IV. Subject: **Creating Distribution Lists Using the WPS**

To: Distribution

Date: 24 OCT 78
From: Louise

Principe

Dept: OOD
Loc.: ML12-1/A51

Ext.: 2237

Following is a list of step-by-step instructions to help guide you through the generation of a memo and its distribution list.

Creation

1. Create your memo using the abbreviation file (file {2) to call in your memo header, i.e: Depress gold key and then depress the abbreviation key and mh (for memo header). The

following is a sample for you to type in {2:

```
<<mh>>+---------------------------+
|   |   |   |   |   |   |   |   |
| d | i | g | i | t | a | l |   i n t e r o f f i c e   m e m o r
a n d u m
|   |   |   |   |   |   |   |   |
+---------------------------+
```

Ruler settings:
L-------------------------------------T--------------------------------R

Subject: <>

To: <>

Date: <>
From: <>
Dept: <>
Loc.: <> Ext.: <>

At this point you go to the top of the file, then advance to each <>, rub word out, and fill in the appropriate information.

2. Type the body of your memo and file it.

3. Now you are ready to list process to compile your distribution list for the memo (see appendix).

4. At this point you should decide which group (or groups), see appendix, will make up your distribution list (see appendix). Prepare your spec accordingly. For example, if it is to go only to OOD members then your spec should read as follows:

If <group> =<*>OOD<*>
then process record

If your distribution will include OOD and Marketing Committee (MKT), then your spec would read:

If <group> =<*>OOD<*>
or =<*>MKT<*>
then process record

If you want to exclude your bosses name (for example, Gordon Bell) from the distribution list the spec should read:

If <group>=<*>OOD<*>
but not if <name>=Gordon Bell
then process record

5. The form below is set up for distribution lists for memos. It is not necessary to put a page mark in your file since it is already in the form -- however, when list processing it will ask you if you want to add to the bottom or top of the memo -- always say "a" to add to the bottom of the memo as the form indicates.

V. **Example of a Form to be used for memo distribution**:

-------------------------------NEW PAGE--

D I G I T A L INTEROFFICE MEMORANDUM

```
0        10        20        30        40        50        60
70      79
L........0..T.....0.........0..T.....0.....T...0.........0....T.
...0........R
DIST:<!s><dist>
                <name>               <ms><>      <name>
                <ms><!e>
```

Example of a Form to run labels

<name>
<ms>

List Processing

6. Depress lp and carriage return. The screen will display as follows:

-- LIST PROCESSING MENU --

P = Merge list with a form and print the result

D = Merge list with a form and put result into a document

T = Test a selection specification for errors

Type the letter and then press RETURN

OR Press Gold MENU to recall the Main Menu.

7. Each of the three selections will lead you through the list processing process.

8. Now you have merged your files and have your memo with the distribution list attached at the end on a new page. Be sure to put in a new "print command" if your memo is more than one page long so that you don't get the header on the distribution list page. It should be put on the last page of the memo -- just before the distribution page.

9. Occasionally you will have a distribution list that is random names, not any particular groups. To do this easily, create the memo as before and type in the body; however, when you are finished typing the memo, hit a carriage return and "GOLD GET "your form file" (shown in #5). Then delete

the <name>, etc. and type in your names and mail stops.

Some Helpful Hints:

1. For memos always generated by your boss (for example, Gordon Bell) you can adjust your memo header in the abbreviation and give a different code, thus creating another memo header for memos only generated by your boss. For example: "GOLD Abbreviation mb" gets us the following memo header. Where as "mh" is a regular memo header without any name or mail stop, etc. filled in.

```
<<gb>>+---------------------------+                    ID#<>
|   |   |   |   |   |   |   |   |
| d | i | g | i | t | a | l |   i n t e r o f f i c e   m e m o r
a n d u m
|   |   |   |   |   |   |   |   |
+---------------------------+

Subject:  <>

To: <>                                     Date:  <>
                                           From:  Gordon Bell
                                           Dept:  OOD
                                           Loc.:  ML12-1/A51
Ext.: 223-2236

                                           follow up <>
```

2. You can also set up specs to be kept permanently in files for lists you use often (for example OOD spec, MKT spec).

3. The Library file (file {3) is for commonly used paragraphs or lists that are not used as often as others. For example, in the Library file, I have Engineering Committee and other Groups not always used for distribution.

4. Be sure NOT to keep a list of OOD or MKT or any of the other groups in your "list" in a separate file. This way, you only update

one file and always have an up-to-date list.

5. After creation of a file by name, it is quicker thereafter to access often-used files by number instead of name, especially when list processing. As you create your memo file, jot down the file number. In using list processing, the following file numbers would be helpful:

List processing calls for	file #
name of list	?
name of spec	?
name of form	?
put results into	?

If there are any questions or helpful ideas, please contact me.

Let's assume the worst. In 16 months Intel will have a reasonable
bit processor on a chip with a 20-bit (e.g., PDP-10) address size.
Their machine will become the industry standard just as the 8080 ha

1. Can we have someone "play Intel
and "play Intel chips buyer" and build some of the competitive

example systems? What are the costs?

2. Can we get the PLAS address extensions solid and put in hardware and then in software (i.e. languages such as FORTRAN and COBOL) so we can see how they compete? Can Fonz 11 take this?

3. Can we implement a much smaller (8-bit or 16-bit) VAX so that we can be competitive at the boar level? What's the cost...at each level of integration? (I.e., where do we/can we compete?)

4. Review Fonz 11 for goodness against 1...especially our bus and peripherals versus current a planned ones from Intel. (I assume the new serial bus is able utilize these peripherals.)

5. Should we just influence them t get an ISP we want, and then use it widely? What if it were th ISP? Suppose our competitors adopt it...clearly a true stateme

September 2, 1980

Mr. Jack Carsten
Intel Corp.
3065 Bowers Avenue
Santa Clara, CA 95051

Dear Jack,

Just a brief note to say thanks for bringing all your engineers here to present the Intel product line and to discuss your process directions. I hope you found it worthwhile, because we were certainly impressed with what we heard. Also, I feel that there is already a better rapport between the two groups.

I hope we can continue to be a customer and a supplier.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Digital **Interoffice Memo**

Subject: **Intel Visit: Now + Parts; Future 8-, and 16-bit Machine (8086); and Fonz 11**

To: Distribution

Date: 3 NOV 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

F/U 11/10

I visited with Gordon Moore, President, and Bill Davidow, head of their Microcomputer Division.

We're doing an extremely poor job of understanding what they're doing and where they're going. In interface chips, there's no competition--their thinking is 2 years ahead of us and increasing. They've not learned the software from us, but by themselves--they're behind, but next go around will be forced to improve. They have lots of programmers but don't know about SW engineering...though they will.

Bill and I made the current competitive chart:

	8080	**LSI-11**

Speed	1	2-(3)->50(for arithmetic)
Memory Size	2K(4K)65K(rom) 4K(16K)56K(RAM)	
Level-of-Integration Sold	<u>chips</u>, boards	boards, <u>chassis</u>, <u>systems</u>
Bus Power (drive)	70ma?(18")	70ma(>)
Software	Assembly;PL/M	Op.Sys. + high level language
Use	terminals control for standalone things, hobbyist	high performance processing: control, comm., arithmetic, languages.
Price of computer part (including mem.& interfaces)	100-500	500-15,000

Note, with the current bunch of competitors of 8- and 16-bit microprocessors we have **<u>NO</u>** competition...next go around things will be different.

Let's get the volume customers now. In one year, it'll be too late!

We do not know the interface chips they're about to introduce. They're not a part of our use, competitive concern in LSI-11, or a source of ideas. Their chips are internally programmable!

It looks like we should be using the keyboard/display/SDLC interface in the LA120 and VT100 for display. [<u>Bob</u> and <u>Ed</u>, what's the story?] [Similarly, <u>Julius</u>, why aren't we using their SDLC chip instead of killing one supplier and making another one unhappy by forcing them to build our unbuildable design?]

[Lorrin, is it reasonable that your charter includes the transfer of knowledge about new chips and the monitoring of marginal DEC designs?]

Future 8- and 16-bit WATCHOUT!

The 8086 is a faster 8-bit 8080--by a factor of 2-4. Hence, there'll be more competition. But we'll be competitive providing we stay to arithmetic based application, and possibly offer microcode.

The 8086 is a code name for a 16-bit microprocessor, which will use 8080 peripheral chips, but will likely be incompatible. Their users don't particularly care, they say, because they are not user programs. In 3 months he'll let me look at it, and delivery is January 78 (I think...but sounds optimistic). Bill, formerly with HP minis, is pushing for a 20-bit address, using a base address scheme. He points out that with 65K RAMS in 1980, the one million bytes only requires 128 chips. Note this is equivalent to the average sized, current PDP-10's!

I find it hard to imagine what the computer market will be like when this basic hardware is available so widely and cheaply. Dick has promised to lead us to this understanding, because it will affect us drastically!

	Fonz 11	**8086**
Memory Size	? 16 bit VA	20 bits
Speed	1 (need FP)	1 (FP?)
Software	11-base	market outside of Intel

Are the resources we have in the low end adequate, given the peripheral chips situation?

How can we solve the virtual address space problem on the few chip 11, assuming they don't do too bad a job with a 20-bit address? PLAS? VAX?

Is it clear that they will set the Instruction-Set Standard for the 80's with this, just as they did with the 8080?

Our 1 Chip 11 - Probably a Significant Bad Idea

It feels like we could, by chasing the 8080 (minimal), lose our traditional business! Now let's assume Intel has a very good 1 chip, 16-bit processor. A 1 chip, minimal (slow) processor without a reasonable address space is a clear loser. Our competitors of small systems will use the 8080 for the very low end, fixed program. We won't have the peripheral support chips, hence at the systems level, (e.g., VT100, or LA120 with floppy or fancy comm.) with memory there'll be a loss!

The situation for performance classes could be:

VAX
.
.
.
White Dwarf
.
.
.
8086 if they don't screw up
Fonz-11
.
.
.
LSI-11 (look, we win)
8085, TI 16-bitter
.
.
.
8080
.
.
.
4004

SUBJECT: INTEL, A PATH TO A FAST, CHEAP AND GOOD NI. WHY NOT?

I am concerned about what seems to me to be stupid behavior in
regard to acquiring Ethernet chips from Intel. Our current plans
call for parts in March 83, followed by volume in June 84, with
luck. Based on the unluckiness and inexperience of Tewksbury in
this regard, I believe we will not get a product using such a
chip until 5 years from now at the earliest. Furthermore, I
don't believe the Tewksbury mob has any need for such a chip
because it is irrelevant to interconnecting computer systems due
to our expensive bus interfaces and the fact that the interface
cost is totally irrelevant to the total cost, especially
considering the obsolete, SSI/MSI systems they design.

Meanwhile, I believe Intel will define and supply first pass
chips in June 82 at the latest, and some of their aggressive

buyers and (system definers)will offer and deliver a product in March 83 fully 2-1/4 years before we do! We will have no input to them because we don't talk to them for some reason.

By whatever cloudy thinking process we are using, and I want explained, we will not interact with Intel to define a spec that we can use, we will not have as good a chip, we will have it a factor of 2 later, and we will blow our precious resources who could be designing something in spending all our time interfacing to something like NINE, count-em, vendors.

The side-effect is that the small systems group, seeing the unavailability of these chips will go off and create an off the wall, and temporary (cause ultimately the market will force us to the standard) alternative in order to put their systems together.
Similarly, they will not interface to Intel because they know that Intel is smarter than they are and won't know what's going on so as to use the Intel chip that is available. They too will require chips which they will start to design, and will come up with the chip such that they will get to the market sometime in 85, given a 1 year wait, a 2 year chips schedule that will take 3 years and a 1 year time to get it in the product.

The net bottom line is that we will have 2, inferior Ethernets fully 2-1/4 years behind our competitiors. Furthermore, I expect these networks to be different than and incapable of speaking

to
each other or to the real Ethernet. This of course will create
another implementation to the real one for a grand total of 3,
with much resources and kludginess.

Dick, would you please get with Bill Demmer to transfer money and
some smart engineering, implementing person(s) from TW with the
explicit goals of:
.Influencing and buying the Intel Chip;
.Designing the small NI into your terminals hopefully, and small
systems for sure so that we will have products that are
competitive with the people who will be using the Intel part; and
.Simultaneously putting an NI on Qbus using standard parts for
interconnecting to NI based systems?

SUBJECT: INTEL: GROVE MEETINGS AND GETTING A POLICY

The purpose of the meeting was to prepare for the Intel meeting and to understand our relationship with Intel at this time. Various people exchanged their own levels of frustration. Currently, it appears, the latest information is coming to me. Little, signicant new product or process infromation comes via the established channels.

For starters, I would like purchasing to develop a single contact point to administer our relationship. It would escalate issues versus holding them in a file.

GROVE MEETING
Dick was calling Grove to change the nature of what we thought was the visit agenda (microprocessor peripherals, general relationship with respect to process transfer).

Our agenda would deal with some shorter term issues: the relationship, problems we have on working on the NI, the poor working relationship on the HMOS I transfer. It would propose an escalation procedure. We would like to be treated like a good customer, versus what we get now by reading about designs in Electronics when they are becoming available. This would include infomation about new peripherals and micros (like te 432). We would like to know about their process direction, especially
2

micron and double metal. Roy is interested in getting information on start-up, as well as various schedules of products. We would like to get a commitment as to what we see as
their bus strategy. Also, we might ask how they'd view chip sales.

The meeting attendees will include: Clayton, Moffa, Zeh, Bell,
Tranos and Fetterman.

INTEL INTERFACE POLICY
Dick volunteered to update what we want our policy to be with respect to Intel. It will include:
.Micros competitive aspects (note their board business now appears to be somewhat larger than ours and is growing rapidly).
.What do we expect from them as a supplier and who is responisble
for managing the various parts of it (getting proces and product
information).
.Do we want to exchance process information?
.How do we think they are doing vis a vis VAX? is there a possible area of co-opertation?
.Other CAD co-operation?
.What is our position about using their peripherals?
.What is our position about using their 22-bit architectures (ie
the 8086 and the 432)?
This would be put together in conjunction with the MOS strategy.

This policy is second on Dick's list, after the main strategy,
although the two are somewhat related. It also deals with some of the issues I had outlined in my 7/28/80 memo on the Intel visit. Specifically, I asked:

.How much do we believe they are a competitor, supplier?

.Can we make competitive products without them? (The sense

of
the meeting was yes, but we could get information from them but it's a hassle. Certainly not worth continuing if the future is going to be like the past.)

.Do you see our need to work with them in the same way I do? (Very muddy sense from the meeting.)

.When will we give up the 11 and user their ISP's and software?
(We won't do it consciously because there isn't a very good interface to even see what they are doing. Note IBM is using the 8086 in their wps, and I am not opposed to using it in ours or in our VT/LA where there will be a large amount of fixed functionality and we will be hitting the 11 address space problem in these terminals over their lifetime.)

All, in all, I feel updating our policy so as to answer these and other questions is pretty important and I was very glad to have Dick volunteer to do it.

SUBJECT: IMPRESSIONS ON VISITING INTEL: YOUR MOVE (FAST PLEASE)

I met with Noyce, Gelbach, Carston, Davidow, Kaufman and also received technical presentations on future products and processes, including Ken Fine, who is doing well and is much appreciated.

I want to accept their invitation to meet with various managers
here. We are a 20M$ buyer and have leverage. Dick, I would like
to work with you to get them here and to frame some of these questions:

.How much do we believe they are a competitor? supplier?

.Do you think we are going to be able to make competitive products without them?

.Do you see our need to work with them in the same way I do?

.When will we give up the 11 and use their ISP's and software?

.How are you going to plan in what is a difference of opinion between me and what your current, de facto direction is? (Maybe
I should go to work for Intel or market for the Japanese or back
to the university or argue for a DEC early retirement plan... and

you can suggest this too.)

Their Strategy
I have a set of memos which are available showing my evolution of thinking on Intel and our relationship since 1972-75. A recent Dataquest memo states that there is a major shift into a value-added component, away from semiconductor manufacturing and into design, software, and systems integration. There's a shift since 77 to all forms of systems level products from memories. Microprocessors have increased from only 13 to 26%, microcomputer systems 18 to 22%, and they have a 50M end user channel.

My view of Intel has evolved, but hasn't fundamentally changed from the point of viewing them as the leading edge supplier who is also a potentially significant competitor. Fundamentally, I believe their strategy is to have the best MOS Process technology and to use this firts in memories and then in micropcrocessors to create leading edge products that will command premium prices. They see software and ISP as the lockin/lockout. Furthermore, they see increasing the level of integration as getting more revenue, but detracting from their technology and only to be used to get the high growth and profit they need. They will forward integrate, as needed to get growth. (We tend to backward integrate to get supply and roi.)

If they hadn't existed, we would probably be in a different product position today, as they may have pushed us, or alternatively we may have been pulled into a higher level of integration.

Some, possibly new, but summary observations about them and us:

.Overall, their top level management has worked together a long
time and is extremely bright. Noyce invented the IC, Moore is
one of the brightest persons I've met, and Vadez wrote the
classic on processing. I have had substantive discussions with
them on software. Basically the requirement for an officer is a
PhD... with a few minor exceptions of people that sell the product.

.They seem to work harder than we do. This seems to be a direct
result of having to manufacture and not sell at higher levels of
integration, where one is dealing with inherently unquantifiable
metrics. (Apparently they have a fettish about measuring
everything, which is a result of training and need in the semi
process area.)

.They have assimilated the art of architecture and language
design faster than any group I have ever seen. Furthermore it is
pretty well understood throughout the hierarchy, especially the
top! In the 8 years I have been visiting Intel, I have seen them
converge to, and in a couple of specifics (eg. Floating Point)
surpass our practice and understanding. For example, in 74 the
8080 (a 16-bit address space), evolved to a 20 bit address space

(the 8086) in 78, and in 80 they made a strategically correct decision to make it a 32 bit VA, and multiuser. I feel this basic architecture of the 8086 with its enhancement is adequate
to compete with VAX in most environments and where it has some
problems in the large scientific and engineering domain, the problems can be solved by simply having superior technology (speed) and doing the softare right. Our first enhancement of
the 16 bit VA on the 11 wasn't good enough, necessitating VAX.
In addition they are experimenting with a higher end machine (the
432 which is supposedly a 148 power machine) that is potentially
better than VAX.

.They really do understand the right things about software. Their goal is to develop "a full complement of compatible higher
level languages across all machines". They are in the midst of
providing the standard languages of Cobol, Ada, Fortran, Pascal
and PL/M on ALL of their microprocessors! Remember we said we
market tools (BASIC, Cobol, Fortran)? Here, I have a very serious reservation about our survival now with our software base, based on recent experiences in the government and in WPS8
where we have a 100KW program that can not be enhanced or even
kept working. Our massive machine language investments are neither worth much against this, but foreover turn out to be millstones to carry that we can't afford to either maintain or
enhance. (Mitch, I'd like to believe you have some really bright
MBA type that can push symbols rather than count beans that could
help me do the analysis of this.) They have, flat out,

outlawed
assembly language programming. Furthermore, their compiled code
is all runnable in the same environment and mixable. They have a
single backend compiler. We have too many who like to work at
too low a level to be a threat to them. In contrast, this means
that they can, with far fewer dollars produce spectacularly
better results.

.They are working the operating system and this environment too.
The raw context switching times are quite impressive. Their high
level slides are worrying about the right things like
abstraction, decomposition, consistency. They use our words
intalking about architecture (eg orthogonality and
completeness).
They adopted the IEEE standard for floating point which I am
convinced represents a significant step forward for numerical
computation using floating point.

.They have really gotten their product architecture at the BUS
level together. In the same timescale, we have diverged and
gotten substantially worse. The tragedy at DEC is that we must
support these evolving half-done busses and are kept away from
using their stuff because our bus (eg. Tiny) isn't the 8086 bus
which it was designed to be compatible with. Thus we get a
double whammy- an inferior product that has to be evolved and the
inability to use the industry standard parts (which necessitates
building inferior parts with a slower techology, to go on our
evolving bus, or using expensive MSI).

.On the process side, they are evolving at an incredibly fast

rate. Note, that they are changing processes about every 2 years, going from 4 micron in 78 (HMOS I), to about 2 micron HMOS
II with double poly now, and projected HMOS III in 81-82. They
are assimilating software and new software techniques, we are going off to develop a proprietary process technology that is guaranteed to put us further behind. Here, our historical instincts and policies are not right because the evolutionary time scale is substantially faster than our decision making! This has turned out to be a classic blunder in planning high technology whether you apply it to governments, industries or to
firms. (Note, I have a paper on planning / policy making in high
technology, based on a case study in Brazil.)

.Their product array is both together and good, as you can all
read in their book, MICROSYSTEM 80 ADVANCE INFORMATION, but you
probably have to talk with them to get a copy. It shows how things are integrated together. There are a large number of chips and plans that we should have influenced and been aware of,
but had nothing to do with. We are afraid to talk with them because they are bright and intimadating. By keeping our heads
in the sand they probably won't notice us. In contrast, we have
built a bus evolution at the chip level that doesn't allow us to
use their work, even if we knew what it is. Their microcontrollers for floppies, and com and crt are pretty impressive. Althoug we might not have used them all, we clearly
wouldn't have made the chips we did in this way. I find that they care about architecture now at the chip level and this is
substantially more advanced than our laissez faire development.

.They are developing an Ethernet chip and we are ignoring them.
There's a seperate memo on this if you haven't bee a party to what looks like cloudy thinking. But the bottom line is that I
have shown that by the way we interact with them,we: spend significantly more money, get two poorer products, get them a factor of 2 or 2-1/4 years later, and as a side-effect set up a
bunch of competitors. The two marginal products then have to be
onverged back to the mainstream.

.They have built a packet bus for their 432, which on the surface
looks incredible in its ability to absorb memory cycles and provide performance. The 432 is supposedly 148 speed, with the
ability to mix multiple numbers of processors to gain more performance. It uses HMOS II. The architecture is more advanced
than VAX, but the big question (HOPE) in our mind is does it work? From the superficial discussions, I think it may be just
conservative enough to work. We can not count on it failing. Thus an interesting side question is what would one do with a one chip processor that is equivalent to Comet? (Clearly no market now, except to those crazy universities and a few of the
engineers that are all looking for a personal computer which has
1 Mbyte of Memory, a high resolution tube, etc.) Of course the
packet bus looks better, on the surface than our BI, but then in
4 years when we get the real BI, we could be better.

Overall, I was quite impressed that they had progressed rapidly
in the last 2 years since my last visit. We clearly have our heads in the sand and don't have the foggiest view of them, because afterall, we don't benchmark against them. They have

the
power to put systems together from the boards they supply to put
Mid range systems together that dominate us in every dimension of
cost, performance, reliability, architecture, and higher level
languages. The best historical analogy I can think of is Friden
with its mechanical calculators versus the LSI-based hand
calculators. But since they are so nice, they wouldn't dare
given the 20M$ (2.5%) we buy from them. Also, it is sort of
painful to talk with them because they are bright and it is
embarrasing.

Dick, Jim, and Bill do you folks ever worry about the things I
do? Is there any way to get you to look at what's going on
outside? Do you or will you hold me reasponsible for your fate
and ability to compete on a post facto basis?

I have a number of slides which they gave me outlining
everything from process to high level languages. Is there some
way I could present them to you or your interested delegees?

I am trying to get some help here, but then again, I do hold you
all responsible for our product fate in 82-84 by what we are
doing now. The fact that we have orders now and maybe in 81 is
totally irrelevant, it only means that you did the right thing in
75-79. With a little,... make that a lot, of work we can make
it, but we aren't going to unless we change our ways. Remember
how tough it was to put the structure together to see a few rays
of hope in the disk area?

Joe Lassiter (482-2700, X2734), head of Teradyne's card test division and head of the group they just purchased from DIGITEST, is buying VAX's and 11's for the pattern generation function (versus their special processor).

Can you call him and get our groups together?

<u>Hidden Agendas</u>

I don't want to continue all these simulators! Buy from them! Let's get the products we need from them.

The discussion should include a broad range of our needs and our directions. Also, would they market any of our simulators? Let's start a dialog.

SUBJECT: INTERCONNECT MEETING

FROM: GORDON BELL & BILL DEMMER

Last Tuesday, 2/12/80, OOD met and on Thursday, 2/14/80, PMC met to
review the data that is being prepared for dissemination to the
product groups and EBOD. These reviews highlighted a number of cross
product issues that need considerably further investigation. OOD has
requested that Bill Demmer structure a process for converging these

issues associated with the Interconnect Strategy.

Since these affect almost all future hardware and software products,
it is absolutely essential we determine a set of scenarios which are
sufficient (although not finalized) to be used by the five (5)
development areas plus HYDRA for the base plan.

Please do everything possible to clear your calendars for a one day
meeting to address this situation. This meeting is scheduled for
Tuesday, March 4th, in the Site Management Conference Room in
Tewksbury at 8:30am.

Prior to the meeting, a summary of the basic Strategy Statement and
the anticipated system and subsystem evolution that is implied by the
strategy will be distributed. These will be the basis of discussion
at the meeting.

To: Sam Fuller
CC: Bill Johnson
From: Gordon Bell
Date: WED 20-DEC-78 23:06:54 EDT
Subject: more on the interconnect

My off the wall reaction to Wayne's proposal for a new bus was generally one
of disgust. This may be somewhat unfair, but I'll resist anything like this
until you get the act together.   I see it as another local packet switched
(ie within a backplane) bus that is incompatible with the HSC50 backplane and
is new and that there is othing out there fore. Also it only goes on comet
and nebula? and Hydra comm system. I suggested just using a unibus or q bus
for this.   Alternatively, you might figuer that we need a range of packet
wswitched backplane busses, just as we have a range of inter cabinet busses
such as iccs, ethernet an 50Kbaaud multidrop. for other interconnect.
Somehow, we have to get this morass settled down aso we can have some
longevity.   Is it possible that you could make a range of these
busses/modules that could interconnect on a backplane and have them
communicate eventhough they are at different speeds in much the same way we
talkied of a variable speed bus this morining? We just have to be able to
have some way to preserve investment, etc. Does anyone worry about the delays,
ques, races etc with all this packet switching?

SUBJECT: INTERCONNECT PROGRAM REVIEW ATTENDANCE

The problem referred to is quite simple, it goes like this:

1. Sam owns the responsibility for ensuring that we have a viable Interconnect architecture. He has delegated this responsibility to Bill Strecker.

2. Bill feels that he cannot get the job done, particularly in the area of Systems Communications architecture because he cannot get the support of the VMS group.

3. Because Bill feels he cannot succeed, he refuses to be tagged as the person responsible and stand up at the Interconnect Reviews and report "no progress".

4. We in the Interconnect Program want Sam to resolve this issue and get the architecture phase moving. Actually, Interconnect Architecture is just an example of a bigger problem, and that is defining how Sam wants to carry out his architecture responsibilities and get support from the line organizations to

make it happen.

This is not the first occasion of this problem. We have been working
patiently with Sam and Bill for several months to get things moving.
It's not happening and we are at the critical juncture for results. I
believe Sam needs some help to break the impass we seem to beat.
Maybe you can provide some guidance. This cannot remain unsolved any
longer because while we speak products are being cast in concrete.

Given that we are going to take the time to do the planning right this Redbook schedule versus meet an immediate, crisis schedule I'd suggest that the issue of building the homogeneous, distributed computing environment be addressed. The strategy, is given in Part IV of the EBOD Handbook (front matter of the Redbook.)

It seems like the components which are being interconnected are going well, but alas, the interconnection links (busses), their interfaces, and the software to support the structure need significant, overall definition, planning, and a schedule.

These parts include these hardware and software parts:

1. ICCS for high speed interconnection at a single site
2. Intercomputer switching among the distributed machines
3. Terminal interconnection constrained by various current and foreign protocols. This includes all host, terminal, peripheral etc.
4. Hardware interfaces for the above 3 plus unit record interfaces so that the whole net is complete at some future time (when?)
5. Any functional components necessary for a complete system, such as a concentrator, or data base computer
6. Gateways to other networks

Don't we need a seperate section of the Redbook just on this aspect together with who's doing what and when?

What's not being done?

Who'll take responsibility for the section?

BJ, will you get the people together to scope the problem so it can be handled both in the Redbook and then implemented?

SUBJECT: THE INTERFACE CHIP THAT JUST GOT APPROVED

I'm delighted that you got the funding for the Tiny interface chip, but
I have many major concerns that it signalled.
1. Tiny sounds wrong--I thought it was 8086 bus compatible, hence why
do you need any interface chips?
2. Tiny seems to have more and more warts, vis a vis its ability to use
dynamic rams, and do dma, etc.
3. It's another chip for the interim process, not the Hmos one.
4. It's another handcrafted job...and they are always late.
5. It takes resources away from getting a methodology for doing what
I thought you were going to develop as fast turn around using either
standard cells or gate arrays.

Can we look at the whole tiny program? I have a feeling it is an abyss.
(Maybe just you and roy and I and dick).

Subject: Interface to VMS Software Developers (especially universities)

Please send to both Hastings and P Conklin too.

Larry, I just got back from visting MIT who is doing a LISP for us... in
return for some discount. The program looks pretty good, but in order to have
it be most effective it has to be managed (interfaced to) in a reasonable
fashion. Conklin and Poonan were going to do this, but alas they aren't.
Why not???

They have questions, but more importantly they must have a system that fits in
with theVMS runtime system so that other langages interface to LIsp, like it
a standard.

Somewhere in the software oraganization we need a management structure to
handle interfaces to groups doing development of systems which we ultimately
want or are depending on for VAX. Some of these include Pascal (U f of
Wash.), the 2 DBMS type programs (total and 10-22), and ther are no doubt many
others including UNIX which I fervently hope has to run under VMSM instead of
being the root of another operating system. This ca can not be a part time
effort.

LCG (ULF) has had the experience on the 10/20 and they have done it well.
Should it reside there?

Please help.

2 November 1982

Mr. Harvey Cragon
11423 Royal Shire
Dallas, TX 75230

Dear Harvey:

It was delightful to get your letter and encouragement to write an article on interrupts (or lack thereof). Unfortunately, I'm flat out now and don't see how I can. In writing it, I'd have to get into the issues of what's the alternative in cases where they have been used successfully, and how to operate without them in all cases. When there's a fixed program, they can always be eliminated, I believe. The real time programming for the IMP was done totally without interrupts too. SAGE also had an interrupt that could be enabled and used, and like ASC, they used it for power down, too.

I wrote some thoughts on interrupts as they relate to whether a machine has I/O Processors in Computer Engineering, but a fuller article is really needed. Why don't you write the article?

As another matter, I'm incredibly disturbed about the lack of high speed circuitry from U. S. Semiconductor manaufacturers. I noted that TI does get ARPA funding for GaAs, but there was little interest in supplying these circuits to the commercial world.

I believe both the U. S. Military and Computer Industry requires high speed circuits, and the only viable solution is to have a company or company infrastructure that serves both buyers. A single military supplier will be unreliable, expensive and late. A Computer Industry only supplier may not be viable, hence the U. S. computer industry will have to go to Japan for more of its semiconductors.

Is it possible that TI could be that supplier? Would you join with us to supply these circuits? WE NEED HIGH SPEED CIRCUITS!

Sincerely,

Gordon Bell
Vice President of Engineering

I was appalled, and frustrated to find that we still are far away from the above. Thus we defer getting the understanding whether this is really the way of computing!

I thought we had decided to use the 2020. LSI groups the simulators to do work on TOPS 20. When will we get IDEA?

This issue is doubly painful because, as I tried to "reason" initially, we can not afford to make special operating system modifications! Now, I say, get the special interface out of the operating system so we don't have a repeat of this! (This should be a rule in all other internal user groups too.)

INTERVIEW - PART I

What was the first computer that you programmed?

The IBM 650 and MIT's Whirlwind, while taking courses at MIT. Both used assembly language. As a graduate student in 1957 I also took a course on programming the IBM 704.

When you left MIT, why did you go on a Fullbright to Australia?

I always thought I wanted to be an engineer, but when I started working as an engineer on MIT's VI A co-operative plan at a power company and for a very large company, I became disillusioned because of their bureaucracies, slow pace and relatively dull work. So this made me question what I wanted to do. After graduation, I received a Fulbright to defer the question as to what I really wanted to do.

Didn't Gordon Brown at MIT talk you into going to Australia?

Yes, I got to Australia because the head of the Electrical Engineering Department, Gordon Brown was an Australian and said that his friend, Rex Vowels, was just starting a new unmiversity and department and they had a new computer. He asked, why didn't I go and help them start up, teach, and do some programming? - Just consider it a year off from study.

But, you really didn't take it as a year off, you seem to have worked awfully hard during that year. Did you consider yourself, in light of today's software engineers, were you doing software engineering and how much did you accomplish in that year?

A friend, Bob Brigham, was also in the same situation and we both worked very hard at the University of New South

Wales under Ron Smart, who headed the center. I'll say in the position of software engineers we put in a good 60 or 70 hour week and then together we organized and taught a graduate course on the side.

What programs did you develop?

There were three programs. There was a basic program that we started with at the beginning which was just to learn the computer - it took about a week to write the program and then we went right into a big assembly language which we called SODA - Symbolic Opum Duce Assembler . Duce was a machine that Turing had worked on and the machine was probably the most difficult machine that I've ever seen to program. It was built to make it easy on hardware and very tough for the programmer and the machine had a two level store delay lines and a magnetic drum and what we did was to convert it into a single level storage. It was one of the first single level storage systems but the main thing we were trying to do was to convert everything from symbolic programming - it had this awful binary code that you had to use which was both time consuming and difficult.

Your third program?

There was another program that I got involved with which is GEORGE which was a program to convert the Duce into a Polish Prefix Machine. It was written by George Hamlin, a philosopher at the University of New South Wales and he used part of my operating system on his interpreter. Anyway, GEORGE was later built into hardware in a thing called the KDF9 as a stack machine so GEORGE I worked on was probably one of the first stack machines also so from an introduction to computing standpoint, I really worked on two very early concepts many years before they were really embodied well in hardware. In fact, in the program called GEORGE, I really got used to the idea of stacks and when it came time to build the PDP-6 really considered making that a full stack machine as in a machine like the BURROUGHS B5000 that was just coming out at that time but just couldn't figure out how to make it work with small mount hardware and work efficiently and therefore made the compromise that's become traditional in Digital's computers starting with the PDP-6 and then going on to the PDP-11 and the most support for this is in the VAX.

When you came back to the U.S. in late '58 and you looked around at job opportunities, how did you appraise what the opportunities were for someone now with your unique experience?

This was just at the beginning of computers and I guess what I decided to do was to do something that had a very high computing content as opposed to more of a circuits and logic design orientation so what happened was my thesis adviser, Ken Stevens, who ran the Acoustics and Speech Research Lab at MIT convinced me to come back and work there because they had just got a new computer, the TX-O from Lincoln Laboratory, and they were starting to do speech research on that computer so it looked like it was probably one of the most interesting jobs around as I surveyd other alternatives including going to Philco actually to help design their computers. That was a fortunate decision, however, because Philco was later purchased by Ford and Ford ultimately drove them out of the computer business.

You then got acquainted with Digital while you were at MIT with the TX-O, isn't that right?

Right, because the TX-0 didn't have any secondary memory and so initially my job was to write programs for speech recognition which I probably should comment more on because I keep saying the same recurring theme about engineers who try to do speech recognition. But my job was to interface speech equipment to the machine and then do recognition programs and what we needed was good secondary storage so I proceeded to buy a Potter tape deck for the TX-0 and to interface it and in that way I discovered Digital in '59 because they were just starting to sell their system modules and the system modules were compatible with the TX-0, of course, because the TX-0 was really the breadboard for the

Lincoln Laboratory circuits that ultimately became the breadboard for Digital circuits.

Well then wasn't it part of Digital's tradition that they hired their customers and you no longer became a customer but an employee?

Alright, that's happened a number of times. That's how we get users (people who know how to use machines) to help design the next one. Certainly a number of people have done that. I think Dave Cutler who did significant process control work at Dupont before he went on to build the RSX and VMS.

So we can say that you've been building programs or computers your entire career and do you want to say something about the myth about the people who do all of their good work before they're 30?

I think basically overall people do their best work before they're 30 but I think it's possible for people who are over 30 to do very good work too but the main thing you don't want to do is break a tradition of working. Certainly someone like Seymour Cray who is certainly over 30 and has built a number of machines has built them at a constant rate - sort of one every few years - and Hurley Daisy <?> has cranked one out a year but when it was easier to build machines but I think it's important for engineers to continue to stay engineers and to be involved in building all the time - that is, don't break the pace.

Mike Riggle at Digital is one of these, isn't he?

Oh yes, Mike is maybe a year or two older than I am but he is probably the one I envy the most because of the detailed contributions that he makes to all kinds of storage devices, everything from how heads fly to how databases are searched. He covers a tremendously dynamic wide range of topics and he's passed by many opportunities to serve on larger and larger groups but he feels, and I guess I feel too, that he makes the greatest contributions as an individual contributor running a group of about 30 plus all the influence he has with it throughout the rest of the company when he acts in a senior consulting role.

When you came to Digital in 1960, what was the engineering group like?

As I recall, I was the second computer engineer. There were Ben Gurley, who was head of Computer Engineering in the Engienering Group hired me and Dick Best was Chief Engineer and there were a number of people involved in designing circuits or modules but I was sort of the second one to do computer logic and computer programming so I was doing both programming and in some sense doing architecture work and also doing a lot of logic design.

When did you start hiring software engineers?

Tom Hastings claims to be the first software engineer that I hired and he was hired for a summer job - I believe it was the summer of '60 or '61 - to really work on getting the PDP-1 program library into shape and to verify and get IRO routines so that they could work with one another correctly.

Isn't it true that you had trouble getting decent software in the early period and couldn't figure out how you could afford it so some of you went to a restaurant and what did you invent there?

We had seen the power of the user base that I.B.M. had in the share group so we invented DECUS and DECUS was invented solely for the purpose of developing and sharing programs as we had a number of critical programs that we were trying to get written, I think including the <?> arithmetic at that point and time and we all got the users together in order to do that.

Who was at this first users' meeting?

I know Ed Fredkin was there from BPN and Roland Silver. BPN was the most active group and I think we had people from AFCR but there weren't that many because when we first started to do it there were only half a dozen users.

How many PDP-1's did you turn out in the first year?

In the first year, I don't remember - I haven't the foggiest idea.

There were 50 total. When did you stop making them?

We stopped making the 1 somewhere in 1964-65. One of the luckiest things that happened to us was that a machine that we made based on the 1, which is really a PDP-1 but made for message switching, which is the ITTADX 7300 which is a torn tape message switch which could handle up to 256 telegraph lines and switch them to other telegraph lines that was to do the work of a torn tape center that ITT had run overseas so that this could be done automatically. It was then that I invented a thing called the UART (Universal Asynchronis Receiver Transmitter) which was a serial line encoder decoder for telegraph lines but we were very lucky in getting the ITT order because of half of the PDP-1s that were made for message switching and that was a standard product and if that hadn't happened, I don't think we would have survived in the computer business because it turned out every order the PDP-1 had said IO for it and every piece of IO that the 1 offered somebody bought and one of our earliest customers, Livermore, bought virtually every thing we had for sale and we only made one, including a 5 inch precision <?> scope a 4096 x 4096.plotting <?>scope that's still almost unrivaled today in its precision but the PDP-1 was used there to be a converter from 7090 to STRATCH to LARK so it had UNIVAC tapes on it, I.B.M. tapes on it and I think it even had a UNIVAC card reader, an I.B.M. card reader and a CARTER card punch and a funny CRT and we had to make all of that work which was no trivial task. Then we only sold one of each of those so we were lucky to not have many orders like that, although LRL has remained a great customer of ours and we like them because they are so demanding.

I understand that Digital's goal from the very outset was to build a whole scale of computers - from small to large - and I don't remember what ever happened to the 2 and 3 but the next ones were the 4 and the 5 - what ever happened to the large end?

The PDP-2 was a mythical machine that was reserved in case we wanted a 24-bit computer - it was never defined on paper but the number was just held. The PDP-3 was actually defined on paper and one of our customers actually built one out of DEC modules. We were just about to get an order for a PDP-3 from the Air Force and Holland Anderson, who was the Vice President at that time, and I -- These were in the days when you offered everything for sale that was on paper and then you did market surveys by seeing what people bought and then you went and designed it if they bought one so because we were just starting out, we had offered the PDP-3 for sale that was specified and about this time orders for the PDP-1 started coming in like crazy and luckily we went over to the Cambridge and said instead of a 36-bit machine, would you mind taking two 18-bit machines and we were able to convince them that that made a lot more sense and again, that was at a time when DEC was saved from itself by our customers not buying something that we had for sale.

The PDP-4 started you in a new line of business from the PDP-1.

We didn't understand it at the time but the PDP-4 started down trying to introduce lower and lower cost computers and we thought there would be some kind of an elastic demand but really didn't understand what that was like. But the main thing the 4 was designed for was process control so it was easy to interface we designed it for a couple of customers - Foxboro - Foxboro had several process control applications and so it had a lot of IO interface standards so that it could be used in process control and it turned out that the 4 actually then created the 5 because one of the first few customers that bought the 4 was the Canadian Atomic Energy Commission at Chock River and the first thing they wanted was a process control - they wanted a control nuclear reactor and so there was a lot of front end work for nuclear power reactor monitoring and in going up there, in fact I went up there with Ed DiCastro to look at the monitoring requirement which we were thinking of as a special system - and in looking at it and thinking about how you would build a special system to do the separate monitoring independent of the control, we came upon the idea of the PDP-5. The PDP-5 is really a computer that was designed to do process monitoring and recording and work with the 4 so that is how the 5 came about because it was in an era that I think everybody who builds specialized Digital systems discovers, and that is that the best Digital controller is a computer so no matter what we start out with, we always end up building a computer as a controller.

You also claim that the 5 was the first mini?

I think the 5 was the first minicomputer because it really was built to be used and imbedded in a system and although the 5 didn't have quite the characteristics that I think the later 5's successful PDP-8 had, it did have the right attributes. It was half the price of the PDP-4, it was a lot easier to interface to and it was something you could imbed anything you thought about. The 8 went on to be even faster and smaller and because of the way we manufactured it, it was clearly something that you imbedded in another control device because it took less than half of a 19" rack and so the computer was now clearly a component so the whole notion of what I think of as mini, which I like that to stand for minimal computer - that is the smallest computer you can make at a given time for the lowest price and it's something you use to substitute for other Digital control systems.

Let's go back, I've also heard you say in some ways that the

LINK is the first personal computer, but in many ways the PDP-1 for the people using it had many of the attributes of a personal computer and hasn't the personal computer philosophy been sort of whipped back in with your engineering from the very beginning?

The whole notion of a personal computer or personal computing is something that Digital pioneered but we've got to be fair that it really was in a tradition that we all learned about in working with the various MIT computers. In the case of Ken or Win and in my case, the TX-0 where we had insisted on interactive use, that included the cathatray tube and the typewriter - whatever other means so that one had interactive use. It turned out that other computers had typewriters on them and you could interact with them but they didn't have a CRT and usually they didn't have a good file system. That's why I think that the first personal computer was actually the LINK which was designed with DEC modules and had its own file system which
was called LINKTAPE and when Digital took the ideas over from Lincoln Laboratory in the form of the carrier being Tom Stockeybrand that the LINKTAPE became the DECTAPE and thereby one was able to have a personal filing system and be able to write programs directly on the CRT, edit them, compile and then execute them without any human interaction and no other system was offering that at that point and time until we started doing the timesharing systems where we had the large drums and people were able to keep their files on the drums or on disks over a long period of time. Personal computing to me means having a CRT, having a very good interaction and having a filing system so that the machine takes care of the bookkeeping of your large programs.

Certainly the small machines are one brand of personal computing but the other form of personal computing that we went after was timesharing and it should be noted that I viewed the personal computing timesharing as the first really significant personal computing because the goal of timesharing was by one of the inventors of the concept, John McCarthy, was to provide a large computer and thereby give each user what appeared to be his own computer by simply timeslicing that computer up among a number of users and, in fact, that concept was implemented in about three places at the same time. It was done at BBN using the PDP-1 because BBN had ordered two typewriters with their initial PDP-1 and did some of the first work on that - then there was work at MIT by putting several typewriters on a 7090 and then there was work at Systems Development Corporation but that was a little bit later. It was out of those ideas that we created the PDP-6 which was a machine built from scratch to be timeshared so that everybody could have their own computer for personal computing.

When you decided to go to MIT you more or less said that that's where the action seemed to be at the time. Was it a similar choice when you left Digital and went to Carnegie?

In retrospect that turned out to be really perfect timing because what happened was that at the time I left the third generation was just beginning with integrated circuits and at least it wasn't clear to me that integrated circuits were going to take on the proportion that they did today where they went on to become large scale integrated circuits and now on a very large scale integrated circuits. But in '66 the issue was that we were switching from circuits that Digital built to circuits that _____________<sounds like semielectric> companies built and aside from being a little bit smaller, there certainly wasn't much of a difference and that transition really carried on for about six years during the time I was at Carnegie so the main reason that I went to Carnegie was to really give me some time to think about computers and I didn't realize that it was going to be such an uninteresting time during what I really call the third generation where we just made integrated circuits. However, the reason I came back was severalfold: One was that we were entering the fourth generation with large scale integrated circuits and the notion of a processor on a chip was just beginning to appear - in fact I did a lot of work at Carnegie when it became clear that was the way things were going just to make sure to get some of the ideas ready for when processors were going to be very very cheap. All the multi-processor and multi-computer work at Carnegie was really started and predicated on that set of principles and so I

came back really to get DEC interested in going in LSI and get projects going there. The other reason I came back was to what amounted to VAX because at the time, even though I worked on the PDP-11 and the 11 wasn't big enough when we designed it, it wasn't extended to be big enough so it was clear we had to do something else so I was interested in that something else.
Really the third reason was that Ken made me a really good offer that I couldn't refuse and then I guess probably the other one was that I had spent a lot of time trying to understand computing from a sort of computer scientist standpoint and I really consider myself an engineer and got tired and wanted to build something.

From the time you were in Australia you did a lot of writing of what you did, what's your attitude towards keeping records, reports and getting publications out?

I think the main thing is that people do interesting things. It's hard to say that everybody should write up what they do but I think if you're doing work that's primarily ideal work where you want those ideas to influence others, it's essential that those ideas be readily available in some form and writing probably gets the greatest distribution. The important thing is the work, however, because a lot of people who write things - the work isn't worth much.

Why did you write computer structures and why did you put together computer engineering?

Computer structures started when I was really trying to build a kind of a compendium of how to design Digital computers and I started into that work with Alan Newell trying to understand computers and write a text. The more we got into it the clearer it was was that the best way to do it was to show a lot of examples and to make a comparative study and, I don't know at what point, whether Alan got the idea or what, but he certainly influenced me in thinking that some sort of taxonomy was the right way to do it and we built a large multi-dimensional space to map these computers into and

I got interested in numerical taxonomy. The goal started out simply to be able to let people understand computers really clearly and in the process we invented two notational ways of describing computers - VMS and ISP. ISP has been enormously influential in being able to describe computers at all levels and, in fact, was influential in various people's use of simulators. In fact, the program we use here called TUMS which is based on the ISP notation is used for transfer simulation.

What I'm sorry about PMS is that I think PMS is grossly underrated. I think PMS is enormously powerful for everybody to understand the whole domain of information processing because it separates every component or every facet of information processing into component parts that I think everybody, including the layman, can understand and by breaking it apart that way, I think systems just become a lot clearer.

You're talking in a secret language. Nobody knows PMS - PMS doesn't mean anything to anybody and then you say that it helps the layman understand. Why does he have to understand? Why?

I don't know whether he has to understand it or not, I just think it would be useful if people knew more about computers. PMS is a way of letting you dissect a complex information processing system such as a computer into smaller components and each one of these components are primitive information processing pieces. P stands for processor, M is for memory, S is for switches, T is all forms of transduction.

PMS doesn't mean anything. How can it help me buy a personal computer?

I think if people had used it, it would let you see personal computers in a much more clear comparative way just like you can see what the different kinds of animals are by walking through the American Museum of American History - they're all categorized that way - so if PMS were used more, it would let everybody see what those things were, including personal computers, calculators and even teletypes and things that are not strictly computers.

Yes, but I'm into personal computers and you want me to understand all of this about teletypes and everything else, why do I have to do that?

I don't know why you have to do that.

Gordon, I just don't think you've got that argument now.

In all fairness, PMS is used a lot inside of Digital by a number of engineers because what we do is we use it to communicate computing structures to each other and it's simply a shorthand way of describing components and how they interact and what they are and it allows you to decompose those components in simpler and simpler components all the way down to as far as you want to go.

