to get rid of the big Dodge we have that no one here likes. The Fiesta is made in Germany and is like the VW Rabbit. I heartily recommend these. The thing about the VW or the Fiesta is that they are front wheel drives and with Radial tires, one doesn't need snow tires. Similarly, the Honda and Toyota are well engineered and a pleasure to drive.

Gwen's suggestion to get a small, good controlled German or Japanese car to drive plus a used, very cheap, old gas guzzler so as to blend in with the natives sounds like a good idea, that is assuming you will need a second car. Spending time on this is a typical American sport which you'll have to play. Over the past few years it has become increasingly difficult to buy these cars by phone, which is the way I like to play it.

Hope this has been helpful.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Saskatoon, Saskatchewan S7N 0W0
CANADA

Dear Dr. Kavanagh:

Thanks for the thoughtful letter on how we might provide a personal UNIX. I have distributed it to various persons here.

We are working on systems in this area and I would like to get other requests from you. Our biggest impediment is not having a micro with I and D space right now. How severe is this limitation? Also, what do you see as the secondary memory requirements? What priorities at the CRT? How many systems in the net? What functions do they perform? How does it link to your other systems? Pete Conklin is coordinating these inputs and he may also contact you.

I do hope we can help you and provide these systems in the future.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Dear Jim:

Thanks for the reports on TRAC and the proposal to continue now and evaluate TRAC. While I have not read the proposal carefully, I do believe that the work should be continued so as to get the understanding that comes with use of a new system. That is, it is not satisfactory to just build a machine; understanding comes from use!

In many respects, I hate to comment on Jack Lipovksi's promotion to full professor. When I was there, I asked Herb Woodson if my comments were too late, or needed and he stated that the promotion had been stalled on a simple administrative problem (which he explained, but I've since forgotten).

Overall, I believe Jack should be offered a full professorship. Furthermore, I believe he will be more effective at a university than in either industry or government, whether the task be development or research. This approval is given with some hesitancy though, because while he has progressed intellectually, I still detect that he has trouble in working with his peers.

The basis of my recommendation is that I assume he is at least an adequate teacher. I was quite impressed with the dedicated group of graduate students engaged in the research project that he headed. We need this sort of work in computer engineering, as there are enough people developing theory based on non-experimental results. He was effective at getting the design description language group started. Furthermore, he produces a steady stream of interesting ideas. While I don't believe any of the ideas have been applied yet, they are novel, and they do stimulate independent thought. (While it has never been a requirement for a professor to have either novel or useful ideas, I do think it is important.)

Good luck on building TRAC. Please keep me informed as it progresses.

Am looking forward to the book you are writing with Digital Press.

Sincerely,

Gordon Bell
Vice President of Engineering, Digital Equipment Corporation
Professor, on leave, Carnegie-Mellon University

SUBJECT: RE: RE: A MUCH MORE COMPETITIVE UNIX

At least two customers I've spoken with recently perceive that we are forcing them to choose UNIX because we don't have the adequate UNIX support on VMS so that they can buy a VAX, run UNIX + VMS, and then maybe never go totally to UNIX. Either way (UNIX + VMS, or VMS - chosen) we win.

My help is to get the UNIX effort on VMS to a point where it's much better than UNIX standalone. Now, this isn't the case.

SUBJECT: BRITISH POLICY ON UNIX STANDARDS AND PERQS

Brian Randall, told me the there are two policies that are pretty hard and fast these days:

For Research, SRC, the Science Research Council is pushing the 3 Rivers PERQ, made by ICL as THE research machine. The Perqs are to be interconnected via the Cambridge Ring, which is being made by various manufacturers. With it, the standards are Pascal and the unix interface.

The British Software Industry is pushing to standardize the software interface of UNIX complete with the file system, using several languages, not just C. There are apparently 4 levels of standards: the first is the shell, the second is what I mentioned, and the 4th is the whole programming environment and set of languages.

These came as a surprise to me. I hope everyone else knows about them. Bill, Dick did you know?

SUBJECT: UNIX SUPPORT

Pat has made a request to pick this up as a corporate product.
Engineering is not able to add to the product list now; in fact, we're trying to reduce the number of products we're having to engineer.

UNIX should be a clear money maker. It could be coupled to a stricly software business such that the funding and NOR could Joperate "in control". Alternatively, the path must be the continued tin cupping to keep it going.

Given the number of UNIXes we sell, it clearly has to be supported and developed.

What you folks think here?

SUBJECT: A MUCH MORE COMPETITIVE UNIX

It continues to be clear that we are not active enough with respect to UMX on UMS by merely having C(UNIX).

The effect is clear: people will either not buy VAX's or they will buy VAX's with Unix on them.

There are two outside packages that run on VMS and give a full UNIX system which we might market on VAX: UNIS, coming out of SRI originally, and UNITY, from Human Computer Resources, Toronto. Let's pick one.

In having full UNIX in a full co-existence on VMS, we give people the choice on a single system. In this way, I think we'll sell lots more VMS based products for people who demand UNIX.

Now we're really forcing a choice to UNIX, and this is crazy.

Margaret H. Hamilton, President
Higher Order Software, Inc.
955 Massachusetts Avenue
Cambridge, MA 02139

Dear Margaret:

It was a pleasure to visit HOS and see the demonstration of USE.IT. I'm enclosing an ISP description of the first computer (at Manchester) if you're interested in describing a real computer.

I hope we can move rapidly through evaluation to use USE.IT. Based on my first impression, I think we ought to start offering training courses through Education Services for both internal and external people. I'm delighted that Del Lippert and Sharon Keillor are working with you.

In addition, we should then start a number of trial projects. Specifically, I see it especially valuable for these areas:

- field written software for customers (Don Busiek)
- Distributed Information Systems Software (Jeff Tash, Al Crawford)
- Computer Aided Design programs (Tom Smith, John Manzo)
- training discipline in hierarchial design (John Manzo)
- tools which evolve rapidly (Bill Keating)
- a product to offer to our commercial (Anita Moeder) and technical customers (Bill Long, Bill Keating).

I believe all these groups are looking at possible use, but to really move aggressively, they're going to have to try it on real work. I hope we can spend time at your course or doing these critical experiments instead of getting repeated demos.

If I can be of any help in the selling within Digital, please let me know.

Sincerely,

Gordon Bell
Vice President, Engineering

SUBJ: VAX&11 Systems Planning

To: Bill Demmer, Bill Johnson
Date: 7/10/78
From: Gordon Bell
Dept: Office of Development
MS: ML12/A51 Ext: 2236

CC: Joe Carchidi, Dick Clayton, Brian Croxon, Sam Fuller, Bill Keating, Bernie Lacroute, George Plowman, Bill Strecker, Pete vanRoekens

Having just spent a frustrating 2 hours with members of the VAX group talking about getting decent (easily supported, high performance handlers and diagnostics) I/O on VAX, I feel we are destined to fail. Although the architecture group is resposnible for recording the state of the system, Bill Demmer has the responsibility of planning what these systems will be and getting any of the suppliers and users to supply components to the interfaces/structures. The VAX organization feels decoupled from the 11 (its not coupled through me any longer), and the VAX group talks as if it has no responsibility for planning or desigining anything but CPUs. No wonder our customers complain about the lack of systems focus.

By September first I would like a plan for how systems are to be built (as distinct from CPUs with Unibuses sticking out of them with no diagnostics or handlers). This plan should include a hardware/software system support matrix of the busses we have and the ones we intend to have, the options connected to them, and the structures that can be built from them. It should start to couple with the communications groups so that we get some reasonably cost-effective interfaces for high speed lines so that much of the equipment can be supported remotely via standard lines and still not eat up the CPU for this support. This should involve less overhead than current Unibus devices as a goal say for a device such as a line printer. I would like this plan to include the current efforts (e.g. CIOB and ICCB) so as to get these resources oriented to a goal rather than to sustaining floundering projects.

I believe you have the resources, although it may require a bit of redirection of some of the CPU projects which are currently built to have no I/O. With this plan, we might have some faith that users will be able to get real time and any other I/O.

With this memo, let me rescend my support for the task I thought Lorrin Gale was doing (see attached), and put the responsibility and request squarely with its owner, the system manager.

Subject: **LLL Visit on the 4th**

To: Vatche Sogominian, OA

Date: 10 OCT 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-
2236

Thanks for setting up and running the stimulating visit to LLL on the 4th. I really enjoy interacting with and learning from bright people. The visit to the Shiva experiment was worth the trip alone.

I was most impressed with your rapport with the large customer base and the fine environment you provided by having the 25+ LLL staff and management to dinner at your house in Berkley. This was the finest, most tasteful, DEC soiree I've ever attended. All of us were at ease and it certainly helped build a better vendor-user interface. I'm sorry more of us can't (don't know the customers?) or don't (too lazy?) provide this level of hospitality. Of course, it is also nice to observe a competent professional at work.

Thanks also for the room and drive to the airport on Thursday morning. The Claremont Hotel was quite a nice place too.

SUBJECT: HELP ON IMPROVING VAX RIGHT NOW

As you know, the Venus slip is causing incredible competitive pressure by Interdata and SEL. IBM may also be close.

Could we get Hank Maurer to help on a project to look at the 780 microcode to speed up technical benchmarks? We would like to try several approaches:

1. Looking at a specific benchmark such as SPICE, understanding where the time is spent, and then putting various parts in microcode.

2. Looking at Vector Fortran and including some of these operations the architecture.

3. Speeding up specific, basic routines such as FFT, the scientific routines, etc. for inclusion into the architecture.

The goal is to provide the "performance oriented" 780 user a factor of 2 for his compute bound programs.

Grant Saviers, CX

I think there is always going to be a thirst for high performance peripherals on VAX by certain OEM and LDP customers that we'll never be able to, or want to meet, by our mass storage offerings. These applications include: image and sound processing, geophysical processing, nuclear experiments and other data intensive use. Large computation center use is certainly in this category.

Shouldn't we breadboard an interface to the IBM channel so that special users could buy it and interface there own peripherals on a strictly advanced development basis?

Is the backplane interface the best way to get an IBM channel level compatible interface? Or is it SBI? ICCS? Or MASSBUS in the DX20?

We too have a good disk/tape direction in the RM05 and RP08 and I'm not proposing we deviate from this or re-open this question!

Now that the systems groups are to start behaving as systems groups it's clearly Tewksbury's job. Maybe Bill should talk with Ulf about how to build systems.

SUBJECT: RE PRODUCTS CHARTS AND REORGANIZING VAX AND PRIORITIES

It's hard to believe we aren't on to this one. The SEL machine was first shipped summer 81, and a major update last summer providing up to 17 times the throughput of VAX! They have multiprocessors and a modern compiler. The raw speed of 1 cpu is about 3 x a 780 at 200K. The PE machine is about the same.

Our problem is a complete paralysis in engineering that you must fix, including getting out of the focus on marketing and going back to a "balls out" form of engineering. Admitedly, the disaster is caused by having no VENUS (or having it 50% more expensive and what will be precisely 3 years late wrt SEL!). Therefore, in our planning it is essential to kiss VENUS off in anything resembling a strategic product. IT AIN'T! That's why the Nautilus and why we have to do all possible to get it in 2 years versus the 2.5... more in line with the 780.

The main point that many who attended the 32 bit review made was that our main business, VAX was run by people who had no awareness of the competitive issue.

BJ,
In asking the issue to a bunch of people who are asleep, you're simply passing the myth on that engineering doesn't understand. You must understand personally, and restructure the whole 32 bit area to form a competitive group.

We simply don't have time to go down through the ranks, asking the questions, hoping people will learn and getting them to change their priorities.

This is not a learning process ala DEC U. This is survival!!

Subject: **Array Processors and Vector Extensions to VAX and Fortran**

To: Distribution

Date: 28 NOV 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 12/12/78

I discussed the vector extensions to VAX with both Jacob Schwartz of NYU (SETL, compiler theorist, parallel algorithm writer) and Forest Baskett at Stanford. Forest would like to work on the extensions and I say let's give him a contract. He has the ideas and the experience with the two years on the Cray 1 at Los Alamos. Also, I'd like to have him work for us sometime. Since he may never come to the east, he's one of the people that would be worth having a west coast facility for.

Forest believes that the Burroughs Fortran extensions for vectors are good and that we should go ahead and put them into Fortran as a standard. He believes, as I do, that to get the full power of a machine, the language must contain the primitives. Compilers can go a long way to use parallel hardware, but the user can do better if given the access!

The Cray 2 is being discussed with users now and the consensus is that vectors are good and work well in the Cray 1, even though Cray was considering their elimination.

Cy Levinthal at Columbia asked when we are going to have an array processor. I was coy, knowing full well that we won't do anything until we start getting beat up in the marketplace!

SUBJECT: ARCHITECTURAL EXTENSIONS AND REDUCTIONS TO VAX

Jeff's note points out the problem in how we used to think about the VAX architecture prior to MicroVAX and the recent work we've started to enhance the ISP for better performance in AI and selected technical benchmarks (which remain to be seen).

Yesterday, I started a short note on why architecture has to change with time, including looking at directly executable subsets, and the short note is now 4 pages and growing, so I won't argue this motivational and understanding issue here now. Hopefully this'll be available this week because I want the feedback on it. Another note on RISC, somewhat longer is also in the works where I'm trying to get the basis for understanding it apart from the religious, moral and artistic ground it is now being framed on.

What we do now:
1. Jeff, tell us what we gain in time and cost by throwing out the 11 compatiblity mode.
2. Alan, you had the same concern on VENUS. Do we gain any time by throwing out the compatibility mode?
3. Dileep, your last answer as to why it had to remain in contained no data. Get the data that argues that it must remain in and at what cost to all and to special users. (We used to interpret 11's on 10's at about a 100:1 slow down and this was perfectly acceptable for the application.)

It's hard to argue that we want to kludge up all VAX boards by putting chip softcards on them, however, I would argue that say for Scorpio, we have a board option that would execute z80, 8086, 68000, 11, and 8 code, using the few chips that it would cost. The engineering market that sells to people who write software emulators really need this.

SUBJECT: PDP11 COMPATIBILITY MODE IN VAX
```

While I recognize that there was recently a decision of VAXB regarding compatibility mode, I believe that it is time we changed our policy regarding its maintenance in the Vax architecture. We are forcing the inclusion of this capability into all our designs with the results of:

- o Increased Complexity
- o Higher costs, both of Engineering and Manufacturing
- o Longer development cycles
- o Risk to schedule

As just one point of reference, a detailed analysis of the impact on the V11 program indicated that elimination of the compatibility mode would have eliminated one quarter from the schedule. While it may be too late to gain back all this time now, consider that:

- One Quarter's activity on V11 is worth $1.6M in engineering expense

- One Quarter's pull-in on Scorpio systems is worth $100M or more of total lifetime systems revenue

Multiply this by the factor of 4 major Vax CPU's being developed in parallel and you get the point.

Well, what do we get by maintaining the compatibility mode? I'd argue - very little. The reality is:

- We do not support compatibility mode in a way which is really very useful to many of our customers

- This is at most, a transition strategy for a customer who has made the decision that he has outgrown his 11's

- We can effectively network "11's" and Vax's as a transition strategy and this is probably a better supported alternative than the compatibility mode (if it's an "11" program, ship it out to a cheap "11")

- o Nothing will change as far as our customers are concerned for 2 years. Even then, we already have three systems which support compatibility as well as it's ever going to be supported - Note we'd probably be better off giving away 750's to the guy making the transition (still charge for disk etc.) than continuing to carry this excess baggage from the past.

- o As MIP's go up, the likelihood that someone will be transporting an "11" application without also needing the memory addressing, gets less and less.

However, if we're still unconvinced that we can just drop compatibility mode, there are numerous other possible approaches which could be adopted which unburden the CPU design.

- o Complete software emulation - a true comparison is to provide only the same capability present in the emulation mode today - don't enhance it

  - Performance of 1/3 to 1/5 of base machine capability
  - Should take 256KB of memory as absolute worst case - including the 65KB for the program itself

- o Co-processor - either add a PDP11 processor into the base level design as a co-processor or use it as a "Softcard" type of add on like the PC's do. This could follow later than the basic CPU.

- o Write a translator from PDP11 code to VAX code. You made the comment the other day that someone almost had this working for PDP11 to 68000. This would have to be an easier problem than that one. Also, I've noted that there are already a couple of alternatives available in the market place.

- o Network an 11 and a VAX and have the VAX ship out the PDP11 problems.

Bottom line, we could significantly enhance the productivity of our engineering, shorten time to market, and have more cost effective CPU's if we can take what I think is a minor risk around a customer base which seems to be withering anyway. At least let's be a little more creative about how we implement compatibility features. It's an important business decision and can be Management's contribution to increased productivity.

I say we decide now and get on with the savings. I'll admit to not having hard data on how frequently compatibility mode is used, but unless someone has hard data which proves it would be a major loss of sales, I think we should press forward. There are plenty of alternatives, none of which would be needed in any case for 2 years (it's a mute point then).

MESSAGE ID: 5178223306

SUBJECT: EXTENDING THE VAX ARCHITECTURE, CAN I HAVE A NAME

I would like someone assigned to explore extensions to the VAX architecture by adding instructions which do not increase the processor state and who are in line with the VAX complex instructions. I don't want to add vector registers or anything that would disturb the architecture of how instructions are executed. In the last few days, I've encountered several opportunities to extend VAX so as to extend it's life for particular applications and keep it alive.

The applications:
Signal Processing- Alan Oppenheimer, MIT lab, wants to explore this domain.

AI and LISP- The AI community are ignoring it and trying to get it to disappear by the LISP machines and by praying for a decent 10/20. Danny Hillis, MIT said he'd enquire as to whether we might find someone there to do this work. Alternatively, we might get it done at CMU.

GP scientific processing. There's a company in Illinois supplying these packages. We could probably contract the appropriate extension studies.

General microcode support (compiling into a fast, relatively riscy machine). Who's the company supplying this software?

Matrix and other operations for VLSI- Richard Newton, Berkley was receptive about doing this.

Possibly something that would accelerate the scheduling of simulation or the interpretation of these quasi-parallel data structures that occur in DECsim, etc.

One of the myths that I used to (till last week) believe, was that the 10 had a simple instruction set. Maybe it once did, but the plethora of new data types, funny pointers to access them, and the addition to get a big address space has made the
fast interpretation of the ISP very, very complex and difficult
so that now the 10 looks to be significantly more complex than
VAX. VAX does have many data types and operations, and as long as we do not add state, or require different data structures,

I want to capitalize on the fact that fast, larger microprogram
memories are here and are going to continue to be available over the machine's life. I want to get started with this effort
now!

SUBJECT: SPITBROOK VAX CENTER FOR PARALLELISM AND VAX EXTENSIONS

The attached center is moving ahead, albeit slowly. Similarly, Christy's Computation Center for Parallelism (CCCP) is also being put together. Now, I'd like to get a center in Spit Brook to be used for both architectural extensions to VAX for various languages so that the language group can use it; and for working on parallelism. This is why I'm advocating the pair of 782's that can be used as a 784. I also believe that if we do this work, we can get a factor of 1.5 out of the architecture and compilers (eg. Fortran and LISP (another memo to follow)).

Could you folks put together a similar center along with the other two and get postured to start the work in co-operation with the Technical Product Lines who are now losing business?

SUBJECT: CRITICALITY OF VAX COMPETITIVENESS NOW AND IN THE FUTURE

GB3.S6.39
We must have higher performance systems at lower priced systems and at
the high end. Don't we have a crisis, because:

DEC IS NOT THE LEADER IN PERFORMANCE & PRICE/PERFORMANCE MINIS!
(Nor are we heading to be.)

BACKGROUND: SEL has made recent announcements in providing a 17M
whetstones machine. PE has one. Hitachi has a fast, VAX look-alike
that looks good enough to be able to run VAX assembly level software
by automatic translation... assuming they can get their hands on the
assembly listings of VMS, languages, et al. DG and Prime are close,
and IBM has lowered prices on 4341-2's. All these factors just have
to affect bookings to some degree.

We have to mount a task force level effort to assess our position and
then move to redirect resources to be competitive asap and in the
future.   Here's the options that come to mind:

SPECIALS	NON-VAX	VAX-UNI/DUAL PROCESSOR
CDC FORTRAN+Uvector	Titan	Venus
U accelerators	Titan-vector	Nautilus
VAX+FPS 164	Titan-mC	HyperVAX
VAX+2080		COMET-MCA
Qbus 11 mP	U-VAX, U-VAX-mC	Venus-Fujitsu

New P.vector (buyout in a joint venture)
CI+HSC+750(RDMS)

VAX MULTIPROCESSOR OR MULTICOMPUTER STRUCTURES

784 (4Pc, symmetrical 780 utilizing MA780), including 4 Pc.Venus
780's on Ethernet (many are available for experimentation, and
this structure will emerge, given Scorpios as PC's
780's on CI
Scorpio on BI (780 x n) on one BI

LARGE, MULTICOMPUTER/MULTIPROCESSORS
64 computer 16032 mapped into VAX address-space (see Strecker) with
a follow-on of Scorpio or MicroVAXs

I want your help in addressing this critical competitive problem.
What options do you see? What are the efforts and risks involved in

these? Who are the relevant people we need for task forcing? Let's
rendevouz by mail, meet briefly this month to decide on the approach
and then aim for a 2-3 day meeting in early September.

John believes there are VAX problems that DMT would have found.

What's the story?

John also believes there are unreliable VAX systems in the field. How bad?

SUBJECT: DUCHAMP'S VECTOR INSTRUCTION WORK AND EXTENDING VAX

This talk is on the 26th at 1-2:30 in Mr2, 17c... pretty obscure place. I hope the work is good and let me recommend we take this
issue a lot more seriously.

Right now, I want VAX to survive and be a significant architecture in the 90's as I think it rightfully deserves. The situation is touch and go though as we are unable to implement it effectively.

I knew we were at risk with VAX when such a complex machine was architected in 75. A note written then on the issue of microprogramming and its use (or not) is in the mail.

I think we have to continue to extend VAX into microcode to get incremental performance while NOT extending the state which would in turn drastically increase the complexity of what has to be built in hardware. Unfortunately, we should have
made it possible to decrease the microcode too without changing the architecture as in microvax. This is in line with the fact that rams are getting bigger and bigger for microcode, and I don't see a way to add to the state of the processor without increasing complexity. Cohen's thesis which Richard Newton supervised is being sent around too because it illustrates the improvement of the HP1000 in matrices. I don't think we'll do anywhere as well because the HP was so bad to start with.

Maybe the VAX ISP can't be extended to give much greater performance without violating the constraint of increasing the hardware, but I'd like to know this too. To me, this means we'll consider the transcendentals, matrix and other operations (eg. FFT) as primitives. Also, we'll support a system of microprogramming.

We have a serious issue ahead to keep VAX number one.

SUBJECT: MARKETING (AND DEVELOPING) VAX'S TO SAVE US

Data

1. Having just returned from visiting Cal Tech and seeing many distributed VAXs surround and overthrough the Cal Tech computation center, by adopting our strategy (complete with Ethernet), I'm appalled at our abysmal performance to sell VAXs, especially in Educational Institutions.

2. The System 38 is nowhere near a VAX, yet more have sold.

3. IBM's delivered more series 1's!

4. IBM now has a VAX force to STOP VAX. They needn't be worried.

5. HP has continued to grow with the 3000 despite its massive inferiority.

6. Who would buy a Prime when VAX (and a compatible Professional PC) are available?

7. With the 730 we should get computing down to very small groups of
2-8 for the best computing.

8. A 730 ad with no content!

9. OC time devotes no time to this critical area.

ACTION

1. We must immediately establish a techncial effort that only have a
VAX sales goal. Back to the Product (Product Line!)

2. There must be a strong, engineering effort for continued technical
market place needs.

This includes: real time, graphic support, better technical
languages, a relationed data base, high quality terminals and
personal computer support. (Here, aside from ESG, we have a
massive void coupled with poor incompetence!)

3. The commercial market for VAX is probably 10X the technical market
place. We have an excellent engineering group. We must now focus
on Commercial Marketing. Let's get the System 38! Let's discuss
at OC and set the buy in for focus and change.

4. We should market VAX commercial computing in Universities when we
have strong customer support.

FROM: GORDON BELL
DEPT: OOD
EXT: 223-2236

BILL THOMPSON LOC/MAIL STOP: ML12-1/A51

SUBJECT: BUYING ADD ON VAX MEMORY FROM OUTSIDE TO INCREASE PRODUCTIVITY

Given the state (hopefully in the past) of our needing extra memory for vax's, I have authorized the purchase of outside memory. This has created some concern in the Operations Committee. I may have assumed this to be a more general problem of need. Actually, I think that the users of VAX are underconfiguring it with memory, and I wanted to assure them that we would get the necessary memory so that they could get the necessary cycles out of the machine. Given the overall state of the equipment availability, I strongly support getting
significantly more memory to the tune of at least 4 MBytes per 780 so that we can get the most users on and have the least waiting time, hence the highest productivity for the users who are on.

Bottom line: equipment availability still seems to be a problem. If it is VAX, then get the memory size up asap (assuming you have the load). I'll support any means to getting this memory because the cost to buy it out is cheap(er
than inside), but the payoff in terms of productivyity is enormous.

HAPPY BIRTHDAY

VAX

AT FIVE

The personal program for:

<program>

Please be seated at <course1>
Help yourself to the first course:

Fresh New England Salmon & Bass
Garden Vegetables
Hollandaise and Mayonaise Verte

Cordonieu Champagne
Sparkling Poland Spring Water

8 P.M. The band starts up for your listening and dancing pleasure:

THE MUSICIANS

Alan Dawson -- on the drums
Member Dave Brubeck Quartet, 1948-1979, featured on "The Last Set at Newport," Atlantic Records, and many others. Currently can be heard at Lulu White's in Boston.

Artie Matthews -- at the piano
Taught at University of Massachusetts, Amherst. Can be heard on "IT'S EASY TO REMEMBER," Matra Records with Archie Shepp, Alan Dawson, Bill Pierce, Dizzy Reece and Charles Fambrough.

Whit Browne -- on the string bass
Instructor of string bass, Berklee College of Music. Recorded with Buddy DeFranco and Phil Wilson

Andy McGhee -- saxophonist
Member and arranger with Lionel Hampton and Woody Herman. Solo on Woody Herman's records, MY KIND OF BROADWAY, WOODY AT LAKE TAHOE, WOODY'S GOODIES, and Lionel Hampton's THE HAMP.

Jeff Stout -- trumpet
Solo trumpet with Buddy Rich.

8:15 - Proceed to <course2> (Remember to take along your glass.)

Serve yourself to -

Stuffed Cornish Game Hen
Cranberry Relish
Acorn Squash

More Cordonieu and Poland Springs

9:15 - Another move - with glass in hand to <course3>

Enjoy the Salad, Cheese and Fruit Buffet

Green salad and divers dressings

Brie

Bresse Bleu

Bel Paese

Gourmandese

Pears and Apples

Cordonieu and Poland Springs

10:30

THE VAX BIRTHDAY CAKE

Coffee

Dancing and Listening until
Midnight

Thanks for coming and contributing to
VAX

process record

SUBJECT: AN EFFORT TO IMPROVE VAX PERFORMANCE NOW (AND LONG TERM)

BACKGROUND

The competition with Sel, IBM, Interdata, etc. in the high end is supercritical. The long term solution is only solved by a faster machine. For the short term, we have to put together a significant program that will payoff in the next 6-12 months. Ironically, I think we have all the tools and answers, but we simply can't get the act together to do the work. The effort I had hoped to get moving within engineering is simply NOT moving fast enough because the people are already committed to a big workload to get the clusters out. We are proceeding slowly to get a computation center that could be used to work on speed up in Hudson... CCCP Christy's Computation Center for

Parallelism.

A TECHNICAL CENTER FOR SPEEDUP (Discussed with Bill Long)
E&S Displays are only connected to VAX. We need one here.
FPS164 (We have a 120, but don't know the limits or capabilities.
Microcode extensions to VAX (Customers do it, we don't want to touch it.)
4 Processor Multiprocessors for single jobs. Customers use it, we don't.
CI to interconnect machines. Customers are configuring systems now.

THE PROGRAM
Identify a team or two within engineering and the Product Lines who will get clear benchmarks and then drive to run these across the various configurations of relevance. We would do the earliest work with the 164 and microcode because these are there and more clearly understood.

THE TEAM
On monday when we discuss the VAX high end problem, I would like the names of candidates who can work here both to lead and do the performance analysis. This is a full time job for at least the next six months! Who are some capable volunteers and what do we lose by drafting them at this time?

We simply cannot wait for the next high end machines, nor do I believe the experimental machines that we are currently dreaming of are timely or sure enough to solve this problem.

SUBJECT: PROMOTING VAX'S FOR PERSONAL COMPUTER SUPPORT
DEVELOPMENT

I just read a quote by Gary Kildall, President of CP/M:

"Everyone uses VAX for Development."

Surely we could make an "official" product to support PC's.
With
Nebula, the base will be even bigger! Given our PC offering
and given
people are doing it, can you find out which P/L's would sell
it? Can
we then encapsulate the product and promote it?

SUBJECT: WHAT WOULD A SIMPLER VAX ACCOMPLISH?

The point is: we are floundering about making any progress on defining the possiblity of a VAX subset, what it is in terms of
hardware and software, and what it might be used for.

By inaction, we're making a de facto decision to get out of the board business and to stay away from the chip business.

Furthermore, we are not getting the chips to make a cost-effective
personal computer and will be driven to the 68,000 for a good machine here on the next versions of CT.
F/J are less than optimum in: cost, performance, address size and
time to market (J-only). The 8086 loses in address size, performance and ability to be programmed easily.

In a similiar fashion we made a belated, explicit decion albeit
a sad, sloppy one to not get into the 16-bit chip business and to cap and gradually leave the 16-bit board business.
Just as I thought this decision was wrong, since 77, I know this
non-decision is equally wrong. Motorola will get better faster
than we will be able to provide competitive semiconductors for a
small system.

The result is clear: not only do we stay out of the 32-bit chip, and board business, BUT we are in significant jepordy in our mainline 32-bit business and emerging CT business.

SUBJECT: SOME THOUGHTS ON MICROVAX

A lot of people have been talking about a sub-SET VAX. I can now begin to articulate why I am uncomfortable with the term, sub-SET. It is not because I think that VAX should not be simplified. I think that it would be useful to make a modification of the VAX definition, to make it more viable, just as we have modified the definitions of past machines, i.e. the PDP-11.

However, I do not believe that the new-VAX, will be only interesting to the chip-and-board people. If new-VAX is to beat the 68000, then it is likely to be good enough to do most, if not all of today's VAX applications, just as many believe that the 68000 could do many if not all of the VAX applications. To me, understanding the purpose of new-VAX, is a key to understanding the nature of the simplification.

As an implimentation strategy, the goal would of course be to get the
device in one chip, with perhaps some off-board stuff, as is done in
the case of the 68000, for floating point and memory management. Another short term plan, might be to modify the microcode of Scorpio, using another design team. One might do this in addition to working on a single chip version, as the single chip version is likely to take longer to get, than Scorpio, at this point in time.

Have a good week.

SUBJ: On Implementing VAX: When Hardwired, When Microprogrammed

TO: PEG
EMC
RAD
TMC

Date: 15 NOV 1982
From: Gordon Bell
Dept: Eng. Staff
MS: ML12-1/A51 Ext: 223-2236
EMS: @CORE

Our inability to remove the 11 mode from VAX's now in design or add data-types for particular uses is symptomatic of our reactionary thinking about the timelessness of the VAX architecture, and the reaction to the fact that every 11 was a new architecture! Yet, the 11 may have been more successful because it changed all the time, even though it cost to have software track it. I know of no great architectures, certainly not those that are replicated in various technologies that remain static and yet maintain the greatness of the original implementation. Nearly all of the great Renaissance buildings have evolved over time; in fact, the greatness of an architecture is probably measured in its ability to be changed with time to both user needs and to technology. MicroVAX does show that we are willing to change for the sake of different needs and lower cost at a given technology. Given our ability to implement VAX's and yet our resistance to change it, VAX may have a short life.

We must act to keep what has become the greatest architecture I know.

A computer is determined by three variables, the first two of which are independent and somewhat exogenous:

1. The technology we build from.

2. The applications we run.

3. The architecture, or environment it provides to users.

THE TECHNOLOGY WE BUILD FROM

Memory and logic are all we use to build computers. The size and speed of memories, particularly with respect to logic determine the architecture more than any other factor. In the early days, we were memory speed bound, now we're much better matched. However, in microprogrammed machines, we're control bound.

The notion of Reduced Instruction Set Architectures(Direct Execution ISP), versus Complex Instruction Set Architectures (Microprogrammed Intepreted ISP) is totally driven by need and cost relationships AND NOT ON RELIGIOUS, ARTISTIC AND MORAL grounds! Why various architectures are "right" at various times, based on these relationships needs to be described historically, because I think we may learn from it... there's no mystery when you look at computers this way, and certainly no cause to say "but why were we so stupid?", and "why doesn't everyone build simple instruction sets like Cray versus IBM (or VAX)?". Several years ago, almost before there were fast, low cost memories suitable for microcode, everyone was sure that computers would be microprogrammed, to hold user programs and high level languages. Then it was "wrong or stupid" not to have user microprogrammability! Yet while microprogramming was provided, it only yielded a factor of 2-3 in performance.

THE APPLICATIONS WE RUN

There are gains to specialize the architecture to the application (or data type). The more specialized the data-type, requiring long sequences of instructions to interpret them, the higher the gain. Backus recalled the origin of building in floating point in the 704 based on the 701: "some customers were using the floating point interpreter and reducing the machine to 50 operations per second. ... in building it in, we got more than two orders of magnitude speed up ". No one builds a computer for <u>real time</u> technical applications use without floating point. Note that while the integer performance range for all the 11's is 40, the Whetstones range factor is 120; and for a more intensive floating point benchmark the range would probably be at least 500! The same is true for strings and Cobol. The trick is to decide what to build in:

basics- clearly these win benchmarks if you read Computer Architecture News. Since the Berkley RISC machine and most micros only understand integers, address integers and boolean vectors, then the benchmarks ignore all other data types

floating point- clearly necessary for the technical market

packed decimal and string represented numbers for COBOL. Again the impressive gains 10-20 like floating point. The tragedy, is that we really don't sell to this market, yet VAX paid dearly to build it in!

list structures for AI programs. This originally only meant addresses had to be handled well, but now it means dealing with typed data, and VAX is reduced to being run as an interpreter when fully typed data is used. Also, since LISP has a very elaborate and different procedure calling mechanism, many operations are required to implement it. Clearly LISP requires help.

string operations for text and database operations- VAX has these, but benchmarks really aren't available to show the gains. Furthermore, strings are really character vectors and unlike decimal strings, the operations are much simpler, hence the gain over a subroutine is only 2-3, since string ops are move, compare, concatenate, and search for sub-string, etc. which are 1 or 2 instructions in a loop. The real gains for text and database machines is probably going to be implementing searchs in parallel using special VLSI.

matrix operations- Here, the issue is how the data is stored and whether the processor has registers to hold the data (eg. CRAY 1) to speed up memory access. A vector in memory machine can be made to work as in the CDC STAR, the foregunner for the CDC 205, but the cost is high compared to vectors in registers. The gain in architecture is the reduction in eliminating the program access, and this may or may not reduce the execution time very much. Here, we should get a factor of 2-3 for a VAX depending on how the matrices are stored (eg. sparse).

vector operations for signal and image processing- The issue is whether we can gain much without special hardware, simply by building in various transforms (eg, FFT). This is less obvious since special hardware and chips will be used to process signals and give lower cost (eg. voice input data). A much better approach will be to build these in and measure the cost and speed-up. Here, writeable control store may be the best answer because it would allow speeding up arbitrary programs.

special data-structures for simulation- Are these operations which speed up scheduling events?

I/O- We could have added special operators for communications protocol handling. This is what CI provides. In a similar fashion, a special instruction was added to PDP-8 to allow it to handle Teletypes in a message concentrator application for 128 lines at reasonable speed! We've got to equal this, 15 years later on a 780!

ARCHITECTURE (AND IMPLEMENTATION)

Historically, processors have simply evolved by adding more processor state! The earliest processor had no state with all operations to memory, evolving to 1 AC, 1 AC + XR, multiple AC's,
sets of multiple AC's, and finally Cray's machines with vector registers. Thus, a RISC with many registers would fit the evolutionary pattern, however, it's easy to see that poor software could actually slow down a machine with many registers by having to save state across procedures. En route, the cache, AND microprogram memory had equally major implications on implementations.

THE 10/20 CASE. The issue with implementation is whether there's direct interpretation of the instruction at a speed the memory can deliver, or whether there's a seperate interpreter that probably won't keep the memory busy. The architecture of the 10 is an excellent case study: the early ISP (the 6) was extremely simple, a RISC (with hardwired floating point); now, the ISP has evolved to be more complex than VAX with more data-types, extended memory and many instruction formats to access and operate on all the data. Unfortunately, microprogramming was used in the KL implementation, thus starting the trend to a very complex, and messy ISP.

THE VAX CASE. GOAL G3 was compatiblity across a range (of 1000). The implications were that all machines had to implement all op codes using some technique (eg. microprogram, or software). Some machines might even implement some op codes directly in hardware. Finally, in microVAX we've developed the methodology that was first used in ATLAS Extracodes (circa 1960) to call VAX instructions in software. Also, like ATLAS, it would have been desireable to implement some instructions directly in hardwire. With VAX, the goal was to win Fortran, Pascal, PL/1, and Cobol benchmarks and have the data-types that VMS needed to run fast. VAX succeeded beautifully, but the bottom line is: because of compatiblity across a range and the target applications, VAX appears to require being implemented as a microprogram processor.
If we could directly execute the ISP, then the large factor might be attainable.

VAX+ Given, this background, the extensions we need to look at for VAX microprogrammed instructions extensions are:

AI languages

TEXT and DATABASE primitives

MATRIX and VECTOR operations for technical benchmarks. Here, the CDC Fortran primitives may be the best set. Unfortunately, there is not yet an ANSII fortran with Vectors. (Let's get one)

SIGNAL AND IMAGE PROCESSING- The MIT Signal Processing Lab and LDP and ESG should provide this guidance.

INTERPRETERS TO EMULATE OTHER ISP's. Given that we have the 11, it would seem more worthwhile to include more used ISP's such as the Z80, or the 8086 or 68,000 so users can debug these kind of programs at higher speed within the VAX environment. Also, they may execute Z80 code directly.

General tools to analyze and speed up particular problems. Here, JRS Research Indutries, Orange, California might help.

We can not in this look, extend the state of the processor, as this would increase the complexity of new implementations and make it incompatible with previous machines. Here, I only expect to gain a factor of 2-3 for particular domains such as LISP.

VAX- In a similar fashion, we can then decide on particular machines (eg. V-11, Nautilus, MicroVAX) to put parts of VAX in software and NOT microcode:

> 11 ISP- Jeff's point is throw it out of the ISP! (I think Jeff should propose to flush it and tell us what he'll save in cost and time to market.) Whether it's in microcode should be left to a particular user.
>
> FLOATING POINT- ala warm, only less warm since the interpreter would be in software
>
> STRING OPS- How many of our users care if COBOL runs fast?
>
> CLOCK AND TIMERS- used infrequently.
>
> OPERATORS to handle memory mapping exceptions

CAN WE MAKE FAST, ONE CHIP AND HI END VAX's?

It would seem to imply that we need to do more in hardware and less in microcode. Alternatively, if there's a shift in technology to have much higher speed memories for microprograms and caches so that microprogramming is more cost-effective, then the choice of VAX, say relative to a RISC may be fine for the future. I note that that GaAs is most likely to be first available as fast RAMs (eg. 1-2 ns)! Similarly there are 1 ns PLAs. Would these shift the method of doing logic back to microprogrammed processors? Strecker's project for faster VAX execution using microprogramming and hardwiring seems to be a way to have it both ways. If we were starting from scratch, this would clearly be the goal. The only question is can anything like a VAX instruction be executed rapidly and in a pipelined fashion? And can it be extended to other application domains? Right now, the indications seem to be that VAX, like the 370, can't be used for high performance implementations.

Subject: **Objective Comparison of VAX and 10/20 Hardware and Software Architectures**

To: Bill Demmer, TW/D19
Ulf Fagerquist, MR1-2/E78

Date: 26 OCT 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 11/9/78

In talking with Bill Kiesewetter, I find he believes there is no fundamental difference among architectures, and therefore we can implement identical functions at the same price and performance for VAX's and 10's.

Could you get together a small team and quickly put this in perspective?

1. Just how do you characterize the architecture...can't we just use the government CFA measures? How did the 10 benchmark on the CFA examples?

2. Go through some benchmarks where we measure static and dynamic encoding for various kinds of problems. This should be in machine language, BLISS, COBOL and FORTRAN. (These are around because I have seen them for some BLISS and FORTRAN examples. Let's estimate the code for the 20 with 30-bit address.

3. Look at the cost to implement various processors and systems. Since VAX has more complexity

in its ISP, it probably costs more, and this had better result in a lower system cost because of the encoding.

4. On the other hand, won't the 10 be as expensive as the new floating point, new CIS, the VAX extension to give 30-bit addresses, are added? The two will then have the same data-types (the main component of cost). Do our customers need the extensions? Have we sold them? How much software will be converted to use CIS, extended floating point and 30-bits? Let's evaluate the cost of these, too.

5. At a system level both VAX and the 10/20 have some interesting problems and we need insight quick!

A. As a 20 owner, I can't get an understanding of the users or the help to get more out of a 20. If indeed 20 programs are bigger (say by a factor of 2) this means there is twice as much work involved in program swapping and in some case this means one half the users.

B. VAX has a small page size and it is possible that the management of these pages may totally consume it for large programs.

Can't we have a simple, closed form model that compares the two for a given load?

Please propose a quick, coherent plan.

Apparently we had poor communication on the above. You are all invited to discuss how we get back on the track*. We made a single O/S in VAX, to get a single O/S in the 11 land. This means a program written on M, TRAX, SCS, or M+ will run on VAX without reprogramming or any fuss!

I also want to discuss D/IAS compatibility and RSTS/E (I mean Basic+ only) compatibility. Please don't come to discuss why we haven't, but rather how SCS and M+ will be brought back into the fold. TRAX also has to be VAXed.

This is the only way we have a viable 11 --> VAX phaseover in our products. Also, it's the only way we can get any VAX commercial software. Let's get serious and think of our users -- I thought the anarchists had left.

SUBJECT: PERFORMANCE DATA ON VAX-11 C

THE VAX-11 C DEVELOPMENT GROUP HAS BEEN GATHERING SOME DATA ON PERFORMANCE. ONE OF THE DEVELOPERS, CINDY HO, IS STARTING WORK ON GETTING THE BENCHMARK DATA THAT IS BOTH RELIABLE AND UNDERSTANDABLE. HER EFFORTS SHOULD BE READY FOR EXTERNAL USE IN ABOUT ONE MONTH.

AT THAT TIME, I WOULD LIKE TO SEE SALES UPDATE ARTICLE WRITTEN ON OUTPUT CODE QUALITY (COMPARING UNIX I/O V.S. VMS IS DIFFICULT AND COMPARES APPLES AND ORANGES).

THE RAW DATA SO FAR (COMPUTE-BOUND BENCHMARKS) SUGGEST:

O WE WILL DO "MUCH BETTER" THAN ISC.
O WE WILL EITHER LOSE TO UNIX (BY 15% FOR 20% OF THE TIME) OR WE WILL WIN BY 30% (OR EVEN MUCH MORE IN SOME CASES) THE OTHER 80% OF THE TIME.

THE VAX-11 C GROUP IS AWARE OF THE COMPLEXITIES OF BENCHMARKING AND IS WORKING TOWARD PROVIDING MORE MEANINGFUL DATA.

*****THIS EMS IS FROM ROSEANN MACLEAN*****

GB3.S5.59
2 November 1982

Dr. Dennis P. Geller, Director
Academic Computing Services
Babson College
Babson Park, Massachusetts 02157

Dear Dr. Geller:

Thank you for your letter. I'm delighted to see that we're educating people to have a healthy distrust of typeset material in general and programs in particular. This is something I learned many years ago too.

What we published was inexcusable. I'm now insisting that a program that is published as a listing should be run and reasonably well tested. Furthermore, all programs that appear in textbooks should be tested!

Thanks for pointing out the problem in our VAX-11 User's Guide AA-H869A-TE.

Sincerely,

Gordon Bell
Vice President, Engineering

SUBJECT: ANOTHER LOW END TOOL, VAX-11 PDP-11 ENVIRONMENT

Would like Gil and Maurice Marks to take a look at this. The idea of checking out 11 software for the single user on anything
other than vax is sounding less appealing. Could you folks look and then say what, how and how much? If we invest in the low end 11 software effort for stand alone, I want to do

it efficiently. This seems like the best way! (The time
saved
waiting for floppies or in just plain execution time savings
would be well worth it.) Can we look at it and dream abou it
before we flush it please??

SUBJECT: RE: PDP-11 PROGRAM ENVIRONMENT ON VMS

I think it could be a real help. There are two kinds of
savings
you can get from such an environment -- (1) the time saved by
NOT having to deal with the physical deficiencies of a target
machine while in the development mode and (2) the higher
inducement to retain common sources and use modern tools
throughout
the development process. (If it's quicker/easier to
recompile and
reload than to patch, more people will do it.)

As you point out, it's also just what you need for playing
with
the host/intelligent terminal boundaries sanely. Avoiding
whatever

tendency there might be to put stuff where it's easier to work with
rather than where it's best for performance.

Our experience with the RSTS/PDP8 development environment showed
up some plusses AND minuses, but I think mainly the minuses had to
do with clumsy procedures and CPU performance. I suggest whoever
looks into this more deeply talk to some of the WPS-8 people who
worked with it heavily, for suggestions/warnings.

Finally, I like it because it gets me closer to being able to do everything from the one terminal in my office! In that regard, I recommend that the "other" terminal, to monitor the environment, be only required in special circumstances, if that's
possible. For most things, I think ^Y checkpoint/restart from
the one terminal would be preferable.

follow up 6/5/78

I was under fire by a government customer as to why they should buy DEC when the future gets a 360/370 processor-on-a-chip (e.g., National's latest announcement).

My answer was:

1. The 370 software was optimized for large memory configurations (although there are small configuration systems) -- this gives us a cost advantage over IBM because of memory size and performance due to movement from disk.

2. IBM has commitments to many other architectures (e.g., Series 1, System 3-15, System 34, 3290, etc.).

3. Our encoding in VAX is better oriented to higher level than the 370. (Sam) Bill, can we start to compile data to prove this? (This gets us cheaper systems by the encoding amount.)

4. We have compatibility with the 11 for bounded applications, e.g., terminals. (They don't have this in their machines.)

They ask why we made a VAX vs. 10/20 and what to buy. I said:

1. The 10 software was implemented at high end.

2. The 10 had to be extended, it was out of address-space too.

3. We wanted more compatibility with the 11 than an emulate mode would have given. There's incompatibility (11-10) on: files and data-types that would have made incompatibility.

4. Buy 11's if bounded; VAX if software fits and compatibility with 11's needed; 10's if current base and software exists.

Date: April 25, 1979
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Follow Up 5/15/79

Given the following:

1. We are (hopefully) under budget for FY79 and squeezed for FY80.

2. There are VAX's in inventory now, but the deliveries are going out.

3. There are 2020's in inventory.

4. We have a strategy that calls for building integrated systems of VAX's and 10/20's.