You said, and I know one thing you've got a collection of, is the <----?> handbooks and you thought that they were sort of a neat thing. If these are good at documenting, why were you instrumental in starting Digital Press? What is that all about?

What's Digital Press all about? I wanted machines and programming languages and programming systems to be really clear and available to anybody and everybody who wants them and that's been the philosophy of Digital all along - to make what appear to be really elegant simple handbooks that describe the machine. If you look at the first one, the PDP-

1, it's very thin and extremely elegant and I think one of the things I'm the proudest of is I wrote the first reference manual for describing how you connect IO equipment into a PDP-1 and then some of the ways in which it was done because I wanted to make it clear how you made a system out of a computer and I guess I've sort of been interested in that all along. That probably influenced the desire to write the Computer Engineering book with McNamara and Mudge because it turned out that the 25th anniversary was coming upon us and I had the good sense of not wanting to couple the book to the 25th anniversary primarily because there was too much that was going to happen.

We decided to write the book to really give our view of why Digital's computers are built - what they are and why they are built the way they are. All the chapters and articles are written by various engineers, including a lot myself, just when somebody didn't write about them, but the notion was to be able to hold a sort of engineering philosophy constant in the walk around and look at all the machines built by a single company in a single engineering philosophy.

In a sense, maybe it all started when I and Sam Fuller and Dan Swiorek were editing Communications EACM and we got the notion that we should describe the historical description of a number of machines and I tried to get somebody to describe the PDP-6,10 family and found out that people just weren't up to that so ultimately I wrote the article and got a lot of contributions from the DEC people but there was a certain style of trying to understand machines that I think we understood and we wanted to go on and describe all the machines in that way starting from a basic - What were the goals that the machine had - and then we went on to describe how the machines turned out based on the goals - and then to look after the fact whether the machine achieved what we wanted to after the fact. That's the kind of style that we used throughout the Computer Engineering. We wanted to set really good examples for people who built things to get in the habit of describing them so that people understood them and then we felt that would influence the way they went about their basic design from a goals and a constraints and really a thoughtful design standpoint.

Do you think new engineers at Digital should read or have a copy of Computer Engineering?

I wish that everyone at Digital would read Computer Engineering as much as I think our competitors read it. We sell lots and lots of copies to competitive companies and it's taught in a lot of other company training classes and I think it's because we do a good job of describing all these different views of how one can look at a computer in the first part and then we go on and describe the whole notion of how design is done in subsequent parts. I just think it's excellent training and I wish that we would formally give the course within Digital.

I know your own sabbatical got a little bit out of hand, that is you were six years at Carnegie, but during that time didn't you get the idea to start the concept of sabbaticals for other engineers?

We have a program within Engineering that I think needs to be drastically expanded and that is the ability to have somebody go away for a year and go to a university to take courses or to teach or to participate in a research program of some kind and I think that we just need to do enormously more of that because anybody who's been working at Digital and trying to build state-of-the-art products for about ten years really just needs to get out of the environment and look at it from another perspective and I think a university is a good place to do that because students are just very demanding in terms of the way they like to know about things.

Do you have these programs with a number of universities now?

Yes. We used to have a program with Carnegie but no one has been there for about five years. There's a program with Caltech and we have a resident there every year at the Silicon Structures Project learning VLSI Design. We have one or two residents at Stanford working on their Silicon Structures. We've had people teach at Berkeley. Alan Kotok, for example, went away a few years ago and taught at Berkeley for a year and I know he found that enormously stimulating. Of course, we have programmed with MIT where our people either go to teach there or certainly go and take courses. Joe Zeh just finished a year there last year and he enjoyed it.

When Digital started, I know, everybody was planning on staying there. I know you're a long way from retirement and there's a long time between ten years, what other ideas do you have to keep the engineers being fresh?

The problem of continuing education is a massive problem as we can see our engineering population getting older unless we have enormously high growth, which is unlikely and so we have to look at every possible continuing education program. MIT is pushing to make a really significant continuing education program and I hope we can really go on and participate with them to do that. That's a very extensive program and we should get involved in it. Until that time comes, I think every engineer's got to take a tremendous amount of responsibility on themselves to deal with the problem of his own continuing education. To mean that means we've all got to do what amounts to, I think, at least one course a year of our own education and that can be any kind of form. It can be teaching a course somewhere so that one solidifies a bunch of concepts, it could be really writing a significant paper which gives you the kind of rigor that you need and that a formal course does, it could be giving a set of lectures at a university, it could be attending a whole seminar series that we have here. Right now I think we're beginning to have a really good set of seminars at some of the sites. Hudson sort of pioneered the whole notion of a seminar series in the semi-conductor engineering group and that's also now where Corporate

Research brings in people. Marlboro has copies that format and they have a series concerned with building large systems - both the technology and the organization of large computers . Those are really good programs and I think that if one attended what amounts to a whole series of those and read a book, you could think of that as a course in say the Organization of Super-computers.

Of course, we've got a tremendous number of regular courses taught by various local universities including the tutored-video instruction that Univ. of Mass. has on Computer Architecture and Programming Languages and things like that.

You really seam to be a proponent from learning from history and you ask your engineers to go to the history lectures at the museum. They'll need this generalization of learning from history - what do you have in mind?

The main reason for studying history is so that you don't have to repeat it. If I look back at all of the four generations where work has been done first at universities then the large corporations and then by us and the whole main computer industry and now most recently by the semi-computer companies, we've all had to re-learn a whole set of lessons that were invented earlier. So the main reason for studying history is simply to learn from those in the past.

For example, recently I was reminded as one of our last lecturers had a number of good examples of being able to tell when something was obsolete. As we get too close to the products, one of the hardest things that we've got to learn is when is euthanasia in a product. I think history provides a lot of good lessons in knowing when products get over the hill and can't be extended.

Several years ago I gave a set of lectures, which I hopefully will become a book, on the evolution of computing in which I went back and looked at what one could learn at just looking at the experience Babbage had in building some of his machines. One of the recurring themes is that people tend to make the same kinds of mistakes over and over again and there's a particular nice set of lessons about the whole notion of generalization - of building elegant products, extending them to be more general, and then finally making them so general that they were incredibly tricky. On the other scale of elegance, there are sometimes some extreme ideas that are incredibly simple that when done properly they can be elegant but very often they just turn out to be naive because the ideas aren't really good enough.

We also see from history that certain ideas go in cycles and waves and we need to be aware of when this is happening. Currently we are going through a whole bunch of new waves of machines which I've been told one time called the "wheel of re-incarnation" which I describe in the Computer Engineering book. Now it's being applied to databases, it's being applied to communications processors, it's being applied to central processors, we're doing certain kinds of arithmetic, etc. What you have to do is stand back when somebody starts around this wheel and see that it's the right thing to do because I think, in general, it isn't.

Why you don't describe it.

The "Wheel of Re-incarnation" is simply that when you start to do a function such as displaying information, that you put some special hardware with the processor to do that function. Gradually you start adding more and more hardware so that the function can be done better and without any help by the main processor. Ultimately what you end up with is a totally generally purpose device which does the display function plus you've now totally unloaded your other processor so you end up with two computers, both of which are probably not doing very much and you've spent twice as much as you need to on the whole project.

What do you think Silicon Mountain has done for Digital?

I think the by-products of Silicon Mountain are really good because it really requires very demanding engineering and aside from bringing in a vital technology, which I think we're going to need in the ensuing years for designing our own special circuits because I think within ten years we'll find that a large number of the systems are going to be built on a single chip and we must have access to that technology, it has taught us a great deal about managing complexity and that's something that every engineering group must know how to handle. The VLSI Group leads in that domain but every group must master it. Complexity management is the orderly interconnection of a large number of parts. What is done is it has also provided a technology challenge to a number of our engineers so that they continue to grow with the technology and that's something that we have to do to keep ourself alive and growing.

How do you best see the U.S. can fight the commercial battle with the Japanese?

I see that there's only one way and that is just to be incredibly strong and innovative. The Japanese are superb engineers, they are very bright and they work extremely hard and they are very adept at not only capitalizing on ideas that are in the research environment, but they are also adept at doing innovative work on their own. I say that there's only one way and that is to be incredibly good from an engineering and innovation point of view, including going back and having very strong mastery of the fundamental materials from which parts are made. This is not going to be easy because the Japanese culture is basically a culture of technocracy where engineering is rewarded virtually more than any other profession.

Do you see this as the same kind of challenge in the 60's with Sputnik that led science education to change? Do we need a similar revolution for engineering education?

I think that the Japanese competition could be an impetus for change in the same way that Sputnik was a signal to change the scientific basic education. On the other hand, I don't think that that was as effective as it could have been. It may have gotten a few more people into science but basically the space race was really more of an engineering problem than it was a scientific problem. I don't think we do a very good job of educating people as to why engineering is a worthwhile profession but we've got to do a better job of that too.

PART II

Mary Jane is a very special person but since you've really started experimenting with Office Automation for a long time, you had one of the world's first word processors. How does that work?

When I came back in from Carnegie I had just finished writing a book in which we had the whole machine on line and we were able to publish the book directly. One morning we decided that we were finished writing and about two days later we had a complete printout of the book with camera running paper - so I must say parenthetically we have not yet achieved that same level of automation in book publishing here at Digital over 10 1/2 years later, but when I came back I wanted to get to a level where everybody lived and worked on the machine so I started by convincing Mary Jane that that's what we ultimately wanted to do. She started out using the timesharing 10 initially to do editing. I did some program writing but I'd say we're about half there in terms of what I think we wanted to do. On the other hand, Mary Jane has gone much further than I expected - than I guess I had hopes we had gone - she really has driven the whole business of Office Automation in Digital and the book she has written will probably be a significant influence in other corporations as well. Our ultimate goal is to really use the machine as virtually all forms of information processing and to get rid of paper, not necessarily that paper is bad, but it's just that it really is redundant most of the time if you've got a really good computer system.

The other goal is to be able to get a computer to do a significant number of the office information processing tasks beyond where we are now - like dealing with calendars, meeting schedules, electronic mail, word processing, paper publishing, teleconferencing with the other people on various subjects.

The way you really did this is almost subversively. You didn't set out to direct a project that had a budget but you just did it and by doing it, hoped that it would catch on and be successful. Now, isn't that a kind of way that you've fostered a number of things? Didn't the original mail system sort of happen and didn't the Ethernet go in without any program or budget for the Ethernet going in? How do you let creative good things like this boil up? What kind of environment does that take?

I think getting anything done takes access to free resources of some sort so first off you've got to have the computer resources to have things like that. In the case of electronic mail, that one really started when <Onulate??> had its origin back with the Arpanet but then our first version was really something that some of us cooked up with Computer Corporation of America where we provided them a computer and they proceeded to write the Electronic Mail Program and we became a test site for it. So I guess its based on the fundamentally good idea that you invest somehow and then you see where it leads.

That's the whole notion behind Ethernet because its something that is basically a good idea, doesn't cost very much, and it's something that everybody can use and by having the interconnection and coming together the way I expect systems to come together, we will be provided with a computing environment that we never dreamed of before. Probably the best example of that was the whole business behind the Engineering Network which is, I think, probably the world's largest computer network with over 300 computer nodes and has the ability for all the engineers to communicate with one another. But that network happened totally in an unplanned bottom up demand way. It came in initially through the software organization based on the need to transmit files and to communicate specs and things like that along the users and then it sort of grew as people could see that it had a lot to offer. In this case the idea behind it was a really superb network architecture name of the whole business of DECmail and all of the protocols surrounding that and the need was there and when that happens people do the right thing. The trick is to try to provide all those ingredients so that people are going to behave in the most creative way.

Let's go back to the Office of the Future or Office Automation. I know that you're a computer user and type and write your own things and it's not going to automate you. How do you see the secretary in the office and the engineer of the future sort of in terms of these aids?

This is another question. You talked about education, the importance of education, but a lot of the people in your organization, whether they started as secretaries or whether they're male or female have developed according to their merits and neither because of the kinds of education that they've had or because of their sex. Again, how do you let the Mary Janes, the Carol Peters, the Joe Zehs - what kind of organization have you tried to create? What are your ideas that are behind this organization?

It has always been the goal of people here to provide a maximum sort of opportunities for everybody so that we're not restricting what somebody can do either by their title or by their formal education, in fact, a really good example of that is the program I call DEC-U which is really almost an engineering granting degree program i.e. for the purposes of Digital we provide a method whereby technicians can become engineers with sort of proper courses. The goal is to let people have that kind of opportunity. Similarly, anybody who wants to do any form of engineering has an opportunity to do that using all kinds of tests and all kinds of courses and things like that. I don't think that's necessarily me but certainly has my support and I encourage everybody to go right up to the limit of their capability.

Why don't you tell us how the word VAX came into being?

VAX was a name that I coined which was the start of the project on April 1, 1975 which was the virtual address extension to the 11, in fact we call it VAX-11. By calling it that, it was the intent to make it something which we finally called culturally compatible with the 11. If you knew about the 11 you would understand the VAX. It's one of those strange things where the name actually stuck throughout the life of the project and ultimately the press got wind of it and we got free PR with it so when it finally came time to name the machine, we called it VAX-11 and now subsequently we've let it become known as just VAX.

In the last four or five years, you really have sponsored distributed engineering on the West Coast, in Colorado, in Japan. Why have you done this?

There are a whole bunch of reasons but certainly a big one is that certain people have a preference for location is one but I guess the threebig ones are I really believe that small groups perform a lot better than large groups, I think that we just got soaked too much in New England and when you have a lot of engineers in one place they tend to spend a lot of time at committees and the things that should be architectural interface specifications and could/should be done that way - we often end up just spending sort of callous hours in large groups trying to get all these details worked out. Sort of the best example of that originally is one of the most complex interfaces we've got is the mass storage control protocol that links mass storage devices with VAX systems. That was worked out totally between Colorado and VAX and VMS Engineering in a quiet clean way - probably the simplest interface work we had and then strangely enough when we plugged it together it all worked. So group size is the other reason - group size effectiveness in making clean interface boundaries .

The other big reason is that there's a significant talent that lives outside of New England and there I refer to the group both on the West Coast and in Japan where we've built the groups from scratch out of natives from those areas. Particularly in the case of those two places, we also have a goal of being able to interface to all the technology that's available in those locations and there's considerable technology both in the South Valley and Palo Alto around Stanford and then of course I have the highest regards for engineering that's done in Japan because that's where all the advanced VLSI work is done and where a lot of magnetic recording and printing technology is the best at this point and time. Of course, the Japanese excel in their electronics that we have to learn about so we're there to couple and learn from these other locations as well as get people who are there and want to live there.

The Seattle location is really the other kind - Dave Cutler's site. That's a transplanted East Coast site where the desire was to have a small really effective tight-knit group and the same way with Colorado and both of those have turned out to be really excellent. In terms of dollars shipped per year at engineer I think Colorado is at this point and time beats every other engineering group in sight.

There is a tiny engineering effort going on in places like Australia and another one in France and isn't there some local kind of differences that help or didn't you make that observation in Australia?

I guess that's something that we've been able to do very effectively at all and those are computer special systems sites. We at Central Engineering have not been able to couple into the engineering that's available on a worldwide basis. I think that's something that I'd like to be able to do in the next five years, e.g. I just returned from Australia where a small group of engineers in the Special Systems Group built a statistical communications multiplexor that we're shipping in the range of about 1,000 units/year. That's a respectable small company in U.S. terms and if we had better marketing of that product, we'd ship even more. That was done for only about a quarter million dollars and right now with engineering the size it is, we can't even write a business plan for a quarter million dollars which really speaks to the big reason why I want small engineering groups because I think they're just much more dedicated and much more effective. Of course, when you do that there are other negatives too which presents an incredible management problem to sort out all the interfaces and to sort out all of the duplicate of products. If you had several hundred engineering groups, probably half of them would be going for the same products all the time.

A lot of the engineers survived through STRATTON 5 and there hasn't been another STRATTON since STRATTON 5. Were the Stratton Mountain meetings appropriate for a certain level of growth of the size of engineering and now do you have to think of something else? What did they do? Why did you start them?

The Stratton meetings which culminated in this grand finale which was teleconferenced to a large number of the engineering sites was started at a time when we were starting to locate engineering in different geographical areas - when we first moved to New Hampshire and Marlboro and outside of Maynard. It was formed as a means of communicating among all the engineering groups. At this point a single meeting doesn't seem to make any sense because engineering at this point is so big that a Stratton wouldn't be able to handle it.

I think what we need at this point is several things that amount to Stratton-like meetings for communicating what's going on and allowing people to present their work and to get feedback from their peers who they don't see. The thing that Stratton accomplished was that it let everybody sort of calibrate where they were with respect to their peers and what I see now with the very large engineering group is that there is even more of a larger gap in terms of capabilities across the various groups and I think people need that kind of calibration and they also need to know what's going on in the various places, e.g. VMS people would certainly influence the way printers are done but there's no way at this point that the printer people who are located in the Mill ever talk to the people in New Hampshire and we desperately need that kind of interchange for some of the product definitions. We probably have much better ability to define products for use because we have so many users within engineering than by going out to the external environment which I'll say is much much less demanding than our own internal users. I think our systems programmers have a much better idea of what should be the personal computer than say the personal computer market as the personal computer market is defined.

When you came back to Digital, you thought of yourself as a computer architect and now I think that you're an urban designer - i.e. you're somebody who really thinks of the Faneuil Hall Marketplace - that whole center - now you had a city planner who deals with millions of people and hundreds of square miles -

No, at this point I don't think of myself as a computer architect working on an individual building.

But your an urban designer?

No, I believe I'm a city planner.

But a city planner talks about and deals with two million people with all of Boston and that is when you can really put all kinds of Ethernets together.

Yes, and that's the kind of thing I worry about.

But the Ethernet is really only at the scale of the urban designer or even an architect.

But you have to link all the Ethernets together and then the Ethernet has to fit with all the other forms of communications.

Now explain about how you're a city planner.

O.K. I'm a city planner because what I'm really involved in is really putting a network system in place whereby all kinds of individual architects can build all their information processing systems at an individual level.

That's an urban designer.

G.B. - An urban designer is what?

Anyway, now I think of myself as a city planner and not a computer architect because a computer architect worries about the individual nodes; I really tend to worry about how the nodes are connected and how information flows betweeen them and what kind of a system one can build from a collected set of nodes. Systems like this include the local area networks, how you connect local area networks together across geographies forming the wide area networks, how technology such as Cable TV are used to interconnect the various computing nodes because as we're finding out as we distributed computing, the need for communication among the nodes just rises expinancially. Also, as we need to form more reliable systems and larger systems, it turns out that the best way to do that is by interconnecting the SPAR system rather than to continue to build larger and larger systems which are difficult from an engineering standpoint. So that's why I think of myself as a city planner.

You started at Digital as a Computer Engineer before Computer Engineering was taught in any schools and while Digital's major business was in modules - then you went off to Carnegie and you came back as a Computer Architect before Computer Architecture was really thought of as a discipline and while the company was really making machines you thought of a new architecture in VAX that changed the way for machines. Now you call yourself a city planner. What does that mean for the new level of products and any kind of new approach to computers and computing?

I think all that's happening is that we're just working with higher and higher or more and more complex things. I started out doing logic design on computers and then designing whole computers and then the architecture of whole computers and now I work with how computers are tied together and how applications are done on those and what the environment is like. It turns out that this is just more of my own interest, not the fact that we've done away with any of these layers over time. What we've got right now is if you look at the whole range of what I call levels of integration, we have a lot more levels of integration now than we did when I started to do computing. When I came as the second computer engineer we didn't have the notion of architecture, we defined something and ended it was in one person's head, it was architecture, and we went about at most one engineer designed some circuits and somebody else designed the logic to do that and then we had a very sketchy handler or a way of using that particular piece of hardware in a single program. Then a user linked together various subroutines whenever he wanted to do anything. Every application was a linking of a particular set of subroutines.

Now today if you go back, we've gone to sort of a maximum set of layering because with integrated circuits we are back down to where not only there is more creativity for the circuit engineer, but there is the whole physical problem of laying out those circuits on chips. The whole notion of architecture is grossly refined where we define a machine and that machine has a meaning over several implementations as we've done in both the VAX and the 11 family in a very elegant way and then you lay on top of that a very complex set of software and languages that to the user are really the architecture of the machine, and that's one use of a particular machine. What you really find is that as I recently did in Australia, is they had built a total homogeneous VAX computing environment where they had their large VAX's in Sydney running sort of central computation centers and they had distributed 730's out into the various regional offices. Then they had control computers in there doing real time applications and all these were completely networked together. That whole system really ran a single computing environment so my interest has sort of followed a lot of that over time, being interested in individual machines and probably still. I'm most fascinated by building a single computer and I get involved in all of those but now with the things that we're doing with networks where its possible to run a single problem on a large number of machines within a network made possible by high speed Ethernet, that's a whole new domain of architecture that I think is really more exciting than anything we've had in the past.

Of course, when you do that on a global scale like we do in Engienering Network, we have 300 computers that are all linked together physically as a single system, that's a really fascinating kind of architecture that I like to see us provide.

When you came to Digital, where there any computers in the company to use in designing computers?

We didn't start using computers in the design of computers or to assist in the building of computers until sort of mid-60's. What we did is have them take care of the bookkeeping of wireless and then when we got a Gardner Denver machine then they told the Gardner Denver machine how to wirewrap the various runs but those were really computer aided manufacturing more than computer aided design whereas now what we use computers for alot is to actually lay out circuits and to check whether circuits are going to operate correctly and to simulate them. The use of computers in computer design really didn't start until the start of the '70's - now we can't do without them.

What's going to be the impact of the personal computer on larger scale machines on the network?

There are a number of people who think that with personal computers and powerful personal computers which we are beginning to see based on very fast microprocessors that it's completely possible to displace any kind of central computing facility. I personally don't think that's really the case nor will it happen. It turns out that alot of what is maintained centrally is databases and it's still the case that databases are cheaper to keep in large disks and so while you can have a personal computer in principle controlling each disk in a central facility, it turns out the cost is all in the disks anyway so you end up with what amounts to the things that look like today's mainframe computers. That's really traditional computing. I strongly believe that all new computing will take on this very highly flattened form simply because personal computers are becoming so very powerful and that the ability to have your own under your own control will far outweigh the benefits of a highly centralized facility so we'll see a very flat kind of system where all the personal computers are with individuals and then anything that's needed on a community basis will be maintained somehow by the community or by some centralized facility. Things that are worth maintaining centrally for a group are orders, or communication links to other systems or filing which we just described. These systems we call personal computer clusters and it turns out with an Ethernet chip that's just being delivered right now in the next 18 months, we will see an onslaught of personal computer clusters being marketed by every manufacturer and they will make claims that they can do exactly what mainframes do and what our distributed minis do and we do what we provide in those kinds of systems, of course.

Can you see the onset of this kind of personal computer system in Japan as well as the U.S.?

For example, one company, NEC, has made a statement by its chairman that every employee should have and operate a personal computer and I believe they are doing that so that they can understand what computers are good for. I think Japan has a special set of problems that relate to inputting Japanese characters and that may slow them down until they get voice, but on the other hand, that just makes the Japanese work harder so that they get good voice input fast so it means that they have very good output because they have to have high quality output in order to get the Japanese <Congi??> output.

<The really big database problem seems to be one that still is with us - the library problem, data processing - that kind of thing that really big computers up til now have been used for a number of crunchers. Do you think the company should now up the personal computer in the new big systems will change that and there will be new big database systems to serve the personal computer?>

It's hard to tell.

I've heard you say that one personal computer isn't enough per person.

I think that already if you look at the number of terminals we have within engineering, there's I think probably more than one terminal per person within engineering. In a lot of our groups and our projects every person has two terminals - one at home and one in their own office. To me, that's kind of the minimum number for people who are actively doing engineering and communicating within the engineering environment. I expect everybody to basically have two terminals or two personal computers and, by the way, I exactly equate personal computers and terminals to be the same thing because Digital's goal has been to do personal computing since the beginning of timesharing in the mid-60's and I could care less whether I have my own computer and its own files and programs that I have to deal with or whether that's a facility that's maintained here in our office like we have for Word Processing or whether it's a central system that's maintained in a group. Right now I'm excited about my first personal computer which is a VAX 730 which turns out to have two users on it - Mary Jane and I - and it's important that we both have the same personal computer because we both share the same set of programs and files and work on and that's accessible from home or from a terminal in my office. I believe that's a reasonably nice personal computer.

You've been involved with research at universities and at Digital. What do you think is the role of research within a company and in particular what's your model for the research group at Digital?

In 1972 when you returned there was no such thing as Central Engineering. Now there is and what is its value and how does it work today?

There's always been a central core of engineering people, it just turned out that they were distributed in various groups called Product Lines which had both the marketing and the engineering function combined together and operated in more of a total profit and loss framework. Today engineering is much more aligned with manufacturing and still retains a lot of the marketing functions for the basic products that we build. In a sense engineering is more of a complete group that its ever been - it has more responsibility that it has ever had. The group that engineering is part of is more of an overall responsibility than it ever had except that we don't put so much emphasis on the measurement of profit and loss of the various products. I think this is not necessarily healthy. You've got to get back to a real measurement of product profitability.

You want us to look at the rest of the company too. If anything, I think that we're returning to a whole emphasis on products. The various groups we call product lines are really doing application products, i.e. products that are predominantly software and they're on top of the basic central engineering organization. We're now trying to strengthen the engineering within the various product lines, in fact, they really are concentrating on products for particular market segments such as Word Processing and the factory - things that were our traditions - but also new areas such as the small business computing.

The difference I see between industrial research and academic research is that in the industrial research that we really have to be much more applied and must be driven by problems that the corporation needs solving versus in the academic world where the problems are totally directed by the whims of the individual professors and to a large extent the graduate students and the problems that the graduate students are interested in solving. I guess mainly there's a focus on the applied and less on basic research. I regard that the universities are doing an excellent job in computer science basic research and that we should really be trying to apply what they have pioneered to particular products. As I see virtually all of the things that we end up doing in our research group, I think that we can find a model that the university has done them to a certain degree somewhat earlier but perhaps not suitable for productization.

I know you use your own personal computer and answer your own mail to some extent, what value has that for an executive to do? Do you think that all Vice Presidents of Corporations , or at least of Digital, should do that?

I think it's essential that all of us use our products. I think that it's the only way that we can have any feeling as to what the problems are in building products for others to use. I use a computer for two reasons - one is that it is faster and because I can type rapidly, also can type and author rapidly using a computer - but there's this other reason which is to really understand how the products work and how easy they are to use and how well engineered they are and how reliable and all of the things that one does by using a product. My only regret is that I can't use every product but we do have something that we call the Mary Jane Test which has been reported on by Fletcher. Anyway, the Mary Jane Test is like my own test only Mary Jane is more effective at getting the engineers to change something that really bothers her in terms of being difficult to use or not having a certain capability. That's why we try out all of the terminals and all of the personal computers and all the mail systems and things like that before we make them public.

The new computers aren't like a new kind of toothpaste, i.e. you can't take a market survey and will peppermint do better than something else? You're really offering totally new ways of living. How do you know what to do if you don't have a trusty market survey like a toothpaste manufacturer?

There's a branch of engineering called human engineering that deals with letting you try out a lot of things, namely, we have a way by which people are formally subjected to new products and then go about testing those product ideas to see how easy they are to use. Even though things appear to be quite subjective, it turns out that when you measure the performance of a system with a person too, that is probably an indicator of how good the system is. Things are not subjective at all in the way that certain kinds of taste is. You can really tell a difference when you look at the amount of time it takes to do a job.

I think it's important that when we design computers that we design them so that they are fun for us to use and that our friends like them too and want to buy them. In particular, I happen to like designing computers for the friends I have in the academic and scientific world because I think they are quite demanding and will give us feedback, both good and bad, about how well they like the products. I have a couple of examples. One was in the case of VAX. As we were about half-way through the design, we subjected the design to Ken Thompson of the Labs who was one of the authors of UNIX and asked him how well UNIX would run on VAX. The second case is a very old one where when we were designing the PDP-6, the pre-cursor to the PDP-10, we asked John McCarthy to consult and help us make a machine that could execute lists very rapidly and cleanly. In fact, the reason that the 10 continues to be the benchmark machine virtually 20 years later is that we really paid a lot of attention to lists when designing the PDP-6 originally.

I think it's important to have a number of close relationships with very demanding companies. In our networking we spend a great deal of time interfacing with some large companies, in particular Dupont, because they have such incredibly large-scale networking and distributive processing demands by which we can test our ideas. We can also, of course, use our own. Digital is an excellent place for trying out ideas for new products. This is how electronic mail was done and this is how the Engineering Network got formed but it's important to do other things as well. I think we ought to be using our products more, particularly in manufacturing and in a lot of our administrative work.

DIGITAL COMPUTER MUSEUM CATALOG

INTRODUCTION

The second duchess of Portland, born in 1714, was an insatiable shell collector. She never found a satisfactory artistic arrangement for the specimens until she hired a student of Linnaeus (1707-1778), the father of botanical classification systems. Then the collection was rearranged according to a taxonomy illustrating evolution and relationships between family members.

The collection of the Digital Computer Museum, relating to the whole family tree of computers from their earliest origins, also needs a disciplined classification scheme. Those who have tried to understand computer evolution have

intuitively considered a tree structure -- the basis of taxonomies -- but none have been fully developed for the purpose (Bell and Newell, 1971; Bell, McNamara and Mudge, 1978; Rogers, 1980; Science Museum, 1975, Sieworek, Bell and Newell, forthcoming). The National Science Foundation tree of early computers shows roots and connections but does not name branches. A number of partial systems and some generally agreed
upon terms exist for defining a classification system. The classification system in Computing Reviews works very well for the extraordinarily broad range of materials including "mathematics, engineering, the natural and social sciences, the humanities, and other fields with critical information about all current publications in any area of the computing sciences" (Sammet, 1980). The work of the AFIPS Taxonomy Committee, Taxonomy of Computer Science and Engineering, provides a convuluted semi-lattice covering all possible issues (AFIPS Taxonomy Committee 1980). Other trees look at only a part of computing (Weizer 1981, Sammet 1969). The evolutionary model has also resulted in the identification of generations (Rosen, 1969).

Generations are the primary organizing element for the collection and the catalog. The first four sections present the pre-computer generations. The fifth section is devoted to the pioneer computers that spanned the revolutionary bridge. The remainder of the catalog and collection is open ended; inclusive of all historic generations, i.e., at least one generation removed from the present technological generation.

THE GENERATIONS

Within the broadly accepted idea of technological generations, clear criteria can be identified to mark each one. These are listed below with examples shown in Table 1.

* A new base technology;
* A new machine structure;
* Satisfaction of a newly perceived need;
* Resulting in significantly different use of computing devices.

TABLE 1. THE GENERATIONS

PRE-COMPUTER GENERATIONS

TECHNOLOGY	MANUAL	CRAFT	MECHANICAL	ELECTRO-MECHANICAL
		1620	1810	1900
MACHINE	Abacus	Tables Gunter's Rule	Planimeter Jacquard loom	Hollerith census machine, Friden calculator
NEED	Taxes	Trade Exploration	Industrial Land Division	Census Business
USE	Counting	Arithmetic Navigation	Surveying Weaving	Sorting Accounting

COMPUTER GENERATIONS

TECHNOLOGY	ELECTRONIC	TRANSISTOR
	1950	1960
MACHINES	Whirlwind UNIVAC 1 ERA 1101	CDC 160, IBM 7090, IBM 1401 PDP-1
NEED	Defense Weather prediction	Space Science
USE	Firing Tables Weather Forecasting Management	Simulation Training programmers Accounting

Generational change is modelled by a series of distinct steps with a new base technology at a significantly different level. The technology base never meets the aspirations and dreams of mankind because perceived needs are continually rising. A new base technology only creates a higher takeoff plane. (Maslow, 1943) With each new invention, one or two prominent people often note that it will fulfill all future computational needs; but each time the demand for more computational power only grows.

A number of ideas and machines are designed and even built out-of-phase with a technology. Ideas that occur before their time often lie dormant in an inventor's notebook until the technology evolves to match the idea. Later historians illuminate these early concepts, showing the contemporary entrepreneurs that they are not originators but only implementers of ancient ideas. In the mid-twentieth century, some letters of Wilhelm Schickard dated 1624 were unearthed. These contained the drawings for the first known digital machine to perform calculations. (Cohen 1980) It is doubtful that these ideas transmitted from Schichard to his friend Kepler influenced any of the mechanical calculators that were subsequently developed. Blaise Pascal, whose single-register, mechanical calculator of 1645 was widely known, appears to have invented this machine totally on his own, as a young man intrigued with a mechanical solution to the problems of accounting, with which his father occupied himself. The inventors who actually develop a baseline machine for a technology are often tinkerers, not scholars searching the literature for ideas.

Increasingly, computing devices are not the sole result of one invention but the convergence of many. As a set of benchmark ideas coalesce into a new machine relating to a new technological generation, then additional, incremental inventions result that also become part of the technological base. A new generation is marked after the project has proven itself, shown not to be a fluke, and has added a new layer to the technological base. The Computer Revolution and beginning of the electronic generation saw the use of vacuum tubes in the ENIAC on a scale of magnitude never before experienced and the invention of magnetic core memory on

Whirlwind. Since a generation is a convergence of inventions, its emergence cannot be marked by a single event. A clustering of events, including patents, publications, and start-up dates are used to somewhat arbitrarily select a particular year.

Three pre-computer generations and three computer generations are clearly distinguished. Although calculating activities started with early civilization, it was not until the seventeenth century that a variety of calculating devices were invented and used. The collections begin in 1620 with the beginning of the "Craft Generation". Prior to that computation was carried out manually, in much the same manner for all of history. Defining computing power as the product of processing rate and memory size, a 20 order of magnitude increase can be measured from the time when people used stone-based, single register devices to the 1980s. The most significant increase -- a revolutionary change -- occurred with the beginning of the computer era. Before then, memory size was essentially constant at one. Afterwards, computing power began to increase at roughly twice the exponential rate of all past generations.

A generation is named for its predominant technology. The starting date of a generation is set not by the idea leading to a project that triggers the generation, but by the incorporation of a technology into a new product, concurrent with significant use. In most cases devices from a previous generation continue to be designed, manufactured, and used, often supplying a base on which the new generation is built. The electronic computer generation is marked at 1950. By that time the ideas of ENIAC had been replicated and the first commercial machine, the ERA 1101, was announced to the market. In the Computer Age, the naming conventions given by industry have been used, and they seem to accurately fit the model.

Table 1 lists representative needs, uses and inventions for each of the generations. During the pre-computer generations, evolution was exponential -- each period being about half as long as the one preceding it. The rapid change is similar to manufacturing learning curves, whereby a particular unit cost declines by 10-20% each time the cumulative number of units of a given type built doubles.

THE TAXONOMY

A taxonomy has been developed in parallel with the collection and the exhibits at the Digital Computer Museum. The taxonomy's basic framework is the PMS classification that describes the structure of computers (Siewiorek, Bell and Newell forthcoming). PMS allows any computing or software structure to be described hierarchically in terms of eight basic information processing primitives, but it does not deal with functional behavior, such as program interrupts that are not implied by a structure. The PMS system is generally used to provide a structural representation of the components of digital computer systems. In contrast, the Museum taxonomy classifies only whole computing systems and their antecedents. The following compares the two breakdowns:

TABLE 2. COMPARISON OF MUSEUM TAXONOMY AND PMS

MUSEUM TAXONOMY CLASS - CODE	CODE - PMS
Memories - M	M - Memories
Controls - K	K - Controls
Transducers - T	T - Transducers
Links & Switches - S	S - Switches
	L - Links
Calcula - D	D - Data Operation
	P - Processor
Digital Computer - C	C - Computer
Robotics - R	

The criterion defining the tree is the structure of the computing device, not the organization that made it or the purpose that it was meant to fulfill. To make an analogy with the animal kingdom, if the bone structure of a horse is that of a fine race horse then it would be classified as such; it would not matter if it were bred by the government and used to pick up garbage. In computing, the EDSAC, built at Cambridge University, is classified as neither an English nor a university computer, but as an EDVAC-related machine in the same family as the Maniac and ILLIAC. Thus, differentiation by manufacturers, countries, or intended users is not part of the taxonomy.

The classical scientific taxonomy system with its seven levels has been adopted to organize and classify all species of related inventions. The two top levels, kingdom and phylum, are technology and information, respectively. The Museum collection displays seven classes within the phylum of information. Each of these seven classes is broken down into order, family, and genus, and then identified by species. Table 3 lists the criteria used for the breakdown of the classes. Specific descriptions for each of the classes are found throughout the catalog.

Table 3. (in process)

Criteria used in differentiating orders, families, and genus.

CLASS	ORDER (Technology)	FAMILY	GENUS
Memory	Machine interface	Storage material	Structure of access movement
Controls	*	Degree of complexity	*
Transducers	*	Phenomena/material	*
Links & Switches	*	Degree of complexity	*
Calcula	Analog or Digital	Degree of complexity	Structure
Digital Computers	*	*	*
Robotics	*	*	*

* - To be determined.

Memory is probably the oldest class, starting with early markings on caves and continuing as a significant part of both computers and automata, and also as all kinds of human-readable aids to the brain. See Table 4 for more complete explanations.

Controls are rooted in early analog devices, such as the Greek water clocks, and have been significant in the mechanization process. At the beginning of the nineteenth century, card controlled looms introduced sophisticated pattern control to the industrial process through the use of a larger scale memory data-set than hitherto used. Card control ended with a great flourish in the early nineteen sixties with the tabulating machines. Again, with the advent of the computer on a chip, earlier technologies of control devices are rapidly becoming obsolete, being replaced by the "on-board" micro-processor.

Transducers take information in one form and put it into another. They are often associated with memory systems, allowing their replication; for example, printing use type (a transducer) to duplicate the information in books (a memory device). Transducers began with the movable type and include the teleprinter, tape transport, telephone, and television. These machines are becoming more and more sophisticated and less and less distinguishable from computers.

Calculators, other than the manual bead devices, did not develop until the 19th century and have been virtually displaced by computers. In the PMS notation, these are the data operators carrying out arithmetic operations. Either calculators have become embedded in computers or miniaturized computers have been embedded in what have traditionally been considered calculators. The taxonomy of Class Calcula is explained in the text. (See Table 5.

Links and switches evolved out of the needs of a large number of subscribers all desiring the use of a single system. The first telegraph was a simple device transferring information from one place to another. But the growth of telegraphy and telephony systems in the late nineteenth century created a need to establish elaborate networks linked together with a switching system. Computers still depend on linking and switching for cross communication.

Digital computers emerged in the late nineteen forties from a combination of calculator, control, transducer, links and switches, and memory technologies. The section "Pioneer Computers" shows the combination of elements that was adopted by the first 16 machines, many of which were patched together based on different technologies. Class Digital Computer is certainly more than the sum of these parts, as the parts have converged and been modified and molded into a new phenomenon.

Robotics actually started very early with man's desire to replicate life and took the form of doll-like automata. The experimentation in the sixteenth century however only served as entertainment for kings and in travelling sideshows. The ideas for what automata might do ranged far beyond the technology of the time. It was not until the second half of the twentieth century, that robots have become economically utilitarian. With smaller and more powerful computers, on board machines for sensing as well as calculating and thinking, robots will become more widespread in the future. This class is presently not included in the collection; but will be included in the future.

Each class, like a species, starts within a given generation, flowers, and dies or is incorporated within another class. Each started almost as an independent thread but is beginning to merge into one or two dominant classes: computer and automata. Figure 1 illustrates the potential scope of the collections, indicating the period in which each class emerged and for those, becoming extinct, the time of their gradual demise.

SUBJECT: UNDERSTANDING COMPLEXITY FOR GUIDING ENG. INVESTMENT

I'd like to work with someone who would dig into understanding
complexity with me. The goal would be to be able to give a simple, but deep presentation of various systems we have because
it's at the heart of deciding the base for our future work. Thus, it is a major engineering cost, time and hence business strategy question.

Recently, I've advised several engineers to use the 68,000 (BUT
ONLY IN C... UNTIL Bliss) because I believe the task they are undertaking is substantially easier if done without program or
data overlays. For example, we spend several hundred dollars to
lay down an instruction in WPS or in some of our operating systems; there's a high cost to maintain them too.

The basic premise is that the overall complexity of a final user
machine such as a language, a word processor or cad system is the
product of 3 factors:
1. The basic architecture on which the target task is built.
2. The structure chosen to implement the target.
3. The target task. eg. PL/1, BASIC, WPS

Diagramatically,

```
3.  The target task_____x_____x____.......x_____________
                        .     .          . .
                       . .    .         .   .
2.  The structure     .   .   .        . .  .
                     .     .  .       .   . .
                    . .   . . .      .     ..
                    . .   .  ..     . .     .
                    . .   .   ....... .     .
```

```
                  . .   .   .       .     .
1.  Base machine____x_x___x___x_______x_____x___________
```

This falls directly out of the fact that we build by layers and layers of finite state machines as in the ISO 7-layer protocol. Conventional machines have microcode, macrocode, O/S, and Languages as their levels we present. The office architecture has: the Individual Machine, the Organization Machine, the Professional Machine, the Generic Office Machine (GOM), the Office Base Machine (OBM), the conventional base machine such as VMS or CTAB, and finally the Hardware machine.

HARDWARE COMPLEXITY STUDY (a good PhD topic)
In Venus, VAX is the task. Venus is the structure, and the MCA and 10K family is our base. Venus is complex, and I don't even know how to measure this. Ulf uses gates, including ram's as a measure. There are lots of measures in software, including lines of code. A trivial, but better measure for hardware might be the number of D-size prints. For Venus, the 4 coupled micromachines, amount of microcode, the timing constraints and other parallelism all increase complexity in some way I know not how to even express or think about. I'd like to get a PhD student to go over our designs historically and see if they can arrive at some complexity measures. There measures would be the basis of correlating design time, errors, cost, etc. Any ideas how or who?

HELP NOW ON LOOKING AT OUR BASE SYSTEMS (To project the Future)
I want help to look at the base structure of say 3 or 4

systems
(eg. Tops 20, PDP-8, VMS and RSX) to examine how they influence
some of the systems that are built on them. I think it can be
shown that this is a major cause of complexity in the systems
built on them. I simply want to show the resultant complexity
of the primitives when exressing trivial tasks like accessing
various kinds of variables either directly or in a procedure.
For example, the expression A = B (12 bit integers) can require
up to 4 instructions and 2 x 5 pieces of data which the
programmer usually has to keep track of. This can become
horrendous if you want variable length data or there's a
procedure.

The outcome of this simple study is going to be the understanding
of how much we think our systems can be enhanced over time.
Right now, I think there are cases where we are committing
suicide. The groups are just big enough to add errors and
maintain them, but not large enough to provide winning products.
The approach will be to look at the new functionality that has
been added the last few years and get incremental costs for this
together with the investment required to maintain what has been
added. In many cases, I think we've gone over the brink! BJ,
what about someone in the quality organization that could help
here? (Again, to do what I really want over time, would be a
good PhD thesis based on looking at our software systems and
software engineering in detail.)

SUBJECT: INVITATION T

We would like to invite you to become a part of Engineering. This is along
the lines of various discussions you have had with Larry and Stan. The
way we believe the organization would work is:

1. You become a member of Si Lyle's staff as Program or Product Area manager
for the OFIS Products.

2. Bob Travis would report to Bruce Stewart (who reports to Bob Daley in
MK) as the chief architect for WPS and OFIS Products.

3. The programming group would report to Bruce.

4. The hardware group would report to Brian Fitzgerald.

Although the WPS work would be your main responsibility, especially getting
orders for the WPS 78, 278 and 200 from the P/L's, for the

short term, the
efforts to get us to full OFIS capability would be your longer term work.
This includes:
1. any R and D in this area, and setting the needs there
2. getting Mail and the Post Office
3. Compatibility with EDT and KED, and perhaps using EDT in the short
term so that we have a WPS compatible editor ASAP across VAX, RSTS and RSX.
4. workding on the compatibility of FMS (forms) and what you have promised in
release 6
5. defining how we are going to get intelligence for editin moved into the
immediate and successor terminals
6. stabilizing future 200's so that we meet our commitments and are
able to get a high growth of products in the next 2 years, followed by use
of 11's as main line, with ability of 200's to front end mainline VAX, 11 and
10/20 standard products in a clear way, transparent to user.
7. solving technical problem of ease of converting to arbitrary language
8. compatibility such that typesetting can be done from a WPS terminal
9. essential compatibility of files so that our programs on the various
systems can read and write wps files with no extra programming

We are committed to become the dominant supplier of WPS systems in the next
three years by:
1. building on and fixing the systems we have now
2. introducing the 278 in the near term
3. moving all the wps software to vax, rsts, and m (and possibly 10/20) so
that we dominate this on the basis of the number of installed terminals

Please join us and continue the fine work you have started as

a Product Line.
Regards,
Gordon

Professor Daniel J. Pease
Syracuse University
Department of Electrical and Computer Engineering
Syracuse, NY 13210

Dear Professor Pease:

It was good to get your letter on the VAX/780 for the Syracuse computing laboratory. I quite agree that the addition of this computer would be of great benefit to your community.

Unfortunately, the Museum runs under a tight budget and simply does not have the funds to support this grant. However, once Syracuse University decides to redo the laboratory and remove the equipment, we believe we might be able to provide a home for the installation. In doing this, we would want to photograph and carefully dismantle the machines so the laboratory can be recreated to a certain degree. We do have copies of all the machines you have in a warehouse, but it would be nice to have the collection as a single exhibit on "PDP-8's in a university environment", provided we can allocate the space to it. Since we are taking a very long term view at the Museum, I know we can all visualize the impact such a laboratory exhibit would make for visitors in say 50 to 100 years... provided we can store, retrieve and then display them effectively.

Since we cannot help you at this time with funds, I am forwarding your letter to the Corporate Contributions Committee in hopes that they might be able to provide some funds to assist. We are sorry we cannot help directly, but we strongly support both efforts to get a VAX there and to be able to archive your machines here at the Museum for future exhibits.

Sincerely yours,

Gordon Bell

SUBJECT: ISI, ENVIRONMENT (TALK WITH BOB BALZER)

Bob'll send information on computing environment they're trying to
build. They're switching to Ethernet, having played with old Ethernet
and Chaosnet. It seems like everyone's wanting to go to personal
machines - mainly because of the long history of machine service
overload. He sees: super terminals or workstations ala SUN, HP, or?
where graphics, editing and possibly small LISPS are run. This
environment has to be compatible with big machine environment where
bigger problems are run. He wants 750's for this. He's not enamoured
with the 730 for this due to CPU. I think he may be wrong - or at
least I hope he is. HP's putting (has) LISP on a 68,000 at Utah.

The LISP conference will be a place to get much info as everyone's

trying to get their machines benchmarked. (3 x 780's = KL = scheme
chip = 4 x 68,000) The 2060's the benchmark - thus, we could have a
really nice LISP-server when we can get the 2080 built! The fact is:
the community is out of cycles and needs a very high performance
machine for attacking new problems.

Neal Goldman will be in Boston next week. He mentioned their software
for multichip projects. IBM's sending someone there to visit.

SUBJECT: VISIT TO STANFORD, COLORADO, AND HOPEFULLY DAVE CUTLER

GB5.41

While I was in the hospital, Ed Feigenbaum (and Bruce Delagi) invited me to recuperate at Stanford. At the time, it sounded like a great idea, because I sure didn't feel like getting back into details then.

The 3 products I worried about in the hospital: 10/20 (Viet Nam), MicroVAX PC, and the Parallel Processor (read the notes on it as a hot product). All are moving, but I'll be in close contact.

THE MICROVAX PC
Since January, I've been trying to get a CRT controllers for a MicroVAX PC. Now that THE CONTROLLER SPEC IS QUITE CLOSE, I'm reluctant to leave it, but fortunately I have promises as to what it is, and when we're going to get it, plus the right people working on it. Also, we should just about have the critical experimental data about how our current system's are working. Jim Cudmore, Sam Fuller, Dick Hustvedt, Bob Huettner and Bill Avery are all working on this now. The problem is more difficult than I thought, when you consider the software problem.

WHAT I INTEND TO DO

Frankly, everytime I leave Maynard, I get a different perspective. For example:

Colorado Hospital- clarity that we're in Viet Nam on 10/20, and how to get the parallel processing done and in the market

California last summer with Jeff- understood that CMOS and ECL are it on gate arrays, and TI's going to lose. Nautilus made the choice to use ECL. Unfortunately, I should have stopped Scorpio too.

I have an office in the Computer Science Department, and want to:

. see what the problems they are working on, and how they work (ie what it's like in their powerful PC network) especially with good resolution and good printing and their Ethernets

. look at and help on two machines they're talking about--
Bruce Delagi is doing one in representing Knowledge
The CS Dept wants a copy of our Parallel Processor... and I want to get them one too, provided they're going to work on the problems of parallelism and help us develop it.