5. Our CAD work is up against the 10 address limit and we want to move to use VAX's there for putting data of the design and all the CAD programs in a single address space (if it makes sense).

6. Jerry Witmore is challenging us to breadboard (demonstrate) the combined VAX/10/20 system we are proposing at his October sales meeting.

7. We need configurations to test the HYDRA-type structures in software. This can be done using one of

the machines to simulate the behavior of Mercury and HSC. This would seem essential to get HYDRA and the Venus and the 2080 systems up and working. We would use this for traffic analysis so as to test the performance.

8. We are about to try to get the critical universities to get VAX's for VLSI - work (these mostly also have 10's and 20's).

BJ, Bob, and Larry could you please coordinate and drive getting a reasonably large number of VAX's and 2020's now to accomplish the above work. I'd like to see adequate systems of this type in MR, TW, WX, ML and MK. This would be 2, 2(CAD and development), 1(VLSI), 1(CAD), and 1...and a spare somewhere. The configuration should also include an interconnect at high speed, say using the PCL for now and ICCS when it is ready.

    BILL HEFFNER
    BILL KEATING
    OOD:
    PEEBLES VIA J BELL

SUBJECT: GEORGE IS PROBABLY RIGHT

Somehow we have to get the personal VAX project going quickly in order to deal with this problem of one-ness and the built-in complexity that it might imply.   The intent of the single VMS is to be able to run a program at any level so as to preserve programs, and more importantly data across the various
systems. The thing that can vary is the user interface and the packaging of the system and the documentation to reflect the specific uses of the variations.

George is absolutely right on the evolution of a complex system.
It implies tons of manuals, and expensive system programmer experts, high support and massive overheads that only the CS depts can afford because the people are free and can deal with the complexity. Also, large organizations want them
to keep their staffs challenged.

Personally, I have had waged and lost all the battles in this regard by trying to get a manual written for a user (here,
I have wanted to try the simple experiment of putting all you need to know if all you know is APL, BASIC, PASCAL, or Fortan,
and simply want to login, create, run (with a library), and debug your program in a single manual). This would have made VAX simple for all who touch it in 95% of the cases. Alas, it

doesn't cover all the intricies of the file system, loader, debugging, writing macro programs, user defined commands, and administering the system. Not only have I lost the battle, but
I found out that we can't even get manuals like this written because the typesetting system and writers are not enough in control of their words that it is a 2+ year project...instead of simply moving a few files from previous manuals around. We
are somewhere in the early 1970's in our manual writing and typesetting capability it feels like.

Yes...we need some work here, and a plan. The systems organizations
as we have them now will never deal with this cause there are hundreds of other issues like Dock Merge that have to be dealt
with. Somehow it is in the domain of the Technical Director of
SW, and we need real leadership here to keep us from going down the current path that will inevitably mean a set of new systems to cope with the complexity.

PS
The IBM approach ain't right...cause it means no movement of computing styles, files, programs, and a mess in the complexity due to the fact that SNA won't be that good in solving the Interconnect problem. I still believe in the concept of where we could go, but it takes a belief and design to do it. The personal VAX is a start.
... assuming it starts someday. (The test is how big the manuals
are.)

George, I'm delighted you have bought some programs from the outside and potentially have saved us t to mkt and precious development resources.   Given that we share a common problem/
vision here, how can you in addition help guide us?

Anybody worried about this besides George and I?

SUBJECT: RE. DEC UNIQUENESS

Read your note and will throw out a couple of comments-

Think we're striving for ease of use for our large customers by
expanding on the generality of the Operating System so as to minimize their training,networking, interchange, etc, problems.
Unfortunately a by-product of generality is to give up some of
the "approachable,friendly, and easy to use" characteristics that the single function user can have in 11 Land (single user
is RT-11, T/S is RSTS, multi programmed real time is RSX...)I suspect that a large part of this ease of use is in the manuals
which are describing a smaller functionality and are therefor easier to read....

It's worrisome in terms of the single function prospect that we're putting so many eggs into the one Operating System approach
which by definition is more complex than a system dedicated to a
subset of the universe. The system your data base prospect gets
will not only be able to run DBMS-32 but also Transaction

Processing, Real Time, Time Sharing, etc which is great for the
General Motors Programming Shop but complicates life for the single function guy. Maybe what's needed most is really good Tech
Writers who produce sets of single function system manuals?

It's even more worrisome that IBM seems to be trying to get where
we came from: the image of the S38 is Data Base; the 8100 is Real
Time; the 4300 is GP; etc. And they seem to feel that SNA will solve
all their compatibility problems? At any rate it seems intuitively
clear to me that whatever DB system you may develop on VMS just
has to be more complicated than say the S38 with its more narrow focus.Better manuals and prebuilt systems can help, but....

Maybe you've guessed by now that I question the one Operating System approach; you're right I do! On the other hand I don't advocate the chaos of the 11 Land where Operating Systems continue to proliferate, but rather a rigidly planned set of compatible, functional subsets of VMS. I would think this would
return "ease of use" to the single function user while VMS would
continue to be the GP system needed by the GM's of the world.

I'll also question the notion that 1 OS is easier to maintain than
several(when blaspheming why not go all the way). I'll argue that
there's a powerful synergism of complexity that more than makes up
for the extra drivers and manuals. In five years we're going to
need some pretty smart people to maintain VMS (Remember when OS370
went critical; ie fixing 1 bug was introducing 1.x bugs? or

when
the TOPS-10 solution was to throw away 1000 SPR reports?)

In sum then I'm suggesting that the multi function capability required by the one Operating System approach promotes ease of
use for our large customers at the corporate levels but has to
cost the single function user in terms of complexity. We can mitigate this to an extent with prebuilding systems and more precisely focusing our manuals but nothing's free;controlled additions to the O/S lineup could help on the ease of use axis.

Regards

<u>Data</u>

1. Having just returned from visiting Cal Tech and seeing many distributed VAXs surround and overthrough the Cal Tech computation center, by adopting our strategy (complete with Ethernet), I'm appalled at our abysmal performance to sell VAXs, especially in Educational Institutions.

2. The System 38 is nowhere near a VAX, yet more have sold.

3. IBM's delivered more series 1's!

4. IBM now has a VAX force to STOP VAX. They needn't be worried.

5. HP has continued to grow with the 3000 despite its massive inferiority.

6. Who would buy a Prime when VAX (and a compatible Professional PC) are available?

7. With the 730 we should get computing down to very small groups of 2-8 for the best computing.

8. A 730 ad with no content!

9. OC time devotes no time to this critical area.

ACTION

1. We must immediately establish a techncial effort that only have a VAX sales goal. Back to the Product (Product Line!)

2. There must be a strong, engineering effort for continued technical market place needs.

This includes: real time, graphic support, better technical languages, a relationed data base, high quality terminals and personal computer support. (Here, aside from ESG, we have a massive void coupled with poor incompetence!)

3. The commercial market for VAX is probably 10X the technical market place. We have an excellent engineering group. We must now focus on Commercial Marketing. Let's get the System 38! Let's discuss at OC and set the buy in for focus and change.

4. We should market VAX commercial computing in Universities when we have strong

customer support.

Subject: **A Method of Segmenting and Seeing Whether and How 10/20 Customers Can Use VAX Now and In the Future**

To: Ulf Fagerquist, MR1-2/E78

CC: Per Hjerppe, MR1-2/E78
John Jorgensen, MR1-2/E78
Larry Portner, ML12-3/A62

Date: 2/14/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Follow up 3/2/79

The attached hypothetical letters to representative customers, based on the one started by John Jorgensen looks like an excellent way to attack this problem. It is the only way to really get at the problem definition, because it has to be done in detail, not just with a sweeping statement (e.g., all service businesses use 10's and have all their programming investment in Macro 10, hence we must supply hardware forever).

Also, given that we first do this at this level, we then have to go down to the next level of detail and really try it. I believe the in-house customer group is the right one to test. Note that we are talking to this group and it ought to be you, Larry and I so that we can get their concerns.

We need a project leader for first assessing the impact, and second, seeing how one would "migrate" use, although I think we must strike the word migration from our vocabulary. I don't think users want to spend any time doing this. They will write new applications on systems we provide as long as there's a reasonable way and cost-effective systems. When I wrote the letters I saw these ingredients:

1. Have a network so that work can be moved easily among machines. Here, this might be ICCS for very fast movement or the intermediate level (1 Mbit) link is probably adequate and preferred as it also permits the distributed location of machines.

2. Really specify what one has to do to write compatibly. I would also like to have utilities that would help (probably written in Snobol).

3. Only put new work on VAX. When programs exceed limit on 20's address (or exponent??), then move them on to VAX. Note, rather than doing extended range exponent for one promised customer, wouldn't it be cheaper to give the user a VAX? Therefore, work would gradually migrate as programs decrease in use, and a given customer could probably live within a given machine budget.

There will be similar rules for our internal development.

To assess the impact then, we would identify all customer classes at a significant level of detail, so the complete list is non-overlapping and 100%:

1. Engineering users with a significant number of 10's

2. New buyers of 20's in engineering

3. Take out all those who only run APL

4. ARPA (subtract it out of the universities part)

5. Universities with minis and deciding on a mainframe

6. Universities with 10's or 20's and running out of capacity

7. Service bureaus with significant investment in macro code

8. Service bureaus programming in standard HLL which can use large VAX as a way to off load their incoming job in a computing engine environment (here the 10 would do front and back end and switching, and VAX would compute.)

9. Other service bureau segments (probably at least two more).

10. Business users in COBOL and DBMS

11. CIS

12. Mfg. at DEC

etc.

The job would first segment the best we could and include enough dimensions so that the users were in separate classes. Then put numbers of installed base, and projected sales, separating add-on.

Further define each of the classes by exactly what they do and what programs they use by talking with them. This might get a few more classes. Write letters or describe the VAXination program to them in hypothetical letters like the ones we've done.

Do an experiment to show that it can work, etc. CMU would be ideal. Take a really hard one (probably the in-house ones) and work with a service bureau.

Who can lead us in this?

The hi end POT would probably have worthwhile comments on this approach.

SUBJECT: SINGLE USERS VAX: WE NEED IT.

I believe we must move significantly faster to get to the market with a high powered, VAX personal computer. The VAX chip will then let us sell them in droves cheaply. THE LIMIT IS SOFTWARE - SO WE HAVE TO START. There are now these:

1. PERQ - orders for several hundred, CMU is using it for their

system with the goal of 150 @ 30K-50K in 2 years. Interactive Systems (Peter Weiner) is going to put UNIX on it.

2. Various Xerox machines - probably won't ever make it to market.

3. West Coast Semicomputer Company - (mid '81 with a 16-bit microprocessor with a reasonable address space).

4. MIT/ZENITH - Zenith's building the MIT Nu design of Professor Ward. Uses a 68000 and high resolution scope.

5. MIT LISP machine - MIT continues to make them. Apparently others are trying to buy them too. About 20 exist.

6. BBN Jerico - Rumour.

7. HP30 - proven dud so far.

8. Probably others. IBM proposed a modified 4331 to CMU for this.

What I'd like to see:

0. Get Ethernet/UNIBUS out NOW so users can build networks.

1. Get the display part and keep it independent of Nebula so that we can get breadboarding of system done on a 780 and COMET if we have trouble. Also, note both the larger machines, may be used in this mode.

2. Get the right interface to the canon printer so we can get LQP page output.

3. Build a significant number (100) of Nebula ASAP (by Jan. 1) for
us and several key customers including several universities.

4. Co-ordinate 3 so that we get the experimental work started.
Some of the universities will use UNIX, so we would use this
effort to co-ordinate the flow between VMS and UNIX. Sponsor
single user VMS though.

Who's in charge here?

SUBJECT: LOW COST VAX'S

We are having a hell of a problem in getting the 11's down in cost at the systems level because we are unable to take advantage
of the set of component chips available. The ii is an attempt at the hardware level to interface these.

There is a similar problem for software busing. These new peripheral chips are totally different and require new handlers and a way of interfacing to our operating system structures.

We are going to have to bring about some major changes in the way we cope with this hardware from the semi folks.

Currently, we can't use it. If we don't we are going to be uncompetitive.

VAX will have the same problem as Lloyd points out.

I want the BI rethought out. I don't see how we can use it. I would like to use IIndustry Standard
chips and provide an Industry Standard Board level bus such as the new, emerging 32 bit version of the Multibus that the IEEE is proposing. No way can we continue to ignore these standards.

SUBJECT: LOW-END DEC ARCHITECTURES

"11" as a Low-End 16-Bit Engine

I believe we have encountered the following problems in using the
11 architecture for implementing low-end products:

1. DEC's early minicomputer implementation of a 16-Bit architecture has caused it to be an older generation architecture. Semiconductor vendors have benefited from five plus years of industry experience before doing their 16-Bit machine.

2. Our standards/software either limit or eliminate the opportunity to update the architecture to make it more competitive.

3. The "11" was not designed with LSI in mind. Most of today's
16-Bit machines from semiconductor vendors are designed specifically for easy implementation in LSI.

4. Transfer cost of DEC CPU's is higher than the market price of

16-Bit products from the semiconductor vendors (i.e. they are
not zero cost).

VAX as a Low-End 32-Bit Engine

It appears to me that these same problems in using the "11" as a
low-end 16-Bit engine today will apply to VAX as a low-end 32-bit
engine in 1986. Am I wrong?

MESSAGE ID: 5178223319

SUBJECT: MORE ON EXTENDING VAX VIA MICROPROGRAMMING

In the September '82 issue of Computer Architecture News (the one where the 80286 is benchmarked to be 2.6 x a 780), I noted
another article entitled: A comparison of Microcode, Assembly Code and High-Level Languages on the VAX-11 and RISC I.

The abstract:
"This paper compares the performance of a simplified pattern matching instruction. The fastest version was microprogrammed
on a 750, the next fastest the RISC, ... The paper presents the execution times ... ."

The example was taken from Yale Patt's introduction to the the
VAX-11/750 Microarchitecture. A microprogrammed 750 executed the string match at the following faster factors:

RISC	5-8.6
	using hand coded and c coded risc (@400ns cycle)
780	8.6-14
	using hand coded, c unix, c vms
750	14-28
	"

Namely, on the 750, you get a factor of 14 improvement over assembly language, a factor of 28 over Unix C and a factor of 18 over VMS C using a microprogram in the 750.

Such an example is probably the best case since the MatchP counts the number of occurrences of a 16 bit pattern in a string whose length is a multiple of 32 bits. MatchP takes 3 arguments: the patern, the stream addres, and the length of the the
string in bytes.

SUBJECT: VAX/VMS RELEASE 1 BOOK

It would be great to have a book that counters Soul of A New Machine.
My problem with it, other than the engineering, was that I don't think
the author liked the subjects at all, nor did he understand them.
Unfortunately, the book was successful as measured by the Pulitzer
Prize, and there is some expectation about what a project book might
look like. Fortunately, VAX and VMS didn't look like DG's project and
hence it really would appear dull by comparison. Also, copies of
books always turn out to be much less significant than the original.
(I sure like dull engineering projects versus the exciting ones say
like Venus.) Therefore, I am highly negative about Soul of VAX/VMS
because it has the markings of a copy, which unlike VAX/VMS was
original and which caused DG to have to have their project.

What I would really like to see is a companion book to COMPUTER
ENGINEERING, entitled COMPUTER ENGINEERING: A DEC VIEW OF SOFTWARE
ENGINEERING. Note that COMPUTER ENGINEERING has sold in the range of
20K copies the last time I looked, so I know there's an excellent
market. Bob Supnik had talked about such a book and we often talk
about this book along with the idea of a DEC Engineering Journal.

Others have talked about writing various articles. I have a tree that
Richy Lary drew that relates various versions of various Operating
Systems to one another, for example to give an overall perspective.

It would seem to me you would be the ideal person to write and edit
such a book. You would gather many articles that exist today plus you
would write the really definitive article or section (set of articles)
on VMS. The issues you raise in your outline could be addressed in a
section on VMS... or even a book on just the Engineering of VMS.

It seems to me you could proceed on a book, but really write it from a
technical perspective, although putting in the people parts, but the
audience is really Engineers (Software and Hardware and others) and
the emphasis is how to do it right. It isn't a book about a bunch of
kids trying to build something where the management is playing games.

What you think? Let's get together on this to brainstorm if you think
it has merit

"CC" DISTRIBUTION:

DAVE CUTLER BILL DEMMER BILL HEFFNER
BILL JOHNSON

GB3.S5.22
One of our vendors, related to the marketing domain, who is

at the top of his field in quality, gave me his impression of DEC as a customer. His view about the marketing space, comparing DEC with others:

Our reputation rests on a few good people but he has not seen them so he thinks their numbers must be small. Mostly, he's imputed that they must exist because we've done so well. He knows that we've hired people, presumeably because of the high growth, that NO ONE else would hire. It's easy to get in, we don't think excellence, and there's no way to get fired. He sees a lot of lazy and incompetent people. He can't understand how we're going to be able to continue with the magic, whatever it is, given these people.

He was as confused as our employees because of the matrix mystique. He postulates that we must have lots of stealing because of the fragmentation, fat and the kind of people. Everyone gets involved in everything. The result, lots of inefficiency, but mostly it is just very, very political with groups constantly bickering about each other and trying to stay away from other groups. The people talk openly about the politics.

Unlike one of his other customers, GCA, who he said was the best because of their understanding and caring about the products. We rank at the bottom in terms of understanding and caring about products.

Other companies: Honeywell's better, clearer, more professional in their interaction; Gillette, a company that everyone puts on their resume, people are professional, while they pass through; Polaroid, extremely poor management.

Engineering staff:
I think we have to have the same problems. During the overall review, I want to highlight our mediocre and incompetent parts and assign them to NOD (Nil Output Division).

Mr. Lee H. Schank
Vice President, General Manager
Rixon Incorporated
2120 Industrial Parkway
Silver Spring, Maryland 20904

Dear Mr. Schank:

Thank you for sending me the information on Rixon. I have sent the material to Bernie Lacroute, Group Engineering Manager for Distributed Systems. I have also sent a copy of the material to Bill Avery, Group Engineering Manager for our Terminals and Computing Terminals and to Al Crawford, head of our Corporate Information Processing Department, and finally to John Rose who is responsible for computing within engineering. Both Bernie and Bill are responsible for our product development and would focus on our use as an OEM, and Al and John are responsible for our internal corporate and engineering group needs.

The best way to start an interaction is by direct contact with the appropriate, direct users. Also, it would seem like Bernie and Al might host a general session where the products and possibilities could be explored. I would hope we could do a thorough evaluation of your products for these uses and possibly visit your main facility in Maryland, provided there is interest.

Thank you for calling your product to my attention. I hope there is some way for us to interact. Could you also send me a more complete catalog, including price list of your various products?

Sincerely,

Gordon Bell
Vice President, Engineering

SUBJECT: 780/VENUS ARRAY PROCESSOR AND KAHAN AS A CONSULTANT

Kahan of Berkley
I talked with Kahan on Monday afternoon about his possibly consulting with CDC. Given that he had knowledge of Venus, he wondered how we felt about this. He stated that CDC was positioning a machine to be competitive with VAX. Given their knowledge of scientific computation, I am quite concerned.

Frankly, I think we need his help and understanding in tweaking Venus because of his knowledge of numerical, scientific computation and benchmarks. Through him we might make minor changes that would influence performance and accuracy greatly.

Who could interface with him? I promised that Sam or I would call him on this by Monday, so we must. Sam will you decide on this and talk with me?

780 and Venus Competitive Concerns
I am vitally concerned about our being too late with Venus and
the need for some interim like the Array Processor by FP Systems.
Initially, we would buy this and integrate it into the architecture as best as possible, but ultimately we may want to
build one and do a much better job of integrating it into VAX
and VMS. Thus, there is a range of alternatives, but I don't think we can do absolutely nothing, hoping FPS will save us.

Given that we now have such a significant part of our business in
this scientific domain though LDP, ESG, Government, and some in
EDU, we can't just let it go down the tubes. We have to get someone to frame the technical alternatives and costs rather quickly and then appraise the Technical Marketing folks so as to
get a direction. Who is going to do this?

ALAN KOTOK

SUBJECT: VENUS AND ITS CONTINGENCIES

Given that Venus is really the cornerstone of the VAX strategy as the follow-on to the 780, the competitors, and my concern about its schedule, we should proceed as follows:

1. VENUS MUST COME IN AT THE SCHEDULED TIME
There is no option to stop work and to go back, get adequate CAD tools, do the design training, and staff such that we have a higher chance of winning. It is up to Ulf and George to do the necessary things to make it win! I intend to help lots here.

I'll discuss with Ken, and we should keep the Operations Committee informed if there are any changes.

2A 780 MID LIFE KICKERS
Are there any? What is the chance of running the clock faster? Using the new part we are talking to AMD about for the SUVAX display? Using an MCA data path?

2B 780 ENHANCEMENT USING TIGHT COUPLING TO FLOATING POINT SYSTEMS
They will be here this month with their VP of Engineering. We must co-ordinate with the persons hosting them to assure that their FPS box can be connected to VAX systems via the CI. This will give us the necessary coupling and experience for this type

of systems. Demmer, please get this cleared at GVPC so that we
can work with them freely when they come.

2C MULTI PROCESSORS VIA THE MA780
Here, we need measurements and help (experience is in MR) on symmetrical mP's, where we should go up to FOUR processors. Bill, let's get at least one four processor configuration and lots more memory for the VMS group so we can start this work.

2D HYDRA CLUSTERS
Anything here to do that's not being done?

2E NAUTILUS AS A BACKUP
Even though there are different persons, Nautilus may not be a
backup, given that it has about the same complexity. We must be
concerned with their lack of gate array design experience and tools, particularly when facing the Japanese competitive scene.

2F SCORPIO MULTIPROCESSORS AS A BACKUP
The team understands complexity and structured design, but does
it understand VAX adequately? Given the competitors are all multiprocessor based, and given our positive experience with the
11/74 MP, and given that we need more performance, can we get our
act together here to make a multiprocessor?

3 THE 2080 AS THE KEYSTONE OF THE HIGH END
We simply must now integrate the 20 into the VAX/VMS architecture. This means that work can be moved freely across
the two machines. The key parts are the languages and files, although we consistently get hung up with the command language!
(This can be limited to a few key languages such as Bliss, Cobol
and Fortran.)

We also need the 2080 as our main computation center machines
for
the foreseeable future. Within engineering, the CAD needs
are
quite clear, and we have to plan on it giving us the mips.

Ulf and Bill McBride must propose a significantly more
compatible
and integrated system plan.

ADDITIONAL QUESTIONS

Any other alternatives?

What are the priorities?

Is it clear who's doing what?

SUBJECT: BUILDING VENUS AND OTHER VAXES

I don't want to lose any time on getting this project
started.

We should have news shortly on the I-box. My greatest fear is that the I-box can't be proved to work, or will work so slowly that the performance will be something like a 780. The first estimates for the path are around 100 ns in the I box. I don't understand pipelining well enough to know what that means though.

Our problem here:
780 mid life kickers
Venus alternative
Nautilus
Staffing adequately to give Venus a fair shot
Cane, and a high performance machine
Scorpio, so it doesn't become a Venus

BJ is thinking of moving the office systems work to the UK. This would leave a team of very bright programmers without a project. They could be the basis of a system that would design the next machine, given a couple of good logicians and electrical engineers. The more I see us grunt away on logic, the clearer it is that it's not the way to do the job.

GB2.S6.68

The State of the Design
It seems like we have:

. text spec of entire machine, since the box names are incorrect, its unclear whether this has any validity
. text spec of boxes, together with some block diagrams, description doesn't reflect the design
. flow charts specifying behavior of a few parts
. behaviorial description, in TUMS of the boxes, non-operational as a complete system. Even if it operated as a complete system, it is unclear what it means due since the timing interaction of interconnect signals like stalls and micro-interrupts are so complex.
. 500 SUDS logic drawings specifying the machine
. 500 SUDS logic drawings for MCAs

. MCA physical layout, simulation description, test patterns, test data as to whether the MCAs meet their specs

What would be the IDEAL state of the Design?
A document describing all the documents and what the design ground rules are going to be. This would
It seems clear that we must have an accurate, structured design at all stages of the design.
Ideally, this design description is in machine readable form so that it can be checked as much as possible by machine.
Since the main design tool is SUDS, this implies SUDS compatilble software that must be written asap.

What would be the IDEAL design system?

0. Information only appears once and notification is made to users of information as it changes. Ideally a data base could do this, however, this has shown to be virtually unworkable using DBMS and the IDEA database. Alternatively, there must be batch update to flag changes.

1. Interactive, with access to any part, with protection of data as to the owner.

2. Report writing ability to get parts out as needed when there are large pieces that need to be looked at or put on the wall. No document should be more than 15 minutes away, with instant access to everything else, including access via SUDS terminals.

3. Overnite batch update of key part such as indexes, rule checking, etc. that is less frequently needed.

4. Calculator functions like the clock checker that operate on the data to give the designers quick access for making critical decisions.

5. Data base-like access of critical information that is structured in order of detail.

6. An index and on line access to all signals, giving:
.name, together with polarity, location, time generated, and the source drawing it is created on (derived from SUDS)

. a list of all the drawings it goes to and the time the pin expects to see the signal (derived from SUDS)

. a text description of the meaning of the signal (designer input, together with date created,

. a list of all the specifications that reference the signal

. a list of all the other documents that reference the signal

. a list of people who are interested in the name so that they can be informed of changes on some sort of periodic basis

A program would be run each period to update the index from SUDS or from a journal tape generated by SUDS. A program would be available to either automatically, or on demand report all the changes to names to the relevant persons.

7. Mail system so that designers can ask for information from one another and have an easy way of structuring the ambiguities.

Subject: DESIGNING AND PRODUCING A TIMELY, QUALITY VENUS ACTION ITEMS

To: Ulf Fagerquist, Alan Kotok, George Hoff, Sultan Zia, Roy Rezac, Bill Walton, Carl Gibson, Dave Copeland, Vehbi Tasar, Dick Beavan, Nick Cappello, Vic Ku, Tom Eggers, John Bloem, Tryggve Fossum, Bill Bruckert, Paul Guglielmi, Sue Nathan
CC: Bill Demmer

Date: 11/15/81
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51

After one week with Venus, it is clear that we have to change:

SCHEDULES MUST BE CLEAR AND WE MUST MEET THEM
We didn't get through the schedule reviews on the boxes, nor did we get around to reviewing the LSCAD and diagnostics parts on Thursday. Of those schedules we reviewed, it wasn't clear what the schedules were, nor how we were doing with them. It seemed like only Tryggve was meeting his schedules. This is awful, given we just replanned. We must have WEEKLY reviews. The focus will be both on the quality of the schedule and meeting them.

Good schedules have to be entered into the scheduling system.

I believe we have to have a totally on line system for looking at all tasks.

MORE RESOURCES
MCA DESIGN GROUP-The IBOX group has requested help in their design including one more logician and several logicians in February for MCAs. Getting their logician is very high priority and should be done this week. In addition, I hope to establish another group in MR1 who would only work on MCA design, test pattern generation and then testing when the MCAs return. They would be the providers of MCAs for the module and box designers. The goal is to free our box designers to design modules for the boxes.

TOP LEVEL DESIGNER AND LIBRARIAN-The top level design must be managed across the boxes, I believe by Alan. In addition, we must immediately obtain a technical librarian who maintains the documents and works at resolving the dangling loose ends by holding them. In programming, these correspond to the chief programmer and program librarian.

We have to explore other areas where more resources can be applied. Beware:
Brooks law states: "Adding resources to a late project delays the project."

HOW CAN WE REDUCE WORK?
I want to explore using the IO System of Jupiter, since it will have been built and debugged by the time Venus is built. Also, given the complexity of the machine, I would like to use an off the shelf 11 to get the bigger address space and be able to use an existing operating system. This would get us some extra breathing room in the program space. I can't conceive of writing the console program in anything like 65 Kbytes.

COURSE ON COMPLEX SYSTEM MANAGEMENT
All of us must take this course by John Monzo this week. Other courses may be required as we go along. I think we need something on the order of 1-2 days per month. One of these, out of necessity, may have to be on Saturday, so as to not impact our slipping schedules even more.

COURSE ON QUALITY
It is clear we also need a course on quality. The documentation of the machine I've seen so far is marginal. There are no conventions for names (eg. VA is used for Virtual Address register within Venus, whereas it is most generally used everywhere else to mean simply a virtual address), and there is inconsistent naming based on capitals, hyphens and abbreviations. I don't know how a computer can possibly equate 3 versions of what appear to be the same name in one paragraph and they certainly confused me. We have to have be perfect in every detail to get a working machine! We have to solve this problem.

FORMAL MEETINGS
We probably should minimize, stylize and streamline our meetings. This should get attended to this week.

OPEN COMMUNICATION AND SUGGESTIONS
It seems to me we are pretty open, but it is clear we have to be very open about things that may impede progress. Historically, we have been quite good about making these suggestions. In addition, there's already been good suggestions about computer operations

using a suggestion system. Although we don't have a suggestion system for the engineers, we must encourage suggestions from everyone on all fronts on: reducing work, being more effective with what we have to do, training and quality... here, we simply can not make any mistakes that requires any kind of rework (eg. eventually editing a document for naming consistency because the names were typed carelessly).

I propose we all be accessable for ideas and problem resolution via mail.

ADVANCED DEVELOPMENT
We need to carry out some aggressive high risk, very high payoff work concurrent with VENUS that could help in reducing future work and improving the quality.

BOTTOM LINE
Venus continues to be the most challenging project within DEC. It has to be a quality product and on schedule. Making it happen is our responsibility.

MESSAGE ID: 5181988022

SUBJECT: VENUS NEED, S1 (AND US), LLL MULTIPROCESSORS

VENUS

Having just returned from visiting a number of customers, the need for Venus is absolutely clear. We must take every opportunity for further inspection ala Cohen's Software Methodology in order to get it on time, and, if possible, ahead of schedule. The M-box in particular critical, and I wonder if an outside review would be useful too? Is there a chance here on the M-box? How?

The decision to use the SBI for Venus may turn out to be quite wise, even though it is costly. By using the SBI, customers can unplug options at various levels on Unibus and Massbus and attach them to Venus. This minimizes perturbation and saves files, etc. . . This also gives us a lot of 780's for sales somewhere. Possibly the 782 configuration might be useful in the transition.

I see a long life for Venus, independent of Nautilus, simply because of the SBI, and the lack of peripherals for BI initially.

THE LLL S1 (AND ITS PACKAGING)

I think it's important to build the S1, if for no other reason than because it's the most complex architecture that one can imagine and they've made a number of contributions in handling vectors and built-in functions. It is also a very tightly coupled mP(16 Pc's) with duplexed central memory and a switch like C.mmp. (Taylor series for transcendentals, FFT, digital filtering) There are only 25,000 100K chips in the processor . . . which is 4x the number in the FPS 164 and only 1/8 that of the Cray 1 at it's current 80ns clock which their verifier confirmed (50ns was the target before they laid it out in it's large form factor). Even though the Titan might actually outperform it for simple benchmarks, the novel handling of vectors, arrays, builtins functions and transcendentals should give it an edge
over the Cray for particular scientific processing, even though people will have to rethink their algorithms with very fast built-in transcendentals (10-50 x Cray when vectorized).

(HP's got some sort of fast FP processor too that has built-in transcendentals using a modified cordic algorithm.)

The machine is drawn on only 1000 A-sized prints -- (25 dips/A-size drawing) which really says hierarchical design works to surpress the redundant and the irrelevant. Note in SUDS, this would be on the order of 25,000 drawings! A count of the drawings should be the best indicator of complexity that designers have to deal with. Therefore, their machine is about as "complex" as Venus? Nautilus just has to work the print count and structure to hold down complexity.

The machine (S1-Mark IIA) is physically large because there are no card cages. It's in the shape of 3 "+" signs laid end-to-end so that all IC's are accessible. Power is totally bussed and fed from both ends. About 1/2 of the machine, the IBOX, has operated. It worked with a small number of design errors (principally the interface) a week after power-up!

S1 (Mark III)