. help sell the Stanford Campus on our computing environment of VAXen, 10/20 interfaces, Ethernet, etc. evolving to clusters.
This involves the CSD, Computation Center, Business School, EE department. Sam is coming out for this, and I want to understand and help it.

. visit the Center for Integrated Systems headed by Jim Meindl, where they are having their groundbreaking. Scientific American had an article on some of the work they do

with
accleration, temperature and pressure sensors.

. visit Berkeley, and possibly Cal Tech. I have offers to visit
the Livermore and Berekely labs.

. see the Western Research Lab and understand their machine, and
how we make it into a several billion dollar product
. look at and use LISA and the SUN workstations; we've scheduled
a day meeting on these and how our architecture and
implementations compare. This is vital to the MicroVAX PC.
. visit Gene and Carl Amdahl at Trilogy. Hope we can sign up
with them as a technology supplier. Wonder what best machine
to implement will be.

. go with the CX and MK database groups to National to look at
their database work and chips; much of this came out of the
Alpha Omega definition. Want to work toward a product within a
year based on MicroVAX, and want to understand how close this
is and if we have to wait on their chips.
. visit LSI Logic, VALID (CAD supplier to us) and see where they
are and where they are going to be.
. visit Les Hogan and Tom Longo at the Fairchild research labs,
and follow up their invitation to look at their LSI and A/D.

. Gwen's going to be there for a week and wants me to sell the
museum.
. other possiblities include Apple... Intel... Zilog.

VISIT TO SEATTLE
Dave wants me to stop by and I hope I can.

THEN ON TO COLORADO
It's been quite a while since I've been there. They are running out
of work since the last time I spent with them on the HSC, and working
on the database machines.

All in all, it looks interesting, and hardly as relaxing as I had
hoped, yet stimulating.

September 8, 1978

Mr. Kazuo Iwama
Sony Corporation
P.O. Box 10
Tokyo A.P.
Tokyo, 149 JAPAN

Dear Mr. Iwama:

Thanks for the fast response to my request for material. I just returned to the U.S. and find we're proceeding reasonably well with the evaluation of the Betamax that's been modified for holding digital information. The important part for us now is to determine how it can be used, i.e., the market.

In order to get a product, we'll have to somehow develop a more trusting relationship because the design alternatives will have to be more fully explored. I hope we can do this.

Sincerely,

Gordon Bell
Vice President,
Engineering

SUBJECT: J-11: AT BOARD, BOX AND SYSTEM LEVEL

J STATUS
Bob Supnick presented the current status. I'm impressed with the design team, their aggressive schedule, and believe in the necessity of the Floating Point Accelerator chip both as a product, and to learn about VLSI design ahead of VAX-11. Let's not spend too much time with the tin cup.

J AS AN AGGRESSIVE BOARD PRODUCT

The most exciting thing about the chip is that it really lets us
go head to head with the chip folks in the high performance market. Intel and Motorola appear to not be getting the performance. Here, it is simply experience, so it feels like we do have good market potential to go head to head with the 68000 and 8086 ... if we deal from performance and software strengths. (UNIX is, however, coming on strong as a way of the semicomputer companies getting software.)

SELLING THE 11 AS A 16-BITTER

As a computer scientist/engineer, I'm really worried about the
addressing problem. In my advanced age, the one metric I use to measure architectures is simply address bits. Thus, what have been called 8-bitters, I would classify as 16 bits, and the 16-bit ones (eg. 68000 and 8086) I'd classify as 22 bits. For building interactive terminal systems, it is awfully nice
to have 20+ bits, cause we've seen that the 10/20 address space
of 20 bits is really quite adequate and only just now breaking
for large programs. The VAX address space lets a whole range of
problems be solved however that we'd never see done on a 24-bit
machine like the 370... also, it will change the nature of programming. The trick then is twofold: make it clear to the
market that we feel that the 11 address size of 17 bits (I and D
space) x number of independent processes is just fine, especially
when we have all the ways to do overlays; AND learn about and develop programs that require 32-bit addresses so that this will
be demanded for large, personal systems of the mid-80s when we
get VAX in a personal computer.

THE 11 SYSTEMS AND THE BUS TACTICS

Therefore, we should plan to use J to go aggressively after
the Qbus board level business. At the system level, for
those
who needn't or won't switch to VAX, we should build the
11/24J
to give us the 11/70 performance at 11/24 price. This gets
us a system that is still below the Nebula in price... to
distinguish the two products (even though the performance is
at Comet level for certain cases). Given our limited
offering
of Q bus system options (comm options, big disks), then it
would seem to make sense to NOT INTRODUCE the Qbus (quad
version)
a system. This also makes sense since all the VAXes use the
Unibus. In this way we could go into a bus holding pattern
until we see how much of the systems will migrate to the NI.
Also, there's a question of what the right sizes are for
building
the various nodes that connect to the NI, where we have these
alternatives:

.All tie directly to the NI with NO modularity of backplane
 (take an R80/81), remove the SI, and put a computer and NI
 there as the Fileserver)

.Build the nodes out of Qbus parts ... like our OEMS do.
Here,
 we should move to have just one Qbus (duals) versus duals &
quads.

.Unibus ... until the NI takes over

.BI (for VAX) to interconnect the various computer components

.Continued use fo system unique backplanes

.Personal computer components oriented to industry std parts.
 (Here, the II bus is being defined.)

What do you think? Is this the right direction?

Dear James Martin:

I enjoyed your stimulating seminar. Thanks.

Enclosed is a paper by one of our people discussing this issue of how one defines the word maintainance. Let me also recommend the taxonomy by Babb & Tripp appearing in SIG SOFT SW Engineering Notes, No. 1. 4 # 4, October 79.

Also enclosed is a Museum brochure.

Hope to see you again.

Sincerely yours,

Gordon Bell

Prompted by a recent presentation on this at MCE, here's my cut:

INDIVIDUALS..

IQ's are higher by 10 points (Fortune 5/82). Higher literacy
Lower wages, but increasing.
They work harder. Net equals more thoughts and actions per yen
Less individualistic and willing to accept other ideas (anti-NIH)

SOCIETY..

More engineers available to fuel a high technology technocracy
Less lawyers and legal documents to waste time
Few MBA's, thus focus on content versus process of technology
Understands meaning of productivity and quality. They apply them
Understands timeliness, the parametric variable of ROI
Clear goal set of production domination with demonstrated success
Coded language which we don't understand. One way flow of ideas

COMPANIES..

Low operating margins are acceptable
Availability of cheap capital

Better professional demographics because marketing is done by US
Technical training programs
Permanent workforce with 1/2 workers in sweatshops structure
Good management and more stable technical workforce
Less venture capital firms to compete in getting critical mass
Protected market resulting from many factors
Better balance and experience in automation
Ability to manage flow of US research into Corporate products
INDUSTRY INFRASTRUCTURE...
Have the basics including materials versus US trends to systems
Collaborative intercompany behavior for research
Ability to segment mkts. to reduce expense of covering all bases
No "Eastern Electric", hence manufacturing is via companies
Successful acquisition and are beyond US technology in semis, magnetics, displays, optics, etc.
Dominance of consumer electronics for manufacturing understanding
GOVERMENT..
No military creating no productivity for a large expenditure
Less of it to support
Supportive versus conflictive
Directs and funds goals to dominate various industries
OTHER..
Have a single, working view of the 5th Computer Generation
Incredible PR and self and US belief that "Japan Number One"
OUR EDGE...
Individualists. Creativity. Much CAD/CAM is US based. Software engineering. Better higher education, even though it's used for foreigners. Science and research base (funded by DOD). Entrepreneurial belief and structures to exploit ideas.

INNOVATION IN JAPAN--A LESSON FOR US?

The Japanese, are innovating in the right way. How can Japan be the model if their new ideas come from other places? Especially because many ideas probably come from the US, a lot can be learned about their processes of innovation that lead to success. This process takes ideas from research through manufacturing and into the market. In dealing with making prototypes and then developing production capabilities, the Japanese are solving the problems that will lead to more innovations. In the meantime, US industry has been transformed into warehouses, managed by purchasing agents, and I haven't noticed how many ideas come from them. Selling ideas to Japan and then buying back the products that incorporate the ideas will lead only to fewer innovations and to industrial decay in the US.

JAPAN'S STRATEGY AND TACTICS

With 100,000,000 people and virtually no natural resources, Japan has progressed from manufacturing low technology commodities such as textiles to complex machinery, such as the micro-miniature area employing precision optics and precision mechanics in video tape recorders and television. High skill, low cost level technology work is being concentrated in Japan while low skill work such as assembly of things like television sets are done in appropriate off-shore low skill areas such as San Diego.

The overall approach to market domination comes in a four phase attack starting from the development of a domestic industry, often using borrowed technology but controlling imports until it is established. Their second phase is to establish the export base with a reputation for quality and reasonable prices. The third step, major market penetration, depends on cooperation among Japanese companies with respect to their models and using marketing muscle, mass volume, and low prices to rapidly gain market share and knock-out the competition. When there is sufficient market penetration they finally move into market exploitation and totally dominate, for example, in precision cameras.

In Japan, government and business work together in a team sense unlike the highly adversary relationship existing in the US.

The group called MITI, (Ministry of International Trade and Industry) with almost an autocratic power, helps amalgamate strategies commonly referred to as Japan Inc. Digital Equipment Company has had experience in terms of exporting a particular product called MUMPS, a data-base operating system for interactive data-base problems. After six sales of MUMPS in Japan, interpreted by MITI as lost sales, the development of a Japanese mini-computer version was funded. In mid-1978 a Japanese researcher at Carnegie Mellon University asked me for the internal structure of DEC's implementation of MUMPS from a so-called computer science viewpoint. This particular episode shows me how they really have integrated academic research with industrial goals. The US certainly does not have the equivalent of MITI, protecting and aiding major corporations as national resources. In particular the US Government seems to be determined to break up corporations such as IBM, capable of undertaking innovative projects.

The Japanese strategy to win domination is hidden. Their behavior is open: they combine and in computers, different companies position the machines to provide a full line from Japan. They have won the advantage of providing a range of machines so the software runs across that system and avoiding redundant, costly development. Also, this work is based on IBM emulation. Such industrial collusion is not acceptable in the US: when people meet in a hotel room, talking about prices or positioning, they often end up in jail. Yet neither the US Commerce Department or the Labor Department appear to have a plan or personnel to maintain dominance in high technological fields that is important to economy and security. More important, both these departments behave as adversaries to each other and to industry.

Japanese industrial tactics focus is on the centrality of work and loyalty to the company. The work ethic at work is an incredible thing to see. A highly stable work force promotes a certain amount of risk-taking because there is little fear of job termination. In the US, with threats of unemployment, risk-taking keeps declining, and with it innovation. In some groups in US companies, it is difficult to find out who can take a risk. For example, a very nice memory component was developed in a large corporate lab, under DOD sponsorship and

I tried to buy it but found that the Defense Department was bidding against me. All this little lab really wanted to sell was about one a year to the Defense Department to keep their research group going. I wanted 10,000 a year. We just couldn't find anyone within the structure of the large organization who wanted to manufacture the product. It was really tragic, a very good product that could be useful to society and the economy. But I really couldn't even find out who it was who made the decision. Why is research funded in the first place if the goal is not to product a useful device? The group is still doing research in the same area, and the Defense Department is still buying prototypes and there is absolutely no way that the device can ever get out of that laboratory through the divisional bureaucracies and into industry. This really points out the poor coupling between the development of ideas and the mechanisms for exploiting them. Our present government/industrial bureaucracy might well have throttled Edison to one light bulb had he lived one hundred years later.

Quality control has been delegated to the worker as opposed to being managed. This participation provides a key to the devotion to the workplace and a sense of achievement within the fabric of societal goals. Incompetent workers become wards of the organization and not wards of the state, such as teh 300,000 retired, handicapped federal workers. This provides much, local pressure to not be a ward. In the US, the freedom of the individual not to contribute to national goals has undermined the the work ethic.

USING ACCULTURATED DESIGNS

If you look in the sixteenth century, it only took the Japanese 18 months to acquire the manufacture of guns and gunpowder from the Portguese. For any product, they consider quality first, then volume for growth and flexibility to allow for the fast turn around needed to maintain full-production capacity in shifting markets.

They do a superb job of being able to orient their production line with quality and flexibility. The whole issue of semi-conductor quality necessary for building computers seemed to come from the fact that the telephone company buys from other sources, acting as a quality filter. Once you've got volume it is not so easy to get quality. The fact that the Japanese have this separate organization buying and selling really has helped their semi-conductor industry. If you contrast this with our situation, the telephone industry is its own captive supplier. They have quality, of course, but they don't have the technology incentive or cost goals because of the long amortization period.

All the Japanese computer manufacturers have acquired their technology within the past ten years by dealing with US manufacturers, either as a joint venture or under license, including: Fujitsu (Amdahl/Siemens) and Hitachi (RCA); NEC (Honeywell, GE, Varian) and Toshiba (Honeywell, GE, Interdata); Mitsubishi (Xerox) and Oki (with Univac joint venture); Yokogawa (HP); and Nippon Minicomputer (DG). In all cases, the Japanese have improved the technology in terms of perceived quality, performance and manufacturability.

In addition, Japanese computer manufacturers have a complete line of peripherals and test and manufacturing equipment, much of which is based on counter-parts invented in the US. The designs range from "reverse engineered", to look-alike copies, to radically improved products based on Japanese inventions. With "reverse engineering" a product is dissected with micrometers, special gauges, etc, and made compatible in nearly every respect. The Japanese make only products for export to the US market that do violate patents. Tektronix look-alike scopes and reverse engineered IBM disks are common. In 15 months, Nippon Peripherals Limited produced a disk that was mechanically identical to the IBM 3340. From comparing the two drives, one might evern conclude that they were made from the same drawings.

LONG-TERM THINKING

Product design based on need, quality, and long-term projections can lead to innovation. But product design derived from the very thick marketing survey only extrapolates straight line trends in a self-perpetuating fashion. US industry has gotten into the habit of short-term thinking, epitomized by these
surveys whose currency drops off rapidly in weeks after

publication. Japanese companies, with long-term goals and commitments, have little need for marketing surveys and the energy and money they waste, partially because U.S. buyers do their market work for them.

NEC, Fujitsu and Hitachi, unlike Xerox, GE, Westinghouse, and RCA, have all persisted with computer manufacturing and after years of investment have established successful products. Their long-range thinking from the outset allowed them to invest in long lasting quality. NEC was no different in terms of corporate structure than the large U.S. companies that went out of the computer business. But the notion that success follows if one sticks to a fundamental idea has been lost in U.S. corporate thinking.

Isn't it amazing that Japan has been able to focus on quality, sophistication, rather than throw-away products: Seiko vs. Timex watches and Nikons vs. Polaroids. In fact, given their approach to man/machine interaction, it is probably impossible for a Japanese designer to come up with a one-step camera. However, it may be that the overall concern for quality also comes into play.

When considering innovation it is important to distinguish items with a lasting value from just another piece of injection molded plastic, something that will soon be thrown away. The life cycle of industrial products is something that we do not pay enough attention to. We are not trained to think about investment evaluation for any long period of time, and that leads to worrying about the wrong characteristics and the wrong problems. Each new product should be evaluated in terms of maximizing its life, minimizing the cost to use, and maximizing productivity. For example, in Japan, all line printers had paper cutters and paper sorts on them.

UNDERSTANDING COMPLETE PROCESSES

The successful production of competitive performance products in high technology industries depends on understanding a complete process that includes basic research, going through applied research and advanced development, to product development. In addition, a parallel and equally complex process is required to design and build the process that manufactures such products. After a new product is introduced, it may then be necessary to modify and enhance it to adapt it to the real or changing market, and finally to eliminate it when it is no longer effective.

The Japanese need invest little in basic and applied research because they are effectively coupling the U.S. laboratories into their advanced development. In contrast, aside from the direct hiring of students and researchers, there is very little flow of ideas from our public laboratories into our own industry. As Carver Mead of Cal Tech points out, "I like the Japanese. They listen. Also unlike American industry, they're willing to build from our ideas." The university laboratories at Stanford, MIT, Carnegie Mellon, the University of Illinois, receiving significant ($20-30 million per year) Advanced Research Projects Agency (ARPA) funding for Computer Science, have post-doctoral Japanese visitors. The university and industrial laboratories of Japan are headed and staffed by researchers who've spent their research years in key American laboratories such as MIT Multics. The flow of ideas from these centers to the Japanese is better than from these centers into American computing companies. Many of our companies don't even know these centers exist or that money is being poured into them.

Most recently, Japan has offered to spend one billion dollars in the U.S. for research, predominately for energy conversion. By accepting these funds, the Japanese can be even more effectively coupled to U.S. research and can "learn" to research, just as they've learned manufacturing, design and advanced development.

MITI, in contrast to the U.S. government, has few laboratories. They do research by funding and promotion of technical interchange. The Japanese have a good set of techniques for managing the flow of ideas back and forth across boundaries based on industrial need.

The Japanese orientation is clearly based on engineering and design for manufacturing rather than on science. In contrast, manufacturing technology in the U.S. has gone out of the engineering school and into the business school. But there is more to manufacturing than the machine shop scheduling problem. Quality control is often not taught! The invention that can come out of a manufacturing operation (often equalling the amount in the product design itself) is being ignored. Manufacturing engineering is segmented in U.S. colleges and in business. In contrast, in Japan people are rotated among the various processes and disciplines, making it equally desirable to carry out any function. But more significantly, this reinforces the understanding of innovation feeding backward and forward in affecting total processes.

The Japanese have shown that they are willing to give up profit for growth. For example, RCA is now a rug maker (or distributor), car renter, publisher, television component distributor; it hardly resembles the electronics company that pioneered televisions. RCA's role is that of a banker and such a conglomerate is no match for a serious manufacturer. Whereas there is extreme pressure on our business for profit and return on investment, these factors are less important to the Japanese companies. In computing, NEC or Hitachi computer divisions took a long time to become profitable. Japanese companies are buying market share. Given the growth phase, these companies would not compete for capital in the U.S. stock market where return-on-investment is the key criterion.

A gradual erosion of carrying out whole processes in the U.S. through a series of incremental decisions has lead to the erosion of U.S. industry as a whole. Not only has control and market share been lost, but also the whole process that lead to coming up with good ideas. The people who really have the vision to come up with the good ideas are those actually carrying out the totality of the manufacturing process and deal with issues of quality day in and day out. Today, these are the Japanese. We are fools if we think that U.S. industry will be healthy only playing the role of a distributor.

TECHNOLOGY AND THE FUTURE

An overriding element of time and patience is the key to the long term success of the Japanese. They have been willing to wait for a whole variety of material goods, but they really work at obtaining up-to-date information relative to developing innovations. They are impatient with trivial nuisances, inventing and using automatic taxi door openers for example, but have been patient in achieving quality performance prior to going into a field.

The Japanese, as I do, believe computers are fundamental for the long term and they are prepared to invest in them and wait. Not only are machines used in all products they build for export, but they save labor too. Labor is both precious and expensive in Japan: There are only about one hundred million people with two percent unemployment. They must have computers to raise productivity; computers are vital to their continued domination of manufacturing. As a separate research area robots are an important component of manufacturing domination. While much of the pioneering work was done in the U.S., the continued work to make robotics practical takes places in Japan.

In the U.S., in contrast, the role of the computer and robot is still debated, while our disgruntled workforce grows impatient carrying out meaningless work on throw-away items. We must return to valuing the understanding of our technology so that we stop being the slaves of Japanese enterprise.

Acknowledgment

The author is especially indebted to his wife, Gwen Bell, who took the transcribed talk, notes and ideas for the talk, and

converted them into the current paper.

Pat McGuire, Mary Jane Forbes, and Sue Hunt typed and edited the final document.

Prompted by a recent presentation on this at MCE, here's my cut:

INDIVIDUALS

IQ's are higher by 10 points (Fortune 5/82). Higher literacy
Lower wages, but increasing.
They work harder. Net equals more thoughts and actions per yen
Less individualistic and willing to accept other ideas (anti-NIH)

SOCIETY

More engineers available to fuel a high technology technocracy
Less lawyers and legal documents to waste time
Few MBA's, thus focus on content versus process of technology
Understands meaning of productivity and quality. They apply them
Understands timeliness, the parametric variable of ROI
Clear goal set of production domination with demonstrated success
Coded language which we don't understand. One way flow of ideas

COMPANIES

Low operating margins are acceptable
Availability of cheap capital
Better professional demographics because marketing is done by US
Technical training programs
Permanent workforce with 1/2 workers in sweatshops structure
Good management and more stable technical workforce
Less venture capital firms to compete in getting critical mass
Protected market resulting from many factors
Better balance and experience in automation
Ability to manage flow of US research into Corporate products

INDUSTRY INFRASTRUCTURE

Have the basics including materials versus US trends to systems
Collaborative intercompany behavior for research

Ability to segment mkts. to reduce expense of covering all bases
No "Eastern Electric", hence manufacturing is via companies
Successful acquisition and are beyond US technology in semis, magnetics, displays, optics, etc.
Dominance of consumer electronics for manufacturing understanding

GOVERMENT

No military creating no productivity for a large expenditure
Less of it to support
Supportive versus conflictive
Directs and funds goals to dominate various industries

OTHER

Have a single, working view of the 5th Computer Generation
Incredible PR and self and US belief that "Japan Number One"

OUR EDGE

Individualists. Creativity. Much CAD/CAM is US based. Software engineering. Better higher education, even though it's used for foreigners. Science and research base (funded by DOD). Entrepreneurial belief and structures to exploit ideas.

Fisher Lee
General Manager
China Computer Corporation

Room A, 5th Fl., 126 Nanking E. Rd.
Sec. 4, Taipei, Taiwan, R.O.C.

Dear Fisher:

Let me drop you this brief note to thank you for the wonderful hospitality that was extended to me on my recent visit to Taiwan.
Most importantly, I was impressed with the large number of VAX's I saw at the universities. It was also very nice to see the fine co-operation between your company and Digital Service. Also, the rapid growth of your company has been outstanding. I hope this growth can continue at the current rate. In a separate letter to Mathew (and you) I urge you to look at installing Ethernets as a way to get much more out of the computing environments at the universities.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, The Digital Computer Museum

CC: Bob Chen, Digital, Hong Kong
Jerry Witmore
Dick Yen

July 20, 1982

Mr. Mathew Miao, President
China Computer Corporation
Room A, 5th Fl., 126 Nanking E. Rd.
Sec. 4, Taipei, Taiwan, R.O.C.

Dear Mathew:

I was delighted to meet and visit you in Taiwan during July 5-7. T growth and competence in your country is really impressive. Everything looked good to me: drive, young leadership, the universities and the overall industrial climate.

Most important of all to me personally was seeing the large array o VAX's at the various universites. I believe you have a great chanc to do really first rate research there by by encouraging the universities to have Ethernets to connect their individual machines a campus together. I would also then like to see all the nets lin together to form a complete network of all the machines. This woul give a very strong project focus to getting going to build distribu processing via networks.

It was a pleasure to discuss the Computer Museum with you and prese the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The wo "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The museum also invites you to supply important artifacts for thei historical preservation. Your Chinese typewriters and terminals wo qualify. The current list is included in the report and grows rapidly.

I'd welcome being able to show you the growing museum whenever you visit this area.

Most of all I hope you can visit me so I can try to repay the fine Chinese banquets and hospitality you extended to me in Taipei.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, The Computer Museum

CC: Dr. Gwen Bell, Director, The Computer Museum

Tom and I started this, In addition, a table of these supplier/competitors is needed in terms of size, # people, R & D.

The basis is whether a company is some combination of
a maker (design & mfg.)
buyer
user
seller

Note that all the audio suppliers are going to Digital (eg. TEAC) and with some saturation are becoming Digital suppliers. Also consumer electronics includes calculators, etc.

SUBJECT: CONTINUING TO BUILD SOME JAPANESE CORPORATE PROFILES

I was surprised to find the large number of engineers (10,000) at
Kawaski, given that Fujitsu is smaller than we are. The one page
matrix of 28 companies by 50 technologies gives a very general overview of the makeup of a company.

Can we continue and make the rest of the grid which gives:
size, growth rate, some financial measures, sites, research and

development attitudes, key technologies they own (with effort)?

For example it's helpful to know the makeup of how much Sharp is
into computing... since it's a 5B company. I'd also list some US
companies like Univac, Intel, Burroughs, AMD, etc for a comparison. My gut says that there's about as much information processing equipment (semis and calculators and typewriters included) coming out of Japan now as the US.

If we had such a profile and dossier and kept it in our market data center library it would sure make visiting companies a lot easier.

Was surprised to find that as we toured Hitachi Central Research the guide carried a 1/2" thick dossier on me/DEC that included various papers including the Fortune article and various visits with Hitachi people.

This feels very important to do.

SUBJ: ENGINEERING IN JAPAN: LET'S MOVE!

TO: OPERATIONS COMMITTEE
PEG
GRANT SAVIERS
JERRY WITMORE

Date: JULY 21, 1982
From: Gordon Bell
Dept: Eng. Staff
MS: ML12-1/A51 Ext: 223-2236
EMS: @CORE

1. The engineering is superb in scope (see 2), cost, quality and timeliness.

The supply of all types is plentiful, including support for quick turn-around of prototypes for boards, mechanisms and plastics. Purchasing and manufacturing people also have engineering degrees. The GO playing, high IQ and literacy shows. The cost per engineer is about 0.7 x US, but not a reason per se. The strong work ethic, focus and understanding of quality both in engineering and manufacturing will result in a factor of two in overall productivity, I believe. We have much to learn here.

2. Many consumer and computer technologies are now indigenous, especially since the saturation of audio/video market. These are now the basis of computing, including:

optics and fiber optics - innovation is rampant in switching
matrix printing - Kanji demands high resolution
xerographic - all sorts of opportunities, eg FUJI-XEROX
fax - for Kanji
Daisywheel -
liquid crystal, electro - lumenescent panels, small crts
keyboards - all new typewriters are electronic (watch out!)
tape, floppies, and small Winis (eg. TEAC)
voice i/o - Sharpe to show proto of 2K word voice typewriter
crt's and videotechnology including disks and tapes
semiconductors - see 3

From a customer perspective, we must be here to buy and understand the possibilities.

3. Semiconductors are very good and getting better. NTT may have a breakthrough in terms of their Hierarchial Design Language (based on Conlan and ISP... I'm obviously biassed) which is oriented to specifying the design rather than trying to tweak it into existence at the tube. Their large CPU chip done in 2 months used it. NTT described the language 1 year ago, inside Japan. They are going to use it as a quick turn-around for small firms supposedly. The big users have similar systems in Research and in some development. Saw a system very much like the Si Compiler.

Saturday morning I was handed two Hitachi CMOS static rams for test and evaluation using 2 micron CMOS with 2 poly. They're running 2 metal now also. In 2 years it's one micron. Saw .8 micron at the research center from a Class 1 clean room (with 0 particles and 16 people in it). One megabit is on target for ship in '85. I make this a 3 year lead.

Several companies are interested to design and build a one chip VAX, which they admire.

4. Tokyo has the urgency of technocracy of Si Valley, without the movement of people. Ideas do move in a very competitive way. "Known" technology like low cost and/or high quality print heads, recording heads, etc. are plentiful everywhere. kanji is a good focus for excellence in printing. We were going to buy heads here, move them to the US for designing and then build them somewhere in the Far East. This makes no sense due to availability of whole mechanisms and the need for close interfacing and no real technology to build on in ML. JEC is promising a factor of 2 better in every dimension (time, cost to design and cost to build), so we do have to give them the chance. DEC Japan-CSS just introduced a Kanji VT80 and LA80 with a 9 month gestation time, based on VT100 case and PS.

Designing and building complete products here will eliminate a whole series of content-free, boondoggling, process-oriented buyers, sellers and negotiators which only add time and overhead.

5. Engineering-Manufacturing organizations do the work and are responsible with little or no marketing organizations. Engineers take responsibility for product definition.

Four years ago when I first put forth the thesis that lawyers and MBAs had ruined US industry, it was little more than a conjecture. Now that everyone has picked the theme up it must be right. It clearly seems right based on talking to my counterparts here.

By having no marketing outside of sales and engineering, delays and costs are reduced, noise is non-existent, and only two groups are responsible instead of three. Product responsibility is clear.

6. Saturday morning I visited a small, but very innovative company doing all sorts of fiber optical devices. These companies are not visible outside Japan, but they provide much of the infra structure for innovative products by the large companies.

7. There are also research results such as the Fifth Computer Generation Project we can couple to. Fujitsu, 3/4 our size has two times the engineers in ISP and lots of technology. IBM has a large, 1000 person facility and just sent a very senior researcher to establish a VLSI research center.

8. There is really no choice: either we make products competitively here under the DEC name, or we buy them on a purely random basis when the suppliers and needs arise as a crisis (eg. LA50). In both cases we need more presence (including being a competitive Japanese company which includes more than sales). This is not to say that we make, not buy everything, but that we need to have the alternative.

We must not become like our former neighbor, HH Scott in learning too late that Japan had much to offer in design and manufacture.

I look forward to PEG, OC and BOD support to establish and then accelerate our Japan Engineering Center.

SUBJECT: ENGINEERING IN JAPAN ; LET'S MOVE

I'M EVEN MORE POSITIVE ABOUT OUR JAPANESE ENGINEERING
BECAUSE;

1. THE ENGINEERING IS SUPERB IN SCOPE (SEE 2), COST, QUALITY
AND TIMELINESS.

THE SUPPLY OF ALL TYPES IS PLENTIFUL, INCLUDING SUPPORT
FOR QUICK~
TURN-AROUND OF PROTOTYPES FOR BOARDS, MECHANISMS AND
PLASTICS.
PURCHASING AND MANUFACTURING PEOPLE ALSO HAVE ENGINEERING
DEGREES. THE GO PLAYING, HIGH IQ AND LITERACY SHOWS.
THE COST
PER ENGINEER IS ABOUT 0.7 X US, BUT NOT A REASON PER SE.
THE STRONG WORK ETHIC, FOCUS AND UNDERSTANDING OF QUALITY
BOTH IN
ENGINEERING AND MANUFACTURING WILL RESULT IN A FACTOR OF
TWO IN
OVERALL PRODUCTIVITY, I BELIEVE. WE HAVE MUCH TO LEARN

HERE.

2. MANY CONSUMER AND COMPUTER TECHNOLOGIES ARE NOW INDIGENOUS,
   ESPECIALLY SINCE THE SATURATION OF AUDIO/VIDEO MARKET. THESE ARE
   NOW THE BASIS OF COMPUTING, INCLUDING;
OPTICS AND FIER OPTICS- INNOVATION IS RAMPANT IN SWITCHING MATRIX
     PRINTING-KANJI DEMANDS HIGH RESOLUTION
     XEROGRAPHIC- ALL SORTS OF OPORTUNITIES, EG FUJI-XEROX
     FAX- FOR KANJI
     DAISYWHEEL-\par   LIQUID CRYSTAL, ELECTRO-LUMENESCENT PANELS, SMALL CRTS
     KEYBOARDS- FROM ALL NEW ELECTRONIC TYPEWRITERS (WATCH OUT!)
5
     TAPE, FLOPPIES, AND SMALL WINIS (EG. TEAC)
     VOICE I/O- SHARPE TO SHOWPROTO OF 2K WORD VOICE TYPEWRITER
     CRT'S AND VIDEOTECHNOLOGY INCLUDING DISKS AND TAPES
     SEMICONDUCTORS- SEE 3

  FROM A CUSTOMER PERSPECTIVE, WE MUST BE HERE TO BUY AND UNDERSTAND THE
  POSSIBLITIES.

3. SEMICONDUCTORS ARE VERY GOOD AND GETTING BETTER. NTT MAY
   HAVE A BREAKTHROUGH IN TERMS OF THEIR HIERARCHIAL DESIGN
   LANGUAGE(BASED ON CONLAN AND ISP... I'M OBVIOUSLY BIASSED)
WHICH IS ORIENTED TO SPECIFIYING THE DESIGN RATHER THAN TRYING TO ~
   TWEAK IT INTO EXISTENCE AT THE TUBE. THEIR LARGE CPU CHIP DONE
   IN 2 MONTHS USED IT. NTT DESCRIBED THE LANGUAGE 1 YEAR AGO, INSIDE
   JAPAN. THEY ARE GOING TO USE IT AS A QUICK TURN-AROUND FOR SMALL

FIRMS SUPPOSEDLY. THEBIG USERS HAVE SIMILAR SYSTEMS IN
RESEARCH AND IN SOME DEVELOPMENT. SAW A SYSTEM VERY
MUCH LIKE THE SI COMPILER. THEY BELIEVE LITTLE RESEARCH
ISNEEDED
IN VLSI CAD!

SATURDAY MORNNG I WAS HANDED TWO HITACHI CMOS STATIC
RAMSFOR
TEST AND EVALUATION USING 2 MICRON CMOS WITH 2 POLY.
THEY'RE
RUNNING 2 METAL NOW ALSO. IN 2 YEARS IT'S ONE
MICRON.
SAW .8 MICRON AT THE RESEARCH CENTE FROM A CLASS 1 CLEAN
ROOM (WITH 0PARTICLES AND 16 PEOPLE IN IT). ONE MEGABIT
IS ON
TARGT FOR SHIP N '85. I MAKE THIS A 3 YEAR LEAD.

SEVERAL COMPANIES ARE INTERESTED TO DESIGN AND BUILD A
ONE
CHIP VAX, WHICH THEY ADMIRE.

4. TOKYO HAS THE URGENCY OF TECHNOCRACY OF SI VALLEY,
WITHOUT THE
MOVEMENT OF PEOPLE. IDEAS DO MOVE IN A VERY COMPETITIVE
WAY.
"KNOWN" TECHNOLOGY LIKE LOW COST AND/OR HIGH QUALITY PRINT
HEADS,
RECORDING HEADS, ETC. ARE PLENTIFUL EVERYWHERE. KANJI IS
A
GOOD FOCUS FOR EXCELLENCE IN PRINTING. WE WERE GOING TO
BUY
HEADS HERE, MOVE THEM TO THE US FOR DESIGN INS AND THEN
BUILD
THEM SOMEWHERE IN THE FAR EAST. THIS KES NO SENSE
DUE TO AVAILABILITY OF WHOLE MECHANISMS AND THE NEED FOR

CLOSE
INTERFACING AND NO REAL TECHNOLOGY TO BUILD ON IN ML. JEC IS
PROMISING A FACTOR OF 2 BETTER IN EVERY DIMENSION (TIME, COST
TO DESIGN AND COST TO BUILD)~, SO WE DO HAVE TO GIVE THEM THE
CHANCE. DEC JAPAN-CSS JUST INTRODUCED A KANJI VT80 AND LA80 WITH A
9 MONTH GESTATION TIME, BASED ON VT100 CASE AND PS.

DESINING AND BUILDING COMPLETE PRODUCTS HERE WILL ELIMINATE
A WHOLE SERIES OF BOONDOGGLING, CONTENT-FREE, PROCESS-ORIENTED
BUYERS, SELLERS AND NEGOTIATORS WHICH ONLY ADD TIME
AND OVERHEAD.

5. ENGINEERING-MANUFACTURING ORGANIZATIONS DO THE WORK AND
ARE RESPONSIBLE WITH LITTLE OR NO MARKETING ORGANIZATIONS.
ENGINEERS TAKE RESPONSIBILITY FOR PRODUCT DEFINITION.

FOUR YEARS AGO WHEN I FIRST PUT FORTH THE THESIS THAT LAWYERS
AND MBAS HAD RUINED US INDUSTRY IT WAS LITTLE MORE THAN A CONJECTURE.
NOW THAT EVERYNE HAS PICKED THE THEM UP IT MUST BE RIGHT. IT
CLEARLY SEEMS RIGHT BASED ON TALKING TO MY COUNTERPARTS HERE.

BY HAVING NO MARKETING OUTSIDE OF SALES AND ENGINEERING, DELAYS
AND COSTS ARE REDUCED, NOISE IS NON-EXISTENT, AND ONLY TWO GROUPS
ARE RESPONSIBLE INSTEAD OF THREE. CLEAR PRODUCT RESPONSIBILITY.

6. SATURDAY MORNING I VISITED A VERY SMALL INNOVATIVE COMPANY
BUILDING ALL SORTS OF FIBER OPTICAL DEVICES. THESE

COMPANIES
ARE NOT VISIBLE OUTSIDE JAPAN, BUT THEY PROVIDE MUGH OF THE INFRA
STRUCTURE FOR INNOVATIVE PRODUCTS BY THE LARGECOMPANIES.

7. THERE ARE ALSO RESEARCH RESULTS SUCH AS THE FIFTH COMPUTER
GENERATION PROJECT WE CAN COUPLE TO. FUJITSU, 3/4 OUR SIZE HAS
TWICE ~THE ENGINEERS IN A SINGLE FACILITY AND TECHNOLOGY AND

ENGINEERING MASTERY. IBM HAS A LARGE, 1000 PERSON FACILITY AND
AND HAS JUST SENT A VERY SENIOR RESEARCHER TO ESTABLISH A VLSI
RESEARCH CENTER.

8. INNOVATIVENESS FOR EXAMPLE, FOR YEARS I'VETRIED TO GET A
CALUCULATOR BUILT INTO OUR LA AND VT TERMINALS, NOW,
BROTHER IS SHIPPING A $200 PORTABLE TYPEWRITE WITH BUILT IN
PRINTING CALUCULATOR. W
WE CAN EXPECT THIS KIND OF IMPROVEMENT.

9. THERE IS REALLY NO CHOICE: EITHER WE MAKE PRODUCTS
COMPETITIVELY HERE UNDER THE DEC NAME, OR WE BUY THEM ON
A PURELY RANDOM BASIS WHEN THE SUPPLIERS AND NEEDS ARISE AS A
CRISIS (EG. LA50)s~ IN BOTH CASES WE NEED MORE PRESENCE
(INCLUDING BEING A STRONG JAPANESE COMPANY WHICHINCLUDES
MORE THAN SALES). WE NEEDN'T ALWAYS MAKE THINGS, BUT WE NEED TO HAVE
THE ALTERNATIVE.

WE MUST NOT BECOME LIKE OUR FORMER NEIGHBOR, HH SCOTT IN LEARNING TOO LATE THAT JAPAN HAD MUCH TO OFFER IN DESIGN AND MANUFACTURE.

I LOOK FORWARD TO PEG, OC AND BOD SUPPORT TO ESTABLISH AND THEN ACCELERATE OUR JAPAN ENGINEERING CENTER.

JERRY WITMORE

March 20, 1979

Dr. Tribus
Room 9-215
77 Massachusetts Avenue
Cambridge, MA 02139

Dear Dr. Tribus:

Thanks for the encouragement on the Japanese paper. I'm delighted to have you share it with people at M.I.T., and would be happy for more feedback on it. It's in the state of trying to be published. If you get the chance, and know the editor of Technology Review, could I ask you to see if they would be interested in it? I've sent it to Fortune Magazine because I know the Editor-In-Chief and thought that their readership was the one I wanted to reach. I would also like to sound out the IEEE, so Weinschel would be a good sounding board for Spectrum, even though I think much of the IEEE regards itself as a bunch of "scientists and citizens of the world", and hence the message is against what they want to project.

I would like to incorporate your two additional examples in the article. If possible, I would love to get permission from the "coach" who suggests doing advanced development for the Japanese to publish his advice on a named basis. Is there a chance that you could somehow get him to write a note to me so that I could get this point of view in the article as typical of how the current liberal, intellectual American regards the situation? Carver Mead's quote on why he likes the Japanese as being ego gratification is typical, and another example would be really nice.

It is becoming increasingly clear to me that we are either going to have to get around to new measures as a society that are not productivity related, or that we should work on the productivity problem. I believe that an economist ought to be able to show rather easily that our decrease in productivity is solely related to our becoming a consumer society where the Japanese produce the goods and we merely do the advanced development, the market research and distribution (all of which only employ a few bright people...as opposed to the many who have previously been happy in producing the goods). Perhaps we should all be happy as Americans who only engage in the intellectual disciplines and consume what the rest of the world supplies us. This certainly makes me worry about whether the bulk of the people who used to build things will be happy, and whether our suppliers will be happy supplying us, given that we don't bring anything to the party?

On your paper, it seems like it is powerful enough already, and mixing Ken in at this point will probably not strenthen it. It might be worth trying to get Ken to work with you on another, but that would certainly be up to him.

Dr. Myron Tribus, Director
Center for Advanced Engineering Study
Massachusetts Institute of Technology
Cambridge, Massachusetts 02139

Dear Dr. Tribus:

I enjoyed the article you are preparing on risk-taking and the use of roi as a sole measure of business ventureness. I am enclosing an article on Japan that is along these lines too, but from a totally different perspective. You may get some ideas there too and at any rate, I would like to get your comments on the article. Some of the ideas in it will be presented at the meeting at Dartmouth, which you are also attending.

Overall, I believe the paper is good although I felt it might have self-served CDC a bit too much. Also, it seems a bit disjoint. For example, it would be good in the example to give the measures by which the projects were judged worthwhile beyond the roi and what kind of pressures there were on them to stop. A chronology of Plato would be good. What was it traded-off against? Was anyone opposed, given that Norris was for it? What led to the inner city projects? Labor supply? Any government help or hinderance? Why is it a big deal? For example, we've had plants in places which are out of the conventional places (that your average MBA would go to).

Some comments (also see them hidden in the paper) which are relevant:

1. There may be an oversupply of business schools and graduates which are driving American business to the focus on the single measure, roi. The MBA is being worshipped to the exclusion of advanced professional degrees, and though useful, it doesn't do a hell of a lot for us in designing, building, selling and servicing computers. Over time, it seems that the business degreed people take over an industry, and the industry becomes obsolete (e.g., shoes, textiles, lumber, steel) because the graduates are only roi focussed. There is no concept of change or innovation. The biggest innovation here has been LIFO accounting (or FIFO...I never can remember), but this slight of hand doesn't make for better design, new applications, and lower cost manufacturing in any of these industries.

2. There can be similar statements for the legal professions, especially in industries that are heavily regulated. We have 20 times the lawyers on a per capita basis than Japan.

3. There is the essential notion of growth and fast upward mobility that allow the roi to be such a single, clear measure. Graduates love it because the message is clear...versus ones an engineer might give, like all products must add a significant dimension for the user. Or, products must be field enhanceable and compatible with others, whereas a single point product might do better roi-wise.

4. Researchers are far from clean. Laboratories are a way to ease the corporate conscience, despite the fact that nothing useful has come out or been transferred into the product domain. Where do the Japanese get their product ideas anyway?

5. The main point of the paper which I have enclosed is that the Japanese make out because we have become roi focussed, and the best way to get high roi is to not manufacture. Engineering and Manufacturing is a real pain! Marketing (identifying what to warehouse, and what to sell) is quite inexpensive and can be done experimentally...and only takes an MBA degree. If you win, it's fame, mobility, and write up in Fortune Magazine. Thus, it satisfies all the neat criteria of roi, low risk, done by relatively unskilled labor (as an MBA has little or no content except case studies and some definitions), and it doesn't require the complexity of managing and making large investments.

6. The point you make is the simple measure of roi is bad. I try to show this more vividly in the ultimate use of roi to eliminate manufacturing within the U. S. and give it to the Japanese. The result is the three island formulation, in which not investing means that we have to be owned...because there isn't any source of funds left except the Japanese to even do the simple task of

marketing (need identification) and distributing.

7. I think there are a bunch of evils associated with worshipping the market research surveys that are now in vogue. This is an outlet to employee MBAs, but the results only extrapolate the past in a linear fashion.

8. Conglomerates really bug me. These make many industries average, drive out manufacturing (e.g., RCA), focus on banking and dilute any knowledge that quality of the product or service matter.

There was a similar case within DEC where we hung in for about six years having been the first company to introduce a computer for timesharing. The initial roi measures were clearly bad, especially in relation to the small computers, but by staying with it, we ultimately put more machines of this class in the field than GE, Honeywell, RCA, Xerox, Burroughs, NCR and CDC. IBM did not recognize the interactive style and only recently (about 10 years later) endorsed it. The important thing was that we knew it was the right way to supply computing, and this wasn't reinforced by market research which only supports the existing. Note that three of these companies are not now in the computing business, both because of their attitudes on roi and their over estimating of their ability as general managers (something you get with an MBA) as opposed to high (or specific industry) technology managers.

Anyway, you have struck a sympathetic bone in me and hopefully the comments will be useful to the paper. I don't see a need to get together until after you see whether these comments are of any use to you. Also, I'd like comments on the paper.

Mr. Hedley Donovan
Editor in Chief
Fortune Magazine
Time and Life Building
Rockefeller Center
New York, New York 10020

Dear Mr. Donovan,

I would like to take advantage of the fact that we met on one of the Doxiadis Delos cruises and, I believe, regarded each other as reasonable sorts. Thus, I hope you will acknowledge this request.

As a non subscriber, non-reader of Fortune, I read the article by Uttal on computers and Japan. Although the article prompted me to want to write a letter to the editor, I didn't because there was too much to say. The enclosed article, by me, is written from the perspective of a computer technologist and business person, hence I think it has the substance that is needed to address this really important issue.

The article was the result of a visit to Japan last summer and I would hope that it could get wide scale circulation in Fortune. It has been circulated within the computer and engineering community and the readers believe there are worthwhile and novel insights. For example, Bob Noyce, Chairman of the Board of Intel, would be happy to write a foreword for it. Also, I have been invited to give it at Harvard's Asian Studies Institute.

Last week when Bro Uttal was here interviewing officers of Digital for a story, I gave him the article for comment. Now, I would like to proceed to get it published in Fortune.

Please help me.

Sincerely,

Gordon Bell

IMPRESSIONS ON HOW THE JAPANESE HAVE CONVERTED WORLD INDUSTRY INTO DISTRIBUTORSHIPS -- CONCERN NOW FOR SEMICONDUCTORS AND COMPUTERS

Gordon Bell
Vice President of Engineering,
Digital Equipment Corporation, Maynard, Mass.
Professor of Computer Science and Electrical Engineering (on leave)
Carnegie-Mellon University; Pittsburgh, Pa.

We must be impressed with the intense drive, technical and manufacturing ability of the Japanese. As an island with few natural resources, and only very bright, hard working people they have set about and accomplished the market domination of virtually all manufactured consumer goods including the components and processes to make these goods. Currently the U.S. has a dominant position in computers and semiconductors. However, there's no fundamental reason why the Japanese won't attain what appears to be a basic goal to dominate these industries, given their history in other industries and helped by our governments.

On a first visit to Japanese computer and semiconductor companies, universities, and a government R&D laboratory, I found them relatively open. This was in contrast to my former experience as a computer science researcher with their one-way scientific interchange and being an information sink. Perhaps their openness is because they are so far along with good products, and their position so secure. Their competence, hospitality, and "apparent openness" made me quite fond of them; but I now fear them more than ever.

Based on a simple system of three islands, two supply energy and manufactured goods and one consumes from the other two, the only apparent stability occurs when the two supplier islands "own" the consumer island.

Furthermore, I question whether we (the U.S.) want to be owned in this fashion, and therefore state we may have a problem. It's not the intent to give solutions here.

Forty-odd reasons are given in the form of "feelings" to support this domination conjecture. These reasons vary from a belief that we are comparatively lazy and greedy to the fact that their government and companies get together and systematically plan to dominate an industry.

The reasons for their ability to dominate are formed from my observations, but like the Japanese, taken freely (generally without credit) from other sources with an attempt to make a better, more complete end product for industrial and government users.

BASIC WORK ENVIRONMENT IS STRONGLY COMPETITIVE WITH PLANS (STRATEGY) AND DRIVE (TACTICS) TO DOMINATE AN INDUSTRY

The new recently announced Fujitsu M200 computer appears to be the highest performance, most reliable, plug compatible 360/370 yet announced. The technology originally from the Amdahl Corporation, was improved and made manufacturable in one computer generation of about 6 years.

The Japanese industry and government team is fundamentally more competitive than any other nation. Competition is built into their culture and reinforced by training. For example in mainframe computers they have carried out a plan to build a successful industry, unlike many companies and countries.

We, the computer and semiconductor industries see a clear pattern based on the Japanese performance in textiles, steel, radios, sewing machines, typewriters, quality cameras/optics, small cars, TV, tape recorders, watches, calculators. (Note the progression from low technology/simple commodities to complex manufactured goods.) Their current position in semiconductors and semiconductor-making equipment indicates they are well on plan to dominate semiconductors as a base for electronics, and computers. This will also be the base of products that are electromechanical and will become more electronic intensive.

There is an amalgamation of the Japanese within an industry which creates something that's often referred to as Japan Inc. The Japan Club is a better name, because there's at least a show of competitiveness at the market level. Not only is MITI supportive, they also have relatively autocratic power. More importantly, they interact with industry in a helping way.

They identified and encouraged DEC's early imports in order to build their own industry as described above. For example, one of our important interactive data base systems, MUMPS* was used in six applications. At this point MITI funded the development of MUMPS on a Japanese Mini. In early July a Japanese researcher asked me for the internal architecture of MUMPS, through an academic channel, in order to study its structure from a so-called computer science viewpoint.

While there isn't direct control an connoted by our phrase "Japan Inc.", there is clear collusion and planning among the government, and companies. Not only is collusion among companies illegal in the U.S., but furthermore the role of government is one of discouraging and being an adversary to industry. In the case of IBM, who developed the mainframe computer market, both the U.S. and Japanese governments are determined to destroy the company and set-up the industry for an American distributorship of Japanese products. IBM is a key resource and should be protected as such.

The Japanese government and companies actually plan to win! Such thinking is totally foreign to us. This includes basic strategy setting among the players to segment and go after various markets (e.g., Fujitsu/Hitachi are IBM System 370 plug compatible -- Hitachi is concentrating on the internal Japanese market against IBM Japan and Fujitsu is concentrating on exports). The companies can plan and talk with one another and do, but certainly compete intensively with one another within a limited domain.

With computers, the Japanese strategy has been to couple individual companies to U.S. Companies for technology acculturation and then to pair companies to build the same compatible machines in a quasi planned, competitive fashion. This is a well-known management technique to make technology gains quickly.

Overall, MITI appears to be very strong and competent! The goal of MITI and the Japanese computer companies is a strong, dominant industry! This is in contrast to our standard regulatory 9-5 bureaucrats, who seem to work for either security or power. However they have no real way to make anything happen. Nor is there any measure of their performance. Who believes that our Department of Commerce has anything to do with our position on imports and exports or any understanding position on standards or technology?

Reicshauer hints at the fact that MITI has high quality people, as opposed to our articulate ones. In addition to the right longevity, power, and process, maybe they segment responsibility and measure results with reward based on performance, as for example "winning" in a trade area. In a few samples, I believe it's simple people quality, and the right process enabling them to accomplish something. Being responsible and measured may be the key variable. Here, this suggests we could probably eliminate the Department of Commerce and have no real change except more output, and less government spending on hand-wringing trips to Japan. For starters, a clear change of management and a clear notion of old fashioned responsibility is in order at the Department of Commerce as we see trade deficits increase with no plan in sight and only a trade trip to Japan by Juanita Kreps as a palative.

As the head of our Osaka sales office, who attended graduate school at the University of Kansas, put it: <u>the Japanese live to work versus the American need to work to live</u>. Thus, there is the basic tactical drive to back up any goal to form a dominant market oriented around a company. This is instilled at birth and trained. Work is a central theme.

A company screens its hires carefully since there is a lifetime commitment. In contrast, a recent Intel ad claimed that no interviews were required for hire. Companies only get graduates from certain universities, more extensive than here.

Housing is provided for the workers and they have what amounts to a lifetime contract. This is bad if a person's incompetent, it also means that it's hard to breathe different life into an organization. On the other hand, turn-over is low to non-existent and a team spirit clearly develops as the various members learn to work with one another.

The <u>pressure to work is fed back producing more work output</u> since everyone is working. Unemployment is non-existent and this creates an environment where non-work is unacceptable. Recall how acceptable unemployment is when the U.S. unemployment starts getting high.

<u>Only half the work is done in large companies</u>; <u>small shops buildsub-assemblies</u>. Since large organizations tend to become inefficient and lithargic, they farm out stable sub-assembly production to small shops on a competitive basis. This limits the organization, provides a buffer, and gets the costs down by

a buyer-seller relationship as opposed to operating through a large bureaucratic organization that typifies governments (invariably large and unbounded), large corporations, and large universities.

Their physical condition certainly reflects working, and they have the longest life span in the world now. On one hand there is much smoking, but an anti-smoking campaign is in progress. However, nearly all Japanese are trim versus being basically overweight. Their diet is conducive to trimness and better health, I'd guess. Although alcoholism is supposedly on the rise, the consumption in business I saw was certainly less than in the U.S.

Invention occurs, though they have large, stable companies. Unlike most large U.S. corporations which lose entrepeneurial drive and operate in a stable non-risk taking fashion, the Japanese structure encourages risk because the entrepeneurs can't escape. That is, the large corporation is the only "game in town". The inventors and entrepeneurs of American business escape large organizations in order to start new small businesses. The effect of mixing the two types in their organizations causes continual reform, rejuvination and risk taking.

I believe their manufacturing output is at least equal to the U.S., even though they have half the population. Numerous factors contribute: investment, equipment, less-overhead at the company and by society, work ethic, more output per person over their lifetime and good management attention to personnel details.

PRODUCT DESIGN IS NOT EGO DRIVEN, BUT IS A PLANNED ACCULTURATION PROCESS

There appears to be less individual egos, although there is a strong group ego! Japan has acculturated customs, technology, etc. from everywhere for centuries and knows how to do it. In the 16th century they apparently set up manufacturing of guns/gunpowder in 18 months once the Portuguese brought them in. Any good idea is fair game, subject to very strict legal patent technicalities. Having adopted an idea they fundamentally understand and improve it.

They seem to be less oriented to technology for its own sake versus what it can do for them in the long run in achieving a particular market domination. For example, they moved more rapidly into semiconductor gate arrays for their computers earlier, quite likely under Gene Amdahl's influence. The computer industry has been unable to get the U.S. semiconductor industry interested in this technology until recently, hence we lag in this basic technology. In Japan since the companies are larger, corrective action can be within a company, or if needed, MITI may force and rearrange priorities.

They clearly think both product and process together in what is a long term view. Again, here they're competitive and they orient the processes to: Quality and Volume (for growth), and finally Flexibility for fast turn-around in order to support and tune the volume. As a quirk, the predominate customer for semiconductors has been their telephone company. Unlike the U.S., where ATT has a fundamentally non-competitive, captive high cost semiconductor supplier. The buyer/seller relationship here has forced a concern for quality that would not be met by simpler consumer use (in calculators, radios and TV).

All of the computer manufacturers have acquired their technology over a one or two technology generation history (approximately 10 years) of dealing with U.S. manufacturers either as a joint venture or under license: Fujitsu (Amdahl/Siemens) and Hitachi (RCA); NEC (Honeywell, GE, Varian) and Toshiba (Honeywell, GE, Interdata); Mitsubishi (Xerox) and Oki (with Univac joint venture); Yokogawa (HP); and Nippon Minicomputer (DG). In all cases, the technology has been improved in terms of quality, performance and manufacturability. The case of Honeywell is ironic. The high performance technology selected for the mainframe is now manufactured more effectively at NEC.

The agreement between Fujitsu and Amdahl Corporation appears to be a good example of the classic Japanese computer acculturation process even though only the first two phases have been carried out. My simple understanding is that in the late 1960's Gene Amdahl explored the basic technology for high performance IBM computers as head of IBM's San Jose advanced development laboratory. As an IBM employee he tried, unsuccessfully, to get IBM interested in building high performance machines. He formed Amdahl Corporation and proceeded to develop the technology. For various reasons, more capital was needed and Fujitsu bought in as an owner. As part of the agreement, Fujitsu got the manufacturing rights to and became the manufacturer for the Amdahl line. In return, Fujitsu was able to use the same technology to design and manufacture computers for their Japanese market. At the beginning of 1978, both Amdahl and Fujitsu have announced their latest computers based on the Fujitsu processes and production facilities.

It appears now that Fujitsu has built a higher performance, incremental performance upgrade, and higher reliability machine than either Amdahl or IBM have so far announced. As an IBM computer it is unorthodox because it is a multiprocessor. Not hampered by the IBM thinking process and appealing to a buyer versus rental market, the Fujitsu machine could have a significant edge, because it also gives users new capabilities that they probably need. Care to bet on the position in 1982?

The current computer <u>manufacturers have</u> a complete line of <u>peripherals</u>, <u>and</u> <u>test and manufacturing equipment, taken from copying and improving counter-part U.S. products</u>. In one very quick casual trip through a computer factory I was able to count a dozen "copied and improved" devices.

For products under license, there is always incremental improvements. Product alternatives range from reverse engineered look-alike, through radical improvements based on key ideas or patents (e.g., video tape recording). Occasionally the Japanese buy U.S. manufactured production machines (e.g., the Gardner

Denver Wire-Wrap machine) where the manufacturer won't grant a license. In general, the emphasis is on making products they can export, versus making manufacturing process equipment that can not be exported.

In one case, (DEC) developed a semi-automatic wiring machine and manufactured a few for internal needs and licensed a U.S. manufacturer. Neither DEC nor the licensee had bothered to patent and protect the design. The Japanese version of this machine appeared in several computer factories. There were Tektronix look-alike scopes and the ideas for a laser printer came from IBM, modified by a Honeywell product and teaching. In the case of disks, they use the reverse engineering techniques (also used by Memorex, STC and Telex) to produce disks identical to those of IBM. They have made improvements in disks technology and will export either head and surface components or complete disks. Geographical separation is not a hinderance, it is a benefit because they are excluded from U.S. laws. With the advent of the IBM 3340 disk organization, NPL (Nippon Peripherals Limited) was put in place to make a comparable product. This "engineering process" required 15 months and produced a disk that was "identical" mechanically. In fact, when comparing the two drives, one might conclude that both drives were made from the same drawings!

<u>A Chronology of Systematic Domination</u>*

"Four phases are involved in the Japanese assault on a market. They include the initial development of a domestic industry, an establishment of an export market base, significant market penetration in the foreign market, and ultimate market exploitation.

> I. <u>Development of a domestic Japanese industry</u>. The Japanese industry is developed and grows rapidly. A number of major aspects mark this development. These include:
>
> (a) Market control. Imports limited essentially to zero. Only a few major manufacturers are permitted. Prices remain significantly higher in Japan than in other

competitive markets.

(b) Borrowed technology. The Japanese borrow heavily from foreign technology, including a large number of purchased licenses and patent rights, and wholesale reverse engineering.

(c) Vertical integration. During this phase, the Japanese vertically integrate their manufacture almost totally.

(d) Major investments. This period sees major investments for modern plant, equipment and technology, both for the final product and throughout the vertical chain of manufacturing. Continued heavy research and development and investment expenses keep manufacturing up to date.

II. Establishing an export market base.

(a) The establishment of widespread sales organizations throughout the United States, and, perhaps, elsewhere.

(b) A thorough researching and understanding of the foreign markets and their various facets.

(c) Establishment of a reputation for quality products and reasonable prices.

(d) A limited focus, especially in those markets less attractive to domestic manufacturers.

III. Major market penetration. Major market penetration occurs usually during an economic downturn in Japan. Previous efforts by the industry have set the stage for them to be successful in this endeavor. It is marked by the following considerations:

(a)
Cooperation among the Japanese companies with respect to models, prices, and markets.

(b)
Focus at the mainstream of the foreign market.

(c)
High inventories because of poor markets in Japan, i.e., an export push at any cost is highly expedient to the Japanese manufacturers.

(d)
Extremely low prices to the mass market to gain high percentages of market share rapidly, i.e., a knock-out punch to the domestic manufacturers. Modern plants, reasonable costs, an established export organization, and good reputation set the stage for success.

At this time, marketing muscle is established. Not only was the export market share large, but the domestic market remained closed. It should be pointed out that this major market penetration had been made by a <u>combination</u> of factors, as outlined. The greater marketing muscle allows the Japanese manufacturers to subsequently gain the profits of their long investment.

IV.<u>Market exploitation</u>. This period is marked by higher prices -- often higher than domestic manufactured models. However, the higher prices are often more than offset by perceived higher quality, both real and imagined. There is also continued cooperation on prices and markets, as well as continued limitations on imports to the domestic Japanese market."

JAPANESE DESIGNED PRODUCTS REFLECT A CONCERN FOR QUALITY, PERMANENCY AND NEED

Product design in Japan seems to have a better tradeoff among quality, product cost versus lifecycle and human usability. The lack of structured marketing as we know it provides the opportunity for products to be designed on the basis of user need rather than filling a corporation's revenue gap demanded by its financial growth model.

<u>They're</u> more <u>long versus short term oriented</u>. Their monolithic culture and history reinforces this attitude. They're capable of waiting us out in an area because we're fundamentally impatient and generally "big bang" product/market oriented and because they want long term business domination. NEC, Fujitsu and Hitachi, unlike Xerox, GE, Westinghouse, and RCA, have all persisted with computer manufacturing and now appear to be winning! This timeliness certainly affects their thinking on quality, and lastingness both in markets and products. And they're willing to invest.

Even though they have a concern for long term, <u>they work the short term very hard</u>. This may follow from the competitiveness/growth. They engineer for quick turn around, they have good processes and the engineers at these large companies work very hard. The official work week is 40 hours, but a more accepted pattern is 50-60 hours...particularly to maintain schedule or to win against IBM, Amdahl or Hitachi (if you're at Fujitsu).

<u>They</u> seem to <u>do "bottom-up" product design versus "top-down" market</u> planning as typified by the expensive, heavy, multi-volume market <u>surveys</u> and the classic Edsel. These reports usually report history and extrapolate it in a self-perpetuating fashion gathering data from a variety of sources consisting of discarded product ideas. Using this approach, we continue to build heavy, gas-consuming cars because the market has historically bought them because there is no choice. They look at the needs, and take existing ideas and improve them.

<u>Products are quality/detail oriented versus being</u> the <u>ultra-high volume</u>, <u>low-quality throw-away</u> types. These are characterized by say, Sieko (versus Timex) and anyone of their cameras say, Minolta

(versus Kodak or Polaroid which assume an idiot user with no concern for quality picture, but must have it now).

With Japanese Quality Control, although data is kept by the factory reporting and control structure (i.e. management) the analysis, corrective actions and responsibility for improvement is delegated to the workers! Even enlightening American factories go through elaborate analysis to understand and engineer the change of processes that are easily understood and correctable by the workers themselves, given they have the tools to understand how well they're doing. Thus, there is "delegated QC" versus "centrally managed QC".

The <u>long term, quality products makes them built products that are hard to beat on a life-cycle basis</u>. While it isn't clear they really consider all life-cycle costs, their small cars now get very high ratings. In the case of computers, they have begun to design and build multiprocessors because their customers invariably buy and want upgrades. Since IBM rents computers, the multiprocessor approach hasn't been developed. The multiprocessors they sell also permit better Reliability, Availability and maintainability. They seem to do a better job considering life-cycle costs than we do!

<u>Products are designed for people</u> with attention to detail. The styling happens to be also attractive to others, but their technical, gadget-orientation really biasses them to designing technical looking, knob-intensive products as typified in hi-fi sets, complex watches, and cameras). It's probably impossible to have them design a product like the Polaroid One-Step camera. Color TV scopes are used to help operators control the large computing machines. More importantly, less people are involved in operating the Japanese computer centers, giving lower life-cycle costs.

PRODUCTS RESULT FROM UNDERSTANDING AND MANAGING A COMPLETE PROCESS

The basis of competitive performance products in high technology industries depend on understanding a complete process starting with basic research, going through applied research and advanced development, to product development. In addition, a parallel equally complex process, is required in order to design and build the process that manufactures such products. As a new product is introduced, it may be necessary to evolve and enhance it, to adapt it to the real or changing market and finally it must be eliminated when it does not effectively solve a need. There must be astute marketing including forward pricing in order to get on the necessary cost versus volume learning curves.

<u>The Japanese need invest little in basic and applied research because they are effectively coupling the U.S. laboratories into their advanced development</u>. In contrast, aside from hiring, there is very little flow of ideas from our public laboratories into U.S. industry. The university laboratories which have or are receiving significant Advanced Research Projects Agency (ARPA) funding for Computer Science (i.e., 20-30M/year), have post doctoral Japanese visitors. These laboratories include Stanford, MIT, Carnegie-Mellon, the University of Illinois, etc. One finds that the university and industrial laboratories of Japan are headed and staffed by researchers who've spent their research years in the mainstream American laboratories. For example, the head of a major research effort at one company was trained at the MIT Multics Laboratory.

Of the large companies with research laboratories, the Japanese emphasis is on advanced development where the output is a breadboard of a potential product. The quality of these laboratories seemed substantially ahead of comparable U.S. laboratories which often engage in research to ease the corporate conscience by having a research lab. For example, our corporate research laboratories were significant in the development of television. In later years even though labs at GE, Motorola, RCA, Westinghouse and Zenith grew in size and number, there was ineffective coupling and the U.S. TV industry has disappeared.

<u>MITI funds and manages other laboratories and corporations</u> to

carry out research that's oriented to getting experience that will eventually produce products. Funding, as opposed to having a captive laboratory, not only provides a system of checks and balances, but provides an incentive. This minimizes what I call the "dusty-lab syndrome". Many of our government labs were initially set up for a mission, and once the mission has been completed, the lab continues to exist. Since there's no real need, or mission, or review, negligible new work is output. We can all recall visiting these labs in which the dust is blown off the equipment for visitors and the same demo is run year after year. The same equations are on the board, with the same usually vague, unattainable, immeasurable, non-milestone based goal for the research. A buyer-seller relationship can help check this to a great extent whereby an independent organization such as a university manages the lab and takes responsibility for results in a competitive, seller fashion. Government labs set up to provide results to the government are most generally incestuous and ineffective. Also this brings the groups together and technology transfer is more likely to take place.

For example, NBS is setting up a lab to research computing interface standards, with industry being expected to contribute people to them to carrry out the work. This is ridiculous! People capable of this research are clearly going to be employed in developing interfaces. A government group dedicated to this will ultimately be tired and useless, assuming it does become successful in creating a standard. A more fruitful way to bring about the standards is to subcontract several competitive approaches and have industry prototype and report on them to NBS. In this way the expensive, bureaucratic staff is minimized at NBS. Again, such a staff will become obsolete even if it could be acquired. Quality output can be managed by NBS through a buyer role, provided the contact red tape is minimized.

The Japanese <u>orientation is</u> a strongly <u>engineering for trade versus</u> strongly <u>science-based</u> culture! Since the rest of the world does their research, why should they bother? This comes about because of their need for manufacturing novel products and their total dependence on the export of manufactured goods. Since our basic federal research funding for computing comes through the NSF, ARPA, and armed services, the emphasis is on science and research. Their funding comes through MITI and from various corporations, and hence the orientation is on international trade.

<u>The culture supports a strong emphasis on manufacturing, not just product design</u>. In addition to the product engineering process there is a comparable and equally important process responsible for the development and operation of manufacturing. This discipline has been eliminated from U.S. universities. While it isn't clear that the emphasis in Japan universities is stronger, there is more emphasis in the companies on manufacturing processes. People are rotated among the various processes and disciplines, making it equally desirable to be in all functions and phases.

<u>The whole culture</u> appears to understand basic learning and demand curves and they <u>are volume (and growth) oriented</u>, subject to the quality-first constraint. Knowledge of the learning curves is everywhere even the government research labs and universities. Their needs and goals are manufacturing/trade/industry oriented. This also means that, like Texas Instruments*, they're willing to dump and lose money for the short term in order to gain the market. This practice, when carried to certain extremes, was ruled to be illegal for a U.S. company. Although the Japanese put on a good act that their products won't be competitive when the yen is so strong, having gone from 300/1$ to 100/1$, it's a big ruse because of our dependency as a distributor now in many industries. This dependency will be elaborated on the following section.

As a corollary to learning curves and market domination, it's necessary and t<u>hey</u> are willing to <u>give up profit for growth</u>. For example, RCA is now a rug maker (or distributor), car rentor, publisher, TV distributor etc., instead of an electronics company that pioneered television. Their role is essentially no more than a banker and such a conglomerate is no match for a serious manufacturer. Whereas there is extreme pressure on our business for profit and return on investment, these factors are less in the Japanese companies. Sony is only moderately profitable, Fujitsu does relatively poor financially and I'd bet NEC or Hitachi computer divisions might even lose money. For now, they may still be buying in which is clearly more acceptable than GE, Xerox and RCA could accept. This makes the Japanese doubly hard to beat, since they can lose money on every one and make it up in volume. They can buy the business dumping and why not if there is long term reward?

INDUSTRY DOMINATION BY THE JAPANESE IS SIMPLY PREDICATED ON U.S. NAIVETY, GREED AND VALUES

Whereas as we watched the first few industries of textiles and steel become dominated by the Japanese, we unsympathetically stated that these industries were tired, the workforce was lazy, and the management was incompetent and unagressive about getting capital. Certainly there is no special societal fondness for the automotive and petroleum industries and now it's fitting to import our cars to straighten out the U.S. manufacturers. Now, the domination of all manufacturing is so clear and pervasive that we must look deeper because all society is to blame and is beginning to pay the price.

The domination can only happen with consenting buyers in the U.S. It is these buyers, (nee distributors, including tired old former manufacturers, that are to blame, not the Japanese. Alternatively our values are too short term and too basic as to see and understand the real long term effect.

<u>The (Unstable) Three Island System</u>

Since it's not clear to everyone what the long term, stable situation has to be, let's look at the end point. A system of three inhabited islands, all of which have adequate food, water shelter and land, points out the dilemma:

#1. supplies energy; consumes negligible manufactured goods;

#2.supplies manufactured goods (is supplied raw materials from several small islands it owns, and from discarded goods of island 3); and consumes energy;

#3.consumes energy and manufactured goods; supplies information.

Given that information is generally treated as a waste commodity of zero value there is no stable state for the system <u>until</u> islands 1 and 2 absorb island 3. Or conversely using any monetary system, island 3's paper or tokens will always be worthless. That is, islands 1 and 2 currency values will be out of balance with island 3, until 1 and 2 "own" island 3.

To a first approximation, <u>the Japanese and</u> their counterpart <u>American buyers have systematically transformed American business from inventor-manufacturer-distributor to</u> simply <u>distributorships</u>. This is in complete keeping with the goals of American business as reported and exonerated in business magazines and the teachings of modern business schools. The goal and reward of American industry is clear: return on investment and profit. Secondary measures like market share are occasionally used. Following only the ROI goal, subject to no other constraints, leads U.S. industry directly to being a distributorship for Japanese products. With this strategy, no investment, no planning, and no risk are required . All a company or its potentially enshrined leader has to do to be successful is to buy the right product for resale. Our electronics industry doesn't have to worry where the money comes from to pay the Japanese and Arabs. On the other hand a group who can only run a distributor is probably fairly top heavy and can easily be replaced say, by a hard-working Japanese group.

This merely confirms the classic definition of a capitalist as someone who'll make and sell the rope to hang himself. In this case it's merely reselling someone else's rope as we become too lazy to design and make rope.

The essence of distributorships is competely counter to the principles which made American industry initially great. Now it's simply with no work, no capital, anyone (everyone) can do nothing and succeed. All that's important for us now is to find the right supplier who'll put up the capital, design and manufacture products which we can distribute.

In computing, the trend has already started with Itel buying Japanese manufactured 370-compatible computers. Thus we expect Itel to have high ROI, and a net flow of dollars from the U.S. The solution is obvious:

> No company must be allowed to buy and distribute a foreign product without an offsetting equal export credit which they must arrange! That is, Itel can get agricultural products to sell or it could export its services. This has to be Itel's problem -- not

Carter's, Krep's, or Congress's problem as we now define them.

<u>There's no way a manufacturer can re-enter</u> various <u>lost businesses once he becomes a distributor</u>. The spirit, and capability to catch-up and manufacture are gone. Society and the investment structure are all aimed at continuing a status quo. In the case of TV, radio, hi-fi, and video recorder products all of which were U.S. products and which the first invention or key patents apply, the cause is hopeless.

Again, we can blame the Japanese, but someone in the distributorships acquired by the Japanese had to buy the sets in the first place and had to choose not to design and build competitive products or to insist on bi-lateral flow of goods. In the case of Motorola, the division was purchased by Matsushita and included both manufacturing and distribution. By 1976, the U.S. plant was reduced by 2/3, but the distribution network was left intact.

<u>We (U.S.) have a higher regard to business training versus engineering and technical training</u>. Here the Japanese are in even better shape because they don't yet have many business schools. Therefore instead of getting MBA's their engineering students get engineering master's degrees. In contrast, more engineers, quite erroneously, regard the MBA as necessary or useful to enter industry. This not only makes the Japanese better engineers for the same educational output, but doesn't reinforce the notion that engineering is the route through to the management ladder, or that an MBA is automatically needed if one is to supervise people. The MBA, oriented at every dual-career person being president, and epitomized by the content-free case study methodology, focusses on the quick buck. This is in contrast to the Japanese concern for deep understanding and the long term.

U.S. VALUES ARE CLEARLY DIFFERENT AND AS SUCH WE MAY BE HELPLESS AND SHOULDN'T BOTHER TO MANUFACTURE ANYTHING

At a government/society level they appear to have their act together much more than we do. In societal issues and in their products they seem to have clear, crisp ranking of goals and priorities. For starters, they know them, whereas nearly all our issues that start out simple become entangled as everyone (a new set of referees) enter the fray. These include: human rights vs equal rights; full employment vs inflation and balance of payments; environment vs region vs country; capital vs labor; and consumer protection vs business protection. But worse than a muddy set of design criteria is a muddy set of decision makers and an unclear decision process. The Japanese processes though more complex appear to be clearer. There is less government but it appears to be responsible and accountable!

Because of the need to export, for example there's educational support for engineering and technology, versus lawyers and other semantic accountants. There is a factor of 2 less lawyers per person than in the U.S. while lawyers wouldn't be bad if they only talked to each other. A productive lawyer can consume much productive and creative output of much of society. The Japanese emphasis (priority) is on physical output because they are a manufacturing island with no other visible means of support. With the increased emphasis in legal training, our priorities seem to be on the manufacturing of paper, intergroup contracts, governing and bickering among semantic accountants.

As a simple explanation, more money is available for investment to enable them to manufacture (for their island) because of lower taxes. This clearly affects their ability to invest in industry. They're supposed to be willing to pollute for profit. I didn't observe this. For example, LPG taxis are used instead of gas or diesel. Perhaps they only kill whales outside of Japan and pollute other enivronments. Their environment is just fine, though high density. On the other hand, taxes can be low because their priorities are clearer, more people work and they spend less on government and defense.

Their government spending for military is far less and nearly non-existent. Although there is some fall out of our military spending for a better society, it seems to be small and clearly a by-product. In the case of semiconductors, computers and related research, the benefit is small compared to what it could be compared to more directed goals such as the Japanese have with export domination.

In a similar way the Japanese spend significantly less per capita for health care and medical research. They can capitalize on our research here, but since they have a longer lifespan, its not clear what the extra expenditures we make buy. In effect, the lack of spending in medicine goes to investments which result in full, lifetime employment which is probably the best solution to personal health.

The <u>Japanese don't have the massive federal research over-expenditures, epitomized by NASA and NIH</u>. Here again, in the rare event there are results, the Japanese will capitalize on our research for manufacture and export. These areas seem to have big expenses and contribute little because much of the work has no goal. NASA goals appear to be vague and tenuous now that they've stopped providing the world with exciting space shots and television pictures from the moon, and the immediate needs for this research escapes most of us. National health research is also equally vague. This work only increases health care costs, by a whole series of secondary effects. Here the Japanese have a greater life expectancy with under 1/2 the per capita costs.

<u>They believe computers are fundamental for the long term</u> and they're prepared to invest and wait for return. Machines are used in all products they build for export and they save labor too. Labor is both precious and expensive in Japan as there are only 110M people and 2% unemployment. They're considering raising retirement from 60 to 65 to get the extra productivity. They must have computers to raise productivity! This is vital to their continued domination of manufacturing. As a separate research area, robots are an important component of manufacturing domination. While much of the pioneering work is U.S., the continued work to make robotics practical takes place in Japan! This is the opposite of say the Australian attitude where there is increasing unemployment and a belief that computers must be eliminated. Australia is now almost totally dominated by Japanese products and the small Australian automotive industry of GM- and

Ford-based large cars and is rapidly declining under the stress of small, high volume, quality Japanese cars.

THE JAPANESE SOLUTION TO OUR BALANCE OF PAYMENTS PROBLEM: SELL (IN JAPAN)

This is the answer our industry wants and will willingly, but foolishly looks to. However, the Japanese rhetoric is only for our gullible government and academic communities and the naive business people. For example, trade envoys from Massachusetts and New Hampshire visit Japan with the expectation of selling high technology goods. They'll succeed to sell a few prototypes. The real sales will come in 5-10 years when these products are resold in volume to the U.S!

There has not, nor will there be any serious trading of American products of Japan. The distributor/trading network entirely thwarts such an effort! The results are clear and we must face this.

<u>Japan is a closed society and market</u>. As the most powerful, homogeneous culture in the world there is a long history of being closed. This can be verified by: reading any of the books or articles on Japan; trying to understand the complexity, yet subtly of a formal tea ceremony; looking at any industry manufacturing case; or just visiting and observing.

The <u>language is a code to</u> further <u>segment</u>. It's not clear how difficult the language is to learn, but it's probably relatively useless without the societal understanding. We only teach Japanese minimally on the West Coast of the U.S. On the other hand the technically trained Japanese have several years of English in order to read the literature.

Even though there are major cultural differences among Japan and other far eastern countries (e.g., China, Taiwan, Korea) there is closer proximity among them than with western countries. This closeness is especially advantageous in finding additional sources of especially low cost labor.

The <u>tariffs support the establishment of any industries</u> they target. Now the computer import duty has been reduced to be on a parity with the U.S., but this matters little since their industry is strong enough to withstand imports! As we've seen in other industries, this is a come-on to further strengthen the

Japanese manufacturers for export competition by having them compete in a token way with the few imports and thereby gain ideas to sharpen their exports.

For example, in the early seventies the Japanese encouraged U.S. minicomputer imports. These occurred and now there is a significant Japanese minicomputer industry. For example, the basic structure of Fujitsu's minicomputer is identical to the PDP-11 DEC introduced manuals and brochure before the patent application, making the PDP-11 non-patentable in Japan.

<u>By the society</u> and the <u>emphasis on personal relationships it's hard for foreigners to break into or sell</u>, especially on a one shot basis. "Doing business" together appears to be done over a long time period and is almost ritualistic. This means that it's essentially impossible to have an effective international company as we know them. A foreign manager is clearly tabu and sales are limited to one-shot deals with trading companies. There is no trading except as joint ventures! A foreign owned company with ?% of the equity is illegal in Japan.

LABOR COST, LIMITED POPULATION, FULL EMPLOYMENT AND FEW NATURAL RESOURCES, CREATES IMPORTANT BY-PRODUCTS

Transportation and meetings run on time and at full capacity. This is in contrast to U.S. facilities, especially the meetings scheduling and performance. I accomplished roughly twice as much per day as in another western country in terms of customer and plant visits. The cordial, formal protocols help meetings proceed rapidly. By operating in a highly scheduled fashion more work gets done and there is less anxiety as to performance.

There's measurement of and pressure for efficiency. That is, the work-out/work-in ratio is high. In a taxi, there's an automatic back door opener so that the driver can load/unload faster. Of course, the factories graph everything. It feels like the notion of efficiency is taught to all. Concepts like fuel efficiency versus speed, weight and pollution are impossible concepts for Americans to understand. Worse yet, having only briefly lived in a constrained environment during wartime, most of us have no understanding of living with finite resources.

Given a notion of efficiency, there's real concern for saving of physical resources too. At the computation center, printout isn't automatic; it's queued and must be requested by badge reader. Lights, always florescent due to efficiency, are off when not in use. Of course small cars, taxis, a good train/subway are other indicators. The cars have bells that ring when the car is going over 100 Kmh! None of these exist in the U.S.

Contrary to a previous "feeling" they are working the environment issue. There were U.S. environmental people at a conference at the same time I visited; the Japanese were politely ignoring them while taking their basically boondoggle-oriented conference registration fees paid by the U.S. government research establishment.

There is a range of basically human and personal concerns. The result is a longer life span. While the subways and high density trains jostle people pretty badly, and there's no segmented smoker areas (and many smoke), there's great concern for the feelings, privacy and treatment of individuals. Although I had special treatment on the visit, on arrival and departure at every organization, I was given hot cloths and refreshments of tea, juice or coffee to be really considerate to westerners. It was hot and humid in July, but taxis and all buildings had air-conditioning. The hotels, though the most expensive, were also the best in terms of privacy, food and service. This included a large hotel in Tokyo and a 15 room old style, inn in Kyoto. The goal is privacy, and ambiance, with incredible attention to simplicity, design and detail. For example, there was a cloth cover over the telephone because it didn't fit the room decor.

Of course, the food is the ultimate in personal concern. Food served in many courses varied from raw fish to pickled vegetables (e.g., potatoes) and flowers (lotus blossoms) with lots of seaweed, fish and fish eggs. Tempura, teryaki, and hibachi grilled meat and fish are more easily digested by the westerners. The bread crusts were removed when sandwiches were served to westerners. There was much concern that the colors of the food matched; the physical looks were important.

There are Japanese baths, and these are great too!

<u>They are compulsively clean</u>. In an indirect way, this really helps the manufacturing of small, precise goods (including cameras, semiconductors, high-speed computers and disk memories.

<u>There's</u> orderly <u>queueing</u> at <u>each server</u>. The Japanese appear to be the world's best self-queuers. There's probably some protocol for resolving conflict when two persons arrive to the queue at the same time. In general, a system of this type has higher through-put. I also suspect there is lower general hostility arising from competing for a finite resource.

<u>Inventions are to labor-saving devices</u>. I saw countless gadgets of this form. The printers at computation centers had paper cutters on them with conveyors to bring output back to a single station. There are no computer operators and people to serve the users! This direct use of facilities not only costs less, but provides significantly higher through-put.

EPILOGUE

On arriving at Sydney, I was struck with the contrast to dense, intense, humid and hurried Tokyo. I was ecstatic to get back, after 20 years, to a life style, people and place I feel more comfortable with.

Sydney's beaches are the world's finest; the weather's great; people spend lots of time out-of-doors with sports, strolling and simple gardening versus the subtle and very complex Japanese gardens; work starts late, runs slower and ends promptly with twice as many secretaries to do half the work -- but they do make their bosses feel good; and the continental and western food, beer and wine drastically improved having moved away from the early English influence.

Thinking about the Japanese competing with the Arabs to buy American and Australian mines, property and factories is frightening, but remote in my mind. Besides, does it matter who owns us? Will they interfere with our way of life? Maybe we'll change them and make them lawyers rather than manufacturers. If enough of them come to live or vacation with us very long, we'll be back manufacturing and exporting to them if anybody can learn the language. If things don't go our way, we can make it illegal, set up an agency, and then sue them with our incredible bureacracy and legal technology.

IMPRESSIONS ON HOW WE AND THE JAPANESE ARE CONVERTING U.S. INDUSTRY INTO DISTRIBUTORS

Gordon Bell, Vice President of Engineering
Digital Equipment Corporation, Maynard, Mass.; and
Professor of Computer Science and Electrical Engineering (on leave)
Carnegie-Mellon University; Pittsburgh, Pa.

The island of Japan, with few natural resources and over 100 million people, virtually dominates world production of manufactured goods, including the components and processes to make these goods. Every Japanese knows that exports are vital to survival. Also ingrained is the understanding that savings and living within one's own means support the ability to manufacture and export. In contrast, the notion of balanced budgets, savings and manufacturing have gradually disappeared from U. S. culture.

For example, the United States still holds a dominant position in the production of computers and semiconductors, but the Japanese plan to dominate these industries. Unwittingly, U.S. industry, government and society continue to aid the Japanese. Forty odd reasons are given to support this conjecture, each one providing a lesson.

The Japanese have progressed from domination of low-technology simple commodities to complex manufactured goods. The progression has been from textiles, steel, radios, sewing machines, typewriters, quality cameras/optics, watches, small cars, television sets, tape recorders, video tape recorders, calculators and on to state-of-the-art semiconductors and computers. Their current position in semiconductors and semiconductor-making equipment indicates they are well on their plan to dominate this manufacturing as a base for the continued and future market domination of electronics and computers. High-technology industry is increasingly being concentrated in Japan while the Japanese-owned low skill textile and television factories are being located in the U.S.

Dataquest describes how the Japanese go about systematically to dominate a market. Appendix 1 describes the four, detailed phases: initial development of a domestic industry, establishment of an export base, significant market penetration in foreign markets and final market exploitation.

BASIC STRATEGY, AND TACTICS FOR DOMINATION

Japanese industry and government operate as a team reinforcing strategy and tactics with appropriate levels of competition. Unlike many companies and countries that have tried and failed, they successfully planned and built a mainframe computer industry.

The Ministry of International Trade and Industry (MITI), with autocratic power, helps to amalgamate strategies within industry groups creating an organization commonly referred to as "Japan Inc." Because there is no direct control, I prefer not to use the term "Japan Inc." but to name the phenomena "The Japan Club" since there's a structure for the essential competition at the market level. For example, MITI identified and encouraged early importing of minicomputers, including those from Digital Equipment Corporation, as a competitive "straw horse" to build their own industry. One of DEC's interactive data base systems, MUMPS, was sold in Japan for end-user applications. On seeing several lost sales, MITI funded the development of MUMPS on a Japanese minicomputer. In mid 1978, a Japanese researcher asked me, through an academic channel, for the internal architecture of MUMPS in order to study its structure from a so-called computer science viewpoint. We expect to catch MUMPS from Japan soon.

The U.S. has no equivalent of MITI to protect major corporations as national resources. In contrast, U.S. corporations are looked on as adversaries to the national interest. IBM, already under attack from Japanese competition, is also under the gun from most U.S. government departments. Together they seem intent on destroying IBM, leaving it and others as distributors for Japanese products.

The strategy of MITI and the Japanese companies to win dominance of the computer industry is clearly evidenced, but it is not understood by U.S. government and industry. In keeping with the priority, MITI is both very strong and attracts competent people. The Japanese companies, while maintaining competition in limited domains, both plan and talk with one another. For example, Fujitsu and Hitachi have developed IBM plug-compatible machines. Coupling individual, competing companies for technological acculturation in this fashion is an important management technique to assimilate technology quickly.

The U.S. Department of Commerce and the U.S. Labor Department, in contrast to MITI, have neither a plan nor the personnel to help maintain U.S. dominance in high-technology fields important to the future of the country's economy and security. Furthermore, these two adversary departments are adversary to U.S. business. Trade trips to Japan by Secretary Kreps only emphasize our lack of understanding of the Japanese capability to use trade to introduce technology into their society. Our trade deficits cannot be turned around by hand-shaking missions, but demand a strategic and tactical plan based on understanding. Our political system is devoid of planning and accountability of government departments; even if the Secretary of Commerce could plan, her short tenure is inadequate to solve this problem. Once a new administration appears, any policies, plans and commitments are reset to zero!

Japanese tactics focus on the centrality of work and loyality to a company. A company screens each new employee carefully because when it hires an individual it takes on a lifetime commitment. The security promotes risk-taking, a phenomena generally unknown in large U.S. corporations. The team spirit is engendered as the various members learn how to get along with each other.

Quality control is in the hands of the workers. Although data is kept centrally, the analysis, corrective action and responsibility for manufacturing and quality rests with the employees concerned. Quality control is generally centralized and the organization of work often does not lead to self-esteem in the U.S. organization. Such participative management provides a key to the devotion to the workplace and sense of value achieved through work. The incompetent workers become the wards of the organization rather than wards of the state. Pride, family tradition, and because everyone is working, nonwork is socially unacceptable, embedding the importance of work into the fabric of society. A similar effect is observed in the U.S. during periods of high unemployment. At this time non-work is approved since others are unemployed.

In the U.S., the freedom of the individual has superseded work as a goal. The employee mobility is high and as a result companies screen very little as the short tenure is assumed. One recent semiconductor company ad claimed that no interviews were required at all. Turn-over and unemployment here are high with levels of consumption also rising so that some Japanese observers have concluded that the Japanese live to work and the Americans need to work to live. The measurable results are simply that the relative per capita productivity in manufacturing industries of Japan is now almost twice that of the U.S! Also, the sales per employee of a Japanese electronics corporation is about $100K, versus $45K for the U.S.

The Japanese government has been able to nurture both large and small companies while the U.S. government agencies seem to alienate the large and aren't effective at supporting the small ones. Much work in Japan is done in small subassembly operations. Competitive small shops keep the cost down by removing it from the large, hard to manage hierarchical organizations.

USING ACCULTURATED DESIGN AS THE BASIS TO DOMINATE

For centuries Japan has acculturated customs, but mostly it adopts and adapts technology. In the 16th century, for example they began manufacturing gunpowder a scant 18 months after the Portuguese brought it to Japan. Shortly thereafter they were banned. Any idea or product has always been fair game for adoption and improvement. Product and process evolution are merged in a long term view of achieving market domination. They orient the processes competitively considering quality, volume for growth, and flexibility to allow for the fast turn-around needed to maintain full-production capacity in a shifting market.

All the Japanese computer manufactuers have acquired their technology within the past ten years by dealing with U.S. manufacturers either as a joint venture or under license, including: Fujitsu (Amdahl/Siemens) and Hitachi (RCA); NEC (Honeywell, GE, Varian) and Toshiba (Honeywell, GE, Interdata); Mitsubishi (Xerox) and Oki (with Univac joint venture); Yokogawa (HP); and Nippon Minicomputer (DG). In all cases, the Japanese have improved the technology in terms of perceived quality, performance and manufacturability.

The agreement between Fujitsu and Amdahl Corporation, though still at an early stage, provides a good example of the classic Japanese computer acculturation process. In the late 1960's, Gene Amdahl, then head of IBM's San Jose Advanced System Development Laboratory, explored the basic technology for high-performance IBM computers. When he failed to interest IBM in building high performance machines, he formed Amdahl Corporation to develop the technology. When he needed more capital Fujitsu bought an interest and acquired the manufacturing rights to, and became the manufacturer for the Amdahl line. Fujitsu was also able to use the same technology to design and manufacture computers for the Japanese market. In only one computer generation, at the beginning of 1978, both Amdahl and Fujitsu announced their latest computers based on the Fujitsu-Amdahl circuits and packaging. Now, Fujitsu appears to have a machine with higher performance and reliability (the M200) than either Amdahl or IBM have so far announced. Fujitsu has produced a machine based on multiprocessing which provides users with new capabilities; furthermore they can buy more processors rather than trade-in when increased computation is needed.

In addition, Japanese computer manufacturers have a complete line of peripherals and test and manufacturing equipment that is based on counterparts invented in the U.S. The designs range from "reverse engineered", to look-alike copies, to radically improved products based on Japanese inventions. With "reverse engineering" a product is dissected with micrometers, special gauges, etc. and made compatible in nearly every respect. The Japanese make only products for export to the U.S. market that do not violate patents. Tektronix look-alike scopes and reverse engineered IBM disks are common. In 15 months, Nippon Peripherals Limited produced a disk that was mechanically identical to the IBM 3340. From comparing the two drives, one might conclude that they were made from the same drawings.

PRODUCT DESIGN BASED ON NEED, QUALITY AND THE LONG-TERM

Traditional top-down marketing is characterized by expensive, thick market surveys that extrapolate history in a self-perpetuating fashion. Here, the goal is to fill various revenue gaps that develop. Using a market survey approach the U.S. continues to build heavy, gas-consuming cars, because the marketing managers can only think in terms of what has sold in the past. Freed from this approach, the Japanese have been able to look at the real needs, and they have appropriately adapted existing ideas. High-level corporate marketing does not design the products; engineers design according to needs using a bottom-up approach and based on technology.

Japanese companies, with long-term goals and commitments, similarly are not forced to depend on a short-term marketing approach. NEC, Fujitsu and Hitachi, unlike Xerox, GE, Westinghouse, and RCA, have all persisted with computer manufacturing and after years of investment have established successful products. Their long-range thinking from the outset allowed them to invest in long lasting quality.

Japanese companies focus on highly sophisticated quality products rather than ultra-high quantity, low-quality throw-away merchandise. The differences are characterized by comparing Seiko versus Timex watches and comparing Minolta or Nikon versus Kodak or Polaroid cameras. Japanese styling is often technical and gadget oriented, typified by multi-knob hi-fi sets and complex watches. It may be impossible for them to design a product like the Polaroid One-Step Camera because of the differences in picture quality. The emphasis is on an educated consumer who will value his purchase.

Concern for quality and long-term values leads the Japanese to build products that have a long lifecycle. Even their auto industry constrained by Detroit's yearly new model concept is now getting very high ratings for durability and serviceability. Accounting models lead to emphasizing production of long lived versus throw-away goods.

PRODUCTS RESULT FROM UNDERSTANDING AND MANAGING A COMPLETE PROCESS

The successful production of competitive performance products in high technology industries depends on understanding a complete process that includes basic research, going through applied research and advanced development, to product development. In addition, a parallel and equally complex process is required to design and build the process that manufactures such products. After a new product is introduced, it may then be necessary to modify and enhance it to adapt it to the real or changing market, and finally to eliminate it when it is no longer effective.

The Japanese need invest little in basic and applied research because they are effectively coupling the U.S. laboratories into their advanced development. In contrast, aside from the direct hiring of students and researchers, there is very little flow of ideas from our public laboratories into our own industry. As Carver Mead of Cal Tech points out, "I like the Japanese. They listen. Also unlike American industry, they're willing to build from our ideas." The university laboratories at Stanford, MIT, Carnegie-Mellon, the University of Illinois, receiving significant ($20-30M/year) Advanced Research Projects Agency (ARPA) funding for Computer Science, have post-doctoral Japanese visitors. The university and industrial laboratories of Japan are headed and staffed by researchers who've spent their research years in key American laboratories (e.g., MIT Multics). In contrast there is no Japanese training of U.S. engineers and scientists; furthermore, the flow of ideas is minimal.

Most recently, Japan has offered to spend one billion dollars in the U.S. for research, predominately for energy conversion. By accepting these funds, the Japanese can be even more effectively coupled to U.S. research and can "learn" to research, just as they've learned manufacturing, design and advanced development. The scientific community is anxious for more funds, independent of where they come from or what the consequences are. Of the large companies with research laboratories, the Japanese emphasis is on advanced development where the output is a testable prototype, often of a potential product. In contrast, U.S. corporate laboratories hide behind the veil of science where the output is vague and untestable. The quality of these laboratories is high versus many comparable large U.S. companies where research is to ease the corporate conscience instead of providing new development. Although such corporate research laboratories (e.g., GE, Motorola, RCA, Westinghouse and Zenith) were significant in the early development of television, the U.S. television industry has declined with few recent local advances.

MITI funds and manages other laboratories and corporations to carry out research that is oriented toward getting experience that will eventually produce products. Funding specific, as opposed to having a captive laboratory, not only provides a system of checks and balances, but also provides an incentive. Many of our government laboratories were initially set up for specific missions, and although the missions were completed, the laboratories continue to exist. Since they no longer have a real goal, or mission, negligible new work is done. The dust is blown off the equipment for visitors and the same demonstration is run year after year. A buyer-seller relationship, in which an independent organization, such as a university, manages the lab and takes responsibility for results can minimize this "dusty lab" syndrome. Moreover, funding for specific projects can bring together diverse groups and promote technical interchange.

The Japanese orientation is toward engineering for trade rather than being strongly science-based. Since the rest of the world provides research, why should they bother? This comes about because of their need to manufacture products and their total dependence on the export of manufactured goods. Since our basic federal research funding for computing comes through the NSF, ARPA, and the armed services, the emphasis is on science and research. Their funding comes through MITI and from various corporations, and hence the orientation is on international trade.

The trade drive causes a strong emphasis on manufacturing, not just product design. In addition to the product engineering process there is a comparable and equally important process responsible for the development and operation of manufacturing. This discipline has been nearly eliminated from U.S. universities as it has moved from the engineering to the management school. There is a decided emphasis on manufacturing processes in Japan as people are rotated among the various processes and disciplines, making it equally desirable to be in all functions.

Everyone associated with science, engineering and manufacturing understands basic learning and demand curves and they are quantity (and growth) oriented, subject to the quality-first constraint. Knowledge of the learning curves (i.e., increases in the combined number of units produced cause a reduction in manufacturing cost) is everywhere. Fred Bucy comments on Japanese competition in TI's 1978 Annual Report: "...the big difference is that TI is the first major non-Japanese company they have run into that understands and uses the learning curve". The Japanese are willing to sell outside Japan at a lower exported price (dump) and lose money often by selling below cost for the short term (see also Appendix 1) in order to buy market share. This practice is illegal for both U.S. and Japanese companies. Although the Japanese pretend that their products are not competitive because the yen is so strong, they are consciously ignoring our dependency as a distributor now in many industries.