This machine is to be the production version of the IIA, with no logic changes, and simply re-partitioned to get speed. It's to be laid out on 50 boards which have 250 x 2 IC's mounted on either side of the 15 x 15 PWB (4/6 mil spacing). Boards would be loaded against water-cooled plates on 1/2" centers. Thus the processor would be 15" x 15" x 25" package or 5725 cu. in. or .23"/flatpak. Note if we packaged Venus this way, with its 20 x 200 (4000 EIC's) could occupy a 10 x 10 x 10 cube! This would cut physical delays by more than x2, especially with edge connectors on both sides. They would be happy to share their packaging ideas and work with us. Joe Zeh ought to coordinate any visits.

They're planning a gigabyte of Mp---which only costs about $1M. This portends a problem in my lifetime . . . we only have about 30 bits for physical memory usually.

Also, I trust the already abominable addressing extension on the 10/20 will get extended again beyond its 30-bits in the next 10-20 years . . . please, please, please don't tell me when it happens.

It can emulate a 10 too probably, but won't since the only reason the proto did was for SUDS.

SUBJECT: VENUS: NOW WHAT?

I basically don't think there's an option of letting a group or manager learn. Those folks are way in over their head and don't know it. I want to put together a set of people and do a set of analysis starting today. I'm in TW this morning and will discuss with Bill, then you guys might meet and then we could all meet at the mill.

Lots of thoughts:

What if we stopped it now? This would be the most humane and reasonable I'd believe. At any rate, we're going to have to face this, so I'd like to ask the question.

Who could manage the project at a detailed/design level to get the
job done? Fuller, Kotok, Stewart

How good are the various designers? (You've probably heard my theory of programmers wh do negative work.) How would you characterize them?

What formal methodology can you install that can allow the design to be verified or to even be converged or checked? Sam might have some ideas here. It might be done with some sort of ai program where the program is used to check the myriad of rules that need be checked. Here, we might get McDermott immediately to help us. The problem may be too big though!

Bill Demmer has got a real problem as it relates to 32-bits, however, I think the same issue is there. Namely, how do we build complex machines. Clearly this changes the emphasis on Nautilus and Scorpio and requires them... Nautilus has the same problem! (Although I have more confidence in the designers.) Their proposed schedule is the same as Venus and they propose the same techniques.

At 5, I'd like you and Bill to have pretty much scoped out where we stand and what kind of information we want to obtain about where we stand (as compared to Comet, KL, etc. along the lines of the design status.

Also, I'd like Bill to look at what whether there are any interesting alternatives vis a vis the 780. Could we realize it in 100K and get the same performance?

The bottom line:
I don't think there will ever be a machine there, given what I saw yesterday. A green, undisciplined, leaderless very large group is what I saw.

I think our thoughts ought to be confined to you, I, Sam, Allen, Bill and Larry for now. Hopefully we can all be at the meeting.

MESSAGE ID: 5176595674

SUBJECT: CONGRATULATIONS ON VENUS PROJECT; NOW LET'S GO FOR CAD AND FACILITIES

Although it's hard to remember the fatal review in May 81, just 18 months ago, today's review of Venus was clearly two orders of magnitude different:
1. team versus collection of non-communicating gurus
2. anarchy versus a management structure with competent managers
3. everyone knowing what their job is and driving to do it
4. put something together versus design it right, check it and then build it. Quality Engineering!
5. seat of the pants versus science and engineering principles
6. a group going nowhere versus a basic spirit that VENUS will be a product, and there will be other follow-ons

Although things felt good with the project and the technology, we now have to go back and work like hell on::
1. The 10/20 network and operating system software that everyone

uses in Marlboro. Clearly these are unaccepatable
operationally to get VENUS and Jupiter finished!

2. Getting the CAD software working (AutoDly... timing verification
is essential I believe) AND

3. Getting the simulator, for the whole machine relible is also
even higher priority.

Am delighted that Jeff Singer is on the CAD software, but we need
to get Dave Copeland the resources to make the systems work.

All in all, even though there are problems, there's a group
who is now set up to solve them too.

SUBJECT: RE: GORDON BELL'S VISIT TO MARLBORO

Do intend to stay closer to VENUS than when I got involved
last
time. For the very short term, ie this week, I want to go
for
these things:
.get on loan a Xerox 9700 printer that can be directly
connected in order to get instant throughput of prints
(Ulf, contact Al Crawford on this. We would replace theirs
when you get yours. We do need this direct connection. I
want the 10/20 folks to get the network connection so as to
make your design network work.
.get a network in place that can handle all this
.get a job floor control system so as to get instant access
to
state of the design
Note these candidates: Albequrque, Colo Springs, Maynard
Modules,
someone else in MDC. Can you get the specs on all these
and any others and then lets decide which ones we are going
to use.
.get 3 designers from the UK or elsewhere (the call has gone
out)
Bernie says we can get 3 now for a year and he will take
them
into Distributed systems after they help Venus and get some
DEC training

I was particularly pleased with where we are on VENUS overall

as there has been so much progress. What I saw:
.A team of technical folks that are starting to behave as a
 team. You are all to be congratulated.
.Confidence that there is a good design basis.
.Equipment coming in to support the team so as to get
throughput
.The Quick Turn Around concept in all the modules and
services
.Buyin and understanding that we can and must seperate the
design
 so as to get parallelism and highest throughput (there needs
 to be MCA designers versus module designers ... Clem is the
 clearest on this point.
.Simulation is almost installed and I want to see how well it
is
 working.
.Structure in the design among the levels so we get a
 clear understanding at all times as to where we are in the
design
.timing verification has to be done, and we understand it's
need.
.Earl Van Horn's ISPS work really looks good. Whether we can
or
 or should use it remains to be seen. My feeling is that we
 could have either the dignosticians or simulator folks
 or microprogrammers do this as a check on the design.
 Note this was done at Intel on some of their recent machines
 except they used Simula for speed. In doing this, the goal
 would be to build the machine in ISPS at the box level in
 detail so that the clocked signals come out at the right
time.
 The goal here would be to get this done in sufficient
advance
 of the logic so that we would have a machine to run on.

We still need to work on a lot of things, including the
testor
to be used by the module and box designers.

Rather than working on process and teamness and resources, I
hope to get into the design asap so as to assess what we can
do

to simplify and get it sooner. Also, the closer look is necessary in order to see what we can do to aid the processes and
resources improvement.

EMS 1-MAY-79 08:36:38 410 1

To: Bill Demmer
CC: George Hoff, Per Hjerppe
From: Gordon Bell
Date: TUE 1-MAY-79 08:36:38 EDT
Subject: Direction in Marlboro

Having heard the MCA review on Friday and seeing none of the people except
dave potter who are to be involved in venus and having it reiterated again
(at CMU) that we have been delivering marginal products in the 10 and that's
why everyone thinks we are moving to VAX, I would like you to get involved in
the definition of VENUS and especially in the staffing. The MCA really looks
marginal to me in terms of being expensive, most likely unreliable due to
low volume nature and my gut really says no. This movement of the project also
feels awful! The field service person on the 10's was present at the MCA
review and I don't want this group or the manufacturing people there involved
as they are not cost, or volume oriented, nor do they

understand quality
beyond having large organizations and this is not what the VENUS should be
all about.

Until Ulf gets back, I would like George Hoff to report to you.

Command:

EMS 2-MAY-79
15:29:49 290 1
To: Gordon Bell, Bill Demmer
CC: Per Hjerppe
From: George Hoff
Date: WED 2-MAY-79 15:29:49 EDT
Subject: EMS MESSAGE ON MCA/VENUS

The review this past Friday was planned to include MSD participation,
however, Ken's visit to Tewksbury created a conflict. I discussed this with
Dave Rogers and thought I relayed a message to you via Mary Jane - it was
decided to go ahead due to your crowded calendar. The key MSD issue in the
technology area is: we should trade-off the Siemens array with the MCA. We
committed to this trade-off at the meeting - Pat Sullivan met with Bob
Stewart before the meeting to insure that we understood his concerns. Bob, as
well as any other MSD engineer interested will be asked to be part of the
Venus technology trade-off review over the next four weeks.

I have reviewed staffing status with Bill today. We have 8 people identified
who will move to Marlboro this month. We expect to fill in the team with
Marlboro people this week.

The majority of the design team will be from MSD - including E BOX,
microcode, manager, floating point and systems architect.

MCA costs versus alternative technologies will be thoroughly reviewed. I will
set up a review of the plan for the technology trade-offs with Bill next
Friday.

The re-assignment of engineers form both Dolphin and Venus has been very
painful. My primary concern at this point is to re-establish momentum while
dealing with a review (and possible change) in the basic circuit technology
and packaging assumptions.

Command:

EMS 4-MAY-79
16:22:06 330 1
To: Gordon Bell
CC: Bill Demmer, Per Hjerppe
From: George Hoff
Date: FRI 4-MAY-79 16:22:06 EDT
Subject: YOUR EMS REGARDING MCA'S, VENUS & 2080'S AND RELIABILITY

I feel we have learned some painful lessons from the KL10 which are reflected
in the simplicity of both the 11/780 and the 2020. Simplicity is a key factor
in 2020 reliability plus a rigorous DMT/PMT process. The reliability of the

11/ 780 with a more complex structure is impressive. I believe that the
application of a mature technology and packaging approach were key factors in
the 11/780 along with DMT/PMT.

The application of any gate array technology to a medium scale processor
presents risks and complexity both in development and production which will be
reflected in time to market. If these risks and schedule impacts cannot be
justified in terms of life cycle operational cost and/or substantial
performance gains, they are clearly unjustified. The MCA technology will be
measured against more straight forward approaches for

Venus.

I believe we should apply a similar philosophy to the review of packaging
proposals i.e. if we add complexity and/or risk it should be clearly
justified in terms of payback to our customers in terms of time to market,
life cycle operational cost and performance.

SUBJECT: CONGRATULATIONS ON VENUS PROGRESS AND REPORT

The presentation, reports and work behind Venus really feels sound to me. The project is certainly about the largest we've
ever attempted and it is important that it be well run, just to keep from stumbling over its shoe laces.

Am delighted that we are over some of the big issues that were
holding us back at Motorola.

I was especially impressed with the sign-off and commitment that all the people and groups involved in both the task force
and the plan had. This is clearly essential and represents a significant management accomplishment already.

Keep it up. I look forward to the formal phase transition. Let
me know if there is anything I can do to help.

SUBJECT: ONE WEEK TURN AROUND FOR VENUS AND EXTRA KL10'S THIS QUARTER

This is not optional. We have to have a plan in place to

attain this by the time the design, now on hold, comes
out.

Will,
I expect a major part of this to come from you. The need will hit probably at the end of this very short summer, I suspect.

The backplane is included too!

For starters, I would like to see if there are any KL10's we could add this quarter to help matters. Are there enough in Littleton? Marlboro? Tewksbury?

A task force, together with a clear leader should be formed no later than mid week to get this vital project under control.

SUBJECT: RE: RE:ONE WEEK PROTO BOARDS

I think this is the right approach. If we can take each of

the
elements of our process and tighten them up (or eliminate them)
we are bound to come out ahead. The how many angels on the head
of a pin discussions can wait till later. The Japanese don't
try to develop some entirely different approach as a first step.
They work on the individual steps. Later they look at the
overall flow and see whether larger parts or even the whole can
be replaced. And in these cases they do a proto type run of the
process before they scrap the old.

It is easy to fall into supporting the status quo. ie. it is not
really that much of a problem; prove it; the cost of fixing it
outweighs the benifits; etc.

Just as we want the output metrics for each of the PEG groups, we
need strong metrics for the supporting organizations. As they feel
they are being measured by their customers (PEG) for the amount they
simplify or complicate the job of producing quality products with a
quick time to market, we will see more of these good ideas.

Ken Olsen, ML10-2/A50

Date: 8/4/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

The equipment (TV and microware) looks good, but the whole operation needs to be much more flexible. The primary purpose is teleconferencing and not doing any fancy video recording or documentation. Given the amount that we move around in the Mill and the desirability of expansion of the system to other sites, such as Marlboro and Parker Street, we need to have a flexible (virtually portable) system, as Ken suggested, that can be installed in existing rooms with a minimum of difficulty. Given the equipment, a conferencing set up should be able to be installed in a room with a given set of appropriate parameters within a half day. To achieve this goal, I have the following recommendations:

1. The industrial design group with Bob Lotz should work to set the parameters for rooms that could be used for teleconferencing.
2. Lake Systems should be asked to put minimal "control room" facilities into a "box" that could exist in any room used for conferencing -- it can all hang out. The control room (box) would hold the viewgraph projecting area.
3. Neck mikes should be available to everyone in the conferencing situation. No desk mikes or anything that would get into peoples way and formalize the situation.
4. The first room, perhaps the big conference room across from my office, needs to be set up and used totally in an experimental fashion. (Dick Schneider is already thinking about this area in terms

of experiments as the office of the future...which we might call OOF.)

5. There would be cameras for audience (3), overall, overhead/top lighted viewing area, and presentation area (where a screen would also be pulled down and be used for slides). This might be both blackboard, whiteboard, and flip-chart area.

SUBJECT: VISICALC ON VAX FOR INTERNAL (THEN EXTERNAL) USE.

I think we ought to get this product out as quick as possible, together with the necessary software that allows plotting on gigi and or the vt125.

We have a pile of these internally and we ought to take one that would get us the most points.

This would get after the personal computer folks by having lots of features that they couldn't compete with.

The version in ZK is really great: lots of extras plus really good math.

Let's meet with Andy on this, as it would seem to be most useful in the technical marketplace. However, Julius's troups are buying lots of Apples just for Visicalc.

We might start by taking the current VAX version and simply putting it on all systems together with the necessary plotting stuff using the vt125 and gigi... compatible with the Visiplot (plot package for Visicalc).

Why not get an approved version that could be run on our internal VAX's and see how people like it and what we can do to make it better and better?

Let's do this now!

Institute of Research - Acoustics and Music is a Paris based group, headed by Pierre Boulez. The Scientific Director is Max Mathews, also head of Speech and Acoustics research at Bell Labs, Murray Hill. They have a 10 generating music waveforms and doing analysis (in x100 real time), several 11's with GT's and disks for human interfacing.

They're visiting us on Monday and Tuesday, Nov. 1 and 2 to discuss the use of 11/34's as controllers for real time music synthesizers.

Bob Morris, will you take on the hosting, please? I would hope Bill McBride (or someone from LDP) could also co-host this, and at least attend as their supplier. I'd like as many of you to interact with them as want to. It should be worthwhile since their bus and signal processing requirements are so interesting, demanding, yet basic. They're going to do the design, but we can interact with them and get the benefit of their Advanced Development.

Please co-ordinate with Bob.

C. GORDON BELL

Gordon Bell is Vice President of Engineering for Digital Equipment Corporation. The native of Kirksville, Missouri, earned his B.S. and M.S. degrees in Electrical Engineering at the Massachusetts Institute of Technology.

On leave as Professor of Electrical Engineering and Computer Science at Carnegie-Mellon University, Pittsburgh, he was previously Manager of Computer Design for Digital from 1960-1966. During that time he was responsible for DEC's PDP-4, -5, and -6 computers. He consulted for Digital in 1966-1972 while at CMU working on various computers and products including the PDP-11.

He has worked in the computer field on computer architecture, modularity of design, multi-processors, and applications. Publications include "Computer Structures" (McGraw Hill), co-authored with Allen Newell; "Designing Computers and Digital Systems, Using PDP-16 Register Transfer Modules" (Digital Press), with John Grason and Allen Newell; just published, "Computer Engineering: A DEC View of Hardware Systems Design" (Digital Press); and several papers.

In addition to his industrial interests, Bell has served the U.S. Government as a member of three COSINE committees of the National Academy of Sciences for computer engineering education, and the National Science Foundation, Office of Computing Activities. He was a department editor for the CACM, a Fellow of the Institute of Electrical and Electronics Engineers, and a member of the National Academy of Engineering.

LOC/MAIL STOP: ML12-1/A51

SUBJECT: VK100 FIX OR VMS (WITHOUT VK100). WHEN A TERMINALS ARCHITECT?

WE need two things:
.a terminals architect who irons out these specs a priori

.fix the VK100.

I claim that the VK was not designed, it was specified after we built something. The 2K sure doesn't bother me, nor do I think it would bother our customers who might, mind you

just
want to use it as a VT100 ... remember lots of our customers including the ECS ones do actually buy 100's and like them.

If a product goes on a VMS system, that is not up to a product
line! Whether we support a VK, is up to VMS. I'm sure there are lots of comprimises that could have been reached to get the product to be suitable, but with no extra cost. (Here, a subset might be a suitable one. The VMS issue is not
the 132 columns, but the control codes.)

Therefore, we have two immediate possiblities:
1. Make it clear that the VK is not supported on VMS! (any customer might really expect to use it since ECS is selling it. I'll be damned if I see us changing VMS and all the utilites
for another random subset that someone just havppened to feel like building one random day.)
2. Fix VK so it will work with the escape sequences, but not in 132 col. mode. This is undoubtedly possible, since 132 cols is usually at the discretion of user and not the system.

Bill,
Please get Don and Charlie Rose to get this fixed right now before we start getting the stupid hate letters from our customers telling us how dumb and unco-ordinated we are.

ps
I wouldn't feel so bad, if I hadn't seen the abysmal attitude we have to the incredible costs created in software by taking this compete laissez faire attitude toward standards by the terminals engineers. It also blows my mind that the VT125 and VK100 are such distint cousins to one another.

We have to start designing to standards, versus providing whatever we feel like!

SUBJ: VK100 Incompatibilities with VMS

With respect to the VK100 incompatibility problem with VMS editors and VAX11-FMS, the product design of VK100 does meet its spec. The "hole" in the process is that it was never intended nor specified to be a full VT100 emulation or replacement. It was specified to have a text mode (ANSI), a graphics mode (REGIS), and a BASIC mode.

VK100 was designed, in conjunction with its associated software, to address a particular need in the ECS market, with potential applications elsewhere. Due to the existence of its graphics capability, the cost and performance implications of full VT100 compatibility, and the lack of a requirement for such a compatibility, it lacks certain VT100 functions. For example, implementation of split-screen would have required at least 2K more RAM and 132 column would have meant even more RAM plus really high-performance monitors. Since the ECS market did not need these, they are not incorporated.

It is entirely appropriate for VMS to not support VK100 as a generally supported device when using VMS editors and VAX11-FMS. If we now wish to change the VK100 requirements to include full VT100 emulation and support as a general-purpose terminal, in the sense of full software support on all systems, we need to put a new development activity in place.

It would seem that the crux of the problem is our need to address specific market opportunities with focussed products and the subsequent expectation that they can be extended to the general market space. Do we need to establish a policy such as described in the attached memo? (This is the first distribution of

the
attached memo.) At least it would raise the visibility level of
non-compatible developments. Comments?

digital INTEROFFICE MEMORANDUM

TO: Gordon Bell DATE: 22 APRIL 81
FROM: Don Haney
CC: Bill Picott DEPT: Video Engineering
EXT: 223-9243
LOC/MAIL STOP: ML1-2/H26

SUBJ: COMPATIBILITY OF NEW PRODUCTS

As one of the outcomes of the April 10 Video Architecture review, I believe a statement was made as to the compatibility of new products versus their predecessors or relatives. Specifically:

"Any new Video Terminal Product which is a descendant, or a relative, of an existing Product must include, as a minimum, all of the standard functionality of that existing product. All user and system interfaces must be uniform between the products."

As the result of the above statement, any product which purports to have VT100 functionality must include (but not be limited to):

24 lines
80/132 columns
Scroll
Split Screen
All VT100 Escape Sequences
Character Asynchronous Interface
7 LED's
82 Keys (or equivalent) labelled per VT100 and resulting in the same ASCII characters/strings BELL function Host Set-up (plus probably more I can't think of right now)

In general, all Video Terminal Products in a particular space shall be considered to be descendants or relatives of the then-current family until a new generation is released. Thus, all video products (VT101 family, GIGI, VT125, CT100, etc.) are considered a part of the VT100 family. In like manner, all graphics products (CT Graphics, GIGI-16, etc.) are part of the VT125 family. VT200 is a new family, but may have VT100 emulation.

The reason for this rule is to insure that Corporate and applications software and systems which are designed making use of various standard functions of a product generation can indeed be utilized by the descendants and relatives.

On the downside, adherance to this rule may seem to make it impossible to develop a "simpler" product than a general family might be. The appeal path to this dilemma is a secondary statement that:

"All deviations to this rule shall be made visible at the Phase O Review such that any new software, documentation, and systems requirements implied by the deviation may be planned during Phase 1."

On the subject of options --- since it is likely not smart to make the support software for a product family depend on the existence of particular options in the hardware configuration, I doubt if it is required that all descendants or relatives include (as standard or as options) all options of the base Product. However, "Standard or optional functions which might be considered as descendants or relatives of a base Video Terminal Product option must include, as a minimum, all of the standard functionality of that existing option."

Does this capture the essence of what we need to state? Comments?

VLSI DESIGN
CMP Publications
1054 Saratoga-Sunnyvale Road
San Jose, California 95129

Dear Jerry Weiner:

I enjoyed the dinner and interview with you, Roderic and Lorri. I'm sending you Mary Jane's book on word processing for the office, Computer Engineering which several of us wrote to describe Digital's computers, and a brief (auto)biography that was done for a Digital Equipment publication just before I left.

Also enclosed are several copies of the Museum Report and I'd like to urge you to write an article on it sometime.

If you send me your topical outline of the next years' VLSI Design, I'll comment on it.

Again, thanks for the hospitality.

Sincerely yours,

Gordon Bell
Chief Technical Officer

Date: 20 JUNE 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

follow up 7/5/78

I'd like to question this project and recommend that we take the same effort (modified to have adequate CAD support) and carry out a project that is oriented to a product and a significant standard, high volume design process.

1. The project would not explore CMOS, HMOS, SOS...use HMOS just as we've decided on! (Decide July 1 -- no travel)

2. Decide on either standard cell or gate arrays as the methods of design. NO CUSTOM DESIGNS! (due Sept. 1)

3. Code the gate array or standard cell library. (Nov. 1)

4. Decide on a test chip. (Nov. 1)

5. Design a product using the

technique (e.g., Pusart, Squid, some comm or CRT option)!
(April 1)

Can we discuss this soon?

SUBJECT: IDEA FOR KEEPING VLSI PEOPLE THROUGHOUT THE SCORPIO PROJECT

Dick Sites asked is there an way we might use stock to lock in these
circuit people who are always being bombarded and don't have

any real
commitment to stay on a project to completion.   Maybe a short term
5 year plan would help, or alternatively a stock plan that starts
when the project is finished. Our normal stock plan doesn't
deal with the reality of the people. On the other hand, I
really hate to think of going this way... as it opens up all
sorts of pandoras boxes throughout engineering. Any ideas?

SUBJECT: VLSI: WE'VE GOT IT. WHAT TO DO WITH IT? (MICROSTRATTON)

GB5.25

Background
Jack came back from a visit to Hudson, excited because we have so much
design talent just finishing projects, and who are trained to do
projects in significantly less time than ever due to learning. On the

other hand, the problem now is what are we going to do next with these
very talented resources?

He suggested that we have a several day brainstorming session.

Sam,
Could you act as the host catalyst to set up a micro stratton type
meeting between the designers of VLSI and the potential users of it?

We ought to shoot for meeting in late June or early July at some out
of the way place, and bring 20-50 people together to learn about the
potential (i.e. some technology update) and look at the opportunities.
I'd also like to see us form some general policies on things we aren't
going to do. For example, why do any commodity, buyable controllers
for floppies, winis, communications (eg. pusart or octart)? We should
carefully evaluate whether we should bother with proprietary, vanity
controllers like Dragon, when the industry will beat us to the market.

It's clear we have opportunities for some exciting products:

1. PPA support VLSI to get higher performance and more processors
2. CMOS TITAN
3. A really low cost, integrated system (Commodore prices and
   functionality)
4. MDC's proposing a new, industrial bus, and this could (or
   should) require VLSI. Certainly the modules could use it.
5. The new world that will be possible with Digital PABX's in

terms of: voice, video (compression), terminals, store and
forwarding of voice/image, control (maybe the best way to wire
a manufacturing plant... certainly the bandwidth is there)

Probably the best way is to solicit a list of attendees from each of
the EMC members, and then ask the attendees to prepare some position
papers. What you say about the idea? attendees? VLSI products?

Pete vanRoekens, TW/B10

Let me reiterate Friday's discussion with your groups:

VMS

It is a great product! Keep up the tradition on follow-ons. Our customers love and respect it, probably more than for any other first product.

Unfortunately, the product and subsequent hardware conjures up all kinds of embellishments desirable in follow-on releases. Don't let this pressure be demoralizing to us.

VMS and VAX are so good that we are entering a product development strategy based solely on them.

STRATEGY

Provide a set of homogeneous distributed computing system products (based on VAX/VMS) so a user can interface, store information and compute, without re-programming or extra work in many styles and sizes, as follows:

as a single, user personal computer with a terminal;
at a small, local shared computer for a group; and
via a large center computer within the network.

This implies emphasis on compatibility with VAX and bringing existing systems into the VAX framework. We will build 11 systems where VAX is not the lowest cost. We will also build 8's, 10's and 20's to protect user software investment and as point product market needs are apparent (eg. a lower than PDP-11 cost personal computer based on PDP-8 for the computer store).

Hydra will be the basis for much of this distributed computing environment.

HYDRA

Although Hydra is primarily targeted at high availability, it is also the structure for providing incrementally expandable capacity at a single site. Furthermore, as many of our customers have multiple VAX systems already, with more to come, it is the structure to provide for an apparently common system, including highly available filing.

VMS must be extended to provide the HYDRA capability.

MOVING AHEAD

The VMS extensions for the HYDRA capability must be done by the VMS group. Therefore, it is essential to figure out how this group can be expanded rapidly without losing control of product quality and the VMS architecture. The latest HYDRA specification represents a good first definition at the capability I believe the larger, central site distributed computing environments must provide. It is essential to begin the planning of these extensions and get agreement on the extensions. I see agreement on the structure and major parts of Hydra (e.g., the files system). Parts of HYDRA are contentious, as to their complexity, implementability, and need. The VMS and Hydra groups must resolve the differences by: discussion, by existence proofs (breadboarding and looking at non-DEC systems), benchmarking/demonstrating the need and by comprimise.

It is essential to get on with the HYDRA extensions now!

Loc: ML12-1/A51 Ext: 223-2236

follow up 12/3/78

When Dave did M, he had stamps made with "Size Is The Goal". As a result, a small, fast O/S was built which hopefully has not been too eroded under customer pressure to do everything.

With VMS there weren't stamps, but there is now an impressive system that runs in 256 Kbytes that will support a few users.

0. We must hold kernel size <u>and</u> program/programmer interface so as to avoid need for non-compatible systems such as RSTS, RT-32, IAS, MUMPS, etc. The model has to be TOPS 10, where we built many engines to run the operating systems and user programs. Here, we must hold size erosion that TOPS 10 went through.

1. Nebula-RL02 must be

small and run with 2 RL02's (2 x 10 Mbytes) as a single (or 2-4) user system. This is the personal computer for the engineering users and CS researchers! (Here, note we need a great, graphics terminal.)

2. We must figure out a way to hold, and preferably decrease the O/S system size so as to head toward an LSI/VAX terminal version in January 1982.

Any problems?

Can we guard this?

SUBJECT: DISTRIBUTING VMS DEVELOPMENT   FOLLOW UP: 11/16/79

GB0005/42/EMS

It seems clear to me we should have a strategy for the above. Clearly we want one main line VMS architecture and implementation group. With the demands we have on: fixes, supporting three machines; supporting other ames; all new devices, smaller capabilities ala diskless, better real time, multiprocessor via multiport, better commercial/DB, and reliability (Hydra). It seems clear that we can distribute all the functions where the architecture is clear and where there is an implementation instance. This lets us possibly distribute: VMS machine support to the hardware groups; device support to Mass Storage group and maintenance to SWS.

Can this be our policy? When can we start?

SUBJECT: WHAT ABOUT A VOICE PLAYBACK/TRANSMITTER UNIT?

Having come back from a long trip and wanting to just call a bunch of people and leave some messages via voice, it occurred to me there's a possible, neat, useful product. I could have done the job if everyone had answer back units. Instead, I propose we convert the PC with TMS into a transmission/playback unit which would call people with various messages, and leave them under the receiver's control. That is, the user would record his own messages to transmit, and then specify the phone numbers and control flow (what to do if no one answers or if someone else answers). The PC would then make the calls and handle any answers back. In effect, its a voice mail system, but restricted to only point to point. A user could also leave it on, dial in leave a message and have the message sent to someone else.

Why don't we try this as a breadboard on the PC/TMS?
(I would have used it this weekend... so the market might have been finite.)

I've not approved a replacement requisition for Ed Vrablik, who has been a corporate technology tracker within R and D. It seems to me that this function rightfully belongs within each group. Having Ed and Rowland Brandwein do this function is nice and necessary however, because when a group becomes lethargic, or overcommitted, or going down a wrong path, it is unwilling to take direction in the face of massive changes in technology and/or market.

Can Rowland play a more corporate role in this regard and make visible ideas for new technology?

Congratulations!

Please go ahead with the project to put 4 on a 34. I'll fund it here as part of the Venus project. We would like to be a test site asap. Dave Copeland will get with you for a configuration.

We do need the extra terminals here like crazy. How does it work having just 1/2 the resolution of the gt? Can a designer
get the same amount of information up? What's the chance of using the same 34 to host multi vt125's for low cost, remote access... or would this be better to do directly into the 20. Why sweat the down line load? (Go ahead and put the floppy on it to boot it).

As an aside, am really impressed with the graphics on the ct since it is 240 lines by 1024 (and if they dropped non-interlace
could get 512 x 1024 which would be pretty close to the gt. Furthermore, this package has its own 5Mbytes for useful work too.

SUBJECT: DISCUSSION RE VS100 AND PERSONAL NEBULA

During two seperate discussions with Bill and George, I think we've arrived at a solution which makes everybody happy and wins.

The VS100 and the Unibus interface to it would be laid out with a scheme that lets the fiber optic link be replaced with a null,
wire link adapter. The fiber optic link adapter would be held up
until we have the connector problem solved. But, we can still enter DMT with the wire adapter in place of the fiber optic link
adapter.

The Nebula would use the modules intact, but using the null adapter in place of the fiber optic adapter. In this way we don't have to spend mucho $'s in engineering, manufacturing and in the field for an extra set of spares, nor do we have to suffer the additional delay that historic with Nebula (we waited 2 years for Combo and the Integrated Disk adapter).

Thus, the integrated Nebula is now just a non-trivial packaging job to deal with heat and noise. Personally, I think this will
be somewhat limiting because no one wants an extra 500-750 watts
near them.

Also, this package is very neat for the professional where one system is integrated in the desk and there's a second slaveone connected via fiber optics. Mary Jane and I were really looking forward to putting the computer away from us (where neither of us have room for another desk) and getting just the vs100 on or near our current desks.

We must learn from the long history of the WS100 (the original PDP-8 about 10 years ago): All of us already have full offices and desks that we really like. The dolly and pedestal mounted 78 and 278 were better, but people really love personal computers of today because they are small and can be moved around a lot and don't intrude. We don't want to give up our desks or change things very much for another tube... especially if it radiates any noise or any heat (like 3 bodies... some of us don't have the airconditioning to handle the problem even). We want to change the furniture and office around a lot and big boxes are big constraints.

I'm really excited about the integrated nebula (above) and think others will be too... provided it doesn't take electrical

resources and is just packaging. I think others will like it too, provided they are naive and are attached to the idea that the computer must be with them. Ironically, the people who want this computer in their desk are those who'll probably not be happy with having a file server somewhere that belongs to someone else.

Hopefully, we'll sell lots... but Mary Jane and I will stick with our Nebula /VS100's as is with the computer in a closet and our own, protected files.

Let's get the work done so we can get Nautilus and the big multiprocessor and Scorpio and the BI and the fiber optic adapter (for the rest of us... and those who want to use a 750 as our cpu) done! Most of all, we can really get big bucks by making the VS100 available as a high quality terminal.

SUBJECT: VS100 AS THE FIRST VT200 (COULD IT BE VS200?)

It really feels clear to me that we should use the VS200, with
a serial port and suitable firmware as the first member of the
VT200 family.

If we push, I think we could sell 50,000/year at $7.5K.