As a corollary to learning curves and market domination, it's necessary and they are willing to give up profit for growth. For example, RCA is now a rug maker (or distributor), car rentor, publisher, television component distributor; it hardly resembles the electronics company that pioneered television. It's difficult to put the whole blame on RCA management because they are constrained by the economic and business temperament of the U.S. environment. Whereas there is extreme pressure on our business for profit and return on investment, these factors are less important to the Japanese companies. Sony is only moderately profitable, Fujitsu does relatively poorly financially and NEC or Hitachi computer divisions may even lose money. None of these companies would compete for capital in the U.S. stock market where return-on-investment is the key criterion. Japanese companies are buying market share and this is clearly more acceptable to the U.S. investors than for GE, Xerox and RCA who left the computer business. They can buy the business through "dumping" and why not if there is long term reward?

JAPANESE DOMINATION IS PREDICATED ON OUR GREED AND VALUES`

As we watched the first few industries of textiles and steel become dominated by the Japanese, we unsympathetically stated that these industries were tired, the workforce was lazy, and the management was incompetent, unimaginative and unaggressive about getting capital. Certainly, there is no fondness for the automotive and petroleum industries and it seems fitting to import our cars as a lesson to our own U.S. manufacturers. Now, however, the domination of <u>all</u> manufacturing is becoming so clear that we must look deeper at the causes.

The domination can only happen with consenting buyers in the U.S. It is these buyers, called distributors, including tired, old, former manufacturers that are to blame, not the Japanese. Our values appear to be too short term and too basic. We really must understand that the following, simple, long-term consequence is <u>complete</u> economic domination.

<u>The (Unstable) Three Island System - Or How and Why We Will Be Dominated</u>

Since it's not clear that continued consumption, with no corresponding export means, let's look at what is the ultimate, singularly stable point simply. A system of three inhabited islands, all of which have adequate food, water, shelter and land, points out the dilemma:

#1. supplies energy; consumes negligible manufactured goods;

#2. supplies manufactured goods (is supplied raw materials from several small islands it owns, and from discarded goods of island 3); and consumes energy;

#3. consumes energy and manufactured goods; supplies information.

Given that information is generally treated as a waste commodity of zero value, there is no stable state for the system <u>until</u> islands 1 and 2 absorb island 3. Or conversely using any monetary system, island 3's paper or tokens will always be worthless. That is, islands 1 and 2 currency values will be out of balance with island 3, until 1 and 2 "own" island 3.

Through greed and short-term values, <u>the Japanese and</u> their counterpart <u>American</u> <u>buyers have systematically transformed American business from inventor-manufacturer-distributor to</u> simply <u>distributorships</u>. This transformation is in complete keeping with the goals of American business as reported in business magazines and the teachings of modern business schools. The goal and reward of American industry are clear: return on investment and profit. Secondary measures, such as market share, are occasionally used. Only a few corporations consider no lay-offs and full-employment to be important; as such, a clear, adversely separation has formed between management and labor. Following only the profit-based goals, subject to no other constraints, leads U.S. industry directly to distributorships for Japanese products. This strategy requires no investment, no planning, and no risk. All a company has to do to be successful is to buy the right product from Japan and then resell it.

This merely confirms the classic definition of a capitalist as someone who'll make and sell the rope to hang himself. However, in this case the capitalist is reselling someone else's rope because he is too lazy to design and make his own rope.

The essence of distributorships is completely counter to the principles that made American industry initially great. The new principle is simply that with no work and no capital, anyone (everyone) can do nothing and succeed. All that's important is to find a supplier who'll put up the capital, design, and manufacture products that we can distribute. In computing, the trend has also started: Itel is buying Japanese-manufactured IBM 370-compatible computers. Thus we expect Itel to have good financial metrics and be a good investment. It will also cause a high net flow of dollars from the U.S. as it becomes more successful.

American business, of course, is only slightly at fault because <u>the U.S. non-business communities</u> (politicians in government, consumers, and academics) <u>have introduced and strongly support heavy borrowing, beyond income</u>. These thwart an environment conducive to manufacturing. Both the per capita rate and amount of savings for both individuals and corporations in Japan is twice that of their U. S. counterparts! For example, the retirement system in Japan is actuarially sound. Of course, the Japanese government operates a balanced budget and taxation supports savings. Furthermore, as a society, they understand themselves simply as an island that must have a favorable balance of trade.

<u>There's no way a manufacturer can re-enter</u> a <u>lost business once he has becomes a distributor</u>. The spirit, and capability to catch-up and manufacture are gone. Society and the investment structure are all aimed at continuing a status quo. Radio, television, hi-fi, and video recorder products are all built using key U.S. developed ideas and patents, yet are no longer built by U.S. manufacturers. Again, we can blame the Japanese, but someone in the distributors had to choose to buy the products rather than design and build competitive products. In the case of Motorola, the television division was purchased by Matsushita in 1974 and included both manufacturing and distribution. By 1976, the U.S. plant was reduced by 2/3, but the distribution network was left intact.

<u>We (U.S.) have a higher regard for business training versus engineering and technical training</u>. In the U.S. many engineers regard the MBA degree as necessary for a career in industry. The Japanese do not yet have many business schools; therefore, instead of MBAs, engineering master's degrees are sought. This makes the Japanese better engineers for the same educational investment. Also, the management of manufacturing organizations are the better equipped to understand technology and products.

By having more people just concerned with distribution, we are becoming a nation of shopkeepers. The emphasis is simply to keep stores open longer and to find new ways to distribute Japanese manufactured goods. Not only does this further stimulate consumption, but it takes people from the primary production work force and makes us merely an island of consumers with no material means of support.

THE JAPANESE HAVE PRIORITIES AND SUPPORT FOR TRADE

At a government/society level the Japanese appear to have their act together. The Japanese seem to have a clear, crisp ranking of goals and priorities. For starters, the Japanese know their goals and priorities, whereas nearly all our goals that begin simple become entangled as special interest groups enter the fray. Some issues that compete for priority include: human rights versus equal rights; full employment versus inflation and balance of payments; environment versus region versus country; capital versus labor; and consumer protection versus business protection.

Because of the need to manufacture and export, the Japanese educational system supports engineering and technology, while we support lawyers and other semantic accountants. There are fewer lawyers per person by a factor of two than in the U.S. The Japanese emphasis (priority) is on physical output. The increasingly large number of U.S. lawyers: consumes productive and creative output of workers; creates a self-perpetuating, non-productive body; detracts from persons who would otherwise enter productive occupations; and tends to build an even larger governing body. With an increased emphasis on legal training, our output is measured by intergroup contracts, policies, laws, rules, regulations and other forms of bickering among semantic accountants.

As a simple explanation, more money is available in Japan for investment to enable them to manufacture (for their island) because of lower taxes. This clearly affects their ability to invest in industry.

Their government spending for military is nearly nonexistent. Although there are prototypes from our military spending, they seem small and are by-products. In the case of research for semiconductors and computers the benefit though impressive might have been as great, given a different goal (e.g., energy self-sufficiency).

The Japanese don't have the federal research over-expenditures, epitomized by NASA and NIH. In the event of results, the Japanese will capitalize on our research for their manufacture and export. The NASA goals, for example, appear to be vague now that they've stopped providing the world with exciting space shots and television pictures from the moon, and the immediate needs for this research is unclear to most of us.

National health research seems equally vague. This research appears to increase health care costs, through a number of secondary effects. By contrast the Japanese spend one-half of what we do per capita for health care and medical research. They can capitalize on our research, but since they have a longer lifespan, it is not clear what we gain with the extra expenditures. In effect, Japan's lack of spending in medicine goes to investments which result in full, lifetime employment which is probably the best solution to personal health.

The Japanese believe computers are fundamental for the long term and they are prepared to invest in them and wait for return. Non only are machines used in all products they build for export, but they save labor too. Labor is both precious and expensive in Japan: there are only about one hundred million people and two percent unemployment. They're considering raising retirement from 60 to 65 to get the extra productivity. They must have computers to raise productivity; computers are vital to their continued domination of manufacturing. As a separate research area, robots are an important component of manufacturing domination. While much of the pioneering work was done in the U.S., the continued work to make robotics practical takes place in Japan. By contrast, in Australia where there is increasing unemployment, there's a belief that computers must be eliminated. Australia buys nearly all Japanese products, produces less and less, and the small Australian automotive industry of GM- and Ford-based large cars is rapidly declining under the stress of small, mass-produced Japanese cars.

THE JAPANESE SOLUTION TO OUR BALANCE OF PAYMENTS PROBLEM: SELL (IN JAPAN)

Can we solve our balance of payments problem by selling to Japan? Selling to Japan is the answer our government and industry want and willingly, but foolishly, look to. However, the Japanese rhetoric is only for our gullible government and academic communities and the naive business people. Furthermore the trade missions are only stocked with powerless, non-responsible, short-lived politicians whose main purposes include visiting Japan and being able to say something to the folks back home. For example, when state trade envoys visit Japan with the expectation of selling high technology goods, they succeed in selling only a few prototypes. The real sales will come in 5-10 years when these products are resold in volume to the U.S!

There has not been, nor will there be any serious trading of American products with Japan. The distributor/trading network entirely thwarts such an effort! The results are clear and we must face them.

Japan is a closed society and market. As the most powerful, homogeneous culture in the world it has a long history of being closed. There is no counter-evidence that an open market exists. The language is a code to further segment. Although business people do learn the language in crash courses, the language is relatively useless without the societal understanding. We only teach Japanese minimally on the West Coast of the U.S. On the other hand the technically trained Japanese have several years of English language training.

Even though there are major cultural differences among Japan and other far eastern countries (e.g., China, Taiwan, Korea) there is closer proximity among them than with western countries. This closeness is especially advantageous in finding additional sources of especially low cost labor.

The tariffs support the establishment of any industries they target. Although the semiconductor and computer import duties have been "advertised" to be on a parity with the U.S. they aren't there yet, but this matters little since their industry is strong enough to withstand imports. Still prices of U.S. produced computing machines are cheaper. In semiconductors the rationale for high tariffs has been protection of infant industries, yet outside of Texas Instruments and Western Electric, Japanese companies have been manufacturing longer than all other U. S. corporations. As evidenced in other industries, this is a come-on to further strengthen the Japanese manufacturers for export competition by having them compete in a token way with the few imports and thereby gain ideas to sharpen their exports.

For example, in the early seventies the Japanese encouraged U.S. minicomputer imports, although there were high tariffs. These occurred and now there is a significant Japanese minicomputer industry. For example, the basic structure of Fujitsu's minicomputer is quite similar to the DEC PDP-11.

Because of the closed nature of society and the emphasis on personal relationships, it is difficult, perhaps impossible to have significant Japanese sales. There are no significant examples to the contrary. "Doing business" together appears to be done over a long time period and is almost ritualistic. This means that it's essentially impossible to have an effective international company as we know it. A foreign manager is clearly tabu and sales are limited to one-shot deals with trading companies. There is no trading except as joint ventures. A foreign-owned company with controlling equity is so rare that it is an effective unwritten law.

JAPANESE HIGH LABOR COST, LIMITED POPULATION, FULL EMPLOYMENT AND FEW NATURAL RESOURCES, CREATES IMPORTANT BY-PRODUCTS TO FURTHER HELP TRADE

Japanese transportation and meetings run on time and at full capacity. Roughly twice as much as in the U.S. can be accomplished per day in Japan, especially those requiring meetings. The cordial, formal protocols help meetings proceed rapidly.

There's measurement of and pressure for efficiency. That is, the work-out/work-in ratio is high. For example, taxis have a driver-operated back door opener so that passengers can load/unload faster. The notion of efficiency seems to be taught to all and factories measure, graph and display key results. Concepts like fuel efficiency versus speed, weight and pollution are difficult concepts for Americans to understand, yet the Japanese "feel" them.

Given a notion of efficiency, there's real concern for saving physical resources too. At the computation center, printing isn't automatic; it's queued and must be requested separately. Lights, always florescent for high efficiency, are off when not in use. Of course small cars, taxis, a good train/subway are other indicators. The cars have mandatory bells that ring when the car is going over 100 Kmh! None of these artifacts for efficiency exist in the U.S.

Contrary to our "feelings", they are working the environment issue by less consumption, for example. This will indirectly make more money and resources available for production at lower costs. For example, cars don't pollute. U.S. environmental people at conferences in Japan are politely ignored while taking their basically boondoggle-oriented conference registration fees paid for by the U.S. government research establishment.

There is a range of basically human and personal concerns which encourage and support productivity. The result is a longer life span in the face of stress on productivity. While the subways and high density trains jostle people pretty badly, and there's no segmented smoker areas (and many smoke), there's great concern for the feelings, privacy and treatment of individuals. On arrival and departure at every organization, one is given moist cloths and refreshments. Taxis and buildings are air-conditioned. The hotels, though very expensive, provide privacy, ambiance and excellent food and service. For example, one expects a cloth cover over the telephone to enable it to fit the room decor. There are Japanese baths, and these are great too!

They are compulsively clean. In an indirect way, this really helps the manufacturing of small, precise goods including cameras, semiconductors, high-speed computers and disk memories.

There's orderly queueing at each server. The Japanese appear to be the world's best self-queuers. Queued systems of this type have higher through-put and make the best use of resources. One might suspect there is lower general hostility arising from competing for a finite resource when queueing.

Inventions are to labor-saving devices. There are countless gadgets to save scarce labor. Computation center line printers have paper cutters and conveyors in order to bring printing back to a single station. There are no computer operators and people to serve the users! This direct use of facilities not only costs less, but provides better service and through-put.

Conclusions

We must be impressed with the intense drive coupled with the technical, manufacturing and marketing acumen of the Japanese. This drive and ability, coupled with many factors of our society, has enabled the Japanese to systematically plan and dominate every U.S. market that they've attempted. Although there's been a "feeling" that the market domination is limited to low technology, there is evidence that nothing is immune.

However, despite a desire to blame the Japanese for dominating our manufacturing, it comes about because there are U.S. buyers and distributors for their goods. Distributors come about because of the intense emphasis we have on profit and return-on-investment. By only distributing and not designing and manufacturing the investment is negligible, giving a high return-on-investment.

The intent of the paper is to describe variously "how" this market/product domination is carried out. Like any good Japanese product, the ideas within the paper have been taken liberally from many sources -- mostly without credit. It should be self evident that, we (the U.S.) have a problem. Each of us, whether we be part of industry, government, or academia, can now address the issues we're responsible for. There's no real need for another fact-finding trip to Japan to further define the problem. Japan is clearly not a place to search for the solution.

Many solutions are required. Freezing the current level of government size spending and non-productive people (e.g., lawyers) would be fine first starts. Living within our collective energy budget is also needed. Rather than engaging in a trade war the following mechanism could simply address the trade deficit:

> No company can import and distribute a foreign product without arranging an equal export credit. That is, a company; such as Itel who buys and resells Japanese computers can get agricultural products to sell or it could export its own services in an equal amount. The trade balance has to be the distributor's problem -- not that of the President, or the Secretary of Commerce or Congress.

Appendix 1. A Chronology of Systematic Domination*

I. "Development of a domestic Japanese industry. The Japanese industry is developed and grows rapidly. The major aspects that mark this development include:

(a) Market control. Imports limited essentially to zero. Only a few major manufacturers are permitted. Prices remain significantly higher in Japan than in other competitive markets.

(b) Borrowed technology. The Japanese borrow heavily from foreign technology, including a large number of purchased licenses and patent rights, and wholesale reverse engineering.

(c) Vertical integration of most manufacturing.

(d) Major investments. Major investments are made in modern plant, equipment and technology, both for the final product and throughout the vertical chain of manufacturing. Continued research, development and plant investment expenses are made.

II. Establishing an export market base.

(a) The establishment of world-wide sales organizations.

(b) Researching and understanding of the foreign markets.

(c) Establishment of a reputation for quality and reasonable prices.

(d) A limited focus, especially in those markets less attractive to domestic manufacturers.

III. Major market penetration. Major market penetration occurs usually during an economic downturn in Japan. Previous efforts by the industry have set the stage for them to be successful in this endeavor. It is marked by the following considerations:

(a) Cooperation among the Japanese companies with respect to models, prices, and markets.

(b) Focus at the mainstream of the foreign market.

(c) High inventories because of poor markets in Japan, i.e., an export push at any cost is necessary and expedient.

(d) Extremely low prices to the mass market to gain market share rapidly, i.e., a knock-out punch to the domestic manufacturers. Modern plants, reasonable costs, an established export organization, and good reputation set the stage for success.

At this time, marketing muscle is established. Not only was the export market share large, but the domestic market remained closed. It should be pointed out that this major market penetration had been made by a combination of factors, as outlined. The greater marketing muscle allows the Japanese manufacturers to profit from their long investment.

IV. Market exploitation. This period is marked by higher prices -- often higher than domestic manufactured models. However, the higher prices are often more than offset by perceived higher quality, both real and imagined. There is also continued cooperation on prices and markets, as well as continued limitations on imports to the Japanese market."

paper 1, printed 10/19/86. Original paper 10/78.

JULY 21, 1982

Dr. Kazuhiro Fuchi
Institute for New Generation Computer Technology
21F Mita Kokusai Building
1-4-28 Mita
Minato-Ku, Tokyo, Japan

Dear Dr. Fuchi:

It was a pleasure to meet with your and your staff on June 30 and discuss the direction for the Fifth Generation Research Program. I was extremely impressed with the program in terms of aggressive goals to build the Relational Database and Prolog machines. Also, I was delighted to hear that you made the excellent choice to use the DEC 20 as the LISP and Prolog machine for starting your applications work.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly.

I'd welcome being able to show you the growing museum whenever you visit this area and discussing the Fifth Generation with you.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, The Computer Museum

CC: Dr. Gwen Bell, Director, The Computer Museum
    Dr. Sam Fuller
    Dr. Tom Kobayashi
    Grant Saviers, Vice President for Mass Storage Engineering

July 20, 1982

Mr. Osamu Seki, Director
Electronics Policy Division
Machinery & Information
Industries Bureau
Ministry of International
Trade and Industry (MITI)
Tokyo

Dear. Mr. Seki:

It was a pleasure to meet with you on 30 June on behalf of Digital Equipment Corporation.

At that time I mentioned that Digital would like to become a member of the Fifth Generation Research Program.

Sincerely,

Gordon Bell
Vice President, Engineering

CC: Dr. Tom Kobayashi

July 20, 1982

Mr. Shigeru Sato
Fujitsu Limited
1015, Kamikodanaka Nakahara-Ku
Kawasaki-Shi, Kanagawa-Ken 211,
Japan

Dear Mr. Sato:

It was nice to meet you again at the talk I gave on Ethernet at Tokyo University.

I'm grateful to you for supplying the early Fujitsu parts to the Computer Museum four years ago.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, The Computer Museum

CC: Dr. Gwen Bell, Director, The Computer Museum

August 2, 1982

Dr. M. Yasufuku
Executive Director
Fujitsu Limited
1015, Kamikodanaka Nakahara-KU
Kawasaki-Shi, Kanagawa-Ken 211, Japan

RE: Visit to Fujitsu Limited

Dear Dr. Yasufuku:

Thank you for your warm hospitality during my visit to Fujitsu. I was very much impressed by your company and its personnel as I wrote earlier.

Upon my return, I reviewed the material you gave me during my visit. For the first time, I noticed that several of the pages were marked with the legend "FUJITSU LIMITED - Proprietary and Confidential". Since you made no reference to any need to maintain your information in confidence during my visit, I assume that I can delete the legend and treat it as non-confidential like the other material you gave me. However, I will not distribute this material outside of Digital. If this is not the case, please let me know as soon as possible.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

JAPAN IMPRESSIONS (Part I)

Reaffirmed to be #1 in Sales and Technology (see slide on IBM hi-end)

Now claim to be #1 in supercomputers

Technologies that are dominated:

- Base materials and production (esp. Quality)
- CRT, LCD, EL
- Printing, fax, thermal, xerography
- Magnetic recording and video disk
- Video, video b/w compression and image processing
- Voice i/o
- Communications (installing systems)
- Fiber optics (installed LANs)
- Packaging and PWB's
- Semis and Semi CAD
- ECL, Bipolar, MOS, CMOS

. Research in J^2, (GaAs and HEMT in factory?)
. Robotics?

The Japanese Computer Industry

. (MITI and Fujitsu, Hitachi, NEC, Mitsubishi, Toshiba, Matshusta, Oki)

. have and are implementing a vision of 5G computing based on AI and high performance processing.

Program includes:

. Supercomputer technology, 1981 + 8 years (VLSI, J^2, GaSa, HEMT)
- new architecture and technology

. Dist. Proc. and LAN's ($40M over 3 years)
. ICOT (the main push)
. Next generation (farther out)
.NTT Si Compiler - a real compiler that's so far produced a 13k t chip in 2 months without using a CRT. Totally language driven with separate backends for CMOs, HMOs, bipolar or ECL. 2,000 people are working on VLSI and this will be used for smaller companies. Also, several new architectures, including 2 data flow.

ICOT - INSTITUTE OF NEXT GENERATION COMPUTERS

. Headed by Dr. Fuchi
. Coupled into universities - 5 people + 5 x 7 company research
. Use a 2060 for Prolog and LISP
. Two machines are to be built by companies (in 2 years)
- RDMS
- Prolog processor
(Data flow for Resolution desired)

. Prof. H. Goto, TU, believes Prolog is wrong and has Mitsui building a 10 mips LISP machine for him.
. Government funded, Company's fund space,...
. They are driven.

. Three Groups: Architecture, Application, Human Interface

SUBJECT: MISCELLANEOUS MESSAGES FROM JAPAN

Engineering Away From Maynard
Have never been more enthusiastic about doing engineering in both

Japan and Taiwan. There's a plentiful supply of dedicated, high
quality engineers and for the products where we have clear interface specs (eg VT100, or a printer) it's ideal. I saw a Taiwan design terminal that went out alternatively in boxes bound
for the US or sold internally at $600 to compete with the VT100.

A major reason why the Japanese and Chinese can be so effective is based on the notion of engineering learning curves. They really understand this implicitly. We should look at the case where upward or sideward or external mobility of engineers interfere with doing it again and taking advantage of the 20% better preformance the second time around. It's essential to keep the team together and do it several times, thereby taking advantage of great learning. We've not managed this well at all.

Software looks like a good thing to look at doing in Taiwan... especially applications such as engineering because the universities are so strong analytically.

In Taiwan one is supposedly able to check out the PDP 10/20 prints because all products are reproduced and go to all plants. This can be fixed simply. One plant is the designated plant to
support a product. Prints are released and kept there. If other
plants need them, they get released. The flexibility in the system makes for high productivity in the print room, but it requires much manpower to file all the stuff. Why?

Power Supplies continue to be a major problem in Japan. I think
we need a concerted effort to understand why. Clearly an engineering problem.

Computer Engineering was highly sought because it has so many papers that go into the philosophy of why something is designed a
particular way. The VAX, 11, and 10/20 papers were taken to be

excellent examples. This may be the best reason to have a DEC Engineering Journal... namely because that it will need pages. Right now people crave information on VMS, DECnet, Ethernet, LAN's, etc of this form. This sounds like something we need to
do within engineering.

Manufacturing

We must be careful not to bank too much on low, far east labor rates as the answer to costs. The Hitachi automatic lead bonder negates low labor costs and reduces inventory. The US semiconductor industry got trapped on this one. I think the work
on simple assembly robots will have a similar effect on producing commodity things. Seiko is very good here and others are investing much too. It's the old story of brawn vs brain (lots of very good electromechanical engineers).

Am really concerned about lurking competitors such as Brother who
are really building great smart typewriters. The step to a programmable computer is a very small one. They are getting the
profit from the commodities to make this happen.

I saw an excellent IBM captive plant in Taiwan making heads for the IBM 1403 printer, which was just cut back by a factor of 2.
IBM set up the whole thing, and bought much of the equipment, but
it's run by another company. This looks like a much better way to go if we want cost. (It'll cream a plant like Boston or Springfield or Albaquerque.)

Quality continues to be so much of a concern that the Japanese are and have installed a complete burn-in facility in Japan. I
don't see how we can continue our strong position by having to do
this. Spares are a great concern too. Much servicing is done by
carrying two.

Marketing
NEC had a great showroom for all it's products in downtown Tokyo.
Ken has been pushing this and based on the one I saw, the idea surely has merit.

The issue of having no separate marketing organization per se really struck me. NEC has half of the marketing in the sales organization (say here in New England and on the West Coast) and
the other part in the engineering organization. The two get together quarterly for a week to exchange demands. In this way the engineers really hear it from the sales/marketplace. Some form of this exchange looks vital for us.

JUNE 21

. Japan Engineering Center Meeting

. Visit Mr. Yanase, TEAC President re our lack of buying drives

. Dinner with Drs. Kanai and Sasaki (head of Semis), NEC

JUNE 22

. Presentation and Demonstration on Kanji at CSS Hakusan by JTC and CSS personnel

. Ethernet lecture at KEIO University (Hiyoshi Campus)

. Dinner with Dr. Aiso and Prof. Tokoro

JUNE 23

. Visit Hitachi Central Research

They want a VAX. Looked at color CRT design.

. Visit Hitachi Musashi Semiconductor plant (see attached) and dinner (Dr. Makimoto)

JUNE 24

. Visit Asahi-shinbun Newspaper on IBM Kanji system

. Press Conference at Hilton Hotel

. Dinner with Sharp Dr. Saski (R&D,VP--now President) at American Club

<u>JUNE 25</u>

. Visit Fujitsu Kawasaki (Dr. Yasufuku, Semiconductor group head--General Manager Semis)--See M382, fiber optics, semis--see attached.

. Visit Mr. Yamamoto, President, at Fujitsu Headquarters re becoming a member of Fifth Generation Research Group.

. Dinner with Yasufuku, Hiraguri

<u>JUNE 26</u>

. Visit Machida (fiber optics) Industry - "one man" company

<u>JUNE 27</u>

. Rikei

<u>JUNE 28</u>

. Visit Electrotechnical Laboratories (ETL) in Tsukuba - Dr. Tojo

(see attached)

JUNE 29

. Visit NEC O.A. Show Room

. Visit NEC Central Research
Dedicated to be Number 1 in C&C (Computers and Communications)

. Engineers do marketing

. Sales and marketing are in 1 group

. There are quarterly, 1 week meetings on Product Planning with 50-100 people. Design engineers must attend (in Tokyo).

Chairman Kobayashi says:

1. All engineers must learn/know English
2. All employees must use Personal Computers

JUNE 30

. Lecture at Tokyo University (Moto-oka and Hiroya Fijisaki. Saw Dataflow Computers (8-control, 16-processor) FOR:1

Have built:

1. Old mP=4P

2. Prolog MC = 16 processor computers, 8 control computers, Z80 message passing, each P communicates 4 control computers. The companies build these gratis.

. Visit NTT Headquarters (sales)

. ICOT (5G) Research Lab, Dr. Fuchi

. Dinner with Mitsui, Zosen staff (sales) Prof. H. Goto (LISP machine)

JULY 1

. Visit SONY Headquarters (See MAVICA, audio disk)

. Visit SONY Atsugi, Mr. Morizono, VP

(see attached)

JULY 2

. Visit NTT Tsu-shin Kenkyu-sho

Electro Communications Lab

. Building T^2L LISP machine

. Building 2 Dataflow machines

. Building "Array" (1 bit machine)

. Address to sales and MC, dinner with MC

JULY 3

. Arrive Taipei - rest, write, swim, dinner with Yen

JULY 4-7

. Visit DEC Taiwan, 3 universities, China Computer Corporation (our rep.)

July 20, 1982

Mr. Haruo Yamaguchi
Nippon Telegraph and Telephone
Public Corporation
1-1-6 Uchisaiwai-Cho
Chiyoda-Ku, Tokyo
Japan

Dear Mr. Yamaguchi:

It was a pleasure to meet with you and your staff on June 30. Since NTT is such an important customer, it is necessary that we understand your requirements and I hope this meeting will lead to a better understanding. It has come to my attention that Fujitsu, NEC and Hitachi are going to provide Minicomputers to you based on VLSI. Is it possible that we might also discuss supplying computers under this arrangement?

Digital Japan wants to be very responsive to the needs of NTT and Digital is a major supplier of computers for communications on a world-wide and multi-applications basis.

If there is anything that any of us at Digital can do to be a more helpful or responsive supplier, please let us know.

Sincerely,

Gordon Bell
Vice President of Engineering, Digital Equipment Coporation

Shinagawa-Ku, Tokyo, 141 Japan

Dear Dr. Mizushima:

Please accept my sincerest thanks for the hospitality you and Dr. Kihara extended to me at Sony Headquarters on 1 July. I would also like to convey my thanks to Mr. Kishimoto who escorted us to the Atsugi Plant. It was impressive to see the Mavica and the Compact Audio Disk at the headquarters. The Video, Personal Computer and Microfloppy were equally good.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly.

I'd welcome being able to show you the growing museum whenever you visit this area. In the future, the museum intends to request that Sony assist in archiving important computer pioneer talks that have been given.

Again, thank you for the hospitality.

Sincerely,

Gordon Bell
Vice President of Engineering

CC: Dr. Gwen Bell, Director, The Computer Museum

Dr. Michiyuki Uenohara
Nippon Electric Co., Ltd.
1-1, Miyazaki, Yonchome,
Miyamae-Ku, Kawasaki-City
Kanagawa Prefecture 213, Japan

Dear. Dr. Uenohara and Dr. Ito:

Please accept my sincerest thank you for the hospitality at your research facility. Dr. Ito did an excellent job of hosting my visit at NEC Laboratory. Although we only met briefly I am greatly impressed by the work there. In particular I enjoyed seeing the computer aided design, learning about research in multiprocessors and in high speed circuitry, in particular Josephson Junction circuitry and the COBOL machine.

In regard to the COBOL machine I have requested we run your benchmark on VAX because I think we should be curious in comparing how well our VAX encodes and executes COBOL as compared with your specialized COBOL machine. I enjoyed seeing the Netec-X1 TV Codec, and think we are a potential customer for such a codec as we are using teleconferencing.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly. Perhaps the COBOL machine would be of interest as an artifact because to my knowledge it is the machine that has been designed for executing COBOL specifically. At the very least, we'd like papers, photographs and descriptions of it for the Museum.

I'd welcome being able to show you the growing museum whenever you visit this area. Again, thanks for the hospitality.

Sincerely,

Dear Dr. Kanai:

It was a great pleasure to see you again in Tokyo on Monday the 21st of June and to have dinner with you and Dr. Sasaki. Our engineers in Marlboro still refer to your excellent lecture several months ago when you visited the United States.

On the 29th of June, I visited the NEC Research Laboratory and met Dr. Uenohara and reviewed some of the excellent semiconductor and computer system's research. I also visited the NEC showroom to look at your fine products. My impression is that NEC is a very fine company dedicated to producing state-of-the-art products. It also appears to be a company that is a pleasure to work in because of such competent people.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

Dear Dr. Sasaki:

Thank you for taking the time from your busy schedule at NEC to have dinner with me and Dr. Kobayashi, and Dr. Kanai. It was a pleasure to see you again in Tokyo and I look forward to your continued visits in Maynard and continuing to buy various computer components from you.

I visited the NEC Central Research on the 29th and there learned of your advanced semiconductor research work, especially those in Josephson Junctions. I hope on your next visit here you might present some of the future directions for high speed semiconductors. We have an interest in high speed gate arrays, too.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly.

Dr. Makimoto
Hitachi. Ltd.
Nippon Building
No. 6-2, 2-Chome, Ohtemachi
Chiyoda-Ku Tokyo 100, Japan

Dear Dr. Makimoto:

I enjoyed having dinner with you and your colleagues, and I look forward to a continued close working relationship between Digital and Hitachi.

Thank you for hosting me at the Hitachi semiconductor works on June 23rd. It was indeed a pleasure to visit Hitachi and learn of your developments in all kinds of semiconductors and in particular the status of CAD work. I was especially happy with the 64K static CMOS RAM you gave me and our people are looking at the technology of this RAM at this time and I hope we can use it.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly.

It was nice to see you again after your first visit to the Museum.

Dr. Takuma Yamamoto, President
Fujitsu
Furukawa Sogo Building
6-1, Marunouchi 2-Chome
Chiyoda-Ku, Tokyo 100, Japan

Dear Dr. Yamamoto:

Thank you for meeting with me on June 25th and discussing how we might become part of the fifth generation research program. On the following days I visited ICOT and Professor Moto-oka and introduced myself to Mr. Seki of MITI. The research program that is going on at ICOT looks very good and everyone is enthusiastic and dedicated to its success. I think there will be very interesting results from this work. I would also be interested in joining this effort.

It was a pleasure to visit your semiconductor work under the direction of Dr. Yasafuku. As a customer of Fujitsu's, we are very impressed with the quality and technology of your products.

It was also a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly. I met Dr. Sato on June 30th and he and Dr. Kurosaki had presented us with earlier Fujitsu artifacts for the museum.

I'd welcome being able to show you the growing museum whenever you visit this area.

Mr. Toshio Hiraguri
Fujitsu Ltd.
1015, Kamikodanaka Nakahara-KU
Kawasaki-Shi, Kanagawa-Ken 211, Japan

Dear Mr. Hiraguri:

I enjoyed meeting you for dinner with Dr. Yasafuku on June 25th and I am certainly impressed with your design capabilities for mainframes. You are to be highly congratulated on the successful design of the M382. It is a very spectacular engineering achievement.

If you are in the U.S., please feel free to visit me.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, Computer Museum

cc: Tom Kobayashi, DEC

July 19, 1982

Mr. Haruhiko Machida
Machida Endoscope Co., Ltd.
13-8, Honkomogome 6-Chome,
Bunkyo-Ku, Tokyo, Japan

Dear Mr. Machida:

I enjoyed visiting your company on Saturday, June 26th. Thank you for taking Saturday morning and presenting the work on your vast array of optical and fiber optics work. It was great to see the laboratory of an incredibly innovative company like yours. I am certainly impressed with all the products and I hope that we can cooperate to supply computers for your fiber optic tomograph and I hope that, in turn, we can purchase fiber optic devices from you for some of our products. We need this innovation for our products.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly.

I'd welcome being able to show you the growing museum whenever you visit this area.

Again, thank you.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, Computer Museum

Dr. Akio Tojo
ETL, Tsukuba
1-1-4 Umezono
Tsukuba Science City
Ibaraki, Japan 305

Dear Dr. Tojo:

Please let me take this opportunity to thank you and your colleagues for hosting me on the afternoon of June 28th at ETL. I enjoyed interacting with Drs. Nakajima, Shirai, Yuba and Shimada and learning of your work in picture processing, speech, vision of the LISP machine and your recent work on data flow architectures. I have admired the work of ETL for many years and I'm happy that we can supply computers to you in Tsukuba Science City. I look forward to our continued close relationship.

I'm happy that Dr. Kobayashi is setting up a research and development laboratory in Tokyo and look forward to our being able to interact with your laboratories there for the design of creative products.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly. I think the LISP machine would be a worthwhile artifact for the museum. I saw the earliest ETL machine in the Tokyo Science Museum. Is there any chance that we could secure some plug-in units, from each of the ETL machines that were in the museum.

I'd welcome being able to show you the growing museum whenever you visit this area.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, Computer Museum

SUBJECT: WHY WE MUST BUILD A GREAT PORTABLE TERMINAL/PERSONAL COMPUTER

TRIP TO JAPAN, STIMULATE THESE MANY THOUGHTS:

MOTIVATION

0. Japanese consumer electronics makers are entering the computer
market both with components (eg. TEAC is 1/2 digital with floppies
and Wini's) and systems (eg. Sony).

1. Lots of small, portable, relatively useful products are now on the
market including:
    a. Computing calculators with narrow paper, and mass storage
    b. Sony typecorder
    c. Brother $200 thermal ribbon typewriter and calculator
    d. Viewman
    e. Purse-sized computer terminal
    f. Low cost Timex computer
    g. Grid systems using Sharp EL panels

2. Emerging Components:
   a. EL and LCD panels
   b. 64K CMOS rams and many other CMOS parts;
   c. 256K rams & large roms
   d. Sony micro diskette
   e. Modem chips, codecs, telephone interfaces
   f. Voice synthesizers and analyzers
   g. A plethora of 2K-8K gate CMOS gate arrays.
   h. Videoprocessors

3. Personal need of a product like Dynabook that does the functions that are emerging in today's personal computers.

4. The size would help drive the cost, styling and the market. We need a more aggressive cost and functional target to push us.

5. Our manufacturing technology is not good enough to build low cost terminals. If we get some reasonable distribution channels going, then we could do a joint venture with high volume supplier such as Brother, Sharp, Sony or some other supplier who is good at low cost, high volume units. They'd teach us.

6. This product is inevitable and I think possibly more desirable than current, bulky PC's. We must work on it before we find that we're behind and that someone else is taking the market.

7. Within a few (say <5 years) a unit such as this will provide the
    functionality of today's large PC's. This is more than many users
    can handle anyway.

SOFTWARE FUNCTIONS - What it does

- Standard, correcting typewriter mode
- Good word processor
- Visicalc
- Scientific calculator (possibly compatible with TI and/or HP programmables)
- Business calculator
- Virtual Terminal (for all common terminals)
- Terminal compatibility with new very small terminal system
- File transfer to/from DEC system
- Standard Basic?
- Games (optional)
- Very fancy alarm clock
- Calendar keeper ala WPS
- Forms entry/WPS math for expense account data, order entry, etc.
- Datatrieve (eg. for names, addresses, comments, fields)
- Voice would ideally be the interface. Failing this, we could use handwritten input and keyboard. Voice annotation and dictation are a must.
- Telephone message interface

HARDWARE REQUIREMENTS

	IDEAL	GOOD	ACCEPTABLE
Display**	24-66 lines;1Kx1K	8 lines	1 line or 8 lines
Print* qual.	"LA100"		"LA12" none?
Graphics	yes	video text	none
TV i/o	yes		none

Keyboard	Brother "std"	--	Brother "portable"
Handwriting	yes (notes)	--	none
Voice	recognition	"Pro 350"	none
Modem	"LA12"		300 b acoustic
Fax	full	no scan	none
File	Sony Micro flopy		Micro cassette
Pc	VAX	don't care	
Mp	256K		65K
Power	solar	6-12hr. batt.	AC
Size	"Typecorder & Sony floppy"		Briefcase/2
Weight	2#		5#
Clock	yes		yes

*   Need not see printing if display is good.

** (Ability to browse & deal with multiple, overlapping windows)<-too wild?

COMPUTER AND CALCULATOR SIZES AND PRICE RANGES

Wrist watch watches	25 - 160	Casio
Purse/shirt pocket calculator	10 - 62.50	thin
Hand held/coat pocket	10 - 62.50	HP35
(Programmable)	62.50 - 160	
Paper stack sized	160 - 1000	Typecorder
Portable typewriter	160 - 400	
Typewriter	400 - 1000	?
CRT-based PC	1000 - 6250	VT182

DISPLAY - I met the head of engineering who has subsequently become head of Sharp. They have various solid state displays and will soon have an 83X8 line LCD. He commented on the Grid System portable computer. Sharp also has Maxwell's Equations in concrete at their R & D center.

Having tried to edit on the Sony (40 characters) and Brother typewriters (16 characters), I think we should not make people suffer, but pay the extra price (say $500 selling price) for something that can be used.

The 8 line display be totally program transparent to a standard 24 line CRT by having two characters define the bottom of the window. On entry it would start at 8, go to 24, and stay there,

scrolling off the
top. At anytime the window bottom could be moved back, independent of
the cursor. Any action on the cursor would snap the window back to
24, displaying the bottom part of the "CRT".

KEYBOARD - I'd like a regular typewriter keyboard although the $200
Brother is acceptable. It should be quiet.

PRINTER - I now believe a printer of some sort is nearly always
required for the foreseeable future. Here, it would be nice to print
high quality so that personal notes and letters could be sent. It
would be possible to have this printer modular, but given the small
Brother portable, the typewriter doesn't seem to add much size or
cost.

The printer would be used to supplement editing, for personal
correspondence, forms, order confirmation, calculator, etc. I typed
on the big, office, Daisy Wheel Brother which had a 16 character
display and did most of the important functions of our WPS. It was
very impressive and especially nice to have no carriage motion until
the line was ready to be printed.

The $200 little, thermal, sub-portable Brother was most impressive!
It too had a 16 character display and includes a calculator mode.
It's the size of a Sony Typecorder, so it occupies about 1/4 briefcase
and is 1 1/2" - 2" x 8 1/2" x 11" - or "paper stack" size" or 1/2 the

size of a portable.

MASS STORAGE - Although it's too late to redo our decision, the Sony 31/2" Micro floppy looks to be ideal and could obviate the need for the 5 1/4". The project engineer gave one of the best presentations I've ever seen on why it will become the dominant drive. He started with goals and constraints and went into detail of all kinds. He believes they've got a technology base that can live for 10 years in terms of form factor and cartridge.

For this computer, it could be acceptable to limit response time to small tapes since they would only store files that would mostly be in memory.

APPROACHES

I don't think we can achieve the "ideal" within two years. Rather than waiting, we can take two, two-step approaches:

1. Build the right sized unit now and put in whatever is possible, giving up some level of functionality. Don't worry cost, but put in the most functions we can for the "Typecorder" size. The next incarnation would have more capability and approach the ideal.

2. Large size first with right functionality, then cost (and size) reduce.

I strongly prefer the first approach targetting small size to get our thinking down. The Nebula with VS100 and good copier

output
is what I want. Therefore, it's important to constrain size, not
function in our design! Such a product could be easily spec'd and
built either here or with one of the major Japanese vendors.

"TO" DISTRIBUTION:

BILL AVERY	PAUL BAUER	ART CAMPBELL
DICK ESTEN	BARRY JAMES FOLSOM	SAM FULLER
JOHN KIRK	TOM KOBAYASHI	AVRAM MILLER
KEN OLSEN	GRANT SAVIERS	JACK SMITH
DON WILSON		

WPS USERS - Leave HP mode and type <CR>

SUBJ: TOKYO PRESS CONFERENCE 6/24/82--INCLUDING HISTORICAL PERSPECTIVES ON DEC

TO: Operations Committee Date: 7/19/82 Mon
Dick Berube From: Gordon Bell
Bob Lane Dept: Eng. Staff
Ed Reilly MS: ML12-1/A51 Ext: 223-2236
Tom Kobayashi EMS: @CORE

(You might find this version of the philosophy of our products useful.)

Thank you for coming. I understand there is competition to have press conferences today. (The Hitachi/Mitsubishi Press Conference)

I'm delighted to be here today and meet you as the Vice President of Engineering of Digital Equipment Corporation. I am also the curator of the Computer Museum, and as such would like to suggest you visit the museum in Marlboro Massachusetts to view the origins of computing. It is now an official, public institution independent of Digital and it is the largest. We archive and display artifacts from the abacus and soroban to the first supercomputers.

My purpose in being here today is threefold:
first, to tell you about our corporation, Digital;
second, to present the history and philosophy of our products, and;
third, to describe the Engineering Center under Dr. Kobayashi, we have in Tokyo.

This year, Digital is celebrating its 25th Anniversary. For the last 14 years we have a Japanese branch.

Our business growth has become a legend in the business world and this growth has been recorded in a recent article, entitled the Astonishing Growth of DEC in Fortune Magazine. This year we became the second largest US computer company according to the recent Datamation Survey, surpassing the companies of the group called BUNCH. We're 137th in the Fortune 500 companies and our growth over this last decade has averaged 36% per year.

We have over 40% of the world minicomputer market. Digital Japan has grown 41% annually over the last 5 years. I hope we can continue to find ways to provide more computing in the important Japanese market, because I believe we have unique capabilities

that are important for your future. These include:
1. computing for the technical and OEM marketplace;
2. better capabilities for engineering micro and personal computers of all types,
3. a means of interconnecting and supporting all types of computers, including personal computers in a distributed fashion in a users environment, and
4. distributed office data processing of all types based on local area networks.

Just as we have engaged in distributed processing, I believe we have also originated and engaged in distributed partnerships. Now, to fully utilize these unique and important products and capabilities, we need to look for new forms of distributed partnerships.

Now, I'd like to turn to the philosophy, and history of our products...
While Digital started in 1957 to build modules, we introduced one of the earliest transistorized computers, the PDP-1, in 1960. Our computers are built on one basic theme: they must completely integrate with their environment and couple to the user and his application in the best way. They must also be friendly and approachable.

The PDP-1 was approachable in two ways: it was the first computer to have an interactive, CRT display for the user; and a user could connect his own equipment to form a total system. All our computers follow in this tradition. These two characteristics made the computer ideal for use in scientific and real time computing. The program, Spacewar, was first written for the PDP-1 and its CRT. It was the first video game and you can see it in operation in the Computer Museum today.

In 1963, we introduced the LINC, which I believe is the world's first Personal Computer. This was based on a MIT Lincoln Laboratory design. A Personal Computer provides direct access by a single user in an interactive fashion so that the user can define and operate programs automatically from the keyboard and LINC had a small, personal tape file system with 1/4 megabyte. A PC must have a filing system for keeping its programs. LINC also had input/output channels for interconnecting experimental equipment. It was used by scientists for many years and several are still in use. We made two follow-on compatible versions.

In 1964, we introduced an alternative form of Personal Computing, which we called timesharing, as the first commercial, mainframe timesharing system. That was the PDP-6 which later became the PDP-10. Today we call it the DECsystem 10 and 20 series and we hope it will be used in the 5th Generation Research Program.

Timesharing and personal computing are essentially the same because they both provide on line, interactive computing. Whereas in personal computers only one user has access to a machine, with timesharing, many users share the machine in order to get the economy of sharing. Only recently, were we able to provide high quality personal computers with the same capablity of our timesharing machines. For example, the CP/M personal computer system is similar to our first timesharing system.

In 1965 we introduced the first minicomputer, the PDP-8. It was important for two reasons: we could mass produce them and the result was a cost of only $18,000 which was the lowest cost by at least a factor of 3 in those days; and the computer was rack mounted and could be used personally or it could be interconnected with other equipment for control of power plants, experimental equipment, and process control. The result of low cost and interconnectability was a large market.

With the first minicomputer, our computers became less visible because they were part of a larger system that was designed by someone else . This is one reason Digital may not be familiar to you here in Japan. I'd like to call this Original Equipment Manufacturing relationship a Distributed Partnership. That is why we have many close business relationships in Japan today of this distributed partnersthip form.

The PDP-11 was introduced in 1970 and became the standard of excellence for minicomputing because it was approachable and could be easily and flexibly integrated into other equipment. The Unibus was the interconnect medium for physically coupling computer hardware components together in a flexible, unbounded fashion. Several minicomputers and all microcomputers use the Unibus-type structure.

In 1972 timesharing was added to the PDP-11 minicomputer, providing very low cost computing to many more users. In this way, the computer started to live with its actual users in a highly dispersed fashion. Also, people started using the resource time sharing system RS03 for many other types of computing, including word and data processing. Because so many computers were dispersed, we had to find a way of interconnecting these machines, DECnet, was developed in 1975 as a set of communications links and protocols to provide what is known to day as Distributed Processing!

Also in 1975, several of us started to work on the VAX computer which we introduced in 1978. The goals of VAX was to provide a computing environment that had none of the limits on program size or program interconnectablity that we knew. In essence, we applied to programming, what we had been applying to hardware interconnectability we pioneered on the PDP-11 using the Unibus. Since then, we introduced other members of the VAX family that could be used in both a mainframe and distributed processing fashion.

This year we introduced three very important distributed computer processing products:
1. a much smaller model of the VAX, the 11/730 which is so small that it lives with and can be used by only a small group of only 4 to 8 users. In fact, I am using one with my secretary for my own personal computing. It has an integrated disk of 140 Megabytes, providing the space of what is equivalent to about four, 4-drawer filing cabinets in what is the space of a single cabinet.

2. a set of three personal computers, including the Professional series, based on PDP-11. Now, a user can have the facility we had traditionally supplied on our timeshared, minicomputers, but on a personal basis in a fully compatible fashion. Thus, applications written on the Personal Computer can grow and then be moved to a VAX group-level, or VAX departmental-level, or VAX central-level mainframe.

3. Ethernet, to allow a user to interconnect all of our products together to form a fully distributed computing environment. In this way, the actual network becomes the computing environment.

In fact, I like to call Ethernet the Unibus of the fifth generation.

By having all these interconnected products, a user can choose to compute in one of five ways:
1. on a personal computer, or,
2. interconnect the personal computers to form a distributed system, or,

3. interconnect terminals or personal computers to the small group level machines, or
4. interconnect terminals or personal computers to departmental level machines owned by a department, or
5. interconnected to a central facility whose computers are also interconnected.

While the methods of computing just described are structural, two sets of applications we introduced this year for VAX are even more important:

A distributed data base system with both relational and CODASYL network-type data base was introduced. This complete system has many components including a common dictionary, forms i/o and other facilities. It is known as VIA for Vax Information Architecture. Not only is it impressive by itself, but it is the only distributed database system I know of.

The complete office system, including word processing, electronic mail, typesetting, and various office procedures such as calendar keeping, meeting scheduling, and forms processing. This is not a promise, but a system that has been in use within our company providing office processing to over 5,000 users for four years. I hope that this system can be made available here in Japan.

I've described Digital and its past and present products. The emphasis has been on quality and innovation. For the last ten years a Digital Engineering group has modified our worldwide products for use in Japan. This year we are starting another engineering group under Dr. Kobayashi to build products for worldwide use. We would like to have this product development center actively developing high technology products and it would grow from about a dozen now to over a hundred employees in 3 to 5 years.

I am delighted to be here and provide this information. If you have questions, I will try to answer them.

Subject: **Japan Trip Diary Index**

To: Distribution

Date: 13 SEP 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.:
2236

follow up 9/27/78

You're welcome to look at this 13 page (single space) document. It is a diary of the visit and formed the basis for the essay on "Some First Impressions of Japan". It's contents:

<u>July</u>

16 - Tokyo

17 - DEC office talk and their concerns over particular product issues; talk at Keio University

18 - NEC computer, their research, and TV manufacture; (the technologies they've assimilated from the U.S. and how they've gotten technology via license agreements)

19 -Fujitsu computer design and their M200; also the factory at Numazu...and how they got Amdahl's technology and are converting him into a distributor

20 - Electro Technical Lab of MITI and U of Tokyo

21 -Sony central research, VTR manufacture, and some interesting new video recorders

22/23 - Sightseeing at Kyoto and Nara

24 - Talks at Kyoto, Osaka and Kyoto Sanyo University

25 - NEC semiconductor manufacturing in Kyushu (Okinawa) where they are.

Gratis ones are sent to Henry Crouse, Carl Janzen, Ron Smart and Don Frost. I'd recommend it if you go there. Call if you want one.

Dr. H. Goto
Professor of Electrical Engineering
University of Tokyo
7-3-1 Hongo, Bunyo Ku
Tokyo 113, Japan

Dear Dr. Goto:

It was a great pleasure to meet you at last, for dinner on 30 June and to hear about your LISP machine.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly.

I hope we can make the arrangements so that you can describe the LISP machine at Digital when you attend the LISP conference in August. In addition, I would like to invite you to give a pioneer talk at the Museum on one of the historic aspects you've been involved with, such as Parametrons. Alternatively, you could give an overview of the historical machine and events in Japanese computing.

Sincerely,

Gordon Bell
Vice President of Engineering
Curator, The Computer Museum

CC: Dr. Gwen Bell, Director, The Computer Museum
    Dr. Tom Kobayashi
    Dr. Sam Fuller, Technical Director, Digital

July 20, 1982

Mr. Mako Watanabe
Deputy Director General
Research and Development Bureau
Nippon Telegraph & Telephone
9-11, 3-Chome Midori-Cho
Musashino-Shi, Tokyo 180
Japan

Dear Mr. Watanabe:

Please let me take this opportunity to thank you for the hospitality extended to me and Dr. Kobayashi when we visited the Electrical Communications Laboratory on 2 July. I especially enjoyed the lunch with you and Mr. Ariyoshi and the interaction with you and your staff. I was most impressed by the VLSI compiler that your laboratory has produced.

It was a pleasure to discuss the Computer Museum with you and present the vision of continuing to build an international, industry-wide museum for this most significant invention--the "computer." The word "Digital" is being dropped from it's name to avoid confusion. Enclosed is the first report and a museum layout which includes an invitation to become a member.

I would like to invite you to become either an institutional or personal founder to make this a significant international museum. You will note that the list of founders includes pioneers such as Gene Amdahl and Bob Noyce.

The Museum also invites you to supply important artifacts for their historical preservation. The current list is included in the report and grows rapidly. Since NTT has contributed so much to computing, we would like you to consider preparing a special exhibit for the museum.

I'd welcome being able to show you the growing museum whenever you visit this area.

Sincerely,

Gordon Bell
Vice President, Engineering
Curator, The Computer Museum

CC: Dr. Gwen Bell, Director, The Computer Museum
     Dr. Tom Kobayashi

LOC/MAIL STOP: ML12-1/A51

SUBJECT: JAPAN COULD DOMINATE COMPUTING BY 1990 IF 5G EFFORT SUCCEEDS

Professor Moto-oka gave a very sketchy overview of Japan's 5th Generation Project on Thursday. He is responsible for directing the research project, and he is broad, bright and listens well. The published report is in our libraries and worth reading because it gives an excellent review of the whole area of computer science and engineering research.

In a discussion after the lecture, Maurice Wilkes warned that the first rule of warfare is to NOT overestimate the enemy. Probably the second rule is to disregard the first rule. We must not panic or be demoralized by the effort. Given their past success in research program management, this project could be successful in delivering to the Japanese industry the knowledge required to build this next generation of computers.

The research program is easy to dismiss because it is so broad. On closer examination, it is very nicely focussed on VLSI design, giving them a tough target that will allow domination of computing. The main thing to understand is that it is not a conventional research program, but a process for gathering knowledge about what to do. Like it's predecessor that allowed the Japanese

semiconductor industry to compete, the purpose is to define what
research to import and where to start. The reason for the presentation at all the major universities is to get critical feedback as to what to NOT do! They want a a 2080 (he asked about delivery) so as to run all the AI software at Tokyo U.

The program has operated for 3 years, and is funded at $50M for
the next 3 years (ramping up). The program has already spun off
a seperate 8 year, $100M program to build the world's fastest computer, which Moto-oka also chairs. There's also been a spinoff in NTT to work on communication networks.

Unless there are major changes in our system, I completely agree
with Moto-oka. By 1990 Japan will be the dominant supplier of
information processing systems, including computers, terminals,
robots, intelligent printing devices, and everything that is computer-based and interfaced to another information processing
entity (ie. human, network, other computer).

SUBJECT: JAPANESE DISCUSSION AND MORE THOUGHTS ON
UNDERSTANDING WHAT TO BUILD

Can you write up your version of this and possibly send it to me by Friday by EMS? Want to try to get the problem formulated and segmented as I raft down the Snake River on 8/5.

Also, appreciate any notes on the OC Woods on organization. Hope you build your version of a product/organizational model.

Am enormously frustrated by not having a good feeling about where we are investing big $'s in plants (and inventory) versus
where the revenue is. For example, we are going balls out to build MOS capacity and design capability. Our management heads, talent and thoughts are all there. The revenue is all coming from Comet and Venus I believe. We are violating the principle that if we don't sell it, then we should buy it (Have you read the policies on Make/Buy that I try to use in our M/E decison making?). Am really scared when you factor in Intel (who'll clobber us in MOS because they sell it) and Japanese who have key hi end bipolar, magnetic storage
and video and speech processing technologies.

Can I get one of your people to help us address this issue across M/E about segmenting and trying to understand TOTAL investment picture?

Similarly, I think we probably should look at selling disks simply to get the cost and volume and quality... but need a way to look at it. It may/may not make sense, but need to understand!

Note that Ken's model of Briggs and Stratton or Tecumseh as being competitive is probably falactious. Both are probably low growth, but both, no doubt are really backward integrated and automated to the foundry and would believe they are highly automated. Both supply a component to a relatively difuse, market (lawn mowers, garden tractors; air conditioners
dehumidifiers, refrigerators) hence they can dominate. The specials like Harley Davidson or Japanese make their own no doubt. In our case, we are not like Briggs and Stratton

because we have only a small foundry (Hudson) which supplies most of the work. Silicon Valley has always been our foundry and we have been an assebly shop supplying to our OEMs in iron and base software. Note that the % labor is significantly
decreasing as we buy more and more out (like the expensive 16K rams). With bigger parts and more performance in the micros cpus, our oems are going to Si valley for boards or chips. Alternatively, the cost is going into the magnetics and if we have volume there and are good, it may be our salvation. It feels like we are merely an assembler and when you consider we are 80% materials and 1/2 our added on manufacture is FAT that shouldn't be there in the first place, we may be heading toward big trouble in the mid-80's.

F/U 10/13

With the Pulsar, a key advantage may be to have explicit page transfers from CCD's (in Mp.MOS--Ms.CCD hierarchy) while **not** switching concept. In this way several will be idle (but probably will be anyway). Could Bill simulate?

Can we get a realistic problem to simulate 16 Pc's?

GB:ljp

October 15, 1984

Mr. John Payne
National Semiconductor Corporation
2900 Semiconductor Drive
Santa Clara, CA 95051

Dear John:

I enjoyed the interaction with you and the members of the team exploring the direct execution of an instruction set last Tuesday.

The 32000

I hope you folks will forgive me for not visiting Israel, but as I told you, we are bidding on a DARPA supercomputer project that would use several hundred processors. The proposal was due October 12. Much interesting work is coming out of this, and I may want to talk with you about designing a hot array processor as an alternative to gain performance.

This is clearly the right approach for some of the specialized functions such as filtering and array data-types, but it may be used in a more general fashion if we can integrate it into the overall architecture.

Dave Schanin was impressed and clearly the right one to interact with the designers. We briefly discussed the 532. Here, the approach feels wrong because it increases complexity and uses a deep pipeline. This is very much like the VAX Venus which is over 2 years late. A machine with the same technology and little pipelining is likely to go faster using a faster clock with less hardware. A small, simple chip gives you faster time to market... and can also be scaled. I don't think a complex architecture like VAX or the 32000 can be pipelined to any degree and the fact that the 16032 grabs twice as many instructions than it uses is a good indicator of the problem. This is pretty much what's come out of the 370 experience too.

<u>Process</u>
I don't think your process plan is aggressive enough. Today, a few users at ISI's MOSIS get 1 - 3 micron, 2 level metal CMOS with stacking contacts. Four foundries are running 1 micron. The trick here is a single set of scaleable design rules. Let me urge National to be a part of this effort, simply to get some feedback and clean up the foundry design interface. Attached is a letter I wrote to Bobby Inman at MCC on the subject.

<u>Direct</u> <u>Execution</u> <u>Chips</u> (ie <u>RISC</u>)
Enclosed are some articles on the MIPS chip. I have recently learned that Skip Stritter, and John Hennessy joined someone formerly of IBM, and they are off making a system product. I'll contact John to see if I can learn more.

Your ideas on a new architecture while interesting, really concern me because I don't think that a designer can cope with the hierarchy of clocks and distance. This adds one more design dimension to the overloaded designer. I don't think the design scales and this is fatal. Also, I'm pretty sure that anything that's serial loses on performance. This has been true over the last 4 generations of computing and I think it's true in your design. I believe you have to bind the design to CMOS, but if you come up with something trivial then maybe look at ECL.

<u>It is vital that you get on with a fast processor chip today</u>... call a meeting at once and see if there are more than these alternatives:

1. surviving and living with the 32000 architecture harmoniously. Just as I became convinced VAX wouldn't cut it as logic clock and memory speeds becoming equal, you have the same problem. The way to survive is to not support assemblers! Stay with your data-types and hence a user could operate so as to not see a difference in the architecture. An evolutionary approach is to look at aligning the current op codes into 16 or 32 bit instructions which are different codings of the current architecture so that it can be executed rapidly. Also, throw out anything that you don't use. You should have a good idea how to do this now as decent compilers are beginning to appear. This may be a much better approach for the 532, which I believe will be difficult to build in any reasonable time and at any reasonable performance as discussed above.

   I hope TI is working on this problem. Maybe a team effort would help. At least you folks should share trace data and design approaches.

   The measure is simply: the number of clock ticks it takes to retire each instruction. It now takes 8 - 10, and I believe you should target 1 - 2!

2. taking what you know of MIPS and then going to a compiler house to get them to write the compiler in tune with what you build. We know some people who could help. It is critical to not start from scratch.

3. make a relationship with Dave Patterson and evolve the RISC I or II design.

4. try to get Ridge or Pyramid to license their architecture, if either is good enough. Alternatively go to one of the semiconductor companies that you "suspect" are working on an architecture and make an agreement with them NOW!

5. put together an external team aimed at a chip which would be done on a quasi competitive basis with your internal effort where there's complete interchange of information between the efforts. This would be have to be managed carefully.

I believe an external effort would be interesting because I'm convinced that a large company environment requires more energy. Here are some alternative efforts:

.Professor Niklus Wirth, recent Turing Award winner and coming to spend 6 months to learn about VLSI at Xerox Parc. He's the designer of Pascal and Modula and just built a computer; he's outstanding. He's at Institue for Informatik, Zurich 8092. He could be a consultant to you to tune up the 32000 because he understands the compiler issue.

. Austek Microsystems, a new startup who do VLSI designs and know system design. Dr Craig Mudge is the president, and he was formerly at DEC and worked on VAX. His team is systems oriented. He's at Technology Park, Adelaide SA 5095, Australia, but would put a design team up anywhere including Santa Clara and Boston. They do designs for money and royalty. This would be a bargain.

.Encore might put a systems team together in a joint venture with you. We discussed this earlier and should have acted, because we could have gotten the Hennesy design team.

I am skeptical of going it from first principles like you're doing because you lack the language and architectural experience. It will take too long.

Languages

We also want to meet with you soon and discuss the whole issue of high quality languages for the 32000, including LISP from LUCID. What is the best way to do this?

Sincerely,

Gordon Bell

Dr. A. G. Jordan
Professor and Head
Electrical Engineering Department
Carnegie-Mellon University
Schenley Park
Pittsburgh, PA 15213

Dr. W. A. Wulf
Professor and Acting Head
Computer Science Department
Carnegie-Mellon University
Schenley Park
Pittsburgh, PA 15213

Dear Drs. Jordan and Wulf:

I strongly recommend that Professor Siewiorek be given tenure at this time. Given his exceptional vitae, it seems redundant to say anything at all; however, I'll comment from watching him work here at DEC as a consultant, where he is truly exceptional. Rarely has anyone from outside been so rapidly accepted and so effective. He can communicate well with everyone from the person in charge of all DEC service to nearly all engineers. The respect he earns is solely based on his engineering ability to select the right approach and then back it up with creative analysis. He's contributed to numerous products and has been instrumental in setting up a data collection/control mechanism for our systems.

I can't directly comment on his precise position in the field, but I believe it's probably in the top five to ten. He is clearly accepted as an international expert by noting his talks, papers, and consulting. Furthermore, unlike many tenure decisions, I see no signs that his output will diminish with time.

The Eta Kappa Nu award last year should be about the best indicator that tenure is required! This award considers the top few people in all electrical engineering in the country -- not just a field.

If there are any points that need clarification, please don't hesitate to ask me.

Sincerely,

Gordon Bell

ID#0261
Subject: Visiting Josh Fisher and associates at Yale
to pg, cc kgf
I called Josh to find out how he'd reacted to my suggestion that they formed a software only company to start with instead of a major company to build their very complex, parallel hardware machine. They would manufacture some of the hardware that came out of the experiment at Yale. Similarly, I have a company in Oregon that would like us to buy them and could manufacture their hardware. In essence, it speeds up the Floating Point Systems boxes a factor of 10-20 by having enough memory.

He said they were really considering my comments over and over again because of the source and severity of the comments.

They've talked to 4 or 5 other groups including VC's and manufacturers. (I said IBM was the only one who could take it on, but he said no way.)

I'm worried a bit because they may be too committed to the machine to be very reasonable. Even with this, it might be possible to have a deal on the following basis:
1. Isolate the software and build a compiler in parallel for us.
2. Let a VC or someone fund the machine, perhaps with us. I said, I'd advise on the machine if there was something in it for us.

He wants us to come visit them. Let's go. They are the ONLY game in town regarding a compiler which would exploit HYDRA without special programming.

Subject: **What I Heard at the January Jungle**

To: OOD

Date: 1/30/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51

<u>Immediate Action</u>

We will implement a "Get Better" Campaign now...perhaps better named, "Feel Better".

Emphasis will be on what's going well, versus critiquing. I certainly will try to be more positive.

Hiring will revert back to previous controlling levels...namely, I will not sign reqs or offers.

Timely and Stable Decision Making--There are a number of issues in each engineering area that are contentious (e.g., charter, what product to build, future direction). These should be resolved quickly in order to avoid the uncertainty, frustration, and loss of people that is often associated with slow or unclear decision making and hassle.

Presenting the strategy --The main part of the program will center around presenting the strategy within Engineering (including Delagi, Savell, Holman, etc.). Bob and Bill will you please arrange the first, all engineering presentation to managers at direct report level, and then to the consultants? These will be the only meetings where all of OOD will present, albeit meetings with dinner. Although I'll give the broad strategy overview, each member of OOD should give the parts of the strategy they are responsible for. This can be in terms of what is really solid in the product or process domains, what is to be done, and what will take a long time. For example, Bill might talk about the machines and the problem of the interconnections at each of the levels. I would like Bob to orchestrate this presentation and what each of us will say. If we did this, it would take about 2-3 hours, given that we all spend 1/4 hour each. One or both could be videotaped for further dissemination.

Messages to me [And Replies]

RP -- Recognize the goal of more central process management, and integration is inconsistent with G and A budget growth of 15%. What do we do? [Here, I believe the key is to push much of the costs of running the various groups out to the groups so that what is central is really rules, measures, etc. Any of the decentralized stuff is done on a contract, rather than a centrally funded basis (e.g., project management, certain tools, personnel, F and A.)] Pay me more to make it worthwhile putting up with this much hassle. [I thought you were really running the place and thrived on it. You mean you don't want it either?]

RC -- Technical product innovation in video, printer, architecture. Sponsorship in mfg and mkt. [I'll try here, note work with Jack Smith.]

WD -- Stability. Overnight think time and discussion prior to declaring responsibility, budget, organization, or strategy change. [I've been waiting in the range of 1-10 weeks. This is variable with change, input, etc. I'll try harder, but you'll have to tell me why I should back off in light of inactivity.]

UF -- Any $ for large 32 bit budget? [Sorry, I thought you and Bill had this one covered.]

JM -- Fewer handgrenades, non-impulse management. [Sorry, I find it too hard to change.] Keep leading. Follow-up on action items. [I believe there should be someone who is helping me full-time in this regard. Who could this be???]

LP -- No new assignments for 6 mos. Help in fighting off the wolves. Occasional feedback. [Fine. I agree.]

BJ -- Don't force solutions until analysis is done. [All I ask is to tell me when to do the forcing... I get impatient if there is inactivity, wrong direction, no schedule, not knowing priority, seeing pain on other engineer's faces, etc.]

JC -- Learn how to act supportive--focus on "winning message" vs "how awful we are". Choose a limited set of dimensions for us so we can win in one or two versus losing on 10-15. [I only suggest or add dimensions when the organization, product, or process has none of its own!]

JK -- Before sending mortar shell, talk to me. Stability. [I want at least 2 out of 3 of us (you, Grant, I) to agree on what we're doing.] Let engineers design the products. [What is it about the products you want to hide?]

The Important Issues to Work [My Version]

RP -- I want help running this place. Hire someone to do your present job. The Product Manager x 3 issue and what the person does. Co-ordinate the strategy presentations. See BJ re Strategy Program Management. CAD (also with BJ). Resolve funding and decentralization conflicts. Get EBOD moving.

BJ -- Get a priority list of what you are doing and then I'll back off. Get rid of as many line functions as possible so you can help me. Charter. Help me get a Strategy Program Management function.

JM -- Measures about the health of engineering. Get time or alternative way (or person) to help the follow-up of OOD group or meeting issues. Engineering salary crisis. We now need really strong college recruiting.

JK -- Get a priority list for Grant, you and I and then get our issues in sync. Make Colorado and their projects really strong. Cover us in the mid-range disk offerings for 11/44, Nebula, Minnow, Comet, small 11/70's etc. where the bulk of the revenue is.

RC -- Get the charter resolved (nearly instantaneously) with DCG...this creates much heat. [Bob, could you also help here?] Roy and Mike need help in LSI future and priorities.

WD -- Leave the place in good hands and get the most out of MIT. Help Ulf. Interconnect.

UF -- Resolve, with all our help, the uncertainty surrounding the future direction of the 10/20. Delegate systems work and thinking to someone else for now and I'll help hold the wolves at bay.

LP -- Your direction is fine, but your hands are full. I'll follow your directions above...although I intend to watch HYDRA.

JC -- We really need you to help Dick in the LSI direction resolution and also all LSI!

SUBJECT: GETTING ON WITHOUT JUPITER--TOPS 30 (SAYS RICK)

GB5.23

I want us to get out of the "we're going to have Jupiter in time" dream world and address how we're going to do the best possible job for our customers who rely on Tops 10/20 and KL's for their computing.

The capability to tightly interconnect CI and VAXen to
provide a
capablity beyond DECneting to VAXen is what we must offer.
Building
another 10 in light of our position and investment is really
dumb.

BACKGROUND AND WHY I WANT TO STOP BUILDING 36-BIT PROCESSORS
When I was in a Denver hospital and could think more clearly,
it was
extremely obvious (especially after hearing that one of our
managers
had committed Jupiter and a follow-on Jupiter to a customer)
that we
just have to STOP Jupiter, get on with building faster VAXen,
and STOP
having to develop two major architectures and 3 operating
systems.
When I returned and looked at the investment required to
finish
Jupiter, it was also clear that we shouldn't do Jupiter. A
few weeks
ago when Ulf described the design methodology and technology,
it was
clear that we could build a Jupiter with 2.5-4 x KL
performance. At
this point, I waivered because I'm currently in to
understanding
different design methods.

in the event an electronic mail system is installed under the
aegis of Admiral Inman's office, it would be helpful to get
your feedback on the current experiment to make a future MCC
electronic mail system an even better tool.

Because activity has not been high, I'd appreciate your
comments on the following:

Did you ever access your account?   [ ] yes   [ ] no

. If no,

do you have a terminal available to you? [ ] yes [ ] no

were you going to access your account personally? [ ] yes [ ] no

were you going to ask someone else to do it? [ ] yes [ ] no

Main reason for not accessing my account is:

To make electronic mail a more useful tool, I would suggest:

Sincerely,

Mary Jane Forbes
Secretary to Gordon Bell

MJ5.27 June 6, 1983

<g> <fn> <ln>
<co>
<add>
<csz>

Dear <g> <ln>:

How goes the MCC-ALPHA OMEGA electronic mail experiment?
ON'T THINK
THEY KNOW THAT WE'RE PROVIDING VAXen in the range of where 10's used
to be. Therefore, we owe it to them to be straight. This is what
we're finally trying to do by talking to a half dozen of them this
week. In the one case, the University of Pittsburgh, in which I
talked with a customer, they were delighted at "finally getting the
facts on which to make a decision". All I said: we screwed up, we're
basing future products on VAX, and the revenue/investment is much
greater in the case of VAX. (I think we had completely oversold
because they were thinking of taking their administrative load from an
Amdahl and moving it to the 10... which I consider idiotic and
immoral.)

I believe there will be something of a real trauma at DECUS if and
when we decommit to the long awaited Jupiter, unless we do it openly
and by saying what we are trying to do for them. Therefore, I would
suggest that there be 3 speakers. Ken or Win would give a big
overview talk, followed by a major announcement of the product
strategy direction. Details would be given in the session with Rose
Ann. The talks:

Ken or Win- presenting an overview message... which summarizes

Gordon or BJ- problems, product strategy, and general direction
with respect to DEC Architecture

Ulf or Pete and Heff- present the technical details

What I would like to say to all of DECUS:

1 We screwed up at the project level on several recent machines.
It was a case of complexity. We have drastically changed our
design processes. We didn't know that the 10/20 had this
problem until Novemeber. Now we see it as a large investment,
getting us a product to you too late and too expensive and too
low in performance. At sometime in the future, if you want to
hear about where we are in design systems, we'll present it.

2 The main development thrust (THE PRODUCT STRATEGY) is based on
a '75 decision to build VAX instead of a line of 10's.
Persuing both lines would have meant a rewrite of all software
to handle addressing and PC's. In '79, when it became clear
that VAX did all we intended, and provided a great
environment, we began a program called to Homogeneous Computing
structure whose goal is to provide cost effective computing at
all levels of use.

Our main development thrust is with VAX where we now have a range, more machines, more users and more software. This results in a ship rate of >10 times the 10/20, and our development resources in the VAX, and compatible 11 part (Pro, and RSX) are in the same ratio.

Two critical aspects of this plan were to higher level interfaces and to build the necessary bridges to have a totally homogeneous architecture. We're well along on this and will announce some more products now.

3 We're well on our way to achieving the architecture, and hope to have computing terminals that execute the VAX interface in the near future. We'll have higher performance machines too.

4 We're going to provide signficantly better products for the 10/20 customer along these lines:

. More users and better utilization of existing resources-

.PC's are the main thrust to off-load;

.HSC will provide more performance, again off-loading

.VAXen of all types will off-load... higher performance and better cost/user in VAX domain are forthcoming

.Pluto will provide front ending to offload

.Sharing of 10/20's on CI permits load balancing.

. More Processor cycles- already 780's better in some jobs, but the real answer is bigger machines. We're going this way in VAX. Three, major product announcements will be made in the next 6 months that address performance.

- Floor space- Disks, distributed i/o, >mips/sq ft (on VAX).
- Compatability with and portability tools to VAX

5 We're providing functions on the VAX that are new to 10/20:

- Large address, and common run time
- High reliability structures-V3B is being announced, nothing of this sort is planned in the Tops area.
- Programming environment and VIA- more languages, data access, data dictionary, special facilities (eg. TPSS)
- Significant office automation software with more to come
- Range of computing styles from VAX PC to large mainframes

6 We'd never really gotten around to pointing out that is the most positive thing we can provide. IN EVERY dimension of goodness, the VAXen in development ALL offer significant cost, cost/performance, performance, performance/sq ft, and functionality over anything we were planning in the 10/20.

PERFORMANCE, PERFORMANCE/$ AND PERFORMANCE/SQ.FT. COMPARISONS

what	when	$	Perf.	Size	Perf/$	Perf/sq ft
KL	74	.75	1.33	11x2.5	1.77	.048
780	78	.4	1	4-6x2.5	2.5	.066
Superstr	83	.4	1.5	4-6x2.5	3.75	.1
Venus	6/84	.6	5	6.5x2.5	8.33	.3
Nautilus	4/85	.25	4		16	
dual	"	.4	8	4x2.5	20	.8
Scorpio	85	.04-.1	1-2	2x2	10-20	.5
Jupiter1	+30mos	.75+?	3.33	10x2.5	4.44	.13
Jupiter2	"	.75+?	5.33	10x2.5	7.1	.21

WHERE WE GO FROM HERE?
I'd like to see a Tops 30 team formed around Pete which would include persons from VMS to plan and build the desired functionality. We might use a customer panel.

We should also get support from one of the PC groups, say Pro or Pro 32 to go after significant integration of PC's into TOPS 30. We should start by getting ALL the development team the appropriate PC's so they begin using them in the desired way... "Software comes from heaven when you have hardware", says Chairman Ken.

Right now I'd like to ratify this direction and get on with TOP30 and what we can confidently say at DECUS.

win re jupiter....

my comments to you this morning will seem like a mixture of a good
news and bads news. However, if you stop to think about it, what
looks at first blush like bad news is really good news, too.

The bad news is that it has taken us longer than we had originlly
hoped to develop a follow-on KL-10 machine (which we've been calling

Jupiter) and it looks now like we're still about three years away.
You have told us that this is too long, and we agree.

Thus, in order to stay on course and sustain momentum in pursuit of
the best possible solutions to your medium- and long-term needs, we
have decided to suspend development of Jupiter and instead, focus all
of our high-end development efforts on our more broadly-based VAX
architecture.

Now, lest you think that we are totally abandoning our 36-bit space,
and summarily denigrating the value of your investment in this family
of products, let me hasten to assure you that we will continue to

agressively develop software and communications tools which will
allow DECsystem 10s and 20s to be more easily integrated into our

corporate architecture and, in fact, to accelerate that transition

process.

Starting next week, we will begin to field support teams who will

works closely with each of our 10/20 users. They will
work closely with each customer to analyze specific needs

and to design a custom set of interim and alternative programs to
satisfy those customer-specific needs.

We believe we have developed a sound general strategy to take our

customers into the next generation and are prepared to work
dilligently to ensure that their specific needs are met.

MESSAGE ID: 5171114445

SUBJECT: PRIORITIES IN JUPITER

I thought we had a product strategy on Jupiter to NOT do everything in terms of adding IBM channels and Massbus devices. Yesterday, I talked to several frustrated developers that say you must have this all back on Jupiter.

We are in direct conflict on this. I have been trying to limit the development on the 10/20's to the point where we can supply a quality product versus trying to do everthing poorly. This often gets mistaken to the fact that I'm against the product or product line. As the originator of the product, nothing gives me greater pleasure than to see it live and be highly regarded ... therefore, it's from this point of view that I come from.

I don't see the 10/20 as a quality product now in terms of being able to couple to other DEC or even IBM or international computers because it tried to go it alone and didn't make it. Customers still give me hell about the networking. This also impacts the reliability... Marlboro nodes are really quite poor and if this were a customer, they would have switched to IBM long ago.

Returning to an interface everything strategy is simply going to impact quality and I say we aren't going to do it. Furthermore, this means we must always support these interfaces forever on the 10/20. If you must have them, then look at getting them on the HSC, where they can be supported across a reasonable customer base and hence get the attention that's need for a successful product.

There are many higher priority projects: getting Jupiter-complete with NI and CI, getting NI and CI on KL's (so you can have a LAN at a site that works), and finally getting compatiblity.

SUBJECT: RE: TOPIC

GB5.38

Am sorry I had to attend a previously scheduled meeting (on a decent MicroVAX PC CRT controller), and couldn't attend the meeting on Thursday.

I concur with Jack. We have to get the party line, and the topic has to be scheduled every week until we have it.

Am really sorry we don't have a party line at DECUS because it seems like we're going to be forced to say by implication we're still on target for Jupiter. If we don't say this, then the revolution could be quite extensive.   Saying nothing will let everyone's imagination run wild. That's why I advocated an announcement at DECUS by Ken or Win. A later announcement of this type could be stronger if accompanied by Venus (but only when it runs).

Somehow, I really don't feel good that we've had to say so much about Jupiter when it's clear it has been a fabrication based on the status of the project! Now I continue to feel bad to not say what we're going to do:

1. Continue in limbo, engineers not flat out.
2. Do Jupiter at great expense for 30 months and no market.
3. Take our licks now with positive message
4. Continue to mislead (by implication) and wait for ability to present a stronger message.

Don't envy any of us in this.

SUBJECT: WHAT'S A K.PLI? FOLLOW UP: 2/29/80

What's a K.pli? What does the HSC cost look like now? Any alternative cheaper routes to connect HSC to systems besides the CI? What's a 2 chn UDA? Isn't UDA 4 chn?

Please forgive me for cancelling the January Woods in Colorado. I am looking forward to the next visit though.

Have enjoyed reading the UDA and HSC Functional specs. My only concern continues to be cost, and possibly power. Why don't you guys take a lesson from the rest of the world and start a mammoth cost reduction effort based on LSI and VLSI. It looks like we have a great architecture here, and I would rather cost reduce it than yield to the next round of pressure
that would force you to throw the whole thing out and start

over because it is too expensive. It feels clear to me that the
way to get the cost/byte down in all the mass storage drives and subsystems, is to work on electronics first and mechanics second. This is going to require incredible cleverness because
there are more demands for new drives. On the other hand, if you go after cost reduction in the electronics by LSI, maybe you can use or reuse electronics more than one drive?

SUBJECT: RE: RE: DAISY CAD KEYBOARD AND OUR KEYBOARD

The way you talk about the keyboard, I certainly applaud. It's how we get winning products. Unfortunately, I thought you had this responsibility because the person doing the keyboard worked for you (via Art, and Paul). Bill was also frustrated. When I got involved there was no real question except to argue out the last details and decide between the two camps.

The problem with the keyboard is that to me, it is through a clear chain: Avery, You, Art, Paul to the person. The only problem I detected was the person didn't know anything about keyboards, the management didn't help him anyway, and there wasn't anythig written down in terms of what the goals were.

I know I'm really going to be sick if I have to use the keyboard as I worked on the original keyboard for the Teletype which had for example < and > over , and .. As a result, many systems use <> for characters. IBM FINALLY GAVE IN AND NOW ALL KEYBOARDS USE THIS CONVENTION! You guys gave up 15 years of progress and reverted to the old typewriter. This is going to get me and Ken much hate mail, which I deserve, for allowing any myth to propogate that there's any other way to run things except by individual responsibility! Many of the programming languages use it, along with the people who have to type on it. Given that a couple of the human factors people said it looked fine to them, I lost much respect for them as understanding humans, factors or engineering. The good news is that training can make money retraining people.

Jack and Bill,
I thought THIS keyboard was closed and I certainly wanted to forget about it until we get the inevitable feedback.

I really hope I'm wrong on the keyboard. Given the way it was designed, only pure, dumb luck will be our savior. Pray!

SUBJECT: RE: RE: WHAT DO YOU THINK ABOUT THIS

I say change the main keyboard back to what is now the industry
standard (including the IBM PC!) Many languages use it. We got
the industry to go to this in 64 with the <> over the ,.! Also
put the shift key back where it belongs. The upper case,. is nonsense because in shift lock position, these are still,. and
not <> so it works fine.

When can you give us back our electronic keyboard and through out the obsolete typewriter keyboard some nut came up with by speaking Ergonomics-eze.

SUBJECT: RE: WHAT DO YOU THINK ABOUT THIS

Not much!

1) soft shift key - no problem
2) substituting [] or {} for <>. <> is a major function in WPS. My complaint is the location of the key--no substitutes please! [] and {} are used in other ways in the text, let's not confuse the issue, or the operators. {} aren't used very much (as far as I know), put <> there. But I really don't see why you are wasting the , and . keys with the same symbol in shift mode, which causes yet another key to be needed.

I'm not a programmer, but I would think that a substitution would cause a major rewrite of software, to say nothing of all the documentation.

As I understand, it is not just WPS users, but programmers also, who use <> constantly.

How can you look at a major share of the sales as a "too heavy a reliance." IT IS THE KEY THAT RUNS LIST PROCESSING ON WPS. DEC'S LIST PROCESSING IS THE MOST POWERFUL AND EASY TO USE IN THE INDUSTRY.

I AM TYPING ON A NICE DAISY WHEEL TYPEWRITER MADE BY BROTHER AND AM ANXIOUS
TO SEE WHAT THE ONE THEY ARE OFFERING FOR $200 FEELS LIKE AND IF IT'S THE SAME ONE THEY'D EELL
ONE THEY'D SELL US.

THE ATTRACTIVE THING ABOUT THE KEYBOARD

1. GOOD FEEL

2. CAPACITIVE INSTEAD OF ELECTROMEHCHANICAL. WE'RE GOINTG TO LOVE THE
EXTRA RELIABILITY.

(I HAVE FREINDS WHO USE OUR CURRENT D KEYBOARD IN HEAVY DUTY USE AND
THEY DON'T LIKE THE SHORT LIFE.) I CAN'T SEE HOW THE NEW ONE WILL BE BETTER.

WHILE THEY ARE LOOKING AT A DESIGN FOR US, COULD I SUGGEST WE GET THEM TO
MAKE IMPORTANT ECO'S?

1. MAKE THE TILT ADJUSTABLE SO THAT IS IT IS REALLY ERGODYNAMIC INSTEAD
OF JUST MADE TO SOUND THAT WAY

2.
2. CUT A FEW INCHES SO THAT IS/ T CAN FIT IN A STANDARD BRIEFCASE FOR USE WHEN WE
WE WANT IT PORTABLE

ALL IN ALL, THIS KEYOBOARD SOUNDS GOOD, ESPECIALLY SINCE IT IS CHEAPER, AND
MORE LIKELY TO BE MORE RELIABLE AND FEEL BETTER..

SUBJECT: AN INTELLIGENT KEYBOARD AS A COMPONENT

In building our low end VT/CT strategy around common components, each of which can be sold in a wide variety of applications, it seems clear that we want user programmability in the keyboard, together with the ability to store information on power fail.

Some features:

1. Alternative, larger keyboards that can be programmed the same way so as to be transparent to the software.

2. The keyboard "tells" the computer about its key set, hence no more fooling around with the foreign character nonsense and having the computer NOT know what keyboard it has.

3. A good place to put the clock.

4. We could add a LCD display, giving it full, independent terminal characteristics.

5. Sequences could be "user programmed" by macros.

Note the vitriolic attitude (quoted below). I feel this way too as a user. Shouldn't we **downplay** KL10's in the field? 2020's are great -- but I have the same quality experience and want us to get rid of KL's within Engineering. They are unreliable!!

> "Quality assurance has apparently hit a new low, especially in LCG. We sold three KL systems in the last week of FY78 and one last quarter, and all the KL systems currently installed are in trouble. This leaves a feeling of gloom and despondency about the prospect of installing the new systems, together with achieving a massive budget at a cost of bookings of 9.6% - Crazy!
>
> The lack of price performance in KL10 systems, appalling maintenance problems, the long and difficult installations, the total inadequacy of KLINK diagnostics to solve anything other than the most trivial problems, the impact of large systems on our ability to reforecast - all of this has brought about the present situation, namely we bid 2020 systems.
>
> The conflict of 11/70/VAX/2020 is a lot less severe than the conflict with the LCG ex-Product Lines. The Company should note that it will take no more than six months to disband or dilute the large DEC-10 selling teams. Next year I would imagine manufacturing are going to

be up to their eyeballs in KL10 processors, which may just succeed in keeping the rubbish, which is installed at present, operating for a few years."

Don Knuth
Stanford University
Stanford, California 94305

Dear Don:

Thank you for taking the time from your busy schedule to talk with us on the TEX system.

Hopefully we can help realize your goal to make TEX the standard accepted typesetting system. Personally I support this goal and urge now that we adopt it here. It looks like you have the base for solving the typesetting problem.

Although it's somewhat premature and perhaps presumptuous, I believe it should be an ANSII and international language standard.

We will proceed to review TEX internally and get demonstrations at MIT, if necessary. To assist this, we may contact Luis for a listing and internal documentation. If the evaluation is positive, having one or two of our people come to Stanford in January, when you're ready, and work on the conversion to Pascal would be an ideal way to adopt the system.

As an almost independent issue, let me urge you to work carefully with Alphatype so that they build a general system and not one that's peculiar to Stanford. (A small company can be flexible, but it may never reach critical mass because it is always building special systems.) We would like to see them build a standard product that can be easily interfaced to various computers -- including ours. Such a device is badly needed. Can I suggest you interface either via a standard format floppy, a magnetic tape or a standard RS232 terminal port? In this way, their product can be used immediately and universally.

We also look forward to discussing the high quality scope TEX needs with Forest.

Thank you again.

Sincerely,

Gordon Bell
Vice President,
Engineering

SUBJECT: ORG. OF THE KO/VT200 WRITTEN DOWN

C O M P A N Y   C O N F I D E N T I A L

Based on our discussion today with Larry and I, would you specify
the organization and responsibilities for the KO project? Ken is
anxious to see this. We all favor clear responsiblities (eg. the
mass storage effort is managed by a person with singular focus).
We favor a project for the system reporting to you, making
maximum use of implementation within the current, functional
groups. The detailed organization would go down to the
individual hardware component (option) level.

The details of the software organization should be forthcoming by
us and Bill Johnson.

I want it very clear that what we are building includes BOTH the
PDT 50 (now KOjr- the 64Kbyte system) and VT200 as I understood
it from the initial requirements.

SUBJECT: RE: KO AND LANGUAGES

You have a really valid concern!

We have to settle the issue of BASIC. For now, it clearly has to be DEC Basic given we don't have a marketing channel into the personal computer market. In the future, we probably
have to get the Microsoft Basic in order to get at this software... including the media.

On OBM: it is unique, taking ideas of Pascal and ADA, and written in Pascal. I have only seen a program in it and it's simple and looks pretty. I talked with Bill Wulf, a strong ADA supporter and he believes the world is going to do this too cause ADA is awfully roccoco and difficult to implement unless you build a machine and operating system especially for it. My belief we should stay within a subset of the ADA syntax with the OBM language. Since I don't know ADA that well, I don't know why we deviated... or if we had to. I do believe that we must not use Pascal cause we need the information hiding and ability to build these better data structures in a clean way as outlined in the architecture we initially described.

SUBJECT: THE KO AND LACK OF PROGRESS AGAINST THE GOALS

We should all be vitally concerned about our future here. It appears we are not making any progress against this project. In rereading it, I don't find anything that I believe we should
change, yet we are dragging our feet within engineering.

Given that the video is relatively firm and part of the 200 series, it should have been breadboard by now, assuming that we are going to meet our product ship goal... or anything remotely resembling a competitive time to market. Alternatively,
if we think th 100 is too easy, then let's go to more lines and
offer a more attractive fcs product.

I'd like to meet with you sometime next week, spend about 5 on the organization and then as much time as needed understanding
how this organization is going to become an aggressive development
team. Also, I would hope to see by then an aggressive schedule
by art for the Tiny, the video, and monitor both as modules for
KO and as a packaged terminal.

Time is passing. Wang is coming out with a very good product here, IBM has one. Our stockrooms are filling up with VT100s and we have to have a super replacement now and in the future.
If you don't believe we can live with the packaging scheme, then
counter-propose, but do it now and get the work started.

I believe the only way we can win here is through modularity, incremental upgrading of the product family in terms of increased resolution and functionality... AND the VT and KO MUST use common components and are one in the same project/ program.

When can we get this together? When can we discuss?

TO: OOD: DATE: THU 28 AUG 1980
10:09 AM EDT
OPERATIONS COMMITTEE: FROM: GORDON BELL
cc: see "CC" DISTRIBUTION DEPT: OOD
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: KNOCK OUT: AN APPLICATIONS TERMINAL AND SMALL SYSTEM

Knock Out: Attentive Modular Personal Applications Terminal
...
Small Computer System

The following describes a system of building terminals and small,
personal computer systems. It is based on the current LA/VT200
and PDT efforts, assuming compatibility between them. It is also
the results of a Woods Meeting of Ken, Stan, Avram Miller, Bernie
Geaghan, Don Gaubatz and I. Bob Daley, Bruce Stewart and Bob
Travis came later and discussed the software options with

respect
to WPS. It is a project that Ken would like to do in 9 months
and we need maximum support from each group.

We will discuss the product on Tuesday at the Operations Committee to enlist maximum support

PROBLEMS THAT KO SOLVES:

.a small system based on the 11, concentrating programming
.lower cost, faster time to mkt. small system
.competitively sized (ie. desk top)
.competition from personal computer systems for WPS and business
.competition of new, stand alone WPS products
.concentration of scarce resources (eg. communications) to get
one good, versus multiple marginal, later products
.unreasonably long vt/la product introduction date
.all capabilities in proposed VT/LA200 applications terminals but
with earlier, first introduction based on common, highly modular,
customer merge and customer replacement approach to repair

PRODUCT RANGE AND APPROACH:

Introduce a common set of modules from which the range of all existing and proposed terminals and small systems can be built,
including: VT/LA200 series, fixed function editing VT's, GIGI,
PDT's, and RX's. Also includes the 11/03 and 11/23 with up to
256 Kbytes of primary memory and 10 Mbytes of secondary memory.

Aimed at evolving dumb, with increasing smart (pre-programmed function) functions, to intelligent (programmable) terminals and
terminal based small systems for both stand alone and host

coupled applications. Aimed at competing with personal computers
and being alternative to using semicomputer company micro for application terminal, but able to extend to larger system application for the single user.

Point of manufacture with customer merge by actual user (eg. secretary) and customer repair by replacement. Assembly requirements similar to Hi Fi. Modularity is a a key selling point, using a combination of rom on modules and floppy based ram
for achieving goal.

Market is anyone wanting to use the base modules and the supporting software for applications (eg. WPS, single user small
system as in a DIBOL machine, technical person's work station,
small business system)

GOALS:

Nine months till first product introduction, followed by a constant stream of new module introductions permitting the building of terminals and small systems with the capabilites well
beyond that envisioned by LA/VT/PDT plans.

Introduce and evolve by adding new modules and capabilities in
what is similar to approach used in the evolution of Unibus 11

Introduce, then cost reduce based on technology opportunities!

Maximum use of off the shelf one chip VLSI peripherals and other
peripheral approaches to get low cost. Use personal computers as
a model of the approach. Be prepared for all opportunities and

attendant incompatibilites and new interfaces such as wands, light pens, joy sticks, etc.

Base the architecure on semicomputer company architectures

Be as compatible as possible with current DEC peripherals, but
trade-off to get cost, sacrificing i/o compatibility in an explicit basis

Trade off cost for performance subject to inability to build fast
access mass storage based products or highly interactive systems

Support a physical address space appropriate to memories

Target applications with implied bounded software, not general
purpose use with implied compatibility, unboundedness, sys gens
and support of all operating systems.

KO IS AN APPLICATIONS TERMINAL- the alternative is to try and build such an application using the control microprocessor instead of an 11 which is now the controller

KO IS A COMBINED CONTROLLER AND SMALL SYSTEM WITH BOUNDED MASS
STORAGE AND INTEGRAL CRT CONTROL (for performance and cost) for
writing large applications programs such as WPS and small business systems. Our competitors use micros and IBM uses the
8086. It is not a gp 11!

Main target application: WPS and OFIS-type products with very good filing capability, sorting, list processing and table manipulation. Visicalc!

MODULES:

Large computer module based on Fonz processor, 256 Kbytes user
ram, system ram, rom, serial port for printer, and standard serial EIA port (US and European use, up to 9.6Kb, EIA data only
lines would connect to local systems)

Small computer module based on Tiny processor, 65Kbyes user ram,
system ram, rom, serial port for printer, and standard serial EIA
port

Rom/ram cartridges for specialized software packages

Telephone interface with 300/1200 baud modem, auto answer, auto
dial, phone line in and handset or telephone out. Ability to dial out for data or voice use.

Ethernet interface sans modem, but includes any necessary rom and
ram to operate interface

DECnet interface, X.25 interface, SDLC/HDLC interface using appropriate ram and rom for protocols

Dumb terminal mux with multiple standard serial EIA ports

Combined controller for T/E 5" diskette and 5 Mbyte Winchester

Controllers handle combinations of the following monitors:

- .BW, RS 170 Composite video and European std giving 240 lines
- .BW, 2 x 170, 480 lines (40 lines)
- .BW, 4 x 170, 960 lines (full page, 80 characters)
- .RGB Color, 240 lines
- .RGB Color, 480 lines

Each controller will handle BW with intensity or simple color and

keyboard interface. Multiple virtual terminals with ability to
assign split screens to various terminals. Four versions:

- .240 line, VT100 compatible, character only
- .960 line, full page black and white, character only
- .240 line, bit map, two plane, GIGI oriented
- .480 line, bit map, two plane, high resolution color

Serial printers with serial port and bus interface such that processor can be used in non-dumb versions. (It is unclear that we should add anything to base printer cost in order to provide for computer modules.)

Keyboard- probably should go to standard serial format

WHAT A USER MIGHT BUILD:

VT200 starter- small computer module and 24 line char gen, keyboard, printer option, telephone option, or Ethernet option
VT200 Basic WPS- above plus floppy. Deluxe WPS editing would include full page monitor

Remote hard copy unit- printer, small computer module, telephone option, keyboard ... unclear what characteristics should be

Student starter- small computer module, floppy, telephone interface, bit map, monitor

Single user deluxe WPS or Small system- large computer module, dual floppy and Wini or 2 Wini, comm option if in a large organization, appropriate printer.

Clustered system with shared single user database- above with serial interface to dumb terminals or multiple crt/keyboard/monitors

SOFTWARE:

Single user, operating system with well defined interface and including all aspects of language, file system, terminal (screen), and communications.

Able to be interconnected to DEC systems and write terminal emulators to other systems by applications or field programmers
using some form of state table or higher protocol description language

Able to be interconnected easily with other single user systems
of the same type for file and message transfer
Explicit decisions made on i/o compatibility, both now and as we
proceed with deign. We have three architectural alternatives:

.fully 11 compatible, which is most likely to be uncompetitive
from cost and performance standpoint

.incompatible i/o, which is marginally competitive based on 11
chip set, but requires modifications to selected handlers

.semicomputer company architecture (eg. 8086), language and operating system to get lowest cost and highest performance, but
may not be able to be brought in on a timely basis.
Unfortunately, our competitors such as HP and IBM are using this
approach! If we can not make changes in our own i/o ISP architecture, we must go this route. (Simple analogy to IBM's
introduction of 360 like Series 1 instead of modifying 370 architecture)

PEOPLE:

.Avram Miller is driving overall program to get the product

defined and resources assigned to implement it
.Ken is architecting the packaging
.Don Gaubatz (and I intend to be involved) will take on the responsiblity for the PMS and ISP (i/o) architecture, together
with Bernie Geaghan who has the implementation responsibility for
the modules necessary for terminals. ? has the implementation
responsibility for PDT.
.Bruce Stewart is driving the WPS project
.? has the responsibility for implementing the base system software including an special handlers, the operating system, language and file system

DERIVATES

WE NEED HELP BAD ON KO BUS DEFINITIONS. ANY IDEAS?