Could we do some test marketing to get user reaction as a function of price? Personally this is the tube I've been waiting
for: landscape, high performance, 1 1/2 pages, and graphics. This product could be as big as VT100 if we market it! How can
we try?

SUBJECT: GETTING THE COLOR VS200 DONE QUICKLY

With the encouragement of the market, it looks like VS100 is a real winner. Unfortunately, this really pushs us to have the color products. I think we ought to mount a big push to get the next color product asap. It is also that Appollo is now moving aggressively with their new color workstation that concerns me... this means we let a small company become a major competitor (the rumour is that their business plan is for 100M in 1-2 years)!

Why can't we prioritize the possibilities and get into a mode where we drive to get the low cost color workstation in a very rapid fashion?

SUBJECT: WINNING WITH THE VT100 FAMILY

With the Plessey PT100 announcement, we ought to get worried about how we're going to win against it. The answer is still clear to me: Put our major effort into really great enhancements - not cost reduction like the VT101 and VT131 where we go for piece! Let's leave these incremental improvements till the VT200 and a radical package.

We desperately need to come out with the enhancements that are implicit in the package space and extra power. These field upgradeable options are:

1. VT103 or PDT100 (why both??) - PDP-11 in the VT100.

2. VT125/Graphics.

3. VTXXX enhancements to do simple editing on DEC system.

4. System WPS278 (An 8 on a board to connect to a floppy).

5. Modems, hard copy, etc. and base for TPG Specials.

Our original plan - The VT100 would then be the VT100 Kernel Terminal or VT100 Terminal System...not just a terminal terminal. The ads are endless: Is your terminal terminal? The VT100 terminal is the base for terminals and small systems, not a terminal terminal. Etc.

SUBJ: VT102 = CT05 REPLACEMENT PACKAGE

We must stay with the modular strategy we embarked on with CT because:

1. We want to design a set of modular components which the USER can mix and match to build dumb video terminals through computing terminals.

2. We're resource limited; modularity gives more products for less cost.

3. The modular approach lets us build several different monitors and let the customer buy according to needs of cost size, and package mounting (eg, desk, modular office, stand, wall, projection - TV).

4. We can build a really high quality set of monitors to add to the plethora of really yeechy-looking/engineered. Monitors should be a great market!

5. With the modular approach, there's much less desk clutter because there's only a cable to the monitor and to the keyboard. It gets rid of the cable to the line and to the printer.

6. Can we really get a 25-40W wall mounted PS that isn't just a separate box? (Why bother?)

7. We can offer a really low cost VT by offering it monitorless.

Note the attached sketch and table of alternatives.

We have at least four alternatives for repackaging the VT102:

Strategy	Integrated Smaller VT102 box (incl. modem)	Integrated Small VT102 box (excl. modem)	Point Product CRT Small monitor, separate box (for PS on wall)	Modular Smallest monitor Separate box (for PS, logic, modem)
# Boxes	2	2, (3)**	3, (4)	3
# Boxes w/printer	3	3, (4)	4, (5)	4
# Cables	3	3, (5)	3, (5)[4, (6)]***	4
# Cables w/printer	5	5, (7)	5, (7)[6, (8)***	6
Cost*	2	1, (5)	4, (5)	3
Size*	2	1, (5)	4, (5)	3
Size* on desk	3	4	2	1
Probs.	cabling on high, size, cooling if small	cabling on desk, size	cost cooling, P/S, cabling when modems and printers used. Power control, if printer and modem. especially with printer and modem.	cost

* 1 = best
** with modem
*** if P/S requires and AC cable

SUBJECT: A STRONG VT125 GRAPHICS PRODUCT VERSUS CUTTING MANUFACTURING

Let's come on real hard with graphics by Jan. 1, 1982, instead of
cutting back 40M in our terminals manufacturing, and losing a great opportunity (and lots of manufacturing expertise we need).
Could you get together a task force of 3 persons representing the
marketing groups, one person from manufacturing, and two persons
from software engineering to see about the feasibility of making
a signficant announcement around the following hardware trio:

. VT125
. LA34/G for graphics output
. DF03, 1200 baud modem

In addition, we should press hard to get a color monitor of our
own into production so that we can take full advantage of all the
things the 125 can do vis a vis slave monitors. Also, this is
essential for the CT family and GIGI.

The software task would be to make sure we have a coherent set of

useful software, including getting a Visicalc that could convert
from tables to graphs, and at the same time, we could partially
stem the tide of Personal Computers bought because of VISICALC!
The Technical group has some of this software and there is a very
impressive program that allows a user to plot data extracted from
DATATRIEVE. Also, we must make sure languages basically support
the 125.

A moderate amount of teamwork here would get us a great deal of
revenue. Let's see what the potential is.

SUBJECT: BRIAN'S COMMENTS ON VT134

There are some clearly neat features here. We'll have to integrate them into CT.

Given that we have produced a string of about 30 losing (financially speaking) products in
this space, there is no way we are going to be building every product
that we can think of. We have two choices: ct or vt134. I want to
decide this damn quick and get us all headed in one direction.

I am tired of producing uncompetitive
products in this whole area. The company can't afford it much longer!

In general, my predjudice is to get the 134 integrated into the ct.

SUBJECT: VT134

LAST WEEK, BARRY FOLSOM (TPG ENGR MGR) CAME TO MK AND GAVE A VERY IMPRESSIVE DEMO OF THE VT134. THAT WAS THE FIRST TIME I EVER SAW A COMPUTER OPERATE THE WAY REAL PEOPLE WORK. THE VERSATILITY AND

RESPONSIVENESS OF THE VT134 MADE ME BELIEVE THAT IT IS REALLY POSSIBLE TO DEVELOP AN ELECTRONIC EQUIVA- LENT OF PENCIL AND PAPER.

THE KEY TO THE VT134'S SUCCESS IS THE THOROUGH INTEGRATION OF THE HARDWARE AND SOFTWARE ARCHITECTURES. THE SYSTEM PERFORMS MANY TASKS SIMULTANEOUSLY AND ALLOWS THE USER TO SWITCH INSTANTANEOUSLY AMONG THE TASKS WITHOUT BEING BOTHERED BY HOW THE MACHINE WORKS INTERNALLY. THE VT134 SETS THE STANDARD FOR THE HUMAN INTERFACE TO A PERSONAL COMPUTER SYSTEM.

WE SHOULD SUPPORT THE VT134 AND PLAN TO USE IT IN THE OFFICE AND CCEG
PROGRAMS. I BELIEVE IT SHOULD BE POSITIONED AS THE HIGH PERFORMANCE (AT A HIGHER COST) MEMBER OF THE PERSONAL COMPUTER FAMILY WITH ENOUGH ROOM LEFT BELOW IT FOR THE CT PRODUCTS. IF WE ARE GOING TO GET SERIOUS ABOUT THE OF-FICE MARKETPLACE, WE ARE GOING TO NEED A FULL SPECTRUM OF PRODUCTS JUST LIKE WE HAVE ALWAYS HAD IN OUR MINICOMPUTER PRODUCT LINES.

REGARDS,

SUBJ: VT162: A POSSIBLE MODULE FOR GATEWAYS AND FOR INTERFACING TO UNIT RECORD DEVICES AS PART OF THE INTERCONNECT STRATEGY

Date: 2/28/79 Wed
From: Gordon Bell
TO: Distribution
Dept: Office of Development
MS: ML12-1/A51 Ext: 223-2236

Follow up: 3/16/79

Is there a chance that the VT162 module could be used as a gateway? Given that it has 50KB capability and lots of protocol capability, it might be really good. Eg. what kind of board would be used to attach it to a UNIBUS for outboard preprocessing?

Also, it would be the module we could use to interconnect our multidrop bus to various unit record equipment. Here, things like line printers could be page, rather than line buffered. Note, this interconnect structure is a cornerstone of the strategy and while little visible progress is evident, it is essential and inevitable.

I am not suggesting that the VT162 be changed at all! I believe the possible users of it should look at how it can be used in this application. (It's attributes are pretty neat: a FONZ, RAM, ROM, lots of COMM port capability with protocol software.)

MESSAGE ID: 5172024905

SUBJECT: VT192

I didn't participate in the final stages of the proposal closing last
week...but I think they wanted to hold schedule and give up the modem
at FCS.

This makes me feel bad, but at least it is back from the position that
the terminals engineers took several weeks ago that we had no
modem...which caused me heart-burn and some sleeplessness. I'd like
to understand how the decision to drop it got made because I think
this may be at the root of a basic engineering marketing interface and
responsibility problem. (let's look at it to learn and not to
crucify). The point on the built-in modem is that we (Ken, Jack and
I) as ENGINEERS decided on the specs. There is no rational data that
can be presented that will disuade us (at least me) because we believe
that the world wants a clean design and we all want to sell a system.
Furthermore, we all want a unique, quality product, not a commodity me
too. We intend to change the hassled way the world buys and uses
terminals. We (3 of us) are assuming the risk, we would all listen to
reason, but we (I) believe that there can be no data because there are
no products like this on the market today, hence market data input is
irrelevant. This is identical to the non-negotiable position I took
on having great modems on the LA12...and the world's buying it.

As a separate issue, we're building modems into Rainbow and the

VT201.
Also, I hope DECmate II will get one. Rather than having 3 unique
boards, I say we can't blow our resources with 3 separate designs -
use one (think of the enginering, manufacturing and service costs)!
We really have to have an options architecture..

MESSAGE ID:
5169182952

SUBJECT: FINALIZING THE VT192 SPEC BEFORE WE SLIP THE
SCHEDULE

The engineering group under H. T. Cho is doing a great job. Characters are on the screen, the basic microcode is up and it looks as if they'll meet their aggressive schedule. The cost of 380, sans OCLI looks good.

We in Maynard are about to slow things down through lack of spec and worse yet, linking the spec to the VT200 series that ships 6 months after the 192. Given the sketchy spec and the fact that the setup has not yet been implemented, the project clearly will not be able to make the schedule or it is certain
to have to change when the spec is finalized when it has been implemented. Overall, this is crazy.

HT is going to be in town this week to finalize these 2 parts:
1. Ken's idea, which looks good, to have a 15" tube. HT will come with a cost and schedule impact. Maynard was to have breadboarded this so we can make a clear decision. Note, it

may not look good because the characters may be too thin.
2. The setup mode. Unless there's an iron clad spec that has been implemented, I say let's revert to the vt 100 spec but with some enhancement that writes the setup instructions on the screen so that the card isn't needed.

When HT leaves on Friday, it should be with firm spec. Jack Ken and I would like to meet to check on how he made out. Bob and Bill can you set this up?

We need the product. Let's all help get it.

SUBJECT: PUTTING THE MODEM OPTION BACK IN THE VT192

This is a mess. At our earliest spec meeting we all agreed to put this in as an option. Now I find that Bob has the job of telling Ken and I that it's not going to be done.

This is in direct violation of what we agreed and I can't find out why it was taken out. Certainly the Taiwan folks believe the extra room and 3 watts can allow it.

I continue to see many VT100 look alikes and I want us to have a unique and great product. By putting the modem in, we are able to sell a very low cost vt100/modem combination that NO ONE can match and we're crazy if we don't take advantage of it.

Bob and Bill will you please get this back in?   It will not impact the slip schedule if we design for it.

(The LA12 is doing great with its built in modems and this will be even better if we do it right.

This must also be part of the spec that's carried back Friday.

SUBJECT: WHY ISN'T OPAL THE VT200?

This message given out at today's meeting - for your files.

I'd like to get together and discuss our plans to get a high
quality
VT for our systems much more rapidly and in high volume.

Why can't the VT group take over the black and white CRT
being
announced at NCC and do the cost reduced follow-on for it and
the
color version?

Note, both of these could be operated with a conventional
serial link
if they had a UART.

We must produce these in high volume and attach them to
Nebula to get
the workstation price in line to compete with Appollo and 3
Rivers.
Here we ought to be at 20K or less/station.

The pipeline looks like this:

16 Ramtek -- --

8

4
Zebra Color --
2 Zebra \par
\par 1 VT125 -- -- Zebra'
\par .5 VT100's --
VT125' --
\par .25 -- -- VT100
& modem --

now 1/83 6/83 1/84

The cost reduction would be done in the factory (i.e. Taiwain) unless
there's significant chip work. Zebra' = VT200 and Zebra color =
Zebra x VT200.

Folks, I don't think we're going to make it the way we're headed.
Let's get our act down to 2 or 3 rings and then perform it!

GB3.S5.23
This message given out at today's meeting - for your files.

I'd like to get together and discuss our plans to get a high quality VT for our systems much more rapidly and in high volume.

Why can't the VT group take over the black and white CRT being announced at NCC and do the cost reduced follow-on for it and the color version?

Note, both of these could be operated with a conventional serial link if they had a UART.

We must produce these in high volume and attach them to Nebula to get the workstation price in line to compete with Appollo and 3 Rivers. Here we ought to be at 20K or less/station.

The pipeline looks like this:

16 Ramtek -- --

8

4

Zebra Color --

2 Zebra \par

\par 1

VT125 -- -- Zebra'

\par .5 VT100's

-- VT125' --

\par .25 --

-- VT100 & modem --

now 1/83 6/83 1/84

The cost reduction would be done in the factory (i.e. Taiwain) unless there's significant chip work. Zebra' = VT200 and Zebra color = Zebra x VT200.

Folks, I don't think we're going to make it the way we're headed. Let's get our act down to 2 or 3 rings and then perform it!

SUBJECT: KEN'S SUGGESTION ABOUT VT200

1. Construct the vt200 project under Bernie.
2. Bernie reports to Bill and is signed on for 3.5 weeks and we trust him ethically.
3. Set up a clear organization to get the work done very fast. In particular, there are 4 interfaces that could be troublesome that we have to deal with now:
   1. The spec on the controller and the crt.
   2. The Software support and needs.
   3. Getting the firmware team in place.
   4. Packaging (which we all agree we can defer on).

I suggest we make life simple, by admitting that the first release is only as a terminal, hence the user space issues don't become a majore problem. All we care about are the graphics and higher level editing primitives. This approach gets rid of items 1 and 2 for a long time.

SUBJECT: RE: SMALL SYSTEMS

Just had some thoughts that might get us out of cost hole in the vt200 dumb version.

It seems to me the big thing we want to invest in is our library
of modules cause each one (a complicated one like a VT200 controller
or a cpu) represents a module start-up, sparing of one to

multi
megabucks. Given that we want to go for lower cost, then why not make a monitor package that would support the card we discussed
on Wed. morning. For power, we would have two options: a version that goes in the monitor, or one that hangs on the wall (I have a vadec 25w ps that does this). Alternatively we put the module and ps in the keyboard for the dumb version.

This would say we get a really good module size/mtg structure that would permit easy mobility to some or all these places as a means to get cost or ssmall size.
(Have just loved the 278 except if it had the mini floppies inside or if it had them in a small carryable box. It is right
size for desk and I carried it to SR easily. No heavier than a vt100)

Could the power system mount in the same way... so as to avoid
the ad hoc power supply systems that will evolve and not let us do this? Given all this, should the modules be the same size as T/E and Floppies?

SUBJECT: SEPERATED YOU ARE GOING TO FAIL, TOGETHER THERE IS A CHANCE

It seems to me that the VT200 as it was going had a chance of being ok, provided that the Mass storage got integrated with it somehow. I never got an inkling of how this was planned from the requirements documents. Perhaps left alone, this would have happened. Somehow, we went too fast in terms of making a box, and it comprimised people's views as to what the 200 was to be.

As a user of a wps78 as both a dumb and intelligent terminal for at least 3 years, no way can I believe anyone should ever have a terminal that doesn't have mass storage. This may not occur as rapidly as I think, but it will be close. Even the fortune biggies are buying personal computers for this purpose.

Therefore, I will categorically state that within 3 years, the dumb terminal market will have peaked, and will be replaced by the personal computer as the terminal. We must get our act together now!

I expect that you folks will have an aggressive plan for building aggressively competitive programmable terminals with mass storage (also called personal computers) before our meeting on Wednesday, or tell me why my model is not valid and that we can and mus continue on the current course of building some sort of high quality dumb terminal and some boxed personal computer that appears to be making no progress.

Note that it has been 4 months since we agreed to this direction at Stratton and 2 months since the meeting with Ken. If you do not agree with this direction, I want it formally stated

by next monday at the llatest, so we can proceed with another plan and something that we all agree on in terms of terminals/
small system direction. (The current VT200 3 year plan is off by 1-1/2 years both in terms of gestation period and specs.)

1/A51

SUBJECT: VT201 AND VS100/VT200 SERIES: OPPORTUNITIES?

I don't think Cathy had looked at the issue of using Wim's design very carefully at all. Avram and Bob are now looking at this in detail. I asked YOU to look at this, not delegate it.
To my knowledge, Cathy has never designed or shipped a product,
so I wonder why you think she could make a very good analysis.

At least part of the issue of VT125 compatibility may turn out to be the old curse of the two planes (a VT100 and a graphics plane) which I ask you to fix. This is a kludge we do
not want to stop right now and not perpetuate. Certainly having
the same crew that gave us this kludgery do the cost reduction
makes all the numbers immediately suspect.

As you know, the terminals are really important. Bob's

only been here a short time, so I can't ask for much. In
order that we don't continue to fail, I hope you'll
spend time with him to get this area straightened out and
headed somewhere. We have far too many resources there,
given
the output... and it's clearly an area I want to see reduced.
It would seem that doing cost reductions on the VS100 offers
a really great alternative to the VT200, especially given
the incredible lead time for those chips.

Jack,
I don't believe that as peers, George and Bill/Bob, can
honestly
look at the issue of using the VS100 as a VT200 due to the
large
number of egos involved. I'd say let them start and then
let's
do an outside review of the thinking.

With the IBM, Wang and VS100 announcments and with the rumour
that Apple IV is full page, then there's going to be much
heat
on the terminals group to produce before '85. I don't see
why they need more than one year.

SUBJECT: VT278 BUSINESS PLAN

Could I see a copy of the VT78 Business plan with a comparison of how we've done against the plan? The 278 volume seems awfully high. What is coefficient that permits us to predict elasticity of this demand curve?

I certainly would like to see our system's plan and evolution based on the 378 and RLX78. Aren't you working on the wrong problem with the 378? When the cost is in the floppy, I thought, the projected cross-over of bubbles vs. floppy was in 84 or so? Are any P/L's driving to get us the large, PDP-8 system? Why not use the WS248 hardware we have right now, as it seems to be exactly what your proposing?

SUBJECT: MORE 278 SLIP AND A NUDGE/OPPORTUNITY TO MOVE MORE TO THE 11

We keep having chip slips. We have PDT's in inventory. We have ideas on how to even get the performance of the PDT 150 up and unbottlenecked. We are aggressively building a PDT 50.
We have a WPS strategy that is 11 based. Given all this:

Can we move much more rapidly to get the 11 wps such that we do not need to market the 278 at all, given that it will be available at some future time? (We can really clean up in the market, I would hope with this approach).

Bob, can we discuss this on Monday? What a few of your troops
say?

Congratuations on the 782
To: Dick Husvedt, Joe Carchidi, Brian Croxon, John Holz
CC: Operations Committee, BJ, Heff, Demmer, berube, lane

Although the announcement made the front page of several newspapers, I don't think it does justice to the significance of the 782. This is how we'll build all future machines most likely.

You are all to be congratulated on creating a really fine product, especially since VAX users need more performance. It really hits the mark.

Please convey my heartiest regards to the Hardware and VMS teams.

I'll be happy to sponsor or participate in any appropriate celebration of this important new branch on the VAX family tree.

Gordon

SUBJECT: OVERFUNDING VT'S

The VT192 really makes me sick. The only thing it offers to the user appears to be less desk space and somewhat less cost. I think it follows the trend of a long series of marginal products that have succeeded the VT100. I hope you'll plot the overall cost pattern of the VT's since the VT100. My conjecture is that none of them were really required in terms of getting lower cost.

Moving the manufacturing to Taiwan was the only real cost savings. There's been no use of modern technology (eg. gate arrays) or no feature benefits. If TPG'd had no VAX, it would have been out of business. As a separate issue, I'd guess the VT201 is also a marginal improvement over the VT125 in terms of cost. Is it?

It's disturbing also to find that we were once going to build common options for VT's and PC's. Did we ever make a plan for options? Each modem is unique (i.e. CT, Rainbow) and still we don't build modems into terminals or Decmate like I thought we agreed to.

Basically I believe we're funding VT's too heavily as evidenced by lots of poor products.

SUBJECT: WANG: LOCAL AREA NETS, THEIR DIVISION, ETC.

GB4.S1.7

Jerry McDowell of Wang gave a sickening, hi-hype talk at a
LAN
conference in Sydney in which he described Wangnet, based on
well-proven CATV as the answer to combined voice, data and
video. He
said nothing about voice, but on questioning, this meant some
sort of
connection of Wang equipment with PABX plus the use of
headsets with
some data/voice channels for operator communication. He
urges us to
use two-cable for the Ethernet modems. Their promised 12
Mb/s CSMA/CD
is now 10 Mhg (Ethernet compatible?). My opinion still
stands: CATV
using frequency agile modems is a poor alternative to
Ethernet for

their several uses - terminals/workstations to their mainframes, at
9.6Kb-64Kb, as an Ethernet, etc. They have nothing in TV-based
products.

It's probably more significant that they have bought satellite
capacity and have established a completely separate company that uses
Wang engineering. The goal is to supply services and do wiring.

Our Sydney office is afraid of them, but yet doesn't know how our
products compare and compete with them, nor is there enough help
coming from the product lines regarding positioning. We need
aggressive benchmarking against them.

Bottom line:

They sell futures (typical date - end of 1984). They market
aggressively. They are getting organized to be even leaner and meaner
in network talk. We're one big fat, happy family with great products
and negligible ability to compete with them at the network level.

SUBJECT: NOMINATING AN WANG FOR NAE

Jerrier Haddad (IBM) just called me on the above. He feels that from an external view Wang certainly seems deserving. It is IBM's unwritten policy I suspect to have a bunch of computer people outside on NAE just to keep the IBM visibility
down... in other words we are like their eeo program.

Someone is needed to either write the recommendation or to be a second nominator (2 or 3 are required). I've never met Wang, nor know of his work specifically.
Do you?
Would you be the main nominator if I got the data?
Would you be a second nominator, given that someone put the form together?
Do you think he ought to be in the NAE?
Who would be a good nominator who knows him (Forresor)?

Whether we do anything with the LASL machine is up to you guys!

LASL probably would love us to build and market it, but I doubt
if we could ever do it without ruining it (eg. making it non-

portable) or in a timely fashion.

I wanted out of this loop. My vote would be to sell T chips to anyone who wants them so that the computer could be built and marketed. It probably wouldn't compete with us and might even test whether a vanilla, RT11 can be sold. Later, we could follow, in our usual way!

September 13, 1982

Nicholas Negroponte
Jean-Jacques Servan-Schreiber
Centre Mondial
World Computer Center
22. Avenue Matignon
75005 Paris
FRANCE

Dear Nicholas and Jean-Jacques:

I thoroughly enjoyed the visit to Centre Mondial with you, Seymour and the rest of your colleagues. The enthusiasm, competence and direction were exciting and certainly contagious. Your aims and ideals are commendable.

Several of us have discussed ways we might be more tightly coupled and be part of your center. In addition to areas we'd like to monitor and use (eg. speech i/o, French command interfaces), I believe there are two <u>immediate</u> areas we might do jointly:

1. Support of personal computers by various small, centralized facilities-

   -such as te VAX 730. I believe that every 100 to 10,000 personal computers will require databases, specialized processing, software development, switching to each other and to other centers. I'd like to see us become actively involved in discovering these functions, importing them from other sites, developing them with you and then ultimately testing the system.

2. Proving the various complete Office Systems we're introducing on VAX to you on a test site basis so that we can work on human interfaces and explore the functional tradeoffs necessary when operating across various systems of centralized and personal computers. This is also related to the first point.

Also, other development opportunities will arise if we have people at the Centre.

Again, thanks for the interaction and good luck with the project.

Sincerely yours,

Gordon Bell

MESSAGE ID:
5175576623

SUBJECT: WORLD COMPUTER CENTER, AND WPS

I am very enthusiastic about the WCC and spoke with both Wade and
Davies about having engineers there to interface and explore opportunities arising from the presence:

1. Telecommunications around low cost terminals and low cost personal computers. Clearly we have to get into this somehow. As a minimum we need to "support" these via VAX's. For every n (say 1000) home micros, I believe there has to be at least one 730-780 class machine with database, program development, etc. supporting them and switching them.

I BELIEVE WE (France, Claude, Engineering) must take on this reponsibility to get such a product breadboard and it could very well emanate from WCC--clearly we all have to sell WCC on this structure and we have to be there and work with them to develop and understand it. Both Servan-Schreiber and Negroponte want us there, even though they probably don't yet see the need for this network of minis that I think will be necessary to support such an array of personal computers. I did write them explaining the need.

2. WCC should be a great test bed for the OFIS product interface work when we have something to release.

Again, I'd like to see WCC as the guinea pig for this using a VAX...together with the terminals. For now, I'd get them hooked on DECTEXT so we can get the learning. Since we have country folks doing the translation, let's put them at WCC and

GIVE WCC the whole thing: All-In-One, DECTEXT, EMS, etc. You
have the world's greatest showplace and potentially the
greatest DEC salespeople, and with a tiny bit of marketing,
you could have the greatest OA marketshare in France. (In
this regard, let me urge you to also market DECmate II as the
lowest cost WPS around and get the whole thing.)

We enjoyed having dinner with you, Christian and Georges last Sunday.
Our trip to Burgundy was great and we appreciated the information
about bicycles.

SUBJECT: THANKS FOR THE CAR AND HOSPITALITY

GB5.56

I thoroughly enjoyed the west coast visit and the time with you and
your co-workers. Susan's preparations and help all made it work too.
Each time I think about Titan, I get excited about the possibilities
of it becoming a multi-billion dollar product, but I'm concerned
whether we're moving as rapidly as possible. I'm encouraging Sam to
think about getting as much help there as you can manage because the
program is so urgent assuming it delivers the power you predict.

The interface with Stanford seems quite nice, and Ed wants me to be a
"consulting professor" that would visit and interact with their
research project from time to time.

I think it's going to be necessary to do this, assuming we're going to
try to get Stanford into the understanding of parallelism (via mP's).
I still believe the short run use (next 6 years) for PPA is going to
be in conventional and modified algorithm languages. We also want to

support Ed's effort on developing and understanding the use of parallelism for AI applications. I'm somewhat skeptical because I
didn't see an AI systems person. The immediate payoff will be to make
us a serious LISP machine supplier...I hope.

I'd like to find a way to help Bruce mend fences so he can get back
and be a useful member of the DEC community. He got quite excited at
the possibility of examining the Trilogy technology Titan. I'd be
quite happy to have a lor 2 module Titan at 3x Titan performance which
I think could easily be built for <$20K! (This would be damn near a
Cray for non-vector problems! Let me urge you to enlist him to come
look at this. The air heat exchanger is miniscule and would fit in a
19" x 19" no more than 20" of a 19" rack.) We're getting their designs for memory interfaces etc. so the work could be minimal.

Again, thanks -- and give my thanks to Gene for dinner and wines.

WPS USERS - Leave HP mode and type <CR>

Jack,

I think we need a major amount of help from you in regard to selling PRO and the CI Clusters. For starters, we really need an audit, by your committee about what's been going on. The goal is to make much more sales and PROFIT. My analysis follows.

CI CLUSTERS PROBLEM
A lack cluster announcement considering that we have a major product. I think the problem is that there's NO product manager for Clusters, and it simply gets done somewhere in the bowels of VAX base products marketing. Note clusters is:

. hardware options on the 750 and 780
.some cable and a connector (probably a Product Manager for it)
. VMS 3b.n, part of a release
. HSC which is clearly and seperately hyped

Note the absence of anyone who cares whether this works as a system, or that this collection can be sold as a significant system whose whole is greater than the sum of the parts. Rick Case's memo showed that we could promote it as the whole which is at least equal to the sum of its parts in terms of performance! Colorado recently just tried it all together. (There was no one there who took the system responsiblity.)

Fundamentally, we need your help to judge what so far is an non-existent act, and then help us get it together.

PRO PROBLEM (OPPORTUNITY)
PRO was late with its software, and it has been poorly advertised internally. Rumours abound. For example, it's incompatible with RSX and VMS, and there's a new PRO out soon on the Qbus. (This one hasn't been started yet.) All of these problems mean poor sales.

It's vital that we have a set of products that get customers onto DEC standards and files. PRO has great compatibility with Operating System interfaces and file systems with VMS and multi-user RSX. A great variety of programs from Fortran to third party software run compatibly across the PRO-RSX-VMS trio. No other system or vendor has the compatibility across PC's, team, group and mainframes like PRO does.   PRO will still ship about $100M this year, but is below plan and still needs more care and pulling.

Again, I think we need an audit, and help from your committee.
Please help.
Gordon

Dear Sir:

I am very enthusiastic about Stu Wecker visiting and teaching at Berkeley.

Let me take this opportunity to recommend him. He's bright, hard-working, and should do well there. His vitae accurately describes his work.

Sincerely,

Gordon Bell
Vice President,

Engineering

SUBJECT: CONCERNS FROM WEST COAST TRIP AND VIEWING MAYNARD FROM AFAR

Having spent a few days on the West coast talking to folks at Intel, Berley and Stanford where I gave a talk on 36 lessons to be learned from the computer generations, I was able to get some perspective of DEC engineering.

.Timeliness and competitiveness. We aren't hurrying enough. Intel is substantially ahead of where I though they would

.The University research is diverse and of really high quality.
My impression is that we should not be investing that much in research, but would be better putting really good advanced development in place and building really good coupling to the universities to leverage theirs.

.Our universities program is pretty good, but we aren't focussing on results. We spend the money and now need to follow up.

.Stanford has a Canon Printer interface that's pretty neat to do TEX typesetting. Left alone, we'll have something inferior in a couple of years. Theirs is really good and simple based on an Z8000. Is there a problem that we have a bunch of obsolete engineers or are we dumb or are we lazy or do we have so many people that they have to spend all their time talking instead of doing?

.All universities want to go all out with the high quality personal computer. At least 5 companies are trying to build it, because given the slightest imagination, one wants one. This criteria rules out the Product Line requests and Product management interests for such a product... but this is good too because. We have told too many people of our intent to build this product and as a result, we have stimulated a demand we can't fulfil. Also, we have selected the furtherest universities possible (Washington and Berkely) and one of the most open ones (Berkley) to place the product.

.Was impressed with Knuth's and Kahan's arguments why we should have used the proposed IEEE Standard for Floating Point. Clearly we made an expensive blunder here. Bill, will you go through the analysis of changing it to meet the standard. I think we need to do it. Can someone help me understand who is going to share in this blunder (Sam, Bill Demmer, Bernie Lacroute, me, Bill Strecker, Mary Payne, Dileep Bhandakar... please check any or all or anyone else.)

.CDC is supposedly trying to produce a machine to compete with VAX, given they lost business to it.

.780 isn't going to hold until Venus and even then, we are going to have to increase our ability to get more performance in this area. An array processor looks like the only short term possibility.

.Ed Feigenbaum at Stanford described his brother in laws role at a designer at Honda, in LA. They work every evening until 10 except Wednesday which is reserved for the family. Occasionally they test cars on Saturday. He won a design award and was decorated by the emperor. They are competing with 2 other groups in Toyko and Germany on their next car.

Given that TRW has just signed up to market Fujitsu, our options are dwindling. Sony and NEC already have their own distributorships.

Overall, I am concerned that our product cycle times are increasing at a time when we can not afford it. Also, the stuff we are planning just doesn't seem that good.

The pace is quickening at a time when we are getting big, old, tired and lazy. Also, the technology rules are changing and I see a bunch of engineers who can only design with standard IC's.

If we weren't so young (physically) we could go for early retirement. But barring this, I suggest we look at some of the other alternatives.

Any ideas?
Are we ready to discuss this?

GB1.S5.34
James Martin gave a very good talk on DP and DDP.

1. Engineering should sponsor a similar talk and learn.

2. We should review our CSW product direction regarding 4th generation languages. Some questions:

   a. Can we encourage SW houses to write these languages quickly AND have them be tightly integrated into the rest of VAX hardware? (This would give us a significant advantage over IBM.)

   b. Is our approach to parametized SW generally good? (The test should be the lack of COBOL programs.

   c. Should we do fixed applications programs at all? Should they only be based on 4th generation languages?

3. Relational Database is essential too. We should look at hardware to speed this up includng ICL's CAP.

4. He believes that users want 2 types of terminals:

   a. Executive - big, symbolic, color, high resolution, graphics, pointing, keyboard.

   b. Troop - cheap, B/W, graphics.

several wheelies
whole round of lan clusters
hsc, vsv, print server, and pluto are our nemesises vs uda..
what we learned,
vlsization

100 Memorial Drive
Cambridge, Massachusetts

Dear Dr. Wildes:

I recently learned that you were working on a historical report on Whirlwind. Since I am interested in the underlying history of our computers, I would very much like to get a copy. Also, Digital Equipment Corporation has a publishing group, Digital Press, which is starting a historical computing series and they might be interested in publishing your work.

Could you please send me any material you have on this subject?

Sincerely,

Gordon Bell

Given the recent look at the repackaged printer for Word Processing, I would like to look at the following design ideas before it is too late to do anything about them. As a WPS 78 user, I have some predjudices, and would like a shot at seeing if we can do anything.

.less EMI in the FM band

.serial connections to the printer for ease of plugging/unplugging

.use of standard, serial terminals especially the LA34 to reduce the space.

.place for a modem or acoustic coupler

.less acoustic noise by getting floppies somewhere out of the way...let me urge us to consider TU58 and bubbles as an alternative for better convenience and for packaging and noise and really good performance when operated as an adjunct to a host processor.

.copy stand and place for papers if used as a terminal on a stand

.have the terminal mountable on a stand, but make the stand so that people can sit at it more comfortably.

.less static susceptiblity and better software to avoide loss of files.

.non-homely looking because we have the VT100 to start with

.easy to move around both in tethered (cabled) and by parts when it is necessary to carry it up and down stairs...make it so that one non Amazonian woman-type person can unpack, assemble and move it. Here, note the high payoff because all the WP Salespersons are women.

Subject: Bubbles for White Tornado and White Tornado Versus New Editing Terminal

To: Distribution

Date: 3/6/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Bubbles for White Tornado

Wouldn't bubbles make the WPS system connected to a large computer viable, whereas now it takes too much line and central capacity, and ends up performing poorly? With the 256Kbit bubble memory at costing less than a $100 interfaced, and giving about 8 pages of text, this would really be a hot system. I would assume that another bubble dip could cache most of the WPS program, which is the other component of response time.

Are we thinking about this?

Are we looking at using the TU58 as the main removable memory with the bubble as a cache for the lowest cost system?
Could we/ should we try it?

Using WPS as the Basis for the New Editing Terminal
Since I don't know what is being planned here, I have to ask a few simple questions:

Why can't we just use the White Tornado and WPS system? (Having just spent an hour doing 15 minutes work using the EMS editor, it seems to me we gain a lot using this editing terminal and creating this as a standard...which may even evolve with time.) Too expensive? Even used only as a page editor?

Is the text editing terminal compatible with anything we make or anyone else sells? or thinks they want?

My point is simple...let's make the DEC editing facilities those of WPS!

Jack are you pushing this?

Follow-Up: 9/21/79

CC: Pat Courtin, MK1-1/D29
OOD

Let's get this settled now. Pat Courtin has raised my concern especially as it relates to UNIX. Will different implementations (i.e. VLSI VAX, Nebula...,Nebula/BI, COMET, 780, and VENUS, all execute the same programs? Who's in charge here?

The same issue exists with VMS and P/L specific hardware/software. How can we keep system integrity when people add to it? Can someone from VMS consult/approve these extensions?

Also what about the interconnect space (e.g. BI, NI, CI)?

GB:swh

Dave Cutler recently talked with me about our now, seemingly over emphasis to processes, and the need for large staffs to do CAD tools.

We do need strong technical groups to build and integrate these tools. These people are critical to our survival, and they must design and implement an engineering enviroment where engineers get work done easily. It should be still noted that these people technically are only in the denominator of a productivity equation, when we make new hires.

What worries me most is our growing dependence on people who are hired specifically to operate facilitating processes that have nothing to do with the direct production of products or knowledge. Certainly we're used to personnel and finance as part of helping us operate an organization, but they are both constant or diminishing in size.

Again, we do need people to facilitate various processes (allocation of RAD, TMC, University Research, the budget). It is far better to use part-time people within engineering than to hire from without people who know absolutely nothing of the technology or products we build, and can only faciliate.

Subject: Marketing Software, etc.: Any Opportunities
To Dudley, kgf staff

We seemingly have an opportunity:

1 An idle salesforce that needs to be in the market to continue their learning and our interconnection to it
2 a need to learn about selling software, since there will come a time where software may be our main product and source of revenue
3 many companies here and abroad (eg. Australia and UK) who can give us exclusive distribution rights

Some possibilities:

0 Ally, of course
1MASS-11, the Wordprocessing package we run on VMS, and is compatible with the DECmate. This operates on the IBM PC and is being converted to run on the 370. They can also put it on UNIX. DEC is coming out with a competitor and will not recommend it as they do now when they're about to lose a sale. GM has standardized on Mass11. The group has no marketing effort!
2 Angusglow, UK, Leo Shiner, Pres. 101 Marlybone High Street, London W1, 486-0702 has two products to sell here:
  .DG CS Cobol that compiles for PDP-11's and will run soon on VMS. This exploits the fact that the PDP-11 has a poor Cobol. It allows DG OEMs to move to DEC and DEC OEMs on 11's to have a compiler.
  .An ISAM to replace the 11 RSX RMS that is faster and has more features.

Lots of people have contacted me about point products. I think we ought to look at these and figure out how to do them profitably.

<u>WHY COMPUTERS EVOLVE (RAPIDLY)</u>

. SCIENCE (KNOWLEDGE TO BUILD WITH)

. COMPONENT TECHNOLOGY (WHAT'S PROVIDED & WE CAUSE)

. DEVELOPMENT (WHAT WE PROVIDE)

. GOVERNMENT (BY NON-INTERFERENCE)

. USERS, e.g. (DEMAND & DEVELOPMENT)

(INFORMATION CARRIED BY ELECTIONS VERSUS MASS)

(MAXWELL VS NEWTON)

. CLEAR SEGMENTATION INTO LEVELS

. COMPUTERS ARE FUNDAMENTAL (AND VERY EASY TO UNDERSTAND)

. COMPUTER ENGINEERING (PROGRAMMING) EXISTS AS A WELL-DEFINED BODY OF KNOWLEDGE THAT CAN BE APPLIED

. INFINITE NUMBER OF APPLICATIONS

. ECONOMIC DRIVE TO COMPETE WITH (SUBSTITUTE FOR) OTHER INFORMATION

SWITCHERS, STORERS AND PROCESSORS

WHY MULTIPROCESSORS HAVEN'T EMERGED YET

. ENGINEERING CONSERVATIVE.

. THE MARKET DOESN'T DEMAND THEM.

. WE CAN ALWAYS BUILD A "BETTER" SINGLE, SPECIAL PROCESSOR.

. THERE ARE MORE DESIGNS FOR NEW PROCESSORS THAN WE CAN BUILD.

. PLANNING AND TECHNOLOGY ARE ASYNCHRONOUS.

. INCREMENTAL MARKET DEMANDS REQUIRE SPECIFIC NEW MACHINES.

. POINT PRODUCTS EVOLVE; A RANGE REQUIRES MUCH BETTER PLANNING

AND CONTROL.

. WE HAVEN'T BEEN ABLE TO PROGRAM THEM YET WITH A HIGH DEGREE OF

PARALLELISM.

I talked with Heidi Mason, of Acquity, who put us together with SST. She's convinced that we should merge and will help in the process. Acuity, is a company that consults in marketing strategy and got involved with them in trying to determine a more focussed strategy.

The points we might make to them are:

.Starting up is inherently risky... about 4%. A merger is the best case to hope for. This is argued in the paper I wrote on the industry and which they may have read. (She believes they have a .4 chance of making it for ? years without us. This is probably high.)

. We can make startup a sure thing due to capital, helpers, sales company. This means staff folks (K,G,H,R,R,J,J,K,S) plus several companies ready to help now.

. Implementing a product strategy aimed at producing a full product line is the real NICHE (way to win). A standalone small product won't be able to be differentiated and get off the dime. We have 6 companies now implementing this. Together we have the world covered.

. We share the same vision of a product strategy and they can do as much of it as they are able to. We are excited about the ability of this product to be made smaller and to go into portable products.

.We have two product companies ready to put software on their product.

. The company will not die, but will move off the dime.

. We're synergistic. They have a now product, we'll make it go to 10M by Jan. Ken will take the product breadboard now and use it in selling ECC.

. We have an exciting set of companies to work with. They would be happy with every group. They do want to know what the group looks like.

. We are pioneering a new organzitional structure.

. The rewards will be right... especially the expected return.

She (they) were worried about our whiplashing because of our inability to get back to them last week when, just the week before, we had said we would move when they wanted to. The answer is simply that I and they had been unable to convey their product ideas, hence we were looking at other alternatives! Also, we are fund raising.

They want to run their own show, but realize they need much help. They also want to learn, and feel they can with the proper mentors. It's critical to get the manufacturing and marketing going now, so this is a great time / test.

We have to assure them we won't be heavy handed, won't install a new management structure, will teach, will let them have some leaway to learn and implement the kinds of products that fulfils our corporate goals.

WHY USE THE NATIONAL CHIP?

32-bit architecture
32-bit wide data path and access to memory
Best Memory Managment
High speed floating point
VAX-like: Languages and techniques developed for VAX are applicable
VAX=UNIX like: Best implementation engine for UNIX
High likelihood of long delay for the 68020

CONCERNS
Second Source: Will Fairchild, TI or Rockwell come through?
Program development environment is immature
Design group is in Israel
To: Ken Olsen and the Board of Directors
CC: Ed Kramer, Jack Shields, Jack Smith and Win Hindle

I would like to strongly recommend that we buy an interest in Trilogy for the following reasons:

1. We can build several, significant VAX products that offer a factor of 2 to 8 increase in <u>performance</u> times the machines we are introducing in the next two years.

We have NO technology in house or in development that approaches this; we know of no technology that rivals this at IBM or in Japan.

Nearly all of our customers require significantly more computing power, and the application of very large scale, high priced computing technology to minicomputers constitutes a major breakthrough in the design of minicomputers.

2. High performance, minicomputer-priced computers, coupled with our ability to interconnect machines would hold American Bell and other customers who may leave DEC for IBM. Just the announcement of our agreement may keep customers.

3. Minicomputers built with this mainframe technology will have an order of magnitude higher <u>reliability,</u> and as such, some may NEVER fail. Sevice cost, which constitutes half the total system cost is reduced a factor of two. Service is by simple replacement at the user's convencience.

4. The technology as a whole is a breakthrough, and forms the basis of both direct descendant technology and other systems:

a.Their Computer Aided Design is the best we've seen. With it, designer productivity is an order of magnitude better than with our most advanced systems.

b. Their mainframe design techniques are useful in mini- computers. We have already learned much from the Amdahls.

c.The packaging and semiconductor technologies are state of the art, yet conservative, and extendable to another generation and probably lower cost machines. These technologies are coupled to the critical manufacturing processes development.

d.The method for achieving reliability and obtaining higher yields through redundancy is truly unique, and a breakthrough. It goes directly to the ultimate goal of building a computer that will never fail. The current state of the art only permits the diagnosis of faults.

5. The technology is being developed by Gene Amdahl, who has built great high speed computers for the last 30 years.

6. We have able designers who want to start now.

Indeed, the only reason NOT to go with Trilogy is one of risk. We believe the risk is manageable, the people are the best, and our entry will increase their likelihood of success by additional resources and a different view.

We have the opportunity to participate in a breakthrough. Let's go.

Gordon Bell
19 June 1983
Thoughts On the Low End
To Jack and Jim and Ken and Win

Why You Might Not Want To Work In the Low End
The simple answer is that anyone that's good, wants to do state of the art and relevant products. The obsolete, vanity architectures are part of the root cause. Poor products breed more poor products. Most of the products are irrelevant to the market; none have any significant market share! Good people only want to work on good products.

Other answers: it's basically an assembly operation where you take off the shelf micros and peripherals and put them together. The challenge is in the software of the applications, and good sofware folks are not encouraged to write the control software (Firmware), because this is being done by hardware folks who don't have the background.

The Engineering Environment
I've felt unwelcome, and given the activities, I've not been anxious to look at poor projects when the support for changing them is also nil. A manager just has to be crazy to enter this arena. We're lucky to have a good one now, but

he's our fourth in less than 3 years, and this should indicate something's wrong. Surely, the engineers feel the same way.

The physical envionment isn't great, and the processes for cad, simulation and software aren't there either.

The hardware and software folks are too far from one another geographically!

Base Architectures
The 8 and 11 are machines that aren't state of the art, and one simply can't build competitive software on them because of the address space! It is virtually impossible to write any modern application, in a market-practical time on either of them. We shouldn't be. We should simply support applications that exist and can be written easily within their frameworks. However, we need to go like hell on: Rainbow, UNIX (probably on all products 11, 68K and VAX), and MicroVAX! There are lots of protos going to select from.

The 8 has a bizarre addessing scheme, making it a 8/12/15-16 bit computer (pick one) and the 11 is a 16 bit computer. The 8086 is a 21 bit computer, the 286 a 24 bitter and the 68,000 and VAX are 32 bit computers. Addressing is the ONLY thing that's important in the potential production of software. This, along with the fact that DEC vanity architectures are insignificant in the market (because we didn't sell chips) means we're irrelevant.

Base Busses
There are either no busses, or so many busses that one can't build anything: CT/Q/Ubus have varying degrees of disks, crt's, comm, telephones, etc. None are going to last past 85, and ALL are incompetitive with the Multibus! This is still a mess with the dream, realities and plans being seperated too far in time.

CT
A tragedy. All of us are finger pointing. There was no mangement or review at the critical times.

The problems of the PRO are: address size, chip performance, compatiblity with the 11 (which is pretty good), and the fact that NO ONE outside of DEC is writing software for it. Maybe the biggest problem is just being late. I do have a lot of respect for it though.

DECIDE IT'S FATE. Selling like hell is clear. My gut feel is to make a J-board for the PRO (let's build the proto anyway), and NOT make a PRO out of the Qbus... requiring more boards and options etc. to be built. It makes a nice story that you can upgrade your PC to a shared system or to run any random O/S on any random Micro, but I don't think it can be done competitively, and by the time we prove or disprove it, the market will have gone.

Rainbow and Building an IBM-compatible line of computers
I wish to hell we were IBM bubble-pack compatible. I wish people would listen to Cudmore and Folsom. Their dream: build 3 machines- RB50 in Japan, a floppy based and a wini based machine. All should use the same options. These would be configured to have great performance for the WPS+ software that can now be demo'd on the Rainbow. Get market segmenation by a label if necessary... but frankly, I'd like to put our WPS+ software on the IBM PC!!!! This would get us presence and compatiblity across the DEC line.

VT's
The two products which are took two years (not 9 months) are both retread of the vt100 and vt125 with no real improvements in screen size or performance. They're cost reductions that should be done in plants (the 220 was) and appears to be pretty good. We didn't get any features (VT phone, calculator, programmability), a bigger screen, or higher performance to compete with PC's. This area is dead for many reasons including the fact that PC's are proably the way to go. Who's encouraging the design of competitive versus quick time to market products... that still take TWO years?

LA's
By mismanagement and poor factory performance, the Japanese have driven us OUT. The 12 isn't bad, but there's nothing else. The LA100 product plan is a dream, and the quality of

mine is poor. LN's are masked by the sad work in imaging on paper that we can't afford.

Bottom Line
I think the area must be fixed. It's not irrepairable, but left alone much longer, it'll be more poor products (and lower margains).
can't build a machine on the 11
anyone can do it, is it worth it
intellectually, it's an assembly operation
people who take long projects, eg vlsi'd dragon are at risk
it's not even a sw challenge
the pro proves it
tools expectation and profits are poor
close to maynard == 1/distance. get lots of help
  Maynard envirnoment is terrible
associates are poor.
expectations that everything is done instantaneously, no time to learn. software takes longer (history and address size)

you can't design any systems be cause all the energy is going into trivial busses: ct, q, none, 422, real stuff's on the ubus.
good busses build good fences but you can't build anything good
 ct=tms, u has comm and hi end disks, q has size and dream, bi has potential
qbus no good schemes to be competitive with multibus

weren't allowed to compete with the 11 RT... piss hole in the snow!
(11's a sleepy environment) Sales are minimal. Just replacement sales. in order to be competitive you have to compete
not a competitive t/j (late)... related to remoteness of engineers to market? vaxness

no 3rd party sw versus 8086/68K related to nature of market (chips)

Mr. Alec Peltier   15 August 1980
Chief of Immigrant Visas

Operations Branch
American Embassy
London
England

Dear Mr. Peltier:

I am writing to explain our situation regarding Professor Maurice V. Wilkes with whom we have made arrangements to join the staff of our Corporate Research Group.

Professor Wilkes has been a towering figure in computer engineering and computer science from the invention of computers until the present day. He is one of the small handful of men who originated the modern computer; he was personally responsible for the construction of EDSAC 1 which was working in May 1949. Some of the concepts first proposed by him, such as "microprogramming," have continued to grow in importance until today virtually all computers manufactured in the world are designed using this technique which he created.

For the last decade Professor Wilkes has been Head of the Computer Laboratory at the University of Cambridge (England), where he was previously Director of the Mathematical Laboratory for a quarter of a century. I will not attempt to list all of the honors and awards which he has received over the years; this information is available from standard reference works such as Who's Who (see copy attached). Suffice it to say that he has been one of the intellectual leaders and respected senior statesman in computing for the last three decades. He is a Fellow of the Royal Society, a Fellow of the Institute of Electrical and Electronics Engineers, a Fellow of the British Computer Society, of which he was the first President, and a foreign associate of the U.S. National Academy of Engineering. He received the Turing Award and the Harry Goode Memorial Award, two of the highest honors in American computing. He has received honorary Doctorates from five universities in three countries, together with other honors from around the world, including recently being named as a foreign associate of the U. S.

Academy of Sciences. In summary, he is a distinguished scientist and engineer of world reputation, possessing unique background and qualifications not available elsewhere.

Dr. Wilkes is urgently needed to run our research program on techniques for making computer systems more secure. This program is not only important for us as a major computer manufacturer, but also may have a significant impact on U.S. leadership in computer technology throughout the world. Dr. Wilkes' presence is necessary to move this work forward. Also, we need his interaction and leadership across all our research.

Dr. Wilkes is scheduled to leave England the last week of August and will start to work here September 2. He has made all personal arrangements including letting his house in London and renting a house here in Mass. We were lead to believe several months ago that his visa was in order but he was told by your office a few days ago that it would be 1 to 3 months before he could get his permanent visa. This is totally unacceptable. Please check into this urgent matter, expedite, and return TWX the status of this situation. Your help is most urgently requested in this matter.

I have known and interacted with Dr. Wilkes for many years. We need him here. Won't you please, please help us? What other information do you need? I will be calling you and Dr. Brewster after you have received this.

Sincerely,

Gordon Bell

SUBJECT: WILKES OFFER

Professsor Wilkes will be back to Cambridge in about 2 weeks. At that time he would like to get an offer. Could you work together and put something up that would be appealing? In many respects, I think he could be given some kind of grand title, like honorary senior scientist...but on the other hand, I feel it m might take away from the Senior Consulting Engineer title. In any case, I feel Strecker, Kotok and Cutler should be consulted. He certai has indicated a need for money.

Although I'll be out of the country, I think the letter should go out by the
end of frist week of Oct. Therefore, I can call back if you want my reaction.
I would like to have him here. he'll act as an irritant and generally be
good for us.

SUBJECT: WILKES: PLEASE SEND STUFF AND HELP

I had a thoroughly enjoyable evening last nite with him and I am delighted that he has a place to stay. I think Sam and I should sign up for a significant amount of time to have him be
a part of our technical reviews so that he can get a feeling of
what is going on so that he can both help in defining our research
direction and do work on his own. Also, I want him to become a
critic to our environment and question us.

We also talked about the problems of coupling and what universities
and industries can do in regard to research. I am counting a lot on him to help straighten out our thinking and dealing with

our identity crisis vis a vis research, A/D, and university research (and this interface.) I described the evolution of the CMU relationship and what I think may have happened in terms of coupling, need to couple, size, ability to influence us, etc. We may try to write this down after he's here so we can help this problem.

Bob, I believe you agreed to send the poop on the IEEE standard floating point so that he can get a reading on it from David Wheeler. Please do it ASAP.

Similarly, Dave Rodgers, would you send him the Ethernet spec so that he might comment on it in light of their many years fo experience with their Ring? (He wants to make sure that it will do all the things that a ring witll do.) He also visited MIT on Friday and would have gotten them to review the spec like I had asked you to earlier. If you do not intend to do this, please get me the spec so I can send it.)

Jim and Bob,
Who is expediting the VISA? He is concerned.

I am looking forward to having him work for us for the next 15 years. We need this wisdom, ability to look at alternatives, and basic smarts.

SUBJECT: GETTING THE WORKSTATIONS ON A WINNING TRACK!

The Workstations effort really makes me feel uncomfortable:

1. George is doing a fine job, but he really needs support and detailed supervision.
2. An Onyx engineering manager is needed in order to get the product out.
3. There are problems in implementation (eg. fiber optics) and in architecture (eg. incompatible with VT125/201). Many of the decisions lack common sense.
4. The product strategy as unfolded, doesn't go out and really deal with getting a competitive product for Appollo. It doesn't get us clear out to Scorpio and there aren't competitive metrics.
5. There's an incredibly large (25 person) A/D effort aimed at redoing the work the VMS group has done. I don't want this work done outside of the VMS control! Clearly resources to redirect.
6. The 32-bit Nebula can't use the boards as is and as such have to be redone. This may be competitive with Appollo in terms of cycles and psychology! It also helps the issue of more cycles for 780's since we got no Venus for 2 years.
8. The effort is isolated from and unsupported by both VAX/VMS and terminals.

In short: tactics, strategy and support aren't there to win.

Let's get this settled before I go on vacation on August 23.

MESSAGE ID:
5183917624

SUBJECT: GETTING THE WORKSTATION BEFORE IT'S TOO LATE

Am glad that Pete has been requested to facilitate this
project.
We are simply not making enough progress because:

1. There appears to be no overall direction into which the
product or product family fits.

2. The product changes definition lots (eg. one fiber optic
connection per Unibus interface, 1 mb/s versus 10 mb/s).

3. It is perceived that the design is constrained to use
fibers!

Ken has stated that the use of Fiber Optics is NOT a
constraint!
Ken wants only to have a competitive product to beat HP,
Xerox,

Appollo, Three Rivers, Symbolics and IBM (when they annouce).

4. There continues to be technical problems with the approach,
which are clearly exacerbated by a serial link: protocol, low bandwidth, inter-lock, and general complexity.

The approach, based on a high speed serial link to a high speed
dumb terminal we are now using really is looking shaky, because:

1. The inherent limit of the slow serial link means that this system will not work with the color workstation, and it may even
be marginal for the VS100! (Over a second to fill the screen.)

2. The one link per Unibus connector has driven the cost up, and
means an even higher load on a host.

3. The cost on a host of needing a dedicated Unibus, at $12K on a
780, means that this is looking more expensive and marginal.

4. I don't think we will be able to bound just what a system like
this will do when there are some number of terminals on it, due
to traffic interactions.

5. The VS100 is NOT customer installable, causing more expense.

6. Our customers wanted a standalone workstation, complete with
VAX processing all to themselves, and all we are giving them is a
shaky, dumb terminal that is expensive, slow and undefined.

7. The world, such as HP, is supplying the workstation they

want,
and on Ethernet to boot! (Maybe ESG should OEM the HP product.)

8. The next product of a MicroVAX driving a CRT is a true workstation, and we should build toward this end versus the dead
end we have taken.

Proposal:

1. Take the current Videoprocessor, lay it out and have it connect directly to the Unibus, say using 2 modules.

2. Put the Videoprocessor in the Low Cost Nebula package, giving
us a true Workstation that:
 can standalone,
 that sits on Ethernet and that can work with all VAX processors,
or that sits on Ethernet and has NO disk and can be used as a true Workstation where the files are operated remotely.

In making this, we have a worksation that fits on any VAX and can
be located at up to 2.5Km away from the host, versus tied to a
single host, and is compatible with what we will do on the VS300,
and the MicroVAX based workstation.

3. Don't offer the product on other VAXs, thereby making sure we
are able to offer a bounded, customer installable product.

SUBJECT: THE NATIONAL CHIPS AS MICROVAX...

BACKGROUND

On December 1, I chartered Roy Moffa to run a task force to look at the problem of being competitive in the low end. He's worked with Cutler, Husvedt, Supnick and Strecker to come up with an aggressive set of alternatives. Jeff Kalb got us to look at National, and Ward has been a helpful sponsor.

Looking at the chart of Board, Personal Computer and multi-user System products, I think we can see that there's a big price gap caused by having the large, proprietary chips of the 11 and VAX.

1. VAX products are only in the large systems space. There's no plan to get a small processor that allows us to compete with the 68,000 at the chip, board, PC .
2. The 11 products are relatively expensive. A commodity micro is needed for lower cost products at board, controller (eg. VT200) and PC levels.

For the last few years I've maintained that the only important
variable of an architecture is the virtual memory size. The fact
that VAX provided 32 bits is why it's great. Similarly, a 48-bit
address for the System 38 is why I worry about it. The so called
16-bit and 32-bit micros are either 17-21 bits, or in the case of
a 68,000 the limit is really physical memory which is only 20-22
bits worth. Therefore, none of the emerging micros are aimed at
providing what VAX gives, except the National 16032 and 32032
which have copied VAX's paging scheme. Therefore all systems,
including the Hitachi and HP micros are going to have the
problem of address limits. Note that Appollo did a pager for
the 68,000 to get around the problem.

The 8086 is the established 16-bit standard and the 68,000 is
positioned to become the 32-bit standard with Motorola, Mostek
and Hitachi as the suppliers. The 68,000 with 32-bit data path
is coming, but the "fix" to add paging so that it can address a
large memory still isn't out in the open.

I don't think we want to let the 68,000 and the 68,000 when it
gets fixed with a 32-bit address become the sole standard.
Clearly, we can't stop them with VAX because we don't have the
design or distribution system for chips. The 11 is inadequate in
address bits. There's an important consideration of bus
standards too as the Motorola backplane is good, but not great.

The Unibus and Qbus are clearly inadequate to compete in the microprocessor market of the 80's.

ENTER THE NATIONAL 16032/32032: MICROVAX
It looks like we have a chance of getting back in the low end game by using the National chip and simply defining it to be MicroVAX for the following reasons:

1. It uses the VAX data types (byte, word, floating point and pages). Thus, all files will be VAX compatible. A higher level program will not know the difference whether it's computing on VAX or on National hardware.
2. There is less work in converting our software to be machine independent than being able to get a chip of the complexity we need for VAX. MicroVAX for PC use is about 100 man-years.
3. As we try to make higher performance machines (eg. VENUS), the complexity of the architecture means it cost more in time and to develop the hardware. This directly affects competitiveness. We are wrestling with the same issue on how to build a useful machine for DEC in Palo Alto.
4. By having portable software, VMS would get even better and easier to maintain.
6. By being portable, and machine independent at a higher level, we have the opportunity to make substantial changes to the underlying architecture for extended addressing and protection and make sure that all today's programs will run. If done right, we're buying future flexibility.

The task force is suggesting an aggressive offering providing the following:

1. Chips on the Qbus to go after board business. The software
would be an extension of Pascal and MicroPower for the real time
market!
2. Chips would be place on the CT motherboard immediately to give
us the first 32-bit Personal Computer (Hardware only). Dick
Husvedt wants to put a subset of VMS, called MicroVMS, on it so
as to run VMS programs as a Personal Computer!
3. We want to drastically increase the throughput of the bus
system. Therefore, we want to work with National and establish
BI as the new standard for microprocessor interconnect.

MICROVAX, PERSONAL COMPUTER SOFTWARE
Not everything would be converted. The goal would be to let
the programming environment be the same on the two machines.
The following languages would get MicroVAX back ends: BLISS,
Fortran, (PL/1,C,Pascal,ADA... that use the PL/1 compiler),
BASIC, ... Cobol?, Visicalc.

VMS becomes MicroVMS for Personal Computing. Here, EDT,
Mail, RTL, SORT, File utilities, debugger, DCL, Linker, and
radically different Screen manager for PC. Also, Datatrieve.

CHIPS AVAILABILITY
We could get 16032 chips now, with 32 bit data width version
called 32032 in December. The path width is irrelevant to
our needs except where it affects performance. A faster part,
the 32032A is available in early 84.

NEXT STEPS
There are lots of issues with the above. In the long run it's likely to be cheaper as we move to a higher levels. In the short run, doing products we didn't expect will cost us.

Right now I believe that we ought to figure out how to do this MicroVAX, and if it still looks good, then go ahead.

What youse think?

SUBJECT: RECOMMENDATION OF EQUIPMENT TO WORLD COMPUTER CENTER

The Contributions Committee allowed 50% discount on the 600K 2060 these folks wanted. I believe this was quite generous and fair. The Operations Committee might consider some more help here in order to deal with the remainder in an expeditious fashion. Currently the other 50% would have to be gotten by the LSG group, or by European Marketing or by France marketing.

Every report says they are going strong there and will do well.
Mitterand is behind it and researchers and budgets are getting in place and working.

This remaining part is small to us, but could be one of the most positive marketing things that we could do in Europe and France. It would let the French Govt know we love them and we would get a number of researchers on our machines! The follow-on business when the technology gets exported will probably be worth it. In addition, they will end up buying a number of other machines too when the center gets going.

SUBJECT: WORLD COMPUTER AND HUMAN RESOURCES CENTER

Following my suggestion of December 12th, 1981, I want to propose
that we make a donation to the World Computer and Human Resources
Center.

This Center, created by FranMITTERRAND and to which partici
pate famous scientists like Seymour PAPERT (MIT), Pierre BOULEZ
(France) and is headed by Jean-Jacques SERVAN-SCHREIBER as Presi
dent and Nicholas NEGROPONTE as General Manager, is going to em
ploy 100 scientists (50 from France, 50 from other countries).

In spite of a strong pressure from French bureaucracy to buy CII-
HB equipment, they decided to go DIGITAL. Their project is to buy
immediatly :

1 VAX to DEC France
30 SU VAX through MIT

and they ask us to make a donation of a DEC 20/60.

I had yesterday a meeting with Jean-Jacques SERVAN-SCHREIBER and
Nicholas NEGROPONTE and I got their committment to make publicity

for DIGITAL. I consequently see many advantages in this operation

* 100 people (of which 50 French) will permanently work and make programs on our equipment, to which we should add all the participants on a non permanent basis.

* It will be a permanent window for us.

* It will open doors with Government officers who will get a fee ling that we are somewhat privileged.

* The fact of seeing that President MITTERRAND himself has allowed the Center to use DIGITAL will give more courage to buy DIGITAL potential users belonging to Government protected market.

* Knowing Jean-Jacques SERVAN-SCHREIBER, we can be sure that a lot of advertising will be made around the Center and consequently around DEC.

* It will be an excellent publicity against competition and build a good image of DEC both in LCG group and VAX group.

* It will motivates our employees.

* Last, but not least, the Center's activities seem interesting from the human point of view and it would be good to have DEC participating to it.

Consequently, I would like to ask the Donation Committee to consider favourably their demand.

Nicholas NEGROPONTE is meeting Gordon BELL on Monday 5th. He will

mention him that he needs fast delivery. On our side, we would do
the maximum to help for fast installation of DEC 20. We are delivering a VAX 780 next week, the order of which will be confirmed end of April if we reach a global agreement.

Best regards,

SUBJECT: RE: FUTURE PACKAGING OF 278 AND 11/23

It would seem the CT crt is most ideal. It does tilt, it only is the crt and can be positioned anywhere.

I think you have a runaway situation with the cabinet. It was the goal at one time to be able to ship it in a cardboard box
through UPS and have the customer put it together like
he does a hifi. Now, through a series of minor transformations
you have incremented the thing to a stationwagon as being defined
as what portability means. I don't have a stationwagon, nor do
I intend to get one. I suuspect that there are other customers in the same boat (or without this sort of boat).

Apple is going to continue to cream us. The 278 will only help them by further draining our cash. I figure their ACE is the Apple III with lots of memory AND a Very Good WPS system which is finally possible because of the screen, the bigger memory and their expandability. Note the add in the May Scientific American.

The reason Apple will get more sales than us or Wang is the carriability (We need a word cause you have destroyed the meaning of portability) by having it associated with the 278. (As a by-product of stationwagon portability, you get a whole set of costs ... that we ignore in our costing
and thinking. Since they are there, it either means continued
negative profit on each one or continued ignoring us in the marketplace.

Damn it, We gotta have a computer that the user can use in many of the varied ways he will, it has to be carriable, assemblable and expandable. Also, it had better be big enough to get our software on (probably 128K ... not 64K as we dreamed last nite).

SUBJECT: THE 278 I HAVE; I'LL BE HOME ALL WEEKEND AND I WANT IT UP

I have been delivered a piece of disfunctional crap!

Pleae call the necessary hardware and software engineers and get the god damn thing fixed.

Paula left me a note indiceating a problem with it
in reaggard to whether it types correctly
when initiallized.

Also, it has the same bug it used to have when initialized in terminal mode. namely, I think it thinks its a typewriter.

In this regard, typing rub out evokes a backslash, not a backspace
and a delete.

It sounds, I think, noisier than the 78.

I thought this had been checked before it was delivered.

I don't know whether it works as a wps cause there is no floppy, therefore, bring a floppy.

I gotta have this system up, and I don't like being left with no operational system.

Please get people moving as I have a heavy weekend ahead and as of this instant, there is something'th that is worse than a dumb terminal staring at me.

SUBJECT: THE 278 ORG., THE LOW COST COMPUTING KEYBOARD AND JOHN KIRK

I think Ken and I unknowingly have been pulling at both ends of John. I've been working with him to go after the very low cost computing keyboard; and Ken, very concerned about the 278, has been pushing him back into the 278. This is what we'd use for building the portable and very low end wps.

Our first priority is clearly to get the 278 out, and to have it successful, including any enhancements involving John. For

starters, Mike, could you get the 278 organization clearly spelled out so there are full-time persons on the 278 with a clear organization and clear decision making? I'd like Ken (and
I) to feel comfortable with the organization. If John is essential, then let's try to get him back in full-time, otherwise, he could continue as it's primary designer and consultant as in the past.

I sent a note to Gary Cole to present this. Please contact him to get it on the meeting agenda. I also suggest that Gary have the whole team photographed and sent to OC. We also