I am concerned that we have the right kind of focus on the issue of the II definition. It has been the assumption that the II is the interconnect of KO. As such we would expect II to have a long life such that a set of options built to II would be rebuilt on the next generation of microprocessors. My goal would be to see II have a 10 year life. What I see in II is a random collection of signals that are a superset of all the lines that all the semicomputer companies need to operate their peripheral chips. They build in a relatively freewheeling fashion on the basis of what fits on a chip, independent of how it couples to any neighbor chips at the system level. Thus, it is hard to believe that II will last very long. It will simultaneously shrink and the result is that it will grow!

Our performance in designing the Q bus is hardly exemplarary. We put out a Q on a quad board, reduced it to a dual with the same pin out, and then proceeded to have to add the 22 bit addressing and parity, resulting in 4 versions to date.

The dilema, the Q22 as we know it seems to large, yet by the time we make an II that might work, it could be substantially worse.
Also, I would hate to think we have a whole set of II-based modules for the KO and a completely independent Q bus based for

our board, box and small systems base. Somehow, we would like to
be able to use the Q stuff too.

I don't have the answer, but I know we have to get through this
very, very quickly. It seems like we have the knowledge in the
company to formulate and solve this problem. In the KO, the two
systems groups (T andd F based) are proceeding quite
appropriately to design systems based on their speculations of
II, but their principle thrust has to be on just getting things
together and not on the busses. Therefore, I would like to look
at getting the II definition really much more task force directed
with membership by people who really know what the peripheral
chips are and how they are likely to evolve. The whole thing of
course, would be a two week affair by not more than 5 persons,
given our understanding we have now.

Could I have your suggestions on how we are going to resolve this
so as to get a bus for KO (whether it be II, Q22, Q22 sans
drivers, etc.) that will have a 10 year longevity and will allow
us to use peripheral chips and build the 100 or so boards that
will ultimately be built for the KO module set?

Please help.

SUBJECT: KO BUS, MACHINE, QNI/UNI/LNI/NI

Wayne, I wonder about whether we are thinking far out enough? On one side, longevity will kill us in terms of today's cost and time to market, on the other hand, the evolution will kill
us in the future. There seem to be two issues: simple, program and dma i/o; and how to couple multiprocessors. This later one is a mess when you get into the sw. I'm sorry I couldn't stay on Friday morning. Your solution of packet switching between T and F sure doesn't feel right in terms of the software as I know it now.

Could you send the prolog bus around to us all?

Can you help more in terms of trying to sort the mess out? (Also think VAX ultimately is involved, plus NI .... it supports your model of F/T seperation via packet message switching)

Are you aware of what is supposed to be a QNI? Glorioso says it speaketh to NI. They are going to build several. Here's

what I'd like for all our boards that speak to NI: two connectors-
one to a local cable whatever that is; one to the modem (tap).
Is this possible? (Have asked to meet with all the folks building
this stuff to be assured that this is what is happening.) How
come their QNI has DMA and fits on a quad and the UNI is hex and
doesn't have it?

SUBJECT: THOUGHTS ON KOBUS AND ADDITIONS TO THIS MOD TO QBUS

This week, we are pursuing these two paths for the KO Bus:
1. Kotch/Miller are persuing the bus, based on an improved multibus approach
2. Bernie is pinning down the minimum bus, and then exploring the
incremental additions to satisfy the goals discussed last friday.

In doing 2, I expect Bernie to come up with a trajectory of
designs over the path from minimum, to the bus Paul is designing.
It is important for us to continually discuss both designs from
now till friday so as to understand the complete continuum. In

our discussion this evening, I found KOB(min) to be:

off board bus with simple programmed I/O and no DMA

(This would be fine for both Tiny and Fonz. It assumes DMA is
local to Mp to support the video and disk transfers are buffered.)

It is clear, this will evolve to support low cost DMA and as we
run out of bandwidth with Wini, NI, and get pushed by higher speed communications requirements. Therefore the following progression of bus capabilities will no doubt, occur:

DMA and Memory accessing
DMA of options and DMA of system processors ... note not all Pc's
have to have DMA as this is an implementation attribute, not architecture. Thus this values for this dimension are:
0. No DMA
1. DMA of System processors
2. DMA of System Mp (but not Control Mp)
3. DMA of all Mp on all Pc's (this is the only value to completely satisfy the goal of full state availability)

Clocks
Here, I think we just decide:
0. Central clock on the backplane
1. Clock on a processor that is active when placed in a particular slot (say 1)
2. Arbitration among multiple, possibly active clocks

Inter-Pc transfer of data to Mp
The problem here is for both data and for signalling, see below.
Some possiblities for data interchange:
0. Only one Pc can transfer data among among all the C's
1. A central board that allows a Pc to transfer data to any Pc
(Note this could be packaged with an option such as Wini or NI so

that it is available only as needed. However, it would be desirable to have each processor have this.)
2. All Pc's have ability to access all other Pc's Mp

Inter-Pc signalling (interrupts or semaphores) among C's
There has to be a method of posting events among the various computers. Here, there are more options, but I remember:
0. In the case of dedicated controllers like the VT200, have a
dedicated interrupt to Tiny via the on board connection and then
some method for global interrupts
1. Allow an adjacent controller to interrupt a particular processor such that there is a specific, positional relationship
2. Have only a single, system interrupt to Cs together with local
interrupts to specific control, computers as above
3. Have a single clock so that all Pc's interrupt together and
look for messages at preassigned locations
4. Have each Pc have an interrupt address by which any other Pc
can interrupt it in the most general fashion
5. Have a preassigned set of lines for each of up to say 4 C's
such that any C can interrupt any other one

Interrupts to Pc via Controllers,K (i.e. K's to Pc's)
0. 0, or 1 or 2 above as in Pc-Pc using either a local C or a Cs
to service interrupts
1. Specific addresses with Pc's assigned to handle them

ARCHITECTURE VS IMPLEMENTATION
We should remember that we don't have to implement every function
in every computer module. It is important to make the software
independent of any particular scheme... ie. the software should
be able to simulate a variety of alternatives without

rewriting.

THE KO BUS, and Computer Structure, my gut feel

Given where we are, it feels like we should:
0. Build mostly program interrupt controllers except when there
are the right kind of chips for DMA
1. Introduce DMA on the Tiny, if it is not very expensive (say $5
or 1% on the low end system) Make Tiny's Mp globally accessible.
The design goal is global accessiblity for all state.
2. Have the convention that slot one is the system computer and
it also supplies the clock. All interrupts come to the system
computer.
3. Allow on board interrupts when Tiny and a controller are on
the same board (or physically interconnected). Also, allow
convention of adjacent boards to interrupt Computer next to it.
This would use a C-D interconnect convention of some sort.
4. For C to C signalling, the best alternative would be a set of
addresses that are position specified such that any slot can call
any other slot (address) by writing in another's Mp (and
interrupting it). If this proves to cost more than $5 or another
1%, then have a clock by which intercommunication can occur by
convention.

This would give us a system structure of a system hierarchy consisting of a single system computer, Cs, which fields all interrupts and does block transfers of memory among the other control computers, Cc. Multiple Cc's could exist which could interrupt the system machine on a single interrupt line.

In addition to KO, we would extend the Qbus architecture

along
very simple lines in order to allow multi Cc's, and to allow Cs
to have private memory (on C-D) so as to decrease the bus time
and increase performance.

For starters, let's make sure the above alternatives are complete. Then by friday, I hope we can have the cost over the
base for the various options in order to come up with a good, lasting design.

SUBJECT: RE KO BUS VIS A VIS MULTIBUS

Should we look at the multibus when going to the multiprocessor
systems involving both f and t? I would hope that multibus would include a simple ii for when we are simply connecting dma and program controlled peripherals. Am deathly afraid of the issue of F and T connected via a packet interconnect. It is not upward compatible in any sense that I can see. (We could make it, but the performance issues would be a bitch.)

SUBJECT: RE: KO COMPUTER

I ain't doing it. The one most caught up in it and driving this defomity is us (you and I) and I don't believe it is me. I am getting two designs: one around a tiny with the smallest amount of memory that would be, because of modularity not more
than 10% more than a vt100 and would be expandable to an apple
II with floppy and 65Kbytes; the other would be your monster

box with power for the world and would be 256Kbytes and the Wini, etc. The delta, you should see, is very great between these systems.

I don't intend to see us build an uncompetitive system. I don't believe that a single back panel can cover this range though. You rejected the notion that the apple II uses that the processor and basic video are on the backpanel. Options plug into it to give floppy, etc.

Let us get the data on the options, we have put the people in one location with a name assigned to each part. We are drawing the whole system on a big sheet and then we are going to work on how we want it partitioned. Also, we are asking each person to give several designs. We have found:
an 8 chip design will connect to T/E, we also have a 20 chip that does program controlled data transferred under interrupt control and a 30 chip design does the works relieveing the processor. Apple II uses the 8 chipper, and we would probably
rule this out because it doesn't let you run a comm line at the same time or causes lots of rereead/rewrites... the Apple III seems to use the 20 chip design so as to be more useful in an organization with the ability to interconnect them.

Right now, I intend to get the data, look at it from what I think are going to be the softwAre architectural issues and to then recommend an approach by which I think will successfully cover this range of products. Also, I will make it very explicit what the choices were (eg. how much 132 columns are going to cost, etc.) if you can figure out how or who you want to look at this for review or changing it. Fundamentally, during this critical stage, I would like to get enough time to run in a very tight design mode in very much the same way I worked on VAX.

What you think?

SUBJECT: MEETING ON WEDNESDAY

Imperative it be at my house. Have a 78, 278, and 100 for reference and can have a full Apple II, and GIGI I. We want these to look at and not to carry around or waste time in the

air or riding.

Don Gaubautz will have all the power, cabling and space constraints for keyboard, floppy, modems/comm, winchester, scopes, etc. on our desks by Monday. Will get more info as needed. He'll also find out about ability to drive cable tv from a computer.

Call me Friday or weekend. Currently have Daley for sw, Gaubautz (Rand D who's trying to design this system ... we have been labelling GIGI II), and A Miller who's trying to design a bounded system like this.

Can also have other people, but am not sure it's productive. Also, why do we need anyone on SW?

The smaller the better.
gordon

SUBJECT: GOALS AND THOUGHTS ON KO PACKAGE AND MODULE MODULARITY

We need some clear goals for modularity. There is a myth (which may have basis in fact) that modularity is expensive. In some cases like television sub-assemblies, it seems that it has not cost. The key is to understand what the really expensive investments are. I believe the modules we want to preserve are:

all the pc board modules that attach to a bus such that a customer can be assured (sold) that any module he has will be able to be used on an upward expandable version (This also let's us refine and add modules over time unlike we do now where every terminal is a new engineering project and has no basis on the past, nor can use anything we ever do in the future.)

software that runs across the range (our needs) such that we can add additional software modules and the old software will still run

NOTE: We must build KO on these principles otherwise we bring nothing to this marketplace. It is how we are going to get low cost. Also, the personal computer companies are going to take all our dumb terminal business away.

Furthermore, we must be modular in order to take advantage of cost reduction chips and build better terminals as the technology makes it possible. Here, I believe we want to set a goal of being able to track 10 years of evolution, or at a minimum, the next set of modules after those we see that consitutes all of the VT200 and PDT50 as we postulated them before the KO.

The things that are cheap to redo include: any random package (take a lesson from the television industry which uses the same basic sub assemblies and packages it as portable, consoles and in varying tube sizes). This also may mean that there are power supplies in varying sizes. Thus, at our last meeting, we

postulated a model numbering system that has power. Let's refine
it to include processor, available module slots and power and use
it for now. For example, Tiny/5/95, would be the first box and
capable of doing the WPS job. (Note there are 4 spares beyond
the Tiny-video board.)

In order to make the dumb terminal, all we have to do is to make
the tube housing big enough to hold the Tiny board which has
video on it and to decide how much power to put in to hold the
second board that we surely must have to have any escape.
Also, there would be a small power supply in the monitor or at
the AC power if the cost warrants it. This is a long way from
the 4 boards and power needed to build the WPS and hold the
floppy. Therefore, it seems to me, we can get the dumb terminal
as cheaply as the VT/X which is the cost-reduced box we are
talking about because there is no seperate box, cabling, back
panel and the power is only big enough for the terminal. Thus,
we have protected our investment by really only building a second
module power supply and we use the great Tiny/video board and its
associated software etc. This means sparing etc. is common. Can
we do this on a cost-effective basis?

CHARACTERIZING MODULES TO USE IN PACKAGES

Thus, it seems like our table of modules should include:
power, ic's, equivalent ic's, processor cycles required from any
other module, processor cycles available to any software running
there, connections to outside or inside the box (eg floppy),

and
what the functions the module performs, and any rom/ram assumptions. We need this table made on a weekly basis in order
to keep track of who's doing what and how the system is changing.

CHARACTERIZING PACKAGES TO HOLD MODULES
Our packages should be characterized by the module space they provide and if we don't think the power is seperate, the power
that can be dissipated by the box. Thus the boxes include: the
keyboard (and we might make some that leave room for modules; the
monitor that can be made to hold 2 modules and power supply in
the dumb terminal version; 95 watt box for low end wps; and 200
watt to hold both disks and run multi terminals with lots of bells and whistles.

EVOLUTION OF SOME PACKAGED SYSTEMS (PACKAGES FILLED WITH MODULES)
Ideally, we would have seperate modules between video and procesing so that we can mix and match as we transition between T
and F. Since the first video doesn't appear that way, then it
feels like we should really be skeptical of packaging this way
and just accept the direction. Therefore, it would seem we would
evolve:

T/2/25 inside monitor- 1 board in tube housing with a spare using
Tiny. No spare memory for programming. The dumb terminal.

T/5/95 Box with monitor that enables us to put floppy etc. to build the WPS system

Graphics would be added to either box, but we should watch out
that we don't require cycles because we need some guarantees to
build the WPS

F/?/200 Box which allows us to build either fancy wps or vt's or
multi terminals with hard disks.   Here, let's let the Tiny
continue to do what it had been doing so we don't have to migrate
the video control software on two systems.

Let's look at the issues of modularity. It is especially
important to hit the dumb terminal this way.

Can we do it?

SUBJECT: KNOCK OUT: AN APPLICATIONS TERMINAL AND SMALL SYSTEM

Knock Out: Attentive Modular Personal Applications Terminal ...
Small Computer System

The following describes a system of building terminals and small,
personal computer systems. It is based on the current

LA/VT200
and PDT efforts, assuming compatibility between them. It is also
the results of a Woods Meeting of Ken, Stan, Avram Miller, Bernie
Geaghan, Don Gaubatz and I. Bob Daley, Bruce Stewart and Bob
Travis came later and discussed the software options with respect
to WPS. It is a project that Ken would like to do in 9 months
and we need maximum support from each group.

We will discuss the product on Tuesday at the Operations
Committee to enlist maximum support

PROBLEMS THAT KO SOLVES:

.a small system based on the 11, concentrating programming
.lower cost, faster time to mkt. small system
.competitively sized (ie. desk top)
.competition from personal computer systems for WPS and business
.competition of new, stand alone WPS products
.concentration of scarce resources (eg. communications) to get
one good, versus multiple marginal, later products
.unreasonably long vt/la product introduction date
.all capabilities in proposed VT/LA200 applications terminals but
with earlier, first introduction based on common, highly modular,
customer merge and customer replacement approach to repair

PRODUCT RANGE AND APPROACH:

Introduce a common set of modules from which the range of all
existing and proposed terminals and small systems can be built,
including: VT/LA200 series, fixed function editing VT's, GIGI,
PDT's, and RX's. Also includes the 11/03 and 11/23 with up to

256 Kbytes of primary memory and 10 Mbytes of secondary memory.

Aimed at evolving dumb, with increasing smart (pre-programmed function) functions, to intelligent (programmable) terminals and
terminal based small systems for both stand alone and host coupled applications. Aimed at competing with personal computers
and being alternative to using semicomputer company micro for application terminal, but able to extend to larger system application for the single user.

Point of manufacture with customer merge by actual user (eg. secretary) and customer repair by replacement. Assembly requirements similar to Hi Fi. Modularity is a a key selling point, using a combination of rom on modules and floppy based ram
for achieving goal.

Market is anyone wanting to use the base modules and the supporting software for applications (eg. WPS, single user small
system as in a DIBOL machine, technical person's work station,
small business system)

GOALS:

Nine months till first product introduction, followed by a constant stream of new module introductions permitting the building of terminals and small systems with the capabilites well
beyond that envisioned by LA/VT/PDT plans.

Introduce and evolve by adding new modules and capabilities in
what is similar to approach used in the evolution of Unibus 11

Introduce, then cost reduce based on technology opportunities!

Maximum use of off the shelf one chip VLSI peripherals and other peripheral approaches to get low cost. Use personal computers as a model of the approach. Be prepared for all opportunities and attendant incompatibilites and new interfaces such as wands, light pens, joy sticks, etc.

Base the architecure on semicomputer company architectures

Be as compatible as possible with current DEC peripherals, but trade-off to get cost, sacrificing i/o compatibility in an explicit basis

Trade off cost for performance subject to inability to build fast access mass storage based products or highly interactive systems

Support a physical address space appropriate to memories

Target applications with implied bounded software, not general purpose use with implied compatibility, unboundedness, sys gens and support of all operating systems.

KO IS AN APPLICATIONS TERMINAL- the alternative is to try and build such an application using the control microprocessor instead of an 11 which is now the controller

KO IS A COMBINED CONTROLLER AND SMALL SYSTEM WITH BOUNDED MASS STORAGE AND INTEGRAL CRT CONTROL (for performance and cost) for writing large applications programs such as WPS and small business systems. Our competitors use micros and IBM uses the 8086. It is not a gp 11!

Main target application: WPS and OFIS-type products with very good filing capability, sorting, list processing and table manipulation. Visicalc!

MODULES:

Large computer module based on Fonz processor, 256 Kbytes user
ram, system ram, rom, serial port for printer, and standard serial EIA port (US and European use, up to 9.6Kb, EIA data only
lines would connect to local systems)

Small computer module based on Tiny processor, 65Kbyes user ram,
system ram, rom, serial port for printer, and standard serial EIA
port

Rom/ram cartridges for specialized software packages

Telephone interface with 300/1200 baud modem, auto answer, auto
dial, phone line in and handset or telephone out. Ability to dial out for data or voice use.

Ethernet interface sans modem, but includes any necessary rom and
ram to operate interface

DECnet interface, X.25 interface, SDLC/HDLC interface using appropriate ram and rom for protocols

Dumb terminal mux with multiple standard serial EIA ports

Combined controller for T/E 5" diskette and 5 Mbyte Winchester

Controllers handle combinations of the following monitors:
    .BW, RS 170 Composite video and European std giving 240 lines

.BW, 2 x 170, 480 lines (40 lines)
.BW, 4 x 170, 960 lines (full page, 80 characters)
.RGB Color, 240 lines
.RGB Color, 480 lines

Each controller will handle BW with intensity or simple color and keyboard interface. Multiple virtual terminals with ability to assign split screens to various terminals. Four versions:
.240 line, VT100 compatible, character only
.960 line, full page black and white, character only
.240 line, bit map, two plane, GIGI oriented
.480 line, bit map, two plane, high resolution color

Serial printers with serial port and bus interface such that processor can be used in non-dumb versions. (It is unclear that we should add anything to base printer cost in order to provide for computer modules.)

Keyboard- probably should go to standard serial format

WHAT A USER MIGHT BUILD:

VT200 starter- small computer module and 24 line char gen, keyboard, printer option, telephone option, or Ethernet option

VT200 Basic WPS- above plus floppy. Deluxe WPS editing would include full page monitor

Remote hard copy unit- printer, small computer module, telephone option, keyboard ... unclear what characteristics should be

Student starter- small computer module, floppy, telephone interface, bit map, monitor

Single user deluxe WPS or Small system- large computer module, dual floppy and Wini or 2 Wini, comm option if in a large organization, appropriate printer.

Clustered system with shared single user database- above with serial interface to dumb terminals or multiple crt/keyboard/monitors

SOFTWARE:

Single user, operating system with well defined interface and including all aspects of language, file system, terminal (screen), and communications.

Able to be interconnected to DEC systems and write terminal emulators to other systems by applications or field programmers
using some form of state table or higher protocol description language

Able to be interconnected easily with other single user systems
of the same type for file and message transfer
Explicit decisions made on i/o compatibility, both now and as we
proceed with deign. We have three architectural alternatives:

.fully 11 compatible, which is most likely to be uncompetitive
from cost and performance standpoint

.incompatible i/o, which is marginally competitive based on 11
chip set, but requires modifications to selected handlers

.semicomputer company architecture (eg. 8086), language and operating system to get lowest cost and highest performance, but
may not be able to be brought in on a timely basis.
Unfortunately, our competitors such as HP and IBM are using this
approach! If we can not make changes in our own i/o ISP

architecture, we must go this route. (Simple analogy to IBM's introduction of 360 like Series 1 instead of modifying 370 architecture)

PEOPLE:

.Avram Miller is driving overall program to get the product defined and resources assigned to implement it
.Ken is architecting the packaging
.Don Gaubatz (and I intend to be involved) will take on the responsiblity for the PMS and ISP (i/o) architecture, together with Bernie Geaghan who has the implementation responsibility for the modules necessary for terminals. ? has the implementation responsibility for PDT.
.Bruce Stewart is driving the WPS project
.? has the responsibility for implementing the base system software including an special handlers, the operating system, language and file system

SUBJECT: RE: DAVE KOSKO

I believe it is encumbent on you and the developers to make him succeed and
to get help from outside if he isn't getting the work done that is necessary.
One of the first tasks that seems necessary to me is to get a good RTE into
a system so that we have some idea of what a 780, a comet or nebula will
deliver, where the bottlenecks are, what we will do when the higher
speed terminals are attached that will ultimately make more conversations
into vms and cripple it in terms of number of users. Also, the high powered
editors will all suck up much power and we'll be wondering why there
can only be 10 users on a 780.

I'm delighted to hear that you are committed to success this time around. Losing a competent manager during the buy in process seems expensive to me though.

GB1.S1.59
14 October 1982

Dear Dr. Thorsheim and Dr. Roberts:

Ken Olsen gave me your letter with reports of The Community and Its Institutions: A Symphony of Communications and The Impact of Space Development on Educational Motivation.

You asked to be kept informed about the Communications and Signal Processing Center at North Carolina State. This effort is primarily aimed at future architectures for high speed signal processing to encode all forms of images and voice. Since the Center is doing the work and we're only receiving it, it would seem appropriate that you get information directly from them.

You might write us again.

Sincerely yours,

Gordon Bell
Vice President, Engineering

SUBJECT: WED. MORNING (7:45) MEETING WITH KEN AND DEVELOPERS

You are invited to the above meeting with developers.
Ken is going to come to it. We (Ken and I) are agreed on the approach for now:

design both small (vt200) and large (pdt50) concurrently
go out like crazy now with the vt200 (the vt200 as we knew it but only 24 lines, floppy, and 65Kbyte x 2 , comm.) followed
by the large fonz based one.

On Wed. we expect to see just where we are on the modules. (power, ic's, functionality, pin needs, bus latency, bus bandwidth, etc.).

Asked Ken to arbitrarily select some module size (within some general range of 6-8 x 7-12 and try a dummy mock-up so as to understand overall power, cabling and users ability to build it in field . (Here, we'd have various trial implementations with Ann, Mary Jane, other secretaries, engineers, perhaps a marketing or sales person to make sure that anyone can build it.)

If there were ideas in our approach to get cost in the VT200, I would like to know about them, cause I don't want to blow any of the goals that were set for the 200! The only change I think we've made is to do a VT100 version (should be trivial) now, rather than figuring out the whole mess somehow and then getting the whole mess into production somehow. Tothis likes an excellent development strategy, but I want to ask whether I'm missing something or if there are some ideas to be utilized in order to make it happen. Again, I repeat:
introduce, and then cost reduce
introduce, and then evolve it

I want to get Art and Bill's concerns in particular about how we are doing on the 200 against their visions?

SUBJECT: L.COST (ICCS)-- FOLLOW UP:11/9/79
GB0005/36/EMS

I understand the concern about CI cost. The situation looks like the following to me:

<u>Given</u>
C(780; 18K), C(750; 7K); C(730; 3.5K)
C(HSC or Hg; 2K)
L(ICCS;780: 3K; 750: 3.5K; 730:2.5, Hg: 2.5; HSC:2.5)
Ms(disk, 8K)

T.comm line (0.5K)/line
T.terminal 1K to 5K depending on # active

A minimum system sans terminals costs

2 - C(750), 2 (Hg), 16 lines; 2 Ms;

2x(7+3.5) + 2 x (2+2.5) + 16 x .5 + 2x8 = 63

of which L(ICCS)= 12 or 19% of cost. This seems a bit high...10% would be better, but have I, figured right?

A bigger, 32 line system:
2x(7+3.5) + 2 x (2+2.5) + 32 x .5 + 4x8 = 87
or 14%, and 18% if C(HSC) is added.

Would someone calculate this accurately?

MESSAGE ID: 5180664684

SUBJECT: AN AGGRESSIVE, WINNING, EVOLVING LA12 VS ROBIN II?

I think we've convinced ourselves that you could have a winning portable (and desk top) printer/editor/computer if you'll simply rapidly evolve the LA12 by adding over time:

1. larger ROM and RAM (64K CMOS statis)

2. battery for keeping files

3. a micro cassette for removing files

4. higher resolution print head.

This would provide the corresponding nice product evolution:

1. Full editing, a built-in calculator, a printer with built-in spooling for PC's, and useful as a PC printer/portable terminal/portable editor.

2. Ability to store data over time and to become more like a personal computer. With the right stuff, you might be the low cost PC we need e.g. a video output chip or a LCD is all it needs.

3. Full use as a Teletext Terminal and as a poor person's WPS.

4. More use by having higher quality printing.

This approach to be an aggressive, competitive portable unit supplier is in direct conflict with your direction, where you have no control over your destiny and have to provide a kludy option box (Robin II) so that all terminals can use this kludge too and you find there's a Robin-sized market. TI, GE, Teletype and Si Lyle's company will all have nice integral, portable units because they don't have your constraints both to produce Robin II as the universal kludge box that fits all our terminals and they don't have a messy organization where the designers are smeared everywhere across DEC Engineering with no product identity. At the very least, you might package Robin

II with
the DFO3 simply to save cables, power supplies and user desk space if
you want to consider the user..

My guess is that you'll have to produce Robin II because you'll never
get it through the bureaucracy because it might be a good product.
Alternatively, maybe one of the engineers or product managers who can
program will simply ECO the board and write the program if he can get
a listing of the LA12 firmware.

VT's must have the ability to edit a full message ala the LA12 editor
simply to off load a VAX host if we sell DEC MAIL.

GETTING A REALLY PORTABLE TYPEWRITER ASSUMING WE DON'T DO IT.

I'd like to work with you in getting a really nice unit from Japan.
We still may want to even for cost reasons. They listen well, are
concerned with quality, user convenience, size and the correspondingly
lower cost. They also are heavily automated. Brother's got the start
of something good, and with just a little help they can produce a
great product which we and others can market. I think Brother, who
wants our business badly can be of enormous help just like they helped
Centronics into (and out of) the business.

Subject: First impression of LA34 with built in modem

Overall, the built-in modem is realy nice as fooling around with the acoustic
coupler, cord etc. is a drag. It passed the test of my not reading anything
to work the terminal, but I haven't called into a machine that expects tabs,
but that should be ok.

Somehow the keyboard seems to require some real work . It sure feels sluggish
and cheap, with stickiness and plasticness as some of the ways I'd describe
it.

The rolpaper memories of my childhood are brought back. Cutting the finger,
living with an array of wierd size sheets of paperand trying to take the curl
out of them to hold them in my otherwise 8.5 x 11 world. The curly paper also
curls around the roller too. I would like to have only a short carriage, but
since others may want the wide p

paper for goodness knows why, it probably means the product has to be o big.
I am also using a TI terminal which is also hard to read and use too. Yhr
hand rest below the space bar is fully as cheap feeling (like it might break)

as the TI. Now that they have gotten us into their price market
I suspect I
can expect future products to be even poorer quality feeling.
If someone
say like HP goes the quality route, they probably can get most
of the market
taht IBM doesn't have.   Also, the Japanes might get in and
do both price
and quality to upset us all.

I like the noise level...it being better than a selectricor a
36. The FCC
I hope will get on the stick because I don't listen to a low
power radio
station (my favorite at this time of day) and use the terminal
simultaneously.

(note I have not edited this and am not really that bad at
typing... the
stickiness is doing it to me.)

All in all I hope we sell a bundle...I would like to stay firm
in my resolve
to review all terminals before we ship them or even earlier so
as to argue a
little bit about what they should feel like and what the output
should be.

Teh print qualtiy is nice and I'm excited at teh HRDM
possibilities.

TO: DICK CLAYTON
    ART WILLIAMS
cc: MARY JANE FORBES

SUBJECT: LA34

I believe there are several problems with said device.   On a new
role of paper the spring is too tight and makes lines too close to
gether.   On end of roll, the spring hits the   paper collar and makes the
roll holder ride out of the retaining socket.\par
Since I don't have a typing table of the right kind so that I can
operae with   tractors and form feed, and I can't get used to the
roll paper,   I'm   returning my la34. so that someone less critical thatn
I can use it.   It doesn't feel up to the la36 and this is quite
depressing to me.

I do like the builtin modem.

I didn't get around to changing the keyboard, but someone can

look
at mine and see if this is a problem.

I predict some more ecos due to the way the carriage slides acrosss the page in a catching fashion.

Command >

How can this be in trouble?

What happened?

What's the level of the head designer(s)?

Are there consultants who can help?

Can we buy a head from someone if we can't engineer it?

What can be done to get it back on a more aggressive schedule (eg. derating the head by slowing it down)?

Who's looking at the alternatives?

Loc: ML12-1/A51 Ext: 223-2236

Steve Coleman, ML12-1
Bill Green, ML1-4/E34
Mike Tomasic, ML12-2/E71

Two conditions have come up which the Marketing Committee would like your leadership in regard to pricing and delivery to effect the market, NOR and profitability. Please come forward with appropriate proposals.

<u>LA120</u> - Our internal requests have come through at less than 1/2 the original forecast. LA36 forecasts are up! Given that there is only slightly more cost (150) and much more NOR (750), we should not make the lower cost, lower profit terminals.

This is doubly immoral because the higher speed will be paid off in less than a year by less user time. Delivery can effect this!

<u>Memories that use 16K chips</u>

We can't get 4K bit chips! We have to move our customer base to memories that use 16K chips as opposed to the increasing forecast for 4K chips. Certainly price and availability can control this.

Bill Long will schedule you at Marketing Committee when you have a plan.

SUBJECT: LA200/VT200 SPECS AND SCHEDULE

Sorry I can't be at the review. Mostly I have only one concern: HOW CAN WE WAIT SO LONG FOR IT?

It has most of what I see as important and am glad to see the calculator, telephone interface, etc. that we are putting together this summer. Am working with Jim McIninis, and Bill Zimmer and Anton Chernoff as to its contents and how to access them. Our discussion Friday centered on a quick implementation of a WPS/EMS compatible set of options for editing, tickler, notes, setting parameters (not in WPS), calculator (also not in WPS) just to get the experience of implementing functions in a fixed function terminal. After this we would try to improve the human interface, but right now we need to implement something in order to understand the internal architecture (versus the more subtle issues of the human interface). Also, this would get us to do something rather than just attend meetings and talk.

Why don't you assume that the functions you need will be specified by Jim in Q3. What would the schedule look like then?

Is there a way to work on a terminal with Vt100+ resolution and these features and then ease into the high resolution and/or color that we are queasy about?@ (Make sure that the power wand logic will support the resolution.)

Another way to look at this is to plot the family tree of La and Vt products starting with the 30 and 05. The tree shows offshoots like the vt 52, but the key parts of the tree are the start of a branch when the project starts and a nodule on the limb when fcs is and the end of a branch when the product is retired. (This enables you to compare the project historically in terms of development time, and product lifetime. With these, I'd feel better knowing we are ok in terms of history. Could you get the key dates and events for these and do the plotting (this is what the PDP trees I plot are.) (the tree might contain la30,36, 34, 180, 120I, 120II, proposed 12, 34g, 200, etc. and vt 05, 50,52, 61,62, 162, 101,102, 131,etc.) Until there is a better measure, I think it is worth using history as a metric... that's why I personally plot the trees and have them from 1960 out to 1990. Given the bigness of this base I'd hope you will, and if not, let me have the data so I can.

Bottom line: it's good, probably too late, but get some way to test this based on history. Believe the parts and specs can/will/must be ready more rapidly. What can we do to stage it differently so that it is timely and can protect the base?

GB9.5
Subject: LAN and PC server, backbone of products. Nestar Visit
importance, It's clear that the LAN, complete with communications gateways, and ability to connect PC's and terminals (eg. using a concentrator) is pivotal to our products. In this regard, we need to move this to the same priority as our basic, meat and potatoes product (eg. CT/Plexus/Auragen system). We're looking at:

1. Interlan ($6M/year, 70% OEM, based on Ethernet, financed by JH Whitney et al). We've met once, like their product, and have ask them to NOT build an end user sales force, but rather have us do this so they can become the LAN technology company.

2. NESTAR ($6M/year, 100% end user, based on Arcnet, financed by Rank). My Silicon Valley sources say they're in trouble, with people bailing out.

It sounds like they pretty much have the product that Ed is proposing (sans the accessories and programs distribution aspect). They have a range of file servers from 30 to 150 Mbytes and link to Apple and IBM PC's with the appropriate code to distribute programs. In addition they have low cost servers constructed from IBM PC's. A net can gateway to IBM as a 3270 terminal.

Their president, Chuck Hart and chairman, Harry Saal, are visiting next Wednesday at 9. Karl's hosting them with Ed and Steve. It would be good to have other folks come too to hear about the company and products. I'll be back about noon. I hope Henry and Ken can be available to talk with them. Obviously they're interested in us when I ask how we might distribute their product.

In addition, we need to look at the other alternative suppliers and possible competitors:

1. 3Com (Bob Metcalfe's company. Bob invented Ethernet). Made a recent agreement with Xerox and Visicorp to supply interfaces to IBM PC's. Aimed at a disk server but extends the XNS protocols into the human interface. Unclear who's doing what or who'll market the products.
2. Bridge... Ethernet based and has interesting products.
3. Ungermann-Bass is mainly Ethernet. The largest at 20M, and oriented to networking.
4. Corvus (30M). They have a 1 Mbit Omninet that's easier and cheaper to use than Ethernet.
5. Excelan (Ethernet), Appletek, Hinet (500Kb), Comtel, NSC (very high performance) are others.

Subject: **Language Support in New Terminal (e.g., LA120s)**

To: Distribution

Date: 20 SEP 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

F/U 9/27

In listening to DECUS and other users this last week, I got a couple of inputs:

1. Users of APL like the LA36.

2. Users of BASIC believe the WANG approach which puts language syntax elements on keys is quite nice...and wonder why these aren't available.

With the BSR and/or LA120s (and future LA120) we could provide this (and perhaps other) capability specialized to COBOL, FORTRAN, and BASIC.

Could we breadboard such a system and see how it would feel by trying it within DEC?...and if useful, try it on some customers.

Ed and Roy, could you get several of us together to see how it might get kicked off and what it might look like?

Is it worth doing?

How effective would it be?

(John Xenakis, could you give me a quick, simple analysis in terms of improving throughput?)

Will this provide a very good mid-life kicker on the LA36?

Subject: **Large Systems Strategy Team**

To: OOD, Marketing Committee,
Large Systems POT,
Ulf Fagerquist
Midrange POT, EBOD,
Alan Kotok, Jud Leonard

Date: 20 OCT 78
From: Gordon Bell, Bill Demmer,
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 11/2/78

Approved

A strategy team composed of MSD/LSG hardware development representatives will be formed to develop a large systems hardware development strategy proposal. The effort will be the first phase of a process to establish firm engineering plans and business plans for the large systems area. The first phase is focused on hardware development strategy and is chartered to complete a proposal by the end of Q2.

Membership: George Hoff (team leader), Alan Kotok and Jud Leonard. Additional assignees will be pursued by this group from MSD/LSD as the need arises.

Goals

.Assess potential VAX-780 competition in the 79-82 time frame. Propose FCS target and cost/performance target for a 780 replacement which will head off competition and protect/expand 780 base/market share.

.Evaluate alternative solutions for a 780 replacement considering available technologies, bus structures and positioning relative to Comet and available market.

.Positioning of Dolphin vs VAX high end product must also be considered and alternatives presented to the POTs and EBOD.

.Primary metrics to be considered in evaluating alternatives are: development cost, development risk, total start up cost, product cost, product performance, RAMP, schedule and feasibility vs available/achievable resources.

.A major goal is to minimize risk and achieve efficiency in this product space by attempting to find common solutions in the area of technology, bus structures, IO subsystems, power subsystems and packaging. We cannot afford to introduce multiple high impact items to manufacturing and the field in a relatively low volume area.

.The overriding consideration is to maximize net revenues and to protect and grow the base of customers who have invested in Digital products.

.The team will consider coexistence/consolidation alternatives for the VAX and DECsystem 20 product families through the mid 80's.

.The team will review progress with Gordon Bell, Bill Demmer and Ulf Fagerquist on a bi-weekly basis.

Non Goals

.Detailed financial analysis of markets and business plans.

.Software strategy.

.Detailed engineering plans.

Dear Jack:

Thanks for the offer to attend the conference, and I regret that I can't attend because I'm recovering from a by-pass operation, and am trying to limit my commitments, especially those requiring travel. I would have liked to hear about the Cray, Dennelcor and CDC machines. Bill Strecker's attending from Digital, so I feel we're represented.

If it's not too late, let me urge you to reconsider the speakers from academia and invite someone who has produced results. None of the speakers, besides Kuck have every built anything. The folks at Carnegie and Manchester are about 10 years ahead of their colleagues in understanding parallelism and how to build systems. The attendees should understand that parallelism does exist and can be exploited to varying degrees using dataFLow and multiprocessors.

Sincerely,

Gordon Bell

Vice President, Engineering
October 11, 1982

Dr. Robert Ewald
Dr. Bill Buzbee
Los Alamos National Lab
Computing Division
MS: B260
Los alamos, NM 87545

Dear Bob and Bill:

Let me express my greatest thanks to you for hosting our Alpha Omega technical definition meeting and the site visit to LANL. I know everyone was as impressed as I have been with the LANL resources and your ability to manage them.

I'm sorry you had to suffer through our deliberations on the program definition, but at least you understand what some of the pressures are on our program. It's going to be a frantic time ahead as we try to sort out and define the next stage of the program. I hope we'll be able to extend the program to include work on PUP II. It seems to me, that's exactly the kind of base we should be helping prove so that your researchers can be as effect as soon as possible.

We'll be trying to get AO defined as soon as possible so that we can proceed on to the work.

Again, thanks for the fine hospitality of you and your staff.

Sincerely,

Gordon Bell
Vice President of Engineering
Chairman, Alpha Omega Steering Committee

GB3.S8.5

June 18, 1982

Mr. William Buzbee
Los Alamos National Laboratory
Mailstop B260
Los Alamos, N.M. 87545

Dear Mr. Buzbee

Enclosed is the paper Gordon wrote upon his return from Japan in 1978. This is the last iteration.

He also asked me to let you know he doesn't have any IBM information to send.

Sincerely,

Mary Jane Forbes
Secretary to Gordon Bell

SUBJECT: WORKING WITH LATTICE LOGIC

Prakash,

I'm really delighted we're taking an interest in a fully automatic standalone design system like Lattice has. I appreciate our compete system based on CHAS and it's clearly the basis for our major designs. It would seem that the Lattice system might be like one of the point processes say like Applicon, or Caldec where we do PWB's in a very simple disconnected fashion just to get a chip asap.

Is it possible that we are going about the evaluation the wrong way? Here, it's possible that we are going to cause a tremendous hardship on John in time and money by having him come here for harassment and interrogation.

Since we are evaluating several systems, I would like to suggest WE take several benchmark designs and visit each of the vendors and try their systems at our expense. Here, the little book has enough detail to allow a designer to do the job. What will be accomplished by having the 48 people on your list attend a lecture (we all have the book and notes of his last lecture)? Why can't WE do some work rather than putting the onus on him?

I've also ask Cutler and Gutman to couple into your work because they too want a very easy to use gate array. (Here, a very cursory analysis of our boards show a distribution of chips are mostly ssi, then msi, then lsi (if you ignore memory chips). We could win in board area like crazy and at the same time educate our designers and get them ready for VLSI design.

The leadership I want from SEG is to get designs into the design groups really rapidly using no muss, no fuss gate arrays, whether they be tat, cmos, or whatever. Right now, the best system I've seen in my limited wanderings is John's system. Since you say there are several good ones, let's have them all evaluated no later than September 1 by trying several REAL designs.

This is a problem that is solved by analysis, design and work, not by lectures and talk.

WPS USERS - Leave HP mode and type <CR>

SUBJECT: USING LATTICE LOGIC'S CMOS GATE ARRAY DESIGN SYSTEM

LATTICE LOGIC
John Gray visited us last week to sell his software to make CMOS
gate arrays that can be either as flexible or as restrictive as
desired. It does not cope with a particular gate array. They're
at 6 Albany Lane, Edininburgh EH1 3QP, 031-557-3215. The design
system takes an algol like input, complete with macros and
arrays, and then builds the array and the test patterns for it.
It has simulator, timing verification and is complete! No other
software to lash together. Regular logic diagrams are easily
converted to the notation, but some folks may just stay with the
programming notation. Staying away from logic diagrams, may gain
speed of design. I have a manual of their system.

ENGINEERING USE
I'd like to see us try it for making CMOS gate arrays which would
substitute for TTL circuits. Someone inside would get the
software, try it and then act as the clearing house.

Ideally, this would get integrated into the SEG training

program.
Given that the introductory course is a week, I think it would be
worth 2 days to learn this method and do a design so as to give
people the confidence that can start to cope with VLSI.

EDUCATION SERVICES COURSE
John may contact Del Lippert about setting up a DEC Education course, complete with a VAX that people would take from both inside and outside DEC. The course would take students in who
have a known, working TTL design, and would take 2 days and the
output would be a tape to a Silicon Foundry which would be part
of the course results. The goal would be only TWO days to a working chip. The chip would be returned to the students in a
few weeks or days, depending on the turn-around of the foundry.

ESG PRODUCT
I didn't suggest this, but Pete should contact John to sell the
software for him. It looks like the right way to do your own chips in a very flexible way without the massive custom hassle.

We've got to get our engineers away from costly ttl and into modern design. Let's try this, cause nothing else is working.

Lowell Wood
Lawrence Livermore Laboratory
Univeristy of California
P.O. Box 808
Livermore, CA 94550

Dear Lowell,

I'm having great fun creating a DIGITAL COMPUTER MUSEUM and I have heard that you might have some old computers or components that you might make available to us.

Our displays begin with pre-computing calculating devices, such as Napier's bones, a Thomas arithmometer, etc. and move right up to the fifth generation of computing devices. We have a lot of Whirlwind in storage and some on display and have recreated the TX-0 as it was at MIT in the fifties.

If you come to the Boston area, I'd enjoy personally showing you the display...and am interested in obtaining more non-DEC early computers.

Regards,

Gordon Bell
Keeper, Digital Computer Museum
Vice-President Engineering
Digital Equipment Corporation

George A. Michael
Lawrence Livermore Laboratory
University of California
Leader, Computer Research Group, L-76
P.O. Box 808
Livermore, CA 94550

Dear George:

Thanks for organizing the stimulating conference on high speed computing and for hosting the conference. The interaction among users and builders was interesting and intense. Thanks for allowing me to attend; I learned a lot. As members of the Digital Computer Museum staff, Gwen and I also found the interaction worthwhile.

Please also pass along my thanks to the Workshop Committee and Workshop Staff.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

GB2.S5.5

Dr. Creve Maples, LBL, 415-486-6323 has built, is benchmarking and plans to put in service (in January) a facility that is very much like our architecture.

They have a fast switch (40 Mbytes/sec) among concentrators, disk servers and compute servers. The compute server is interesting; a standard Modcomp machine controlling and monitoring the tightly coupled multiprocessor made of 6-8 Modcomp processors(like PPA). The control machine places identical binary images in each of the machines and the user specifies message passing among the parts on a very simplistic pipelined and/or parallel basis. They assume very large grains (seconds/minutes synchronization) and the disks feed the work in a pipelined fashion.

The very simplistic approach (on the 4 Pc system) avoids going after fine grain parallelism and has been benchmarked to outperform the 7600! (A big gain is the disk).

Again, with 784's together with CI/HSC we can sell this now and do the same thing. Note the MA780 must be reimplemented to be a very large memory -- say >32 Mbytes/box!

I'm encouraged that we can and must now sell this simple structure based on simple parallelism within a job . . . if we can get on the ball.

Creve has done a nice job and has built an interesting and useful system. Let's get him to come, speak and consult after it's in production in January! Who'll invite/host him? (We need this knowledge for PPA and for marketing the 784 and CI clusters).

Gordon

P.S. The tragedy is we would not sell him 780's or interact with him to build this out of VAX's three years ago!

follow up 12/4/78

Julius asked why he has a high central engineering tax. Could it be that he is paying for both the 11 and 20 commercial software developments that we looked at in the Minnow task force?

If this is not the case (and the Technical Group is paying for the commercial 20 development) as has been the past case, please see that there is the clear allocation of commercial product development to Bill's and Charlie's groups.

Bill has been effective at getting a significant amount of software and hardware for commercial using the standard techniques of engineering and management commitment by getting us to sell futures to our customers (e.g., minnow to ADP) and to DECUS.

<u>Ulf</u> I want to approve any "future's" we're announcing at DECUS in this regard!

Subject: LARGE COMPUTER

IN THE PROCESS OF REVIEWING THE CORPORATE PRODUCT STRATEGIES WE HAVE AGREED ON
THE NEED FOR A FOLLOW-ON SYSTEM TO EVENTUALLY REPLACE THE KL10. THIS WILL BE
KNOWN AS THE 2080 AND WILL BE DEVELOPED IN MARLBORO, THE CENTER FOR ALL FUTURE
CORPORATE HIGH-END DEVELOPMENT.

THE HIGH-END BUSINESS CONTINUES TO BE VERY IMPORTANT TO US AND WE WANT THE
FIELD TO CONTINUE WITH THE SPECIALTY SALES EFFORT FOR 10/20 PRODUCTS. IN
ADDITION WE WANT TO MAINTAIN THE LCG SALES UNITS OR WHERE THESE DON'T EXIST TO
PROVIDE THE EQUIVALENT WITHIN ONE OR MORE, IF PRACTICAL, OF THE MARKETING
SALES UNITS. WE BELIEVE THAT THIS IS IMPORTANT TO AVOID DISPERSING THE SALES
RESOURCES AND THUS MAINTAIN THE ADVANTAGES OF CRITICAL MASS.

IN ORDER TO MAINTAIN OUR COMPETITIVENESS WITH EXISTING 10/20 PRODUCTS, WE WILL
BE ENHANCING THESE FROM TIME TO TIME AND ASSURING THAT THEY ARE
PRICE-PERFORMANCE COMPETITIVE. IN ADDITION, WE HAVE A SIGNIFICANT
MAINTAINABILITY ENHANCEMENT PROGRAM UNDERWAY FOR THE KL10

IN ORDER TO PROVIDE GREATER FOCUS FOR OUR TECHNICAL MARKETING EFFORTS OF 10/20
PRODUCTS, WE ARE CREATING A NEW POSITION OF PRODUCT GROUP MARKETING MANAGER
FOR LARGE SYSTEMS. WE ARE PLEASED TO ANNOUNCE THAT JIM MILLER WILL SHORTLY BE
RELOCATING FROM SALES MANAGEMENT IN THE FIELD TO FILL THIS POSITION.

FOR YOUR COMMENTS. PLEASE REPLY BY EMS.

THANKS..

OK by me. I think you are saying too much and now is a great time to stop giving model numbers, names etc to the field and to our customers. I am in charge of the effort here for the new machine and fully support it, but I do not support the "LCG Open Mouth Policy". As of now, please act to stop it.