should put down an organization chart.

The big question: are we going to sell it in any interesting

way, or are we limited, as we have been in the past by selling
through the small, but high quality wps p/l?

Have just asked Bruce to look at things that make it better (faster). Despite Ken's enthusiasm and that of our secretaries,
I don't see it beating anyone in terms of price and performance
... and competition is just going to get worse.

Therefore, given that we have only a so-so product, we are going to be totally dependent on our proven, superb marketing.
At some point, there should be a business plan that says this is going to be done well in terms of units, profit, etc.
There just has to be a way to get the product to our own customers, otherwise, we are doomed to the current abyss!

At least the 3 wps systems I typed on at NCC seem to be faster
and cheaper to produce (Burroughs, IBM, and Wang). I suspect there were many more in the basement that the Japanese had.
This, simply means the burden is on finding some way to market
the 278, cause the product will not sell itself. If we can now, just be REALISTIC and CALM about the situation, we have a chance to do something, if we persist in pandamonium, we will continue to get creamed.

Please, please, let's start thinking and stop shouting.
We have a real, important marketing opportunity.

SUBJECT: RE: RE: NOTE ON CONTROL OF THE 278

I don't think the 278 is going to matter very much in the grand scheme of things. Let's start now to get it under control though. I believe, probably like Ken, that the main thing is to get the 278 out. All the folks working on it would
have charged their time to something, but with the 278 as a cause they've probably worked much harder and with more focus. Thus, from a corporate viewpoint, we are probably ahead. Also, the decision to switch package
types was made by Ken, I believe, and given this, it's up to you to get the best deal we can with it. Is there anyway we can salvage the parts and use them internally?

Just get us under control as best you can... but get the product out.

SUBJECT: THE 278, WHAT COST, WHAT PAYOFF, WHAT RISK?

I think we had better start listening to our engineers. I'm ready to. Shall we get together this weekend, or how about early monday morning. This sounds like a potential disaster of even greater proportions.

If/when we get the new stand, it will be a megabuck project. Is this really going to get us any increase in sales? At an increased cost, I have real trouble in answering why we should do it.

SUBJECT: THE DECMATE PEDESTAL DISK SYSTEM d i g i t a l INTEROFFICE MEMORANDUM

TO: Stan Olsen

DATE: 01 MAY 81
FROM: Gary Cole
DEPT: DECmate
Product
Mgr.
EXT: 264-7478
LOCATION: MK1/1C6

SUBJ: The DECmate Pedestal Disk System

Over the last two weeks I have become increasingly concerned about this product and whether it is a viable device for CPG to commit its 100m$ plan to for 1982.

First Issue: Product Readiness

The product is not going to be ready for ship by
the end of May. UL/CSA certification will be delayed
until mid-July (nothing ships without it.) DEC 102
testing is not completed and the unit fails drop test,
FCC and static testing as of today.

Second Issue: Product Design

The product design is good in concept, but not so
good as implemented. It is virtually unserviceable by
the average terminals group field service technician.
Over an hour is required to replace a drive, twice as

long as servicing the RX78. The pedestal is mechanically unstable - top heavy, and requires an extendable front foot assembly to be used when the keyboard shelf is attached. 3) It is noisier than our existing RX78 4) Although it is not at all hard to "install", you must have an elevator and fork truck to move it (>150/LBS) which seems to be to be the wrong requirements for a customer installable product. It cannot be carried in a car without 2 or 3 people to lift it in or out.

Third Issue: Product Cost

The pedestal disk was intended to reduce our system cost by 180 dollars. Recently it has been determined that its 1982 manufacturing cost will be $435 more than a table top RX78 system and $271 more than a H978 mounted system. These figures are the most recent available from new products group in Westfield and are 40% above the engineering estimate of last month. This reduces our gross margin by 3-4 million dollars in CPG in FY '82. I consider this totally unacceptable.

Fourth Issue: Product Risk

We are putting the entire future of WPG and RPG on the line when we start delivery DECmates, I believe that we have a substantial risk of catastrophe by proceeding with the crash project production and ship of the pedestal system. I have interviewed most of the members of the 278 project team and find that most of them share this view for various specific reasons.

Recommendations:

1. DO introduce the DECmate using the RX78 tabletop floppy and H978 optional desk, as scheduled at the end of June.

2. DO NOT introduc e or commit to delivery the RX02-P pedestal disk until

   a. DEC standards are met, UL/CSA & FCC compliance is achieved.

   b. Cost is, at the very least, made competitive with the RX78/H978 and consistant with our business plan.

   c. Serviceability and quality issues are brought up to reasonable issues.

3. If it does not appear that (2) can be achieved with 6 months, then let's abandon this effort and direct the funds toward the minifloppy, which is certain to reduce cost of our system by 500$ or more.

Other than the pedestal, the 278 if fully ready to be shipped in high volume as a highly reliable, customer installable product. I recommend that we do so.

I also recommended that we reconsider making the H9780 (Cube/Desk) assembly available as an extra cost option since it is very attractive and makes a very functional workstation. The design of that product is complete, and a hundred units are in stock.

DECmate Transfer Cost Summary

FY '82 Transfer Costs. (Actual or best estimates as of 4/30/81)

Components

RX78-RA (existing tabletop RX02)	$1063	<committed>
RX02-PF (new pedestal RX02)	$1498	<estimate>[$1073 planned]
H978-AA (existing 78 stand)	$164	<committed>
VT278-AA (@10K build rate)	$1172	<committed>

2-drive systems (95% of sales)

VT278 with RX78	$2235
VT278 with RX78 with H978	$2399
VT278 with RX02-PA	$2670

4-drive systems (5% of sales)

VT278 with 2-RX78 with H978	$3562

VT278 with RX02-PF $3586

At a volume of 10,000 sales in FY '82 the use of the RX02-P will reduce gross margin by 4.3 million if H978 were to sold as an extra cost option on RX78 system or 2.7 million if the H978 was bundled into every system at constant price.

SUBJECT: OUR PERFORMANCE IN MEETING 8-BASED WPS COMMITMENTS

I think it is necessary for us, Owen and Stan to meet and
discuss
history. Get a history of: date, content, commit date, and
actual
date and then we'll meet.

Stan is worried about our ability to meet dates and be
competitive in
the 8 area. Let's discuss this.

Also, we should discuss why this is not going to be the case
in the
16-bit area. What's different? We want a very responsive
development/introduction cycle that is much better than the
278 in
order to be competitive. What's the best we can do here?

SUBJECT: WPS ORGANIZATION FOR ENGINEERING AND PROGRAM MANAGEMENT

As part of the evolution and expansion of Word Processing within Digital, we are planning on making the following organizational moves within the engineering and product management function. It is not anticipated that there be any structural changes within the various organizations, except expansion to meet the product development needs. The groups will remain located in Merrimack.

1. Jack Gilmore and the Program Management function for Word Processing will report to Si Lyle as Program Manager for Office Information Systems, OFIS. This will include the current and future Word Processing products, various editors with

word
processing capabilities and the Electronic Mail System under
development and future office applications.

2. Bob Travis's Word Processing Software Engineering organization
would become part of the Software Engineering organization in
Merrimack and report to Bruce Stewart.

3. Bob Gray's Word Processing Hardware Engineering organization
would become part of the Engineering Organization in Merrimack
and report to Brian Fitzgerald.

This move is designed to give greater emphasis on OFIS products
within our basic central products, especially their availability
on the 11 and VAX products. This follows direction from last
year's Product Strategy. Also, there will be greater
emphasis on converging current, standard editors to be part
of the OFIS system in a compatible fashion to build off the
strong field sales support and customer base and the WP
Product Line.

The current and planned hardware and software developments will
continue on the 8 based systems agressively, since the 8 will be
the mainstay WPS product for the foreseeable future!

SUBJECT: GETTING THE WPS MARKET; COMMENTS BY REDPATH (AND GB)

Fundamentally we have a paradox now within DEC when we have a product line that's fundamentally a very high volume product because by definition:

Winning as a product line means losing the market!

In the 2 cases of channel/product, product lines we have to lose cause we can't get the necessary coverage to get market share. Product goodness is generally irrelevant because better products wouldn't get us much more total market share. We should clearly recognize this dilema and set about to constructively solve it by beefing up the Product Lines that provide us the natural learning and feedback mechanisms and focus that we must have to make and tune the products. All I want is a way to "get the market share".

Plan I

On Thursday, I hope to get from Bruce a collection of packaged systems we can make out of parts in inventory (eg. 11/34's, RK's of various types, and VT100's) that we can deliver starting in FY82 in high volume so that potentially we can PUSH OUT SOMEWHERE BETWEEN 250 AND 500 MILLION $ IN REVENUE TO THIS MARKET, SO AS TO BECOME A SIGNIFICANT SUPPLIER! This only means about 10% more NES and everyone selling! This would be organized as some sort of task force to get the right, fixed configurations so that we minimize the paperwork, order

processing, etc. in a streamlined fashion for the field folks.
If we can put together these systems from inventory, we have the potential to solve one big part of the inventory problem and at the same time, get the market. In such an exlosive environment, Buzz, will by any means, end up as a heroic Product Line, and furthermore as a PL entity will be essential for expertise.

Before we go off in any direction to push this, the first 2 steps would seem to be: can we get the products (Buzz and Bruce); and then test within the folks we have whether we are convinced we have the products to do this. Here, I'd like to get a few key veterans to look at this, like Ray Redpath, and ask them for a gut reaction. Then, we go into the 3rd phase, looking at how we'd partition the business to maximize ALL EXISTING SALES AND PRODUCT LINE CHANNELS. This would be done under Buzz's leadership, with some arbiters.

If I'm wrong in any of this, then I say we should relook at the whole mess, and then, I submit we should probably look at going about the business this way. This is plan II.

I'm confident the OFFICE products approach is going to be very good and competitive, thus I want us to be ready for them too. Also, from an engineering perspective, we are spending about $10M/year (and with engineering overhead this amounts to $20M/year). Since this is representative of the 8% corporate engineering number, then we should be getting about $240M/year in NOR. I believe with these products, we can easily get this amount, and I'd like to see us go for it.

Given, this feeling about the products, it seems essential that we ask for an independent assessment by the sales, marketing folks and perhaps an outsider. Clearly what I'm advocating is a radical change in our thinking, and that alone is probably a reason to reject it and go back to our old way of waiting to see if the customers beat our doors down to buy the product, then running around like crazy to see if we can deliver them. (Here, this approach is probably not going to work cause there's no way for them to find out that we have any products.)

As officers and members of the marketing committee, we ought to try to sort these issues out calmly. The time is right!
Can we discuss it on Thursday?

SUBJECT: WPS P/L AND PRODUCT DIRECTION

Stan is considering two WP product line groups: stand-alone and
shared.

Over the next two years the product directions look like (in priority):

1. Fix the shared systems; make the enhancements that are morally, legally and business-wise necessary. Sell it! Don't do combined WP + Data Processing using Dibol - do only WP.

2. Get the 278 out and aggressively cost reduce it to get the big stand-alone market. Incorporate the functional enhancements of the shared systems into the 278 that are easy to do.

3. Plan and implement the OFIS program for large, shared systems on non-8 standard sytems ASAP in a WPS compatible fashion. This includes EMS.

SUBJECT: WPS STRATEGY, ESPECIALLY THE 200

Our meeting tonight seemed to focus on the issues of whether to continue on with the 200. More than ever, it has to be a marketing commitee approval as to whether to continue to sell it.

My position on the 200 is still the same: Engineering- it will

require more enhancements both for market viability (to comm. with other systems, and all the other things that got us the long list of enhancement needs), and for Europe. It has different
code than the 78/278 hence it will take our resources. It is definitely interim and I can not see blowing any more resources
on a direction that we don't want to go in.

Customer/sales perspective- given the interim nature of the product and likelihood of needing communications or extra processing capability as my wps people get more sophisticated,
I can't see selling it (buying it if I think customer wise) when
it has such a clear, limited life.

Field service perspective- 8's just don't have the spares, the
training, the diagnostics and the overall learning that is needed to make this a really solid product. Also, the power density of 3 RL's in a cabinet makes me wonder about it and certainly makes me make sure it gets the DMT it must have.

Overall, I don't believe it is in our best interest or our customer's to sell it.
It morgages our future, gives dreams that won't be fultfilled (I still believe customers are buying futures as they know computers evolve and get more feature with time), and will not
perform. Worst of all, it is interim and takes us in a direction
we don't want to go.

I STILL CAN STILL UNDERSTAND THAT WE BELIEVE WE MIGHT HAVE TO SELL IT TO GET MORE PEOPLE ON TO OUR SYSTEM BASE ... but this has to be really quantified against the above risk.

We have to come forward with the alternative that is part of the long range which puts the DX filing capability on RSTS and other systems to be the multi-terminal alterhnative. This

would give us the capabilities including the communications ones and have us use a base that can be built on.
Furthermore,
we can sell future because we are planning to put a multi-dumb
terminal version out. In this way, we could sell the 78 and 278 and then evolve nicely into the multi-dumb terminal version
whether it be with DPD or our own. This is completely aligned
with our current direction and it doesn't represent an alternative
interim product that we will have to back out of.
Furthermore,
we can sell any number of existing users of RSTS users on our current WPS stand along systems with confidence. It will also let us reference sell the DPD system.

Tom and Bob,
We are asking for the status of the RSTS DX package that we have and when we could have this part of our product direction
done. It would be mandatory to be able to demo this pretty quick and to have a clear direction that we could sell. The product is quite low risk, but we do need to be able to give a strong message and direction.

Tom Vlach, MK1-1/N34

I made this from Jack's history and trees. Jack can you and Bob Travis clean up the history, and clearly define future parts showing the relationships of various versions to one another and possibly noting releases? Also, we might show "look alikes" on another line. I think we can use it to define future scenarios. Also, it is vital to understand from where we came.

Jack I'd also like a semi-log graph showing cost, and cost/terminal vs. time. This would also have competitor products and futures. These are critical to our future planning. These would be part of the history update.

GB:swh
GB1.S5.17

Attachment - WPS Slide
Thoughts on the dilema of introducing 3 PC's, particularly the 8.

TECHNICALLY it's suicidal to continue with the 8 and do enhancements because the 8 addressing causes inherent complexity in what would be very simple programs. I can explain this in 10 minutes and would like to because it's something all of us MUST understand. It's also the reason why the 11 bottoms out when compared with VAX or the 68,000. What the technical limits mean are simply:

.WE CAN NOT BUILD, LARGE, RELIABLE SOFTWARE ON THE 8!
.THE COST TO BUILD SOFTWARE IS OUT OF SIGHT. WPS has cost us

in the neighborhood of 10 million for 100K instructions. I think this could have been done in less work (due to complexity). This means the cost per instruction is 100-200.
.The cost to add new instructions is also prohibitive. 2 milllion for less than 10,000 instructions, or 200 per instruction.
.The complexity also means unreliability, hence not being able tor produce in volume. Note the problems and dear Ken's surrounding the old WPS 200 that we are still experiencing. Ken vibrates on his own 200 there and its unreliability (and sharedness). This is simply a volume issue too. CSSE doesn't know how to cope with it.
.Worst of all, we program so slowly, the features makes us uncompetitive. No way can we track IBM who programs in PL/M and uses the 8086 for their stand alone WPS.
.There are a small supply of machine language programmers
.The benchmarks say that you can get work done faster on a Wang, independent of what we and our secretaries say.

BUSINESS-WISE, it's suicidal to continue it in anything but hyping it as a Word Processing terminal for shared system or a typewriter in the office market. Large disks, all the other things mean more expense and loss per system. From all appearances, a WP System seems to be regarded as a computer in that people expect enhancements.

I don't see why we can't use the CAT and do all the things the 8 would do and at the same cost. This would give us a good WPS base, rather than a flaky one. Of course, our long term strategy is a code that could run on CT and VAX. Maybe this could be extended to CAT since it's in a higher level language, albeit our own.

EXTENDING THE 8 INTO THE SMALL BUSINESS MARKET IT PROBABLY EVEN MORE SUICIDAL I don't see any way to get the kind of software that the market says it wants without really coupling into the software publishing world. The CP/M card may be a possibility, if the quality is there vis a vis interacting with the 8.

For the newcomer, the 8 is not the beginning, just the beginning of the end ala TRAX! A few customers could really give us a black eye in the same way TRAX did. There will eventually be expectations when all the limits get hit and all the cases get tried.

Bottom line
We are on a slow, expensive, road to nowhere. If anyone follows us, they will be sorry (and very angry with us).

LOC/MAIL STOP: ML12-1/A51

SUBJECT: WE HAVE TO HAVE A WORKING 278 BEFORE WE CAN SHIP IT!

I don't believe the 278 is anywhere near being ready to produce.
It doesn't have the quality, nor does it appear to have been adequately tested prior to it being available to me as a test site. It seems to have all the old problems. The package is disappointing too. I trust these will be solved by the new Gonzales/Olsen package.

Something is wrong with the software/firmware:
.the auto-repeat when you hold down the keys is simply not acceptable and THE PRODUCT WILL NOT BE SHIPPED UNTIL THIS GETS FIXED! I'm tired of these kind of sloppy products, so get it fixed. The VT173 editor on VAX works right, ie. when you hold down the key, the cursor takes off and moves slowly at first, gets faster and in no case moves faster than it can execute. In the 278, holding down the key executes a bunch of commands and eventually they get executed, but it's too late. In the case of the editor, it would seem that you have to remove the function from the terminal macrocode, hand it to the editor to deal with. This auto-

repeat
can work very well, but it has to be designed, not a free for all between the hardware and software folks.

.The cursor seems to be the wrong shape, and I find it disruptive. This was mentioned before. We have some folks who can help immediately on this one, get help.

.This particular keyboard sticks. I thought we got all these out
of the system. If a customer gets one, he'll simply by Wang next time. I hate to think of all the customers who ended up with these keyboards on VT100's and LA's who thought they were
buying quality products.

.When you come up in terminal mode, it could simply report that
it's a vT100, assuming it is. This one drives me crazy cause EMS thinks it's a printer, and I get backslashes instead of backspaces.

.Our WPS Polish Editor. It is increasingly clear to me that this editor is sure costly in terms of the way one deals with the page and cursor. Recall that a Polish editor is one that instead of positioning the cursor to find something, positions
the page. Several months ago I requested that we
try an experiment and build the changes so that it works decently. We know how! EDT, the VT173, the VT134 editor, etc.
all work fine. Let's have a trial change fix for this within two weeks. If you don't have the proposed change, then let me
know.

.The machine I have occasionally produces flaky patterns on the screen. Under certain circumstances, there are random marks that go across the screen. This ain't quality.
Is the machine electrically screwed up? Is it a timing bug where the machine can't keep up with the real time and hence paints garbage? (If there is a timing problem,

then let's figure out how to put up something decent, or to blank the screen for a whole cycle. If the software knows when something is missed, then it would be best to simply turn off the display for the rest of the scan.) Again, do you know about this problem?

.Glare. I trust Ken is solving this one. iIt has to be solved.

.I like the printer, though am anxiously awainting the LA24.

PACKAGING
.I hope Ken has a place for the modem, spare floppies, the manuals (we haven't given him this requirement), a place for often
used information (phone numbers, instructions) and paper.
It would seem that if we have the two floppy case, the extra two floppies could be dummies and be replaced by drawers. Is there enough room to store papers, floppies?

Frankly, I am extremely disappointed in the 278 I have, cause we spent
an incredibly long time last summer in trying to work on all these
details with the Industrial Design group. The 278 is only attended to
superficially. MORE THAN EVER, I WANT THE INDUSTRIAL DESIGNERS OF THE
PRODUCT TO CO-LOCATE WITH THE PRODUCT DESIGNERS, NOT WITH THEMSELVES.
DICK SCHNEIDER AND JOHN HOLMAN, IS THIS CLEAR?

We can take several attitudes about the system (a rehash of what we
discussed last summer when we swore we would stop designing crappy
products:

1. build components, they are small, unobtrusive and it's up to the
user to make it into a clean system and be something useful

2. build it as a system as good as we know how. Unfortunately, like
the 278, this may take up a lot of space, solve many problems
but doesn't go all the way. The user has to deal with the manuals,
floppy storage, paper holder. If I use the 278 I have for
very long, then'll try to get sound deadener (auto parts store), a
good paper holder somehow, put a drawer in it for floppies, and put
a book shelf under it where my legs go. The modem and telephone on
top of the crt though kludgy looking is functional as hell. (Note,
I have to solve Ma Bell's problem cause the modem carrier rings in
my ear... I simply can't believe that Ma Bell has any notion of
quality! We should all laugh when we hear that Ma Bell thinks it is
going to, should or can compete with IBM.)

3. build a set of modules so that the user can build a good system
without having to be a total designer (like case 1), nor a redesigner.
Frankly, I would hope we could take approach 3 with the NEW 278. Ken
believes this is what we have in the new 278.

I hope we are designing for the Dreyfus average man. As one who is
only about 4# heavy in regard to the average, I hope we get these
problems solved before we deliver the product.

Am anxiously awaiting the next version.

It's clear we have the knowledge to build a great product,
now let's get the details completed so we really have one.

SUBJECT: RE: NOVEMBER 1981 FIVE YEAR PLAN MEETING

There are lots of folks involved with the 278.
This was a golden rule project. In retrospect, I goofed by agreeing to do it. It was a typical, kamakazee job like all the others in the low end, done with a small crew of hardware folks, for an inadequate amount. We spent millions in software though in a completely unbalanced way.

Remember the cast of thousands are the ones who are doing the engineering on the products so that we can have profit
enough so that you can sponsor these idiotic projects with Stan. If Stan's P/L's didn't get the revenues from the other products, (like the 100, 120, etc.) sold as part of the large systems, there would be no money to build these marginal products in a half-baked fashion.

I do hope you understand this whole mechanism a bit... just which side our bread is buttered on and who is bringing home the bacon and who is spending the bread money on betting at the races and at the lottery.   Sometimes I think you don't totally understand this. Tell me you do and that it's just an act.

Your drive for interim products at a time when we have an incredible array of mid-life kickers and interim products in order to live tomorrow really blows my mind. I don't believe you bought into Win's corporate Quality push. The crap you are advocating is all very marginal, in terms of cost-effectiveness. It is low in quality, and in no way can 3 half-baked products sell like one average one.

We really can only afford great products, and when we fail at these by making pretty good ones we may be able to skim by. But to start by building average ones is pre-ordained and continued failure.   I want to stamp out average-ness... you get this for free when trying to be above average.

I came to DEC several thousand years ago because there was a notion that it was going to build very good products and I can remember spending lots of time in the hiring process cause we only wanted to hire very good people.

I remember explaining this philosphy to others and they would always ask, where do you get the average people that the world needs to really make things go? At one point, someone told me or I figured it out that the average is something you get as a mistake when you don't make the best. So you really never should hire these folks, you get them for free as errors in hiring really good people.

Products are like this. I don't ever want to be involved in building an average product, and normally if I see one I avoid it too. I really can't stand to worry about them either cause there are so many of them

around and I'd go crazy if I ever thought very long
about them ... it's like trying to keep squirrels away from
the bird food. I view you often are out giving pep pills
to the squirrels... which is ok by me, cause I normally don't
notice squirrels. What I don't want to happen is to
demotivate
the giants who gather our food at the same time we feed the
squirrels who only seem to eat away at it.

SUBJ: Datapoint's Entering into the Office Automation Marketplace

There are a number of things about Datapoint's recent entry into the office automation marketplace that are extremely disturbing to me. First, Datapoint's history has been one of an innovator in both concepts as well as in market development. For example, Datapoint was first to pick up on distributed processing which other people then followed, and today it is a major industry topic. Next, about two years ago Datapoint came up with a concept of a local area network called ARC with up to 255 nodes on a local system. We are beginning to evolve into that direction as well as people like Xerox, etc. I expect that we are on the order of 2 years from a product in this area. However, Datapoint has had a product for at least 2 years.

Datapoint then stated that their entry into the integrated office automation was an evoulution of their ARC local area network. It seems to me that if their evolution parallels our evolution,

we are in
the order of 4 years behind them in the local area networking tech
nology and that if our integrated office of the future approach also
builds on local area networks that we are at least a couple of years
beyond that. If our history effort parallels theirs, and it certainly
has in the area of distributed processing and local area networks, it
appears to me that we are in the order of 4 to 5 years from having a
truly integrated office approach.

Datapoint is now working on storing forward voice and other issues
over their network. Those will be even later in our development. It
really seems to me that the integrated office will be the topic of the
eighties from the point of view of Digital and it will be at least the
mid 1980's before we have a major offering if our evolution parallel's
Datapoint's which it seems to have in the past. If the market will
wait for us, then we will be in fine shape, otherwise we will miss out
as others beat us to the punch. I'm concerned that the market won't
wait.

SUBJECT: SPACE GUIDELINES FOR TOMORROW MEETING

Excuse the poor form as I couldn't go back and edit the draft I sent to John.
One sure gets an appreciation of what systems should be designed like
in using this...but I digress.

The attached is a starting point. In addition, I feel we may be
going wrong direction in SS by having it co-locate in Hudson. Namely,
Hudson is going to expand too in the chips area and I don't understand
where they are going to go. Why don't we just let them expand there
as a semi operation, and not make them go somewhere else because their
site is all used up with hangers on?

We need some really good thinking in this whole area... and it will have
to be done by a good team that will be in constant communication with
us. It will be intense for a month or so while this gets done. Let's
persevere... it is really the design of our organization...

and is
our job.

SUBJECT: GUIDELINES ON SPACE PLANNING (DRAFT FOR YOU)

In order to get our space plan to meet the 1990 constraint, it is necessary to add some guidelines that we feel will meet the corporate desire to have only 20% of the poplulation in Massachusetts. Rather than require a corporate bogie, we are going to take the position of putting together the most aggressive plan possible...and then see what this is in terms of the effect.

To me, the ideal is reasonably clear: make 495 the highway to connect all sites and to have these sites as close as possible.
Coming off the ideal then, here's the guidelines I'd like each
OOD member to use:

1. No growth in Massachusetts.
2. NH is already commited to an aggressive growth. Grow the Comml and Computer Products Groups in accordance with their growth rates. Leave SR2 as space for growth of SR1. Leave Dist. Processing in TW.
3. Grow systems groups in various volume plants to assist in the move to Dock Mergeable products.
4. Establish a major engineering site in SW for terminals, with
residual in Mass at no growth.
5. Establish a major engineeing site in NE co-located with Mfg. for Mass storage. I.e. this would be the growth site. Furthermore, NH and Mass would be off limits for growth.

6. Plan an organizational move to RI in this go around.
7. Cap building 12 as OCE (office of Central Enginnering) for LP,GB,JM,SF, and MK.
8. TOPS to co-locate in a fixed, no growth building with Will.
As this support and central part of this organization grows, it
would co-locate with systems customers and prototype plants.
9. Consider co-location of low end mass store with low end systems.
10. Point 1, would be subject to allowing only growth for LES (not Terminals) into Hudson 2 as planned.

If we can base a plan on these concepts, I think we have the potential for a better organization with more dispersal to Mfg.
and which starts seed operations in the SW, in RI, and somewhere
else in NE for Mass storage (the growth/product portion).

SUBJECT: ARE OUR PRODUCTS/INTRO STRATEGY WRONG IN LE?

Have just learned that one can't buy an 11/23 in Europe because P/L's and Europe have determined that small systems are too expensive to sell. DCG is the only outlet and it is OEM mainly. Some of my university friends would like them and I think there would be eventual payoff by letting them know that DEC does build microcomputers, something that they would never otherwise know. There outlet is via the reseller.

It seems to me we ought to consider the following:
1. Stop development of small systems because they clearly can't be marketed through our current channels.
2. Build a channel for small system and only or predominantly sell them through this channel.
3. Treat this as a special case of good times, and not introd.
the product at the systems level at all. Let the resellers eg. Plessey have all the 23 modules and let them sell the 23's instead.
4. Offer 02's at the systems levels (apparently they exist) and
then price an upgrade kit to 23's when the board becomes avail.

Given that the recent set of poor market showings in PDT, 78??, 03's?, and now 23's at systems levels, should we do some rethinking? Eg. form a low end product line? Make only a single PL responsible for a product (eg. Minc)?

I am experiencing the same proble in the introduction of the personal VAX...namely ESG is clearly the lead P/L, and it would
be good to introduce it there first. Also, I think in this case
we have a real leadership product as the Personal Professional
Computer for the serious computer user with a big problem or work that they want to run.

Someday we ought to discuss these issues calmly.

SUBJECT: WPS ON AN 11 THAT'S COMPATIBLE WITH THE 8

I understand you are contracting to bring in a WPS on an 11 that's
compatible with the 8.

Can we make arrangements for the QC and tester to insure compatibility? This sounds great to get WPS in the very small 11
area...but we need the compatibility to take advantage of the training, documentation, sales, and customer (MSR) support we have now
on WPS. Let's keep up the momentum.

Can you give Jack Gilmore or myself a call?

MESSAGE ID: 5173246145

SUBJECT: PHASE 0 OF A POINT PRODUCT TO GET A DECENT WPS

I just typed on the CT300 with the bounded system. It was great (especially to have an editor that was responsive and didn't scroll the part off the screen I wanted to work on). The only problem with it is that CT is awfully expensive. We have to go into cost reduction to get CT competitive across the boards don't we?

Julie, Stroll, Fernald and I want this product as part of the next office set. It's the same applications software that runs on VAX and CT, so it's compatible with them fully.

I don't see that there's any problem of the fact that the bounded kernel that runs the application is not ctab because this is strictly a bounded product that ONLY runs this software ((Whatever's written in Koala). The only touchy problem is how much interconnect it has. I'm happy with the ultimate minimum... the terminal emulator! Anything else would be done using the CT350. In this regard, it wouldn't even be capable of document transfer to VAX, if we really want to bound it. It would have CX (terminal emulation).

Let's get on with it, but let's REALLY bound it to the above to avoid having the kernel grow to a full blown operating system that handles all communications, disks, etc.

I'd sure like to be a test site when it has some rulers and if it has CX... this is all I ever use. (I love the Digicalc it has and would probably use that and the HP calc it has too). Please, please, please get one for me. It's the least you guys could do for being such a longtime WPS user!

SUBJECT: WPS/EMS/KO DIRECTION AND STATUS

The attached is indicative of the high degree of confusion and unproductive hassle surrounding the WPS/OFIS/KO program across the Corporation. I believe we must do everything necessary to focus management attention on the critical issues and to limit the level of hassle wherever possible. The following is a brief statement of our current Engineering strategy which I propose we use to help clear the air and focus management attention across the Corporation.

1. Foundation Strategy

The KO project has become the top priority project toward the achievement of the Foundation Strategy approved by the Marketing Committee on 25 August 1980. The first version of OFIS on KO will be a single user, "minimum" implementation of Word Processing on a sound architectural base. Clean architecture and time to market are the critical success factors. The functionality of V1 will be defined by Engineering and reviewed with the Marketing Committee.

We will follow KO V1 with greater functionality in V2. We will also be moving later versions to multi-user operating systems. At present, I believe we should do only this for VMS. At this time, I don't want Engineering to be quoting schedules or functionality on any activity beyond KO V1. I want to focus their attention exclusively on the V1 KO project. We will continue to accept product requirements for future versions through our Product Management organization (Si Lyle's group). I do not want Engineering responding to these requirements until the schedule, functionality, and architecture of KO V1 software is well established and deep into the implementation phase.

2. WORD-11

It was also agreed at the 25 August Marketing Committee meeting to begin immediately negotiating with DPD in an attempt to bring WORD-11 into DEC as a corporate product on RSTS. Buzz Brooks has the action item to report back to the Marketing Committee on how WORD-11 will be sold and supported by WPG and the end-user product groups. I am assuming that if we are successful in bringing WORD-11 in house, we will stop selling the WS200 multi-user PDP-8 system. In addition, I am hoping that the Electronic File Cabinet (EFC) will be unnecessary with the acquisition of WORD-11 as a corporate product, in that a bounded version of WORD-11 will accomplish similiar functionality.

3. Electronic Mail

Engineering still has a commitment to produce an Electronic Mail capability (DECMAIL) on VMS and test market this product on VMS as soon as possible. I am giving the above two activities (KO and WORD-11) top priority within Engineering, and I want to defer (temporarily) planning activity on DECMAIL until the organizational and technical issues surrounding KO and WORD-11 are sorted out. Once this is accomplished, we will provide a firm schedule for the test marketing of DECMAIL under VMS.

I hope this clarifies the Engineering strategy for Word Processing and Electronic Mail as it has evolved rapidly over the past several weeks. I need your support to focus management attention and critical resources toward the successful completion of these critical projects. We need now to strengthen our resolve, focus our management attention, and curb our insatiable product/feature appetites until we establish a firm base upon which we can build. Unless we begin to get an underlying technical base, there will be no basis for building anything!

Meetings and memos do not produce products.

I would hope the people who are moved to continue meeting on product direction and requirements would temporarily suspend their meetings and consider how we might sell the products we have and are trying to buy. Please let me congratulate you on the admirable job you have done in stating the product requirements.

I am personally involved in the design of the base
architecture
and feel we are addressing the requirements.

We will not operate in a vacuum, but will have review in a
well
defined fashion. Furthermore, there will be progress reports
as
we proceed with the design. Bruce Stewart, Bob McKenzie and
Bob
Daley will outline the detailed process this next week.

                                     LOC/MAIL STOP: MR1-1/A65

SUBJECT: OFIS STRATEGY NOT MEETING MAJOR TG NEEDS

As I understand it the OFIS strategy has evolved into the
following series of products:

1. WORD-11 on RSTS Q1 FY82 or earlier

2. DECMAIL on VMS Q1 FY82 or earlier

3. OFIS FOUNDATION WP/EM on VMS, and then other op sys Q1 FY83

In addition there is now a new systems level product, KNOCK OUT, which is in some way tied to OFIS strategy.

KNOCKOUT a small personal computer that can be:

Version 1 - 9 months limited WPS
Version 2 - 24 months with full WP

The Technical Group has concerns relating to the OFIS strategy and the new systems level product.

For 5 months TG has asked for the following requirements to be included in the OFIS strategy. Our concern is that these requirements are not being met by Version 1 of OFIS Foundation nor Word-11.

TECHNICAL GROUP OFIS REQUIREMENTS

SHORT TERM (0 - 18 MONTHS)

- o Layered Word Processing on RSX by Q1 FY82

LONG TERMS (18 - 24 MONTHS)

- o Layered Word Processing on VMS by Q1 FY83. WP must include:

  + Optional Character Set -- Scientific
  + Math -- Including formula facilities
  + Ability to embed Graphics in text -- WP hooks into GIGI and other graphic programs
  + Editor for WP and DP must be the same

- o Layered Electronic Mail with the ability to handle graphics, text and data.

- o Layered WP/EM/Adm Function Products which interface with the software bus of LDP's Total Lab Computer

- o Operating System Priorities

  1. VMS
  2. RSX
  3. RSTS
  4. RT (not for EM)
  5. TOPS 20/10

These needs are a must for TG because we have a large market demand to be met over the next three years. If we had the above products today we could sell the following number of packages.

TG LAYERED PRODUCTS MARKET POTENTIAL
(Number of Packages Sold)

	FY82	FY83	FY84
WORD PROCESSING			
VMS	970	1600	2400
RSX	450	700	700
RT	1000	1200	?
RSTS	150	300	150
TOPS 10/20	150	120	80
ELECTRONIC MAIL			
VMS	670	1350	1900
RSX	280	500	400
RSTS	50	100	40
TOPS 10/20	70	70	30
GRAPHICS TERMINALS to use graphics/text interface			
GIGI	14000	16000	20000
VT125	6000	10000	14000

o This worldwide forecast assumes that we had the

VMS, RSX, RSTS, and RT product available Q1 FY82. It also assumes that the RT system is a subset at $2K, versus $10K for the others.

There is a need for the following OFIS action items to occur.

1. Version 1 of OFIS Foundation must include SCIENTIFIC CHARACTER SET, FORMULA FACILITIES, ABILITY TO EMBED GRAPHICS IN TEXT.

2. I understand that Knock Out is likely to delay OFIS FOUNDATION delivery date of Q1 FY83. If this is so, we need to explore with DPD getting WORD-11 on VMS and/or RSX as an actual product.

3. Also DEC needs to solve 1 year incongruity of WP on RSTS and EM on VMS.

TG needs to understand the KNOCK OUT product with the following action items to occur.

1. KO need to formally clarify impact on OFIS FOUNDATION product.

2. TG should be thoroughly informed about the KO product strategy.

3. TG needs the opportunity to position KO product in terms of our own market strategies.

4. TG needs to meet with KO project team to discuss how it fits our market needs and raise issues of concern.

SUBJECT: GETTING CHARTERS AND ORGAINZED TO SELL WPS PRODUCTS

We are about to get our product acact really together here.
Now
I'm concerned that we may not be able to get the market.
Please
tell me it ain't so. But here's how I see it:

We have to win in the WPS and Office Marketplace. The only
way I

know how is to get the whole DEC sales force turned on in a co-operative fashion. I predict the new line of products will
only get us less marketshare, given our present Gerrymandering of
the products and customers among salesman and marketers.

We currently sell:

78(stand alone); and

the DATAPRO award winning WS200. The 200 is unsuccessful
because it is an 8 and also because the large WPS market
has evolved to be like computing whereby there are new
releases and new features... hence it is limited.

We are shortly introducing and have:

278, and 278 RL as standalones;

WS200s in inventory;

WS200 replacements based on DPD ... call it WS200A;
this is bounded to only do WPS

WS200FC, the file cabinet;

WS200WP/DP, the layered DPD product; and

potentially a terminal only version of the 278; and

the Electronic Mail/Office Automation story.

We have no forecasts of the 278 to speak of, no forecasts of the
WP200A, 200FC, or 200WP/DP, and little experience of the other
groups to sell WPS. We have a competitor that has grown at 70%
per year, and we have the capacity to build 278's. We will
introduce the above. It will:

1. Get the WP salesman their bookings based on large systems. Now they can become an old boy.
2. Get some interest in the other P/L's so these sales persons can feel good. This gets us a large backlog in both the P/L's and in WPS P/L's.

3. Create inventory in old 200's and 278's. The sales
and marketing groups will have conspired to reach Nervana
... big, unshippable, backlog in our standard mid-range
systems.
4. Get continued, negligible market share.

I suggest a radical restructuring of the P/L charters along the lines Ken has been advocating BEFORE the WPS Sales meeting next month. It would give these charters:

WPS- sell all WPS products, excluding layered WP/DP!
End user- sell any products they want. (I know they can't afford to get involved in the 278 or the 200.)
TPG- Use the terminals resellers to sell the 278 electronic only version as a pre-programmed terminal, as part of the VT100, Smart terminal series. It is infinitely better than the kludge they will introduce as the VT131!

Frankly, I would like to see Digital and our customers win for a change by letting the customers buy the product they need, independent of P/L. The above proposal would:

1. Get WPS P/L business automatically by drag-along sales and by non-participating P/L's.
2. The key P/L's would learn about WPS and would sell them directly, rather than having to have to call in their WPS colleagues, giving us a cheaper cost to book.

My admittedly limited view in the field is to see a salesforce groaping with how to sell low cost systems with no tools or leadership from the folks back at the ranch (ie marketing, cause they are spending all their time praying, wrenching their hands and talking to the engineers).

If we persist in the Gerrymandering, then all we will get is a
backlog, unhappy customers, continued complaining salesfolks,
continued ignorance about WP systems by every salesperson,
continued needs for having two salesperson covering a customer,
continued inexperience on how to distribute low cost systems, and
continued diddly marketshare. Remember: the bulls make money and
the bears make money, but the pigs get slaughtered.

I think we have the products and I would like to win!
(The above proposal let's everyone win!)

What you say?

Gordon
PS
Independent of how the corporation measures this, I only intend
to measure us on total marketshare. It's irrelevant who
distributes the product!

Buzz, you could help here by forcing this radical proposal that
will get you more business.

Ted, please help.

SUBJECT: LOWEST COST WPS, ETC. USING LA'S AND COMPUTING
KEYBOARD

The recent proposal to make the smallest wps system based on the
following needs filling out, and Ken and I would like to move:

- LA12, a portable system not unlike the TI terminal
- LA24, a super, editing typewriter... WE MUST (like Avram suggests) position the LA24 as a device SUPERIOR to a daisy wheel, in that it has better quality and much more functionality, letting us do line drawings too!
- VT200, half and full page, giving us a WPS in a terminal and based on the fact that a version of our WPS will run in 64Kb
- John Kirk's portable, computing keyboard

BATTERIES, 64KBIT CMOS RAMS, AND LCD'S WILL DRIVE IT
In FY83 the world will be supplying really high quality lithium
batteries with 10 year lives AND 64 KBit, low power, CMOS rams
enabling us to have 2 pages of storage in a terminal for only a
cost of $10. We can also make portable cartridges with the chip
and battery in them that will take the place of floppies for some
applications. Also, LCD's are getting bigger and better. A
display to look at several lines is probably adequate.

I suggested the first two, and thought that we might want to
offer as an option, a simple crt monitor or tv interface so that
the user could do more editing based on looking at more of

the
page. It is interesting to note that we will be facing many
competitors of electronic daisy wheel typewriters in the
future
who also can do all of the functions, buy arbitrary character
sets and line drawing. Inevitably, the market will pull them
to
first have more and more page storage ala the IBM memory
typewriters and then an interface to computers and TWS/telex.
Therefore,

LET'S BE NUMBER ONE IN LOW COST WPS TERMINALS!

WHAT WE NEED TO DO:

. Resurrect one of the many hardcopy-only editors that we used for many years before (circa 65-75) we had crts (e.g. SOS, the BSR editor we used in the LA36, the TI editor) and decide which one is adequate (maybe it's TI, due to base). BRUCE, please use Kaola to program us several of these editors so we can specify the editor experimentally.
. Look at the requirements to add this into both the LA12 & 24 (I trust this is an add-on due to schedule interference!)
. Look at the requirements to add a CRT to both the LA12 & 24
. Make sure the computing keyboard will do this job
. Determine the take away files by allowing a user to attach a standard tape recorder or dictating machine and having the embedded modem for each of the above systems directly drive the tape recorder for file storage ... maybe as simple as one document per cartridge.

Can we get a plan together from the various quarters to do
the

experiments to see just what we have and what we need?

SUBJECT: SLAVED TUBES ON WPS FOR FORGRD/BACKGROUND AND SECT./MGR USE

Your idea of slaving two slopes together for the manager can best be solved by taking two 100's and paralleling the inputs and outputs so that either scope can be used.

Stan and I were discussing a similar system where it would be great if his secretary had a two channel wps system, like a 2 push button phone. Either terminal could communicate with either channel. One wouldd be set up for viewing or mail for the manager (who is presumably less adept at doing these things) by the secretary and then control passed in the same way that a telephone call is passed. The manager would go through the mail or wps message log by hitting a few keys and there would be conventions.

MJ...let's get some switches for our terminals and try this, given
that we have a wps200 and we can operate 2 channels in parallel or
switch to one another.

Also, typed messages would be passed to the manager via the wps in this way. We would have to figure out simple ways to pass message back, but in some respects, just having Stan or Julie do plain old wps editing by typing Y or N for most of the things would go a very long way to working.

Well folks, let's try it. It would be a big help to MJ and I and I suspect it would work well in both the single and dual channel systems.

Any comments. (Jack will you get the hardware switches together
for us to connect right into our terminals?)

As a seperate nifty device a user could use this switch so that they could do foreground and background processing. Often
times I want to simply interrupt a wps or ems i/o and go to another
channel to send off a wps or write down a letter or note without
changing context. Also, this would let a person initiate a long
list processing job and switch to another context.

The awful beauty of this is that it is a simple hardware mod and requires absolutely NO software... Yet it potentially gives us
a really useful capability for either single or multi-user systems.

Another reason why a multichannel system can be made to be useful.

SUBJECT: WRL CHARTER

GB3.S8.54

After visiting the bay area and Stanford, it's clear that the
Lab was
a great idea and represents an incredible opportunity.

1. LISP

I hope that it will provide a home until development
groups reach critical mass; e.g. Mahendra needs an interface

(Xerox, Teknowledge, Stanford, . . . TSI) to do the LISP work.

2. Print Service

The opportunity to get a decent graphics and printer interface with Brian Reid sounded very good.

3. General lab for ideas

In fact, it would be nice to have enough lab space so that we fabricate hardware for various faculty (consultants?)

4. Stanford CS/AI Project

Similarly, if and when Bruce Delagi et al get a design for an AI Semantic Net Machine, it might be worth doing the work there -- (my current feeling is that universities should work on the design, and the detailed engineering and fabrication should be done by companies (to transfer technology and save university resources).

5. University-Engineering Net Gateway

Berkeley asked to have a link to us. Is it possible to make a "safe gateway" at your site so that mail can be sent, and logins can be filtered out? Sam, shouldn't you propose links of this type into our engineering net?

6. SRI Graphics Work.

Titan looks like a great machine to breadboard various graphics algorithms on.

7. Lawrence Livermore Labs -- Packaging

LLL looked much more active than it had in the past. We have an opportunity to cooperate on packaging -- their S1

(Mark
III). (Lowell and Tom are looking for an invitation.)

8. LLL -- mP.

I offered to get them 50% on a 784 (4Pc - shared Mp) for two projects: software to test multiprocessors before they get their Cray 2 (mP) and the S1 (mP); and the dataflow simulation. This later experiment would allow the basic work on dataflow that I think is going to payoff -- the language to drive large mP.

9. AI Applications Group

This could start at WRL, but should move out when it gets larger.

Gordon

P.S. Mostly right now I'm excited about the group because we badly need Titan.

SUBJECT: WS200 VS WD200

I just read the based techinical brochure on the WD200 and I am scared to
death. If we have 100 in field that are commits, we have a major problem.
No way, can I see this being a viable product. Certainly we have to decommit.
I don't even think we want to admit that it can be run as either wps or as a
dp (shared system), cause we don't have any support for the shared version.

Given the small number out there, only $5M, I believe the best thing might
be to use some system like RSTS as the host and use the DX software to get the
sharing and to go back to a different form of shared system.

Right now, I'm also very sceptical of how many offices really want the
shared system anyway. Jack, you have to lead us through a segmentation method-
ology so we can understand where it would work and why? I can't see the average
set of secretaries having this machine in their midst. It has all sorts of
lokc-ups when stuff is improperly assigned, it will have file back-up/ roll

back, etc. problems that are implicit in managing installations. Somehow
fixing these seems like a never ending task, and it's another operating system.
As far as I can tell, the people who really want them are the DP managers so as
to insure tenure by making others depend on them for system support and possbily
programming (DP) which will insure lock-in.

Clearly we have to get out of the WD. For the people who might suit us, I
think giving them a system that does DP, and stores their WP files may be the
best and cheapest way out. Let's be quite open about the possibilites--let's
not try to design our way out of this one, the 8 is well beyond its depths now.

GB1.S1.55
a
Wulf has worked in two major areas of computer science:
machine architecture and operating systems; and
compilers for a broad class of languages and machines.

Wulf was the main architect and leader of an effort that built one of the early multiprocessors, C.mmp, using the Hydra Operating System at Carnegie Mellon University. This work, circa 1970, triggered much of today's work on parallel processing (currently 50 research efforts and about a dozen products are predicated on multiprocessors). In 1969, Wulf participated in and contributed to the design of the PDP-11 instruction set (architecure) especially in regard to programmability.

Wulf's main work for the last 10 years has been in the science and technology of compilers that are capable of handling a large range of languages and machines. The techniques have been reported for others. In addition, his first language, BLISS, has been the implementation language for Digital Equipment Corporation for 10 years. This compiler proved that machines could consistently produce results that were better than system programmer code. Three years ago, Wulf and several associates established Tartan Laboratory to "productize" this knowledge of Production Quality Compiler Compiler (PQCC), ie a compiler capable of generating other compilers from a description of the machine and the languages. The first compilers are now available and live up to the quality, efficency and cost goals. Tartan has the potential to revolutionize the compiler/language industry into an engineering based discipline.

b
I believe Wulf is the best compiler person.

c
As a professor of Computer Science at Carnegie Mellon, Wulf has contributed to the training and body of knowledge.

d
Wulf's contribution has been as projectleader, main idea generator, principle author and principle programmer.

F/U 11/8

I've just spent several hours interacting with several people from Xerox's Research Lab at Palo Alto. Overall, Xerox is paranoid about IBM and Kodak as competitors; and they've been fairly unsuccessful at getting more than the copier in the office. Their acquisitions included publishing houses, Diablo, Versetec, and Xylonetics (a precision plotter company). They're trying to sell word processing systems.

The Palo Alto Lab has probably the biggest collection of bright computer engineers and scientists I know of, and they've put together some quite significant systems that could revolutionize the office.

In contrast we're doing a number of evolutionary products, trying to get the market to adopt them, and we'll learn from and build better ones. I suspect we'll get there much before they do...if only because Xerox may fundamentally just be a company that was very lucky with the copier patent and smart enough to promote it! At $5B, it's hard to think they can make any movements in Manufacturing-Sales-Engineering...and they're afraid to take risks.

<u>Sales</u>
I'd like us to visit them at Stanford to try to sell them office computers. They're putting computers in their word processing equipment and in the fancier copiers. If we wait, they'll do their own thing. Bill/Win, would you join me? There are sales everyplace else (e.g., in Engineering and R/D). Are we selling to them now? I have an idea of organization. Who's the National Accounts person(s)?

<u>Purchase</u>
Also, I'd like to get them to make copier technology available as printers as alternatives to what we use in the form of line printers. (In house use, for example, could be quite useful.) Ed/Bob, should we go?

We should use the Versetec in house.

SUBJECT: XEROX MAY BE A COMPETITOR...

I was wrong. I didn't think they could move fast enough or use their research output in products. Now it appears because of the small size of their startup office products group, they can really move rapidly and get things manufactured quickly... just like a small company. Furthermore, they do have stores and salespersons to sell very low cost products. Probably the secret is they sell very large quantities to a few users to get high ticket orders, just like our salespersons do.

Sounds like another reason we will want to roll over and play dead!

As a counterproposal:
Let's have an aggressive product announcement of the
 .278 for standalone use and as terminal emulation
 .Shared systems with all the bells and whistles
 .Shared systems with Dataprocessing
 .EMS
 .DECset

All these exist, are compatible and have to get to the market!

When can we start behaving as though we want to supply products for this use?

SUBJECT: SCORE ONE FOR XEROX

You all missed an interesting product presentation by Xerox today. As disapointed as I was by the IBM Displaywriter, I am impressed with the 820 and Xerox`s family of Ethernet products.
The presentation today focused on the Xerox 820. Key points on this product:

-Price $2995 includes display, keyboard and two 5" floppies.

-By using th CP/M operating system Xerox can offer a complete set of applications on the 820 due to the software existing on CP/M.

-In addition to WP they are offering a Supercalc(?spelling) which is a row/column table capability.

-When the chip is available from Zilog the 820 will tie directly to an Ethernet cable.

-The story is Gordon that Xerox started the design in January of this year and by April they were gearing up the manufacturing capibility.

What I like about the Xerox offerings is that they are offering a family of products for the office. They now have a series of personal computers in the 820, 860 and Star and within a few months an electronic typewriter. These all will connect to an Ethernet which can provide a file server, a print server, a comm server and within a few months an interface to the 5700. This is a set of equipment that we need to get some experience and I believe we should proceed with our plans for an Ethernet pilot in Tewksbury.

Given that it is going to be at least three years before Digital has a set Ethernet based products I believe that DIS should make available to the internal users the family of Xerox based office products as a second source to the DEC office products. Two points here the 820 is not that much more than the WPS-8 and as I see the value of an Ethernet concept is in the ability to have a multi-vendor highway. In the long run I see more opportunity for DEC and Xerox to get their systems to have a good interface on Ethernet. All the two vendors have agreed on so far
is the lowest level interface. If we bring in Xerox based Ethernet office equipment I believe DEC will understand better
how to build its local area network products.

I have also asked Kevin to submit a purchase order for six 820s for internal pilot use. I would like to see Gordon Bell, Ed Krammer and a few of the other individuals interested in office products experiment with this product.

Xerox will also be willing if some top managers from DEC want to view the 820 and Star to give a demo in New York or with a little arm twisting will bring the systems to Maynard if I have a couple DEC VPs on the list.

I now believe that Xerox will sell the idea of a local area network and I recommend that

DEC take advantage of an opportunity to obtain
some good tools for internal use and at the same time
learn how to build better office products.

It would be helpful if we could get an organizational map of Xerox. I met Bob White, who is A / The Vice President of Engineering of Xerox in Rochester. He knew that we were interested in licensing Ethernet, for example. I also asked him to speak on our behalf to the issue of why not standardize on the PDP-11 and VAX-11 architectures within Xerox. He said he'd raise the issue and get us a hearing somehow. He also said there is a new person in charge of all these products that are relevant and that we should make hay now, while there is a 6 mos. honeymoon and the person can make decisions. The new person is John Titsworth, formerly in charge of operations at CDC. I feel comfortable enough about calling him if there is a need.

We've got to get in bed with someone on this. May I suggest we make it the
#1 corporate target to have it be ATT! Let's sell them on our equipment.
We're their friendly, helpful, non-competitive Mini supplier. And we'll
license, co-develop LSI VAX, etc.

Subject: XTEN Petition by XEROX

I will be happy to send you copies of the Petition. I am also

sending copies
to the reset of youas you might find the market projections for EMS type
services interesting. Dick, the only other info is a 4 page glossy that adds
nothing. I don't have a copy. If the Yankee Group Conf is held on March 21,22
I will bring back what ever info I get and make it available. The seminar
may not be held as Xerox might back out and not provide a key speaker.
Network Analysis Corp is doing a lot of work for Xerox on XTEN, however are
under the tightest non disclosure agreement I've ever seen. An interesting
twist is that XTEN could become SBS's biggest customer if the price were
right. Under such an arrangement, their services wouldn't compete but would
complement. SBS getting the F100 and XTEN going after the rest who can't
afford the earth station start up investment but could afford a roof top
microwave investment.

Dick Eckhouse:

Please contact Alan Perlis at Yale 203-436-8160 to see if we can help them
ins some way on their order for 220K VAX for which they have only 120K.

They have an asst professor , Josh Fisher who is wanting to do Research
on converting vertical microcode to horizontal microcode. He has
apparently done this already to some extent and vax looks good to extend
the work. I said we needed his work and/ or his consulting talent and
we should contact him (Wayne Rosing should?)

SUBJECT: YALE

I have a lot of personal respect for Alan Perlis and the
Yale CS Department is improving. Yale is generally regarded as
a plum, especially to IBM too. The 2 x 2060's are taking over IBM.
It also seems the CS Department is trying successfully to
displace the CC (which is IBM dominated) and this is another straw. Hopefully,

we can support them in various ways to continue our stronghold.

Gordon

MESSAGE ID:
5181987944

SUBJECT: YALE CS DEPT. VISIT:SEVERAL OPPORTUNITIES TO
LEARN/INTERACT

I spent the day in New Haven and found interesting work.
Also, they'd
like to interact with us.

PARALLEL COMPUTATION

Prof. Josh Fisher is heading this. They have three
interesting
activities:

1. A compiler for building dataflow graphs that can be

executed in parallel. I see this as an interesting program for our own PPA. They are currently using it to compile fast microcode for the FPS 164 (see below). The source is T(iny) Lisp, and eventually Fortran. Also, they compile ELI as it's designed.

2. The ELI (Extra Long Instructions) machine is being designed. Consider it as either an ILLIAC IV-like machine with control of all units or a microprogrammed machine. A long, 500 bits or so, instruction controls several (say 20) arithmetic/primary memory units. They want to finish the design and then get someone to build it. I said we might want to build it if someone would pay us to do it,

providing
it looks good.
(Incidentally, we need to build much, much more hardware to
get the experience and learning curves!)

3. CAD is exciting, different but similar to our work on the
2080. It's written in LISP and starts as a data-structure.
They're doing display programs that "view" and operate on
this structure as needed. This is totally different than our
CAD which starts with a display input. Also, they're working
on automatic design across levels.

LISP

John O'Donnell (203-432-4666) heads their center and is remarkable in
his understanding of hardware and software. His group is doing
T-LISP, and they are quite concerned about a really good LISP on VAX.
They may be a resource.

PROF. MARTIN SCHULTZE (APPLICATIONS)

Is doing programs for Numerical Analysis of Scientific problems (CAD,
CAM, Scientific Dataprocessing) including VLSI. ESG's supporting his
work. They're building a large memory for the FPS 164 and it also
attaches to VAX simply. He said the problem with a Cray is simply not
enough memory. He thinks an FPS (or even a VAX) with 100 Mbytes will
outperform it due to I/O limitations. This means PPA should

have 128
Mbytes! (Only a $128K at current prices.)

He's like to work with us on microcode for the 780. Their compiler
really addresses the difficulty in programming the 164. Shouldn't we
simply build the large primary memory for the system, and market: a
780, large memory, the FPS 164, and their compiler?

ROGER SCHANK, DEPT. HEAD (436-0606) AND AI RESEARCHED

ROGER SCHANK, PRESIDENT, COGNITIVE SYSTEMS INC. (203-773-0726)

They have 15 or so programmers and want to build and sell an AI-based
Small Business System. They're leaning toward Appollo. Julius had
better get Bob Daley, Bill Noyce, Norma Abel, John O'Keefe et al there
to persuade them to use our VAX (LISP) since he wants to decide within
a month. The goal is a less than $50K system for 6 users and LISP and
a good database system. The Appollo will be down to $20K in a year.
Let's sell VAX!

The breadboard of this system is quite impressive and convincing!

Subject: **Your trip to the West**

To: Dick Clayton, ML12-2/E71   Date: 6/17/79
From: Gordon and Gwen Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Here's some comments on your request: (Where Gwen and I differ we have made a special note.)

Avoid Fiji like the plague, don't let anyone talk you into it including a travel agent with a deal. It combines the worst of the English and the Indians (who are now the majority of the population). The important thing is there are great alternatives in that part of the world described below.

I don't see how you can possibly see Japan and Australia in this single trip and in a three week time frame. Would certainly drop Japan because it's clear that we'll all spend a lot of time there on business in the future. Have lots of places to go there, but won't mention them here.

The itinerary would look something like this:

Days 1-2: Boston - Honolulu: Kuilima Hyatt on the far side of Oahu. On travelling across the time zones it is important to have breaks to get acclimated and rested. The Kuilima Hyatt is where we stayed and where the natives go to get away from Waikiki. Renting a car at the airport you can see the island and get there

-- a very pleasant resort and a opportunity to see the island, go diving or go surfing, and rest.

Days 3, 4, 5: Taiwan -- time for the office and to see something. (Gordon thinks this could be two nights and not three.)

Days 6, 7, 8: Hong Kong: Repose Bay Hotel (do not let the people at the DEC office talk you into staying in the city.) This is 45 minutes from the downtown on the opposite side, over the wonderful cliff. The hotel is where "love is a many splendored thing" was filmed. It is the classic English colonialist hotel: big verandas, tea served properly etc. You can always eat in the Chinese restaurants etc. but live in old colonial style.

Days 8, 9, l0: Bali: KLM flies there from Hong Kong with a stopover in Djarkarta. If you want extra days for a vacation this is the place to do it. There are reefs for snorkeling, diving; temples and dancing for sightseeing; and excellent Indonesian food. Indonesia also has the advantage that of all the places they still have local crafts centered in Bali with batiks and jewelry and things that one might want to purchase, without being the kind of warehouse that Hong Kong is. (Gwen though, in Indonesia on a UN mission just couldn't go on a vacation -- had to return for Gordon's parents anniversary and this is on our life list as a must to see.)

Days ll, l2: If you are lucky you can fly Bali-Djarkarta-Darwin-Alice Springs in one day. If you are not you may have to stop over in Darwin -- not particularly worth seeing. Alice Springs is the desert outpost and really the place to get the flavor of the Australian outback. One whole day is plenty to see it.

Days l3, l4, l5: Sydney.

Days l6, l7, l8 : Christchurch.

Days l9, 20, 2l: Christchurch, Auckland, Tahiti in one day. Stay at the Travellodge. We stayed there. On every Saturday noon they have a local group of real dancers perform. We saw a church group from one of the small islands and it is really seeing good folk dancing. (The dancing at the Club Mediterranee in contrast was an absurd put on.) It is convenient to the airport, snorkeling, a rent-a-car around the island one day is easy and fun. Tahiti has the advantage (over Fiji) of being Polynesian in stock (not Melansian) and then having the French (not the British) as colonists. The Chinese are in there too to get the gardening and trading and work done. There is nothing to buy there in way of native crafts but the people are open and friendly in contrast to any of the other resort areas like the Caribbean. Make reservations to get a room over water in one of the huts...i.e. don't stay in the main building.

Day 22: The direct flight from Tahiti to L.A. goes at night and then you arrive in Boston the middle of the next day. (Anyway with the dateline you gain and loose a day and it all comes out even in the end.)

If you are planning three weeks with an extra weekend thrown in then you have one day to play with and add to something of your choice. We feel that you might just live through this but there really isn't time for any rest.

You could probably give up 1 day in Tahiti for more Bali time, but the stop is easy and worth it. Alternatively, if you gave up Bali (not advised), then you could get to a couple of the islands like Bora Bora (see Hurricane where we saw the movie being filmed) and Moorea and just use the Club Meditaranee, tacky but cheap and lots of diving, swimming, etc. facilities. There's a really stoggy, expensive Hotel Bora Bora to get rest if that's what you want.

Decide on the exact itinerary before hand and don't make any changes! Spending time in that part of the world getting air or other hotel reservations is a drag. Recommend the Brooks Brothers summer suits that are now supposedly on sale that are wash and wearable. Go out of your way to not take very much...certainly less than 40 #'s per person and only 1 bag plus light carry ons.

Rodnay Zaks
President
SYBEX Incorporated
2020 Milvia
Berkeley, California 94704

Dear Mr. Zaks:

In reference to your letter of November 2, 1978, sorry I'm not going to be able to review your books on microprocessors, although I have perused them briefly.

I'm sending you a copy of our recent book, Computer Engineering, which might contain information of use for future updates.

Sincerely,

Gordon Bell
Vice President,
Engineering

GB:ljp
January 12, 1981

President of Zebco
P.O. Box 270
Tulsa, OK 74101

Maybe you can read the words: "American Craftsmanship" on the Zebco reel. Notice the lack of winder and holding nut. The reel on the left was made somewhere in the Far East.

Enclosed is a photo that was taken last summer on a rafting trip on the Snake River.

Since I'm not an avid fisherman, I was only mildly irate that

I couldn't fish for 3 days. Since I fear and understand the Japanese as competitors, I can sympathize with our dilemma of being able to design and build competitive products in America.

In this case, like many products, it's probably just poorly engineered - not totally the problem of craftsmanship.

Sincerely yours,

Gordon Bell
Vice President, Engineering
Digital Equipment Corporation

BRIAN CROXON
BILL DEMMER
SAM FULLER
JOHN O'KEEFE

DATE: FRI 19 JUN 1981
FROM: BILL STRECKER
DEPT: VAX ARCHITECTURE
EXT: 247-2130
LOC/MAIL STOP: TW/A08

SUBJECT: LICENSING OF THE VAX ARCHITECTURE

I have had several phone conversations with Bernard Pueto and John Banning of ZILOG. They are interested in licensing the VAX
architecture for use in their next generation 32-bit microprocessor.
Pueto was reluctant to discuss the microprocessor without a non-
disclosure agreement, but I extracted the following

information:

1. Single chip processor plus optional floating point chip.

2. Available in 10K/month volumes late CY83/early CY84 (18 months).

3. 2-3 MIPS. We had some discussion about what a MIP is and concluded that the processor performance goal was 2X - 3X 11/780.

4. Would implement (with the FP chip) the full VAX architecture including memory management and excluding the decimal instructions. The exclusion is due to an on-chip microcode space limitation.

5. Is implemented in a proprietary "non-memory type" technology.

6. If they did not get a VAX license they would implement the MCF Nebula architecture (a VAX derivative).

Because ZILOG has a severe time constraint they would like a quick answer from us.

I think we should seriously consider this proposal. As you know, I have repeatedly suggested in the past (with little success) that we more aggressively license/offer as a standard our architectures. I believe that we are rapidly approaching an era in which traditional hardware architectures are going to be dominated by official and de-facto standards and most cost effective hardware is going to be built to these standards.

I also believe we should seriously consider the product implications of the ZILOG processor. Assuming the availability/performance goals are met (clearly we should be skeptical) a gate array NAUTILUS in FY85/86 is a loosing product technologically. Another cut is that in a single/dual processor version, the ZILOG processor would cover the entire current and planned VAX product space. Maybe we should concede the low/mid range to the microprocessors and focus on Hypervaxes and software.

I would like your help on how we proceed to give ZILOG an answer.

8:21 EST

FROM: GORDON BELL
cc: GVPC:
DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: RE: ZILOG CHIPS TO IMPLEMENT VAX

Agree we should be very careful and I don't see how we could license VAX. Although I think the times (competition from Semi-computer companies and IBM) may be very different than in 75-80.

I think we could construct some deal where we both could win, provided they can deliver anywhere near what they say.

We may need Zilog, like we needed Western Digital.

I say we should listen to anyone who promises a chip that's 2 - 3 times a 780. This combines Scorpio, Nautilus and Venus in 1 chip... probably too good to be true, but clearly doable in the next 5 years! I say listen for a little while.