Andy Knowles, ML10-2/A52
John Leng, MR1-1/A65
Julius Marcus, MK1-2/C37
Jack Shields, PK3-2/A58

Follow-Up: 6/15/79

Somehow the decision in ESSC to re-institute the LCG sales unit seems strange, given that the overall projection of 10/20 is only 5% of Europe's sales. Doesn't it stand to weaken the P/L focus, and require more support at a time when we have many other products (that can take up this slack)? While such a structure may make sense in N.A. which has a 10/20 focus, already one could certainly question it in light of increased focus on the low end and Europe's need for very long term commitments to products forever (eg. MUMPS, PDP-8).

Why not de-emphasize and not build the business in this fashion, but go more into 11's, VAX's, and low end systems? We'll get the 5% anyway. Even though we can get incremental sales, wouldn't supporting fewer, higher volume products in Europe be more profitable and satisfy our customers better?

Subject: Interface with LDP on Graphics SW

Just talked with Steve Mullen of LDP re SW for vt 125 and gigi. LDP is
starting an effort on sw because they felt we aren't doing antyting. Isaid
that the graphics work included software and its architecture and if there
were resources, we wanted them applied to be compatiblbe with the architecture
we are implementing so that over time we could migrate sw (interpreter) into
the terminal. We just can't permit a n independent sw effort that gets us no
where...otherwise, all we get is the sw analog of the point product

Bill and Len...please bring the multitudes together on this issue so that we
get a complete product versus a bunch of 1/2 done things. We have the
potential to be the instantaneous grpahis leader and to set the standard of
excellence. Let's not blow it by having armed camps.

As a technical issue, I would like to see the SW interpreter built very much
the way the sort package on vVAX works and that it would take advantabe of
vax especially when used there.   When used on VAX it could be called either
by a terminal, (keyboard interpreter), by a command file, or by any program it
is loaded iwth. When used on a 10 11 or 20, it would be used in a seperate
address space such that it would be on the basis of independent processes
communication. The program should terefore be written in something
transportable such as bliss, basic or fortran...It should not be a macro
program!!!!

LDP Review Team Conclusions

November 24, 1976

G. Bell, J. Fisher, R. Katz, E. Kramer, W. Long, W. McBride, M. Portanova, J. Schwartz

LDP - The lean, aggressive, responsive, supportive PL

Computers to researchers as state-of-art tools.

Computers to applications research, that will end in Engineering, Industrial, Education, Communications, OEM and possibly BUS sales.

1. Traditional LDP - {4 sizes; 3+ disciplines; 4 institutions; ? applications} .

2. Medical - {3-Clinical Instrumentation Systems, Small (group practice) Medical Information System} .

3. Graphics - Being reviewed elsewhere {4+ sizes} .

Recommendations

1. Continue to allocate corporate growth (not 17%) to traditional LDP...requires most technically competent sales and products.

   a. Sufficiently untapped markets (industrial and engineering labs--charter issue).

   b. Sufficiently untapped products
   (e.g., personal RJE station/WPS/Computer;
   Nets and shared data bases;
   Instruments to microcomputerize) which we're currently missing)
   Software Applications (e.g., Peaks)--minimal understanding or plan

2. Encourage a clearer, working 5 year plan by including a detailed product development strategy which complements the marketing summary.

3. Aggressively assist LDP in their low end marketing.

4. Develop 11/60 now, and low end VAX to get them back to "hot box image".

5. Encourage a distinct Advanced Development Marketing Program within LDP (i.e., products they don't ship and marketing approaches they don't use) to help focus planning and to get better products. Proprietary products will also help buffer LDP from need for purely hot, basic products.

6. Medical is probably viable, based on BUS/LDP products but must be watched carefully vis a vis products proliferation and support costs/resources. Some specific issues being:

a. Movement from sophisticated MIS user to >95% solution user.
b. Selling strategy for doctor's group practice.
c. Competition with various other DEC OEM's.
d. Using "free" externally developed MUMPS applications locks us in, and allows users to migrate.

7. There is no formal method of identifying and transporting applications from LDP to the other science-based P/L's (i.e., IPG, EPG, ESG, DCG/LSI). Also, OEM and Components don't have a market orientation, hence a joint plan with LDP/Medical is recommended to capture the OEM/Components business.

8. Pricing is not satisfactorily resolved. We did not review it.

Marketing Committee - Please give me your inputs at Monday's meeting (10/9/78).

Subject: **Some Large, LDP User's Perspective on Our Products**

To: John Leng, Joel Schwartz,
Marketing Committee

Date: 6 OCT 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

I'm just coming back from visiting large LDP users (NCAR, NOAA, LLL and Cal Tech) so I'm a marketing person with a clear bias -- listening only to the last customer input. Beware! Although I've got a separate trip report with their (and our salespeople's) input and observations; here are some quickies:

0. They want, identify with VAX. (They're generally at limit of address space.) They say hold the 10/20 base, but not expand it. VAX is like the 10 was 10 years ago! They want bigger (Cray and 7600) replacements, but for group-level computers. Thus, the Dolphin/VAX is as high a priority as Comet and the Dolphin 10/20.

1.All the little groups are going to gun for the 780! (SEL, DG, Modcomp and even HP!)

2.We're spending a great deal in the LDP development area in the low end and our customers are in the hi end. That is, are we making it where we're spending it? (There's no way to sell MINC's...and who needs it?)

3.These computers are worthless without good terminals (9600 baud), graphics and in some cases color graphics (ala IPG market). We need to be in graphics. Now we insult our users with things like VT105. How would any of us like to sell a VT105, even if it were defined?

4.They have communications and network problems we're not solving. Some are hard, others are obvious and we're negligent.

5.We could get the market. Univac and IBM aren't there now because they chose the infinite commercial market. Furthermore we've got the best, basic architecture (versus HP, IBM, CDC, Intel) for their products. All we have to do is concentrate!

6.I believe we should put a $200K ceiling on the average selling price of all future large Dolphin (VAX/10/20) systems. (The maps will go much higher.) This gets systems into selling price of our sales force.

It keeps us out of the range of the big, slow people (IBM, DPD, Honeywell, Univac, CDC) that make us spend resources in buying and supporting trivia. Now there's a new government rule permitting local procurement if sale is under $300K!

Note a $300K buying price is roughly 5-10K/month <u>or</u> the cost of another person in a group!

We have to believe we can build a computer that is at least as capable as <u>another</u> person in a group. This lets the buy decision be made lower in the organization on a bottom-up decision basis...and we'll chew up the large, monolithic centers and can go around the internal IBM salespeople. (Note we have to have easy to install, and operate centers!)

7.The LDP ads on VAX vs the 7600 are really true!! Few 7600 users or groups of users get more than 1/2 - 1 hour/day. At the prices of 7600's, a dedicated VAX (either in the computer center or in their own area) is much more cost-effective. Whetstones rank VAX at 1/6 of a 7600 at NCAR, LLL ranks:

1. VAX .05 to .1 X a 7600. (They have highly tuned programs.)
2. STAR 100 is .2 to 5 X a 7600.
3. Cray 1 is 4 to 10 X a 7600.

Thus, a dedicated VAX running all night gives better cost/performance, better turn-around and better control for the users (at the group level) than a 7600 especially for the 2000 third worlders!

An ad can really sell this! Let's support the third world computing masses.

8.This group feels we should treat the 11 like we do the 8. They believe VAX is the only architecture capable of being useful as a personal computer. Their programming costs far outweigh their hardware costs.

Overall
Customers generally live hand to mouth and wait for vendor supplied tools or exogenous problem statement. At least one week would be required to do an adequate survey with many users. The industrial sample (Schering Labs and Dupont) did provide good input reflecting long term planning and thought.

LDP sells significant equipment to researchers as tools, and to applications researchers in EDU, IPG, COM, EPG, BUS?, OEM, etc. It behoves us to figure how this research in applications is carried over to the appropriate P/L...or should it be sold through another P/L to start with?

1. Networks - Nearly all users have or are concerned with networking, and want more of it. Compatability or some form of gateways products is essential. Want 10's, 11's (including LSI-11) in net embedded in hardware.

2. Instruments to Nets - Old instruments and free standing instruments are there to be interfaced. New instruments are there to be interfaced. New instruments have micros and minis with somewhat better communications. The IEEE bus is just starting.

3. Terminals - The personal computer for WP and RJE station is ripe...especially to off bad comm. lines and high connect to 370 charges. Note it combines keypunch, card reader, and printer.

Tektronix is really the low end terminal business, and is expected to be better and supply the "great American graphic terminal" at $2.0K! Hard copy is essential on these personal computers/terminals.

4. The high performance market is there and needed for large arrays/big problems.

5. Add ons to 11's to go over 128K on installed base would

be ideal.

6. DBMS is next, to handle data torrent with new, smart, instruments.

7. Word processing is ripe at right price. Also as RJE terminal.

8. Dupont favors a CAMAC LSI-11. (AO would let an OEM or us do this.)

SPECIFIC COMMENTS

NASA (Greenbelt)
Telemetry and image processing (with local displays) and interconnection to central computer via 230Kb line + disk. Using an 11/70 with some address-space hassle...probably due to good selling. Throughput oriented. Standard image processing library functions. No understanding of tomorrow or whole Lab. Wants speed and address space.

UCLA (Chemistry dept.)
Real time lab automation via centralized 11 supporting many instruments and groups. 11/45 --> (2-8's + 11/40 + Nova). Central does plots, calculation and data base storage. Doesn't want more equipment, but rather support what he has already (e.g., LPS), wants better tested software, greater than 128K on 45.

No understanding of IEEE bus; future; buys what's available w/o planning.

New instrument with embedded (non-DEC) mini...no plans/worry about tie-in to his network.

NRL
Largest lab with multi-disciplines, multi-time phases. The application is high reliability for communications and should not be sold through LDP! Trying to build 4.9 yr MTBF system with security. Sell through GSA 66 NOT GSA70! (Note Comm. Application Research.)

Since their application is programming a 2K-4K LSI-11 terminal for local editing, program storage would significantly increase throughput...give more power to individual user. Of their jobs, 90% could be done on LSI-11's! Lots of pressure to network and share files. Would like F4P everywhere so as to get rid of threaded code. $10K was too much for an individual's machine.

Shering Lab (John Hay)
Builds prototypes for production use and supports the

pharmaceutical researcher. Not a good pass off to his or our (IPG) production groups. Wants IEEE bus to get instrument support in instruments. Will really help non-C.S.-type user...which Peaks-11 with LPS helps too.

Their network:

```
              C(168)--L(19.2Kb)--C(11-Hasp rje entry)
                   ! C(128K)--4x C(Labs-local) - T(instr.)
                   ! C(Tektronix)-Magtape.
```

The local lab machine must hold 1 week's worth of data and do switching. Note the network mirrors the org. structure (we observed)! All pharmaceutical labs are organized the same way.

They are beginning to use local computers ala 370/Tektronix 4051 to do editing and to reduce massive 370/T50 support costs! (Is this a big Krypton or VT52 with CMOS-8 Market? I.e., the <u>personal</u> <u>RJE</u> <u>terminal</u>?) (He buys Versatec direct.)

His real function is providing an automated lab. <u>Notebook</u>. The FDA puts lots of constraints on reliability, integrity, security. (e.g., Searle got fried for poor records).

With all new instruments having intelligence, we need a good support plan! We need a good method of converting old instruments!

All the new instruments will drown them in data...hence DBMS in lab is essential to hold all the crap with retrieval!

<u>Dupont</u> <u>Research</u>
2KA + KI.KA used as front end to 190 instruments in 20 buildings. Switching to a network hierarchy with own protocols because DEC10 wasn't there in time!

They have many minis on instruments which they don't know how to support...suggestion of a <u>dummy</u> <u>paper</u> <u>tape</u> <u>reader/punch</u> connection so that instrument could operate as is. Also connect via Teletypes. This presents a software/interface problem!

They're buying Tektronix 4010's due to cost and hardcopy (now 6 mos. delivery).

Their thesis: No one will buy a Graphics (or any other CRT) unless it has a quick look hardcopy output too! They don't like our copier...but want a good one. They believe there's a great terminal in wings at Tektronix with scan graphix to sell at $2K. Len/Herb/Bill what's the story here?

They're standardizing on Intel board to get instruments into central system via 300-2400 board serial. We can sell, and I've invited them here.

Dupont Engineering [note poor match with EPG really IPG Research, not LDP]
Plant instrument, materials movement, robots, ID checking, and transducer automation, through a hierarchial network structure. They're either:

1. Developing local control for a device by using 8080 boards; or

2. Developing intelligent input for a mini.

Their applications are to provide a serial 300-2400 board control/data reporting stream back to a central site. Price is important because capital equipment costs are hassled, although they could fight for LSI-11 on labor costs. The LSI-11 would solve more problems due to speed.

They went to Intel because:

1. Single board was just right for them in terms of parallel, serial ports, ROM and RAM (2K<ROM<4K; 0<RAM<2K - Note 2 to 1 ratio).

2. PL/M is good, even great, and requires no run time support ala Fortran. [They would use BLISS-11!]

3. 1 card = all electronics simplifies maintenance. [Some form of battery backup to hold vital state

information when lines, or central site fails might be useful in Annie Oakly. gb]

When problems get too big they prefer 2 8080 cards versus 1 larger 8080 due to spares, etc.

Their program structures are simple: one task does control; a second task monitors serial line and reports back/changes status.

They want us to supply good analog equipment? They want LSI-11 packaged into CAMAC so as to get 11 programming and network-ability.

The person supplying this input is an ideal candidate to develop IPG products. (He'll visit us shortly to listen to an LSI-11 switch pitch.)

Dupont (Central) Plant Engineering (now IPG/EPG/BUS/LDP)
They do 5 activities which may be the segments of Engineering:

1. General EDP (IBM)

2. Project Control (IBM)

3. Engineering computation using simulation, graphics, and computation in chemical discipline (Univac). Their graphics is for piping...and very sophisticated, coupled with a data base.

4. Plant process control design. (DEC)

SUBJECT: FUNDING THE NEXT PHASE OF A LEADERSHIP 11/73 AND/OR A LOW COST VAX

It seems clear to me that we have to do something to keep our 16-bit business viable in the transition phase.

In retrospect, neither the 23b, nor 24 products look particularly good in terms of price and performance... and we are at risk in these businesses that depend on them.

We must get the necessary breadboard of a really good product together and measure it in terms of competitiveness with the outside world. It is also unclear to me that we can wait for Aztec, ie. we maybe should consider an interim product disk. Given our very high installation and FAT costs for these products, we have to drastically rethink/redo our manufacturing processes to make this product more in line with the thinking on the CT, or a product like the 278.

At the same time we work on the aggressive 73, I would like to urge that we work on an aggressive vax, using whatever techniques/ideas that will get us the 73 (other than the vlsi Jaws chips) to see what the cost difference would be. Both of these would be done as advanced development during 82 to see where we go to market, maybe both.

SUBJECT: FUNDING TIMING

Given your reluctance to COMMIT large sums of money to ideas which
have not yet been proven with real advanced development breadboards
and models (a reluctance to which I subscribe), given that the op-
erations committee will shortly be allocating incremental development
funds for FY'83 and '84, and given that if we are to produce com-
petitive products we can't afford a 15-month gap between a work-
ing model and the beginning of product development, I assume that
most of the scenario B and C stuff is in fact "unproven", that the
April operations committee allocations are for planning purposes,

and that you are reserving the right to not appropriate B and C funds
when the real FY'83 and '84 budget cycles come around, if adequate
progress (e.g. breadboards) has not been made in advanced development.

In thios context, I would hope that the current lack of breadboard of
an advanced 11/73 integrated packaging concept does not prejudice
the decision against funding a leadership 11/73, and conversely, if
the decision isd made to invest in a final generation of winning
16-bit products, you will hold Herb to a commitment to back up his
claims of leadership packaging with adequate advbanced development
models in the next year.

As a follow up to a meeting with Joe and Dennis, please set up a field trip to MIT so that Joe, Dennis, and the software engineering from Typeset and Tools can see TEX and talk/argue with the local MIT users. Let's get their view of why it's needed.

Joe and Dennis tentatively agreed to send a person for 1 to 3 months to Stanford to aid the conversion of TEX to Pascal in order to learn the H, J, character layout ... page layout structure/algorithms. Someone from Bill Segal's group who did the PUB/TYPESET/Runoff programs should also go there. In the event TEX becomes part of Scribe as a standard product, we will use it when it becomes complete. Also, we'll use SCRIBE, I trust.

I say let's bring in TEX <u>now</u> for our standard engineering typeset until one is available from Typesetting. Also let's select and get a "standard" typesetting machine.

SUBJECT: DEC TECHNICAL LECTURE SERIES: FOR RECOGNITION AND INFORMATION

Several of us were discussing technical training today and we stumbled on to an idea that is multi-avaried with single rock.

DEC Contributor Lecture
A signficant, technical presentation / lecture by the contributor at Marlboro and the Museum in the format and style
of the external lecturers who are pioneers. Open to the DEC

community. Carries a 500 honorarium and plaque and poster!
Lecture is followed by reception in Museum and dinner for 50
or
so. We'd have 4 or so a year. EMC would approve them based
on
PEG member nominations.

The purposes: recognition, trying to regain some comraderie that we've lost with having 12 sites, transfer of significant information to the DEC community (engineering mostly). Note, Richy Lary did one of these in the HL cafeteria and packed the place. We need community wide recognition and interaction.

I see that we've made significant product and process
throughs
and this would be a way of honoring and informing one's
peers.

Some things that come to mind: CT, R81, HSC, CI, 782, Ofis (if we ever get it), the timing verifier, the router, DECsim, Engineering Net, NI, NI products, specific machines (2080, Nautilus, Scorpio, Venus, etc.).

Maybe this would have gone a long way to addressing some of
the
needs that we are not satisfying vis a vis recognition. I
know
it might have helped save Cane in the case of Comet... at
least
those of us who recognized it as a major piece of engineering would have had a way of saying thanks and letting the lessons be spread to other groups. This of course will cause lots of problems (eg. an individual, a pair, a team or the team
leader).
I think we can figure out how to cope.

I propose that Bill and Jack cohost such a lecture on June 17 with me for Avram and the CT group. What you think?

GB3.S5.25
I talked with David on Saturday nite, and believe he would be

an excellent addition to our AI Group. He'd be very happy working for us. He would live under Forest's wing and get work direction as part of Bill and/or Mahendra's projects.

He'd also work with Stanford and use their 784/PPA after he gets the Prolog product out.

Sam and Bruce
Why don't we go after some ARPA funding instead of having SRI get the money and then worry about the technology transfer?

We funded him full time last year to do microcode work and to do work in evaluating a parallel Prolog, which he's now working on. In August, unless something happens, he's going to go to work on some other project at SRI and probably take OUR work on microcode and parallelism and apply it to some other NON-DEC product. He's looking at microcoding the Symbolics machine for Prolog, for example, and then would go on to do work for ARPA on a special machine.

Will you folks get together and hire him please now that we've got the $'s in the CFM Project?
.
Dear Members,

The Museum has now been open for a year. A year in which we have learned alot and hope that we know better how to serve you in lots of ways: putting on a wide variety of programs; scheduling special temporary exhibitions; doing a diversity of benefits; and developing new products that let you "have a bit of the Museum" for yourself, wherever you are.

Our "lecture" series to serve our members and bring in the public has also diversified. The Fourth of July we put on our first computer animation festival -- and had one of our best afternoons. This is now followed by a winter Thrusday evening films. A simple talk on "micro-mice" escalated into the Boston Mouseathon, described by Oliver Strimpel in the first article. Museum founder Alan Frisbie from Los Angeles wandered in for the day and didn't leave... and it turned out to be an appropriate repeatable event. A February kids fair included widespread participation, including Peter Rony from

Blacksburg Virginia.

Then, we also "fell into" doing temporary exhibitions in the area near the lecture hall. This started with the exhibit of the original Byte magazine covers put up to mark the magazine's tenth anniversary. The cover of this issue is from one of the works in a temporary exhibit called "The Electronic Paintbrush." The result of a competition sponsored by CalComp for their 25th anniversary, the exhibition was first put on at the California Museum of Science and Industry. It will be here until March 31. "Colors of Chaos" an extraordinary set of computer generated fractal images will be on display in from April 10th through June ... The space works for such exhibits and we would like your suggestions of other things that might be appropriate for the Museum to show.

Before we moved, the annual benefit was established; our fund-raising efforts have also grown and diversified. The Marlboro "yard sale" was transformed into an even more successful "attic sale" appealing to the collectors and tinkerers. In December the first "Real Time Event and Auction" was held providing fun with lots of special holiday purchasing as evidenced by the Report at the back of this issue. Feburary's Fortieth Birthday Party for ENIAC was inspired by Member Annie Roe Hafer and heavily supported by Bitstream, a member company. June 8th will bring our annual with the Board of Directors and another chance to hear from one of them on the state of computing. Each of these are fun and fund raisers that appeal to different parts of the Museum's audience allowing alot of participation of the members with the staff.

Finally, we have produced a videotaped version of the "See It Then" Theater at the Museum. This film has gotten such good reviews for providing a quick and fun overview of the history of computing that we had to make it available especially for everyone who teaches and can't bring their classes to the Museum. If a picture is worth 1,000 words, then these films are worth 100,000 word history reading assignment.

The suggestion box is open. Most of these ideas came to us from members and then they grew. In just reviewing this, its clear to me that the Museum has one of the best and most interested member's groups. And, we're here because you are too.

June 6, 1983

William Perry
Hambrecht and Quist
235 Montgomery Street
San Francisco, Ca 94104

Dear Bill,

It was a pleasant surprise to meet you in California and learn of your interest in The Computer Museum. Bob Everett has been a splendid supporter of our efforts from the very beginning and delighted with your offer to help.

Several recent issues of the museum's quarterly, The Computer Museum Report, are enclosed. They can give you a better feeling of what the Museum has, what it does, and its first supporters.

More to the point, the press release about our move to Museum Wharf in downtown Boston is enclosed. This has thrust the museum from its incubation stage within a Digital building to having to fly on its own wings downtown. This fall we will be undertaking a $5 million capital campaign in order to accomplish this move and provide a small endowment. You can be of the greatest help by joining Lester Hogan's team of solicitors on the West Coast.

Bob plays the role of overall Chairman of Fundraising and I'm on his committee so any ideas that you might have please let one of us know.

I'd be happy to show you around the Museum on one of your trips to Boston and will keep you informed.

Cordially,

Gordon Bell

Vice President of Engineering,
Digital Equipment Corporation

Director, The Computer Museum

June 6, 1983

Brian Randell

Dear Brian,

Gordon and I are both home for the summer. And I am beginning to feel relaxed, rested and ready to face the new opportunities ahead.

Oliver Strimple has been here for the last three weeks and I believe is quite excited to come to the States for a year. He is not interested in a "historic" gallery per se, but in doing a thematic gallery with an historic approach. He will probably do one on "The Computer and the Image" that will open in November 1984. If all goes well, Oliver will come January 1984 and leave a year later. It is not yet fixed with his director so please don't talk about it.

Jamie, Beth, Meredith, Bruce McIntosh (designer), and I will be working on revamping the present materials to do an integrated historic exhibit (using video) and being much more involving. This will open (with luck) on May 11.

As the Chairman of the exhibits committee, I think it would be a very good idea if you would/ or could call a meeting sometime in the winter to review what we will be doing (before it is done). The best time would be between November 1 and February 1. We'll work out a way to bring you over.

Then I think that a meeting of the committee on May 13th - Saturday - to review Oliver's ideas would also be a good idea.

The committee is made up of you, Ken Olsen, George Michael, and Eugene Fairfield (who declined). See enclosed letter. I will see if we can get an alternative IBMer, or a least, I. Bernard Cohen. Any other ideas? Let me know your preference on this.

CBI Bibliography. I'm enclosing my critique. It was written on just an awful terminal that we had in Gordon's hotel room in California. But the job got done. We approached the same problem from different angles.

Books at the store. Books still make up 25-30% of the purchases at the store; but for the amount of inventory and diversity that we must keep any individual title moves quite slowly. Yet, we believe that this is an important element in our stock and perhaps over the years, people will get into the habit of buying from us. (But, I believe that your remark on books at Sturbridge probably were much less costly and technical books than we carry.) Books like Randell, History of Programming Languages, History of Computing in the Twentieth Century, etc. are not impulse purchases. The best selling books are: Computing Catastrophes ($11.95 paper); Soul of a New Machine ($7 paper); Discovering Computers ($10.95 for children); 101 Basic Games
($10 paper). But the people who find the historical book that they want at the museum are very happy.

Thanks for coming,

Cordially,

Gwen Bell
Director

June 6, 1983

Walter Safford
GTE

Dear Walter,

Delighted that I had the opportunity to meet with you -- even for such a short time.

We are very interested in your participation in The Computer Museum and that of GTE. In particular the whole area of applications is an important story that needs to be told. Without insatiable users experimenting and demanding more and more equipment, the progress would have been much slower and computing much smaller.

At the very least, we would like a good copy of the first computer generated telephone bill. Then we would like some ideas of what you think we might do to tell the application story. The time to do this is now, since The Computer Museum is planning its move to downtown Boston. I'm enclosing a copy of the press release regarding this move.

The move to Boston means that The Computer Museum will be weaned from its protective Digital incubator -- and must stand on its own as a generic museum for the entire industry. We have been very fortunate to have been able to get ready-made museum space at a very favorable price allowing us to make the move with a $5 million capital campaign in the fall of 1982. This will get us into new quarters with 55,000 square feet and provide a small endowment to pay off the Industrial Revenue Bond of $1.6 million (at 8.5% interest). Can we count on you to help? What ideas do you have? The Museum is at a very formative stage and your ideas will really count.

Looking forward to hearing from you,

Cordially,

Gwen Bell
Director
18 October 1982

Dr. Arnold Weber
President
University of Colorado
Regent Administrative Center
Boulder, CO 80309

Dear Dr. Weber:

I'm really sorry that I can't attend the dedication ceremony on October 26, but I would like to visit you the next time I'm in Colorado Springs. As you know, we strongly believe in supporting this kind of relationship and stand ready to help in order to set better training of engineers.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

In Macro Wonders From the Latest Micros, December 10, 1984, my picture appeared with a printed circuit board from what I believe will be an impressive, "multi". The above photo is of the founders and leaders of Hydra Computer Corp., a wholly owned Encore company, who did the real work and deserve the credit: Dave Schanin, architect; Russ Moore, head of hardware and Steve Chapin, head of software.

Gordon Bell
Chief Technical Officer
Encore Computer Corporation

In Macro Wonders From the Latest Micros, December 10, 1984, my picture appeared with a printed circuit board from what I believe will be an impressive, "multi". The founders and leaders of Hydra Computer Corp. a wholly owned Encore company, did the real work and deserve the credit: Dave Schanin, chief architect; Russ Moore, head of hardware and Steve Chapin, head of software.

Gordon Bell
Chief Technical Officer
Encore Computer Corporation
Mr. Henry D Pahl, Jr. Esquire
Kenway and Jenney
60 State Street
Boston, Massachusetts 02109

Dear Mr. Pahl:

Enclosed are the following documents which describe the Hydra Computer Hardware:

Hydra Architecture Summary Rev. 1.3 11/8/84
HydraBus Specification Rev. 2.2 4/30/84

Hydrabus Memory Specification Rev. 0.1 5/84

HydraSystem Steve Corbin Module Spec Rev 1.2 7/6/84 and
Chapter 3, System Control Card System Programmer's Guide
-essentially the same as spec, but from programmer view

Hydrabus DPC Spec Version 2.1 9/13/84 and
Chapter 2, Dual Processor Card System Programmer's Guide
-essentially the same as spec, but from programmer view

Hydrabus EMC Functional Specification Rev. 1.0 July 1984

I recommend that they be read in roughly the order given above. The first document is a user and marketing overview, but it does give a context for descending into the details of the other documents.
Rather than spending a lot of time looking at these documents which lack most of the details and issues regarding potential patents, I believe they should be studied in a cursory fashion to gain some familiarity with the computer.

In accordance with our phone call on 11/21, I look forward to the meeting at Hydra Computer in Natick at 9:00, on Friday, 30 November to go over the details of the design with the engineers who developed the product.

Sincerely,

Gordon Bell
Chief Technical Officer

PARALLEL COMPUTING

NETWORK - with LAN or WAN interconect
CLUSTER - with LAN interconect
FUNCTIONAL - one processor per function
CLOSE AREA NET CLUSTER - high speed interconnect
TIMESHARING - one processor per user
PARTITIONED - one processor per process
TRANSACTION PROCESSING - processor per transaction step
FAULT-TOLERANT - different processors assigned per step with redundant computation
CONCURRENT-TASK - parallel processing of a task by partitioning for independent data
PIPELINED-TASK - parallel processing of a task
PARALLEL PROCESSING - processors work on a single task

"If a computer understands English,
it must be Japanese."
-Alan Perlis

THE FOURTH GENERATION

- **Evolutionary use** based on traditional word and data processing, machine-aided engineering and manufacturing, and embedded computing
- **massive inter-communications** and **productivity needs** to increase use
- **well-developed technologies**, including powerful VLSI microprocessors, LANs, magnetics, displays and standard software
- **new organizations** to build new computer structures, but

- **new uses** that evolve from greater access won't be apparent for at least a decade

----

THE NEXT GENERATION: REVOLUTIONARY VIEW

- **Revolutionary use** depending on voice and natural language communication
- **sophisticated inter-communication and productivity needs** including robotics, speech and natural language,
expert systems to handle complexity and improve productivity
- **robotics**, and **artifical intelligence**,
fast-WANs to serve LANs,
based on **U- and VLSI and parallelism** technologies
- **avant garde organizational co-operation**
between researchers and industry to pioneer new computer structures

----

THE NEXT GENERATION: EVOLUTIONARY VIEW

- **Evolutionary use** with widespread **electronic mail** and **electronic-based logic** to encode knowledge (eg. CAD/CAM)
- **need to have information at "fingertips"** (in the system and not in papers and books)
- **evolutionary technology** with larger, distributed memories
- **new companies** to build with evolving technologies

A **GENERATION** is the convergence of:

- **need** (eg. threat of annihilation, greed) freeing resources
- **technology and science** that provide for building machines
- **organizations** that build new **computing structures**

- **use** to confirm a generation (after the fact).

LIMITS TO MICROSTRUCTURES

THE TECHNOLOGY PROCESS TO BUILD IT (e.g., instruments and robots)

DESIGNERS AND COMPUTER AIDED DESIGN

IDEAS FOR NEW STRUCTURES

LACK OF STANDARDS -- TOO MANY STANDARDS

ALGORITHMS FOR EFFECTIVE USE

EDUCATION OF INTERDISCIPLINARY ENGINEERS AND SCIENTISTS TO APPLY

MARKET SIZE AND USEFUL APPLICATIONS

COMPETITION FROM THE JAPANESE

Mr. Bell asked me to make sure this got out to you.

He dictated it and then went on a business trip.

Louise Principe

July 13, 1978

Mr. George Lindamood
National Bureau of Standards
Building 225, Room A231
Washington, D. C. 20234

Dear George:

When you and I set up Tuesday's appointment for me to talk informally with you and the Government's outside economists about what form the Government's proposal for relief in the IBM case, I was not aware of matters which now seem to make it inappropriate for me to talk. First, the company's lawyers are of the opinion that Dr. McAdams is a likely witness in support of whatever relief the Government may propose. Second, the company's lawyers believe that Digital, as a company, will be given an opportunity to present its views in Court as to what would consititute appropriate relief.

The significance of the first matter, as I understand the situation, is that the Court has the power to allow interrogation of Dr. McAdams as to his sources. As a result, I could become embroiled in "discovery" by IBM as to what I did or did not tell Dr. McAdams. The significance of the second matter, as I understand it, is that Digital might well want to present the Court with an affidavit as to my opinions as to what the future structure of the "computer industry" should be. From that point of view, the company might well prefer that I remain independent of Dr. McAdams' "data base" in preparing the Government's position.

I do not wish to appear uncooperative. While I and Digital may question the wisdom of instituting major changes in the structure of the computer industry, we will continue, to provide discrete pieces of information without legal compulsion. This willingness may even extend to providing the Government with a limited number of opinions as to the predicted course of events as to <u>specific</u> aspects of the industry; <u>e.g.,</u> projected impact of fringe developments, such as videotape. However, any such expression of views would be a company function, not an individual one. As in the past, any information provided to the Government would also be made available to IBM.

I personally regret that Tuesday's meeting was not the constructive one which we had foreseen. Both sides were trying to adjust to unforeseen developments, which is always a difficult task. From my point of view, I expect our relationship in standards and commerce to continue and I look forward to an exchange of views on the Japanese computer and semiconductor industry after we have both returned from Japan.

Since our discussion I have re-read the first three chapters of my forthcoming book on Computer Engineering. I believe they give the basis for many aspects of the view I was thinking about. I would be happy to forward to you a copy as soon as it's available.

Again, I'm sorry for the inconvenience.

Sincerely,

Gordon Bell
Vice President,
Engineering

Dear George:

As you can see, I've changed my affiliation. Please change my address accordingly. I'm enjoying your observations about Japan.

I hope your're getting lots of input from the various corporate visitors there. Let me urge you to establish a strong tie with DEC Japan. This can best be done by interfacing with Grant Saviers who the Tokyo group reports to.

Your observation on the 5th generation effort is really correct. More important, I believe, is that Japan has correctly called out the future and have said they'll challenge all comers to race for it. In the past, we have never raced for or even admitted that there was a long range target in computing. While this is significant in itself, the main effect of the project is that a dialog has been opened up with the rest of the world that did not exist. Now they're able to get some real insight, intelligence and feedback about computing which they do not know possess to any degree. In contrast, even today, the Japanese have been late into the PC market which I think is due to a fundamental lack of understanding computers. The project has sucked us in to not ignoring them, and forced us into a race that's structured on terms that are clearly not to our advantage!

Sincerely,

Gordon Bell

"ARCHITECTURE OF THE LISA PERSONAL OFFICE SYSTEM"

Mark Cutter
Brad Silverberg
and Colleagues

Apple Computer, Inc.

Thursday, April 14

1:00 - 3:00 P.M.

Pierce Hall 110

ABSTRACT

This seminar will give an overview of Apple Computer's newly released product, the LISA Personal Office System. It will begin with a live demonstration of the electronic desktop user interface, followed by a three-part technical discussion of the underlying architecture.

Demonstration of the electronic desktop user interface will illustrate use of the mouse, multiple overlapping windows, document filing using icons, integration and sharing of data among the five major applications, as well as selected features of the applications.

The first part of the technical discussion will detail the architecture of Lisa's most distinguishing characteristic, its innovative graphics sybsystem. Two challenging problems were meeting the speed requirements of an interactive system, and developing a window manager that both multiplexes events and efficiently handles non-rectangular screen updates. A variety of graphics primitives had to be supported, as well as high-resolution printing.

The second part of the technical discussion will cover interesting aspects of the hardware, including constant linear sector size of the floppy disk drives, softpower-off and disk eject, and packaging. It will also discuss details of the in-house developed, single-user, multi-processing operating system.

The third part of the technical discussion will describe the Pascal-based development system used to write LISA applications. The interchange mechanisms developed to support data sharing between applications will be discussed, as will be the Lisa Toolkit. The Toolkit makes it easy for third-party developers to write software integrated into the Lisa Office System.

HIGH PERFORMANCE AI

Given the (hopefully) blazing speed of the 2080, we should re-establish ourselves as the leader in this market. The irony is that the six targetted LISP, and now, 20 years later, LISP appears to be coming into its own. Right now the AI researchers need this because they've run out of address space and are switching to the Symbolics and LISP machines built by new startups. The machine will get faster and approach a KL. Thus, it's really important to get a LISP without memory limits AND a much faster machine to address new problems. This will "get" the AI market at many sites.

PERSONAL LISP MACHINES

Symbolics and LISP machines are making merry. Ironically Symbolics is evolving their machine for Fortran, C, Pascal etc. as their customers need it.

Also, Symbolics notes that the machine's special memory management functions are being removed and put in software as the microcode is too inflexible.

Similarly Xerox, PERQ and Appollo are probably heading to sell LISP.

We need LISP on a personal VAX and it also requires the high resolution VT - (Agate, Onyx, Opal) terminals to support it.

Loc: ML12-1/A51 Ext: 223-2236

follow up 2/7/79

The GIGI terminal you are considering marketing might have the BASIC chip designed by LLL in it. This brings up two interesting questions:

1. With the press to the strategy of distributed processing based on a standard set of languages and architecture, is this version of BASIC we would buy from National and designed by LLL an exact subset of DEC BASIC?

2. This is further support of the 8080 ISP which we agreed not to do. The first policy was a set of fixed programs which shielded users from investing any programming in the 8080. While this was targeted at doing anything that made the 8080 visible (and investable) to field support and our users, putting out this BASIC gets closer to this region.

Assuming the product is crucial in the time frame and that we aren't going to get Tiny in time, I would feel we could still have a viable and good strategy if the LLL BASIC is a <u>true</u> subset of DEC BASIC.

What do yous think here?

Livermore, California 94550

Dear Dr. Michael:

Gordon confirmed what I related to you. He hasn't received the CDC6600, 7600, Star, or Cray pieces. He is still most interested in them.

Gordon sent you a copy of his new book, "Computer Engineering" via Roger Anderson yesterday. Hope you enjoy it.

Sincerely,

Mary Jane Forbes
secretary to Gordon Bell

SUBJ: **Los Alamos/Livermore Labs Conference on High Speed Computing and Some Action**

TO: Distribution

Date: 4/8/81 Wed
From: Gordon Bell
Dept: OOD
MS: ML12-1/A51 Ext: 223-2236

EMS: @CORE

George Michael and Bill Buzbee put this three-day conference of about 100 people together to communicate among LASL, LLL and a few other users, some academics (Dennis, Kuck, Fredkin, Schwartz) and builders (ACSYS, Amdahl, Burroughs, CDC, Cray, DEC, FPS, IBM, SEL).

Summary

VAX is a support processor now in this part of the Technical Market. Scorpio, at 780 power, is a pivotal machine because it could provide many scientists with personal computers of Cray 1 power since only a few get at most one hour of Cray 1 time and a 780 is generously regarded to be 1/25 of Cray 1. They want a bigger VAX from us (and SEL is going to soon announce a 3 x 780). They also understand and want VAX architecture to support:

.
vectors
.
multiprocessors and
.

interactive computing with very good graphics

<u>Their Messages</u>:

. High speed computers are vital to our defense/energy needs.

. They want bigger (more memory), faster (2-5) x Cray 1, compatible, easier to use (interactive) computers. Their desires are a factor of five. (During the 70s they got only 2-4 x performance [Cray's 6600, 7600, Cray 1].)

. Seymour Cray could solve their problems if he believed in caches for large memories and virtual memories. They ran out of physical memory, since they use them timeshared.

. Interaction means: being able to see what's going on via graphics, being able to guide the programs, and being able to stop them before they compute too much nonsense.

. Graphics, including color is vital to their computing.

. They believe in (want) vectors ala Cray and CDC 205.

. They believe in (want) multiprocessors even though they have no experience with them.

Tidbits:

The Japanese are coming with a 3 x Cray 1-5 in 1983!

SEL will announce a 3 x 780 ECL 10K in April, delivery July, upward compatible and using old peripherals and memories. They are 60 percent OEM in n.s. mini market, selling 600 machines @ $200K for $120M revenue. No vectors. A uniprocessor. Len Hughes is responsible for hardware, software, and manufacturing.

FSP ships about 600 floating point processors @ $70K. Their new machine with 64 bit floating point might get up to 40 mops with 20 mips at a 50 ns cycle. This is 3 x faster than now. About 75 percent of their machines go on DEC hardware. They are planning to connect to the DR780. This is wrong. It has to be CI! It will take them 14 months after they start.

Carl Amdahl was there, but Gene was out raising the rest of the $100m they need to get ACSYS going. CII-Honewell - Bull invested $8M and have access to their semis. They are going for large, ECL gate arrays not CMOS. They would like to talk with us about a joint venture whereby we could also use their technology.

Bob Barton was there, having just resigned from Burroughs. His notable quotes:

"I quit, but I think they'd have fired me. I never did like cigars."

"My only vested interest is in change."

"Blumenthal's rebuilding Burroughs from deadwood."

.

"Burroughs will probably end up as a front for a Japanese corporation."

.

Burroughs (Blumenthal) had just stopped work on the BSP, Burroughs Scientific Processor. They've stopped work on their high speed semiconductor circuits.

.

John Cocke, Herb Schorr, and several others from IBM were observing. John has built a hardware box to assist in simulation. IBM is really pushing on design turnaround!

John asked me about the effort on the HP 450K transistor chip - we agreed it was approximately 75 man years. He replied, "Boy when those folks learn about computing, we'll all be in trouble"!

.

IBM is adding vector to the 370 architecture.

.

CDC is bidding on a super computer for NASA wind tunnel. Their designer, Niel Lincoln believes they can get 15 gigaflops. The gestation time CDC is aiming for is 4 years on these very large computers.

.

Jack Dennis talked about data flow machine. He benchmarked it on the weather problem. He posited a machine with only 3000 chips (including memory) that would be 100 x Cray 1. I want us to help him build it _if_ it can be built.

.

Dave Kuck, University of Illinois, described their program used to analyze various machines and programs for parallelism.

.

Tim Rudy suggested their VAX might be 1/25 of a Cray.

.

Barry Oliver of HP confirmed they were putting together a first class research lab for computing headed by Joel Birnbaum. Jim Bell is the liason to the development groups. They are putting $20M/year incrementally into this ASAP! Sounds like we should sell 'em machines. (I'm glad we're 10x as bright and more efficient.)

Action

1.

Connect the FPS via CI - we should decide that CI is a public interconnect and get the FPS Array Processor connected to it. I'd like this cleared in our bureaucracy so that when their VP of Engineering visits here in May we can get him to describe the FPP and outline how to connect it to VAX via the CI!

It could be operational as early as June '82. This will both help against SEL and also let people build high speed systems. Bill, can you get someone to take charge of this now?

2.
780mP for Performance Systems - must sell both labs on installing quad processor 780s. We have truly good hardware for it. I believe they are fundamentally convinced that they need this experience before going on to building Quad Supercomputers. (It could also be useful against SEL). This also gives us another shot at getting performance without a technology investment. It also prepares us for Scorpio.

3.
VAX Software Against SEL - software is another way to hold off SEL (and future IBM). I believe we should direct our work at graphics, debugging, control of multiple processes by simultaneous viewing of many parts of an active program etc.

4.
Accelerate Venus - SEL's going to be a pain. We must speed up Venus by:

.
getting it right in the first place via simulation of whole machines not just the MCA's. Ulf should look at our simulation effort which seems to be of questionable use. Tom McWilliams will visit in May and review how they've simulated their new machine (at 7 sec/50nsec clock).

.

getting a Multiwire facility so that we achieve our One Week Turnaround Goal. IBM has many of these in their facilities for prototyping and possibly some production...let's follow! John Cocke, one of IBM's brightest computer scientist/engineers believes it is the best way to build high speed machines. It's more dense and easier to work with then PWB's! We must get into a
non-proprietary higher level language quick. Note BLISS doesn't let us move our CAD tools to other machines such as Cray when we need the speed.

5.

Scorpio - is super vital! At the same power of a 780 it represents a great machine, and an alternative (I believe) to a Cray 1 for many scientists as a personal computer. Note that since a 780 = 1/25 of a Cray, and since few get more than an hour a day, this is an enormous amount of computing. We should also get Scorpio to be used as a quad processor for larger computer. This is why the multiprocessor experiments at LLL & LASL are essential.

6.

Amdahl's (ACSYS) Technology - Ulf should take the leadership in obtaining ACSYS technology.

7.

VAX Architecture Enhancements - for high performance vectors are essential! I'd like to have Bill Strecker convene a small group to do this. The most elegant way would simply be to put 16 vector registers of say length 64 as extensions to the 16 Scalar register sets and have all instructions that are Scalars be vectors of length n specified by some register.

Lloyd Dickman, Dave Kuck, and these folks should all be helpful critics. This seems essential to have VAX vital as a technical machine. Note if we build something that will have a 3-10 x speed improvement for vectors over Scalars, then assuming a given problem can use vectors 75 percent of the time, then this gives us a 2-3 x speed up. (A paper is being sent around.)

8. Dennis' Data Flow Machine - this is the first time this made sense. Jack is going to meet with us in Marlboro, on April 14 in the afternoon. Sam and Ulf should sponsor and invite Ivan Dobes, Dave Cane, Dave Orbits, and others who are interested in high speed machine. I offered to build several chips for him, if he'd design them - presumably using 4 micron HMOS. This would also help get FTA working. If there's a good idea, I'd like to build the machines.

Bottom Line (Technical Leadership)

I don't think we're driving our resource allocation right. The Technical Group is selling 70 percent of the machines and we run a high risk of losing this market by not driving VAX hard enough in this market. We have to change! In retrospect, IBM gave up the university market as they went totally commercial. There appears to be only a few unique features for this market, and we're spending money that appears to go after the more traditional IBM commercial business.

Let's get Scorpio, plus go for these changes:

Technical	Commercial
+ Multiprocessor	slow down Hydra
+ Architectural enhancements	
+ Relational data bases	less TPSS
+ Graphics uniqueness	

We must get a way to measure the dimensions of VAX so we can allocate resources explicitly, rather than implicitly. Some dimensions:

. real time

. security

. files, data management

. programming environment (productivity for various user classes.)

. user interface, including graphics

. languages (commercial, technical, both)

. network and distributed processing

Mr. George Michael
Lawrence Livermore Laboratories
University of California
Leader, Computer RES Group, L-76
P. O. Box 808
Livermore, California 94550

Dear George:

Thanks for the presentation to the Alpha Omega group. I think we covered a lot of ground, and the work looks interesting.

I am concerned about your priorities. I hope there's some way we can help get some multiprocessor work started there in the next few months before you are faced with TWO new multiprocessors (CRAY 2 and S1) that you're supposed to use. I find it impossible to understand why you are not doing the basic work on a real machine such as the 780 multiprocessor, with 4 processors, when the machine has been available so long. It would seem that it would make sense to leave the farther out work on Dataflow to the universities until you get this basic work done. Therefore, I don't have much sympathy with the statement that you have no people to do the work. Anyway, so much for the free advice.

Since I've heard so many concerns about the S1 in the form of rumours, I was happy to visit it at last. Based on the brief presentation and confidence of Tom and Lowell, I am quite impressed and supportive of the machine. If they accomplish their plan of the IIA, moving to multiprocessors and the III, this will be a major accomplishment.

Again, thanks for the hospitality.

Sincerely,

Gordon Bell
Vice President of Engineering

GB3.S8.44

15 November 1982

Drs. Lowell Wood and Tom McWilliams
Lawrence Livermore Laboratory
University of California
P. O. Box 808
Livermore, California 94550

Dear Lowell and Tom:

Thanks for the hospitality and fine dinner when I visited San Francisco and Livermore last week. I especially enjoyed the visit to the S1.

Since I've heard so many concerns about the S1 in the form of rumours by people outside the project, I was happy to visit it at last. Based on you brief presentation and confidence, I am quite impressed and supportive of the machine. If you accomplish the plan outlined in your talk (the IIA, multiprocessor IIA's and the III) this will be a major accomplishment... comparable to a "Cray". The wafer based machine, of course, is exciting too, but beyond my visibility.

The innovation in the machine and design tools is really exciting, and almost independent of how well it performs across a wide set of benchmarks, it is worthwhile to build the S1. Like vectors, it may take users time to fully use the fast, built-in functions. I am especially sympathetic about the issue of building in so much into an architecture using microprogramming at a time the world has just re-discoverd simple, hardwired, Cray-type machines (RISC,801,etc.). With VAX, we also tried to build in all the necessary functions we could for the price. It will be interesting to see the comparative benchmarks because the Cray and S1 are so different in structure, and basic clock speed.

Again, thanks for the hospitality. I trust the world will know when it starts running. If I can be of any help, please let me know.

Good luck,

Sincerely,
Gordon Bell

SUBJECT: LNI/REPEATER BY THANKSGIVING

The LNI's trivial groups are meeting. Please stop all meetings and
ask the attendees to come with breadboards within 2 weeks! We don't
want an optimum design. We want a design. To not have a breadboard
is a disgrace.

After the 2 weeks, set a deadline for the repeater of 1 more week.
Get it out.

I expect to be running these by Thanksgiving 1981. At the demo, I'd
like to discuss the gateways too.

DRAFT 8/21/80 Thu 3:25

Digital Computing Museum
for the preservation of computing history.

PROPOSED PROGRAM

Collections and archives: maintain 50/50 DEC/non DEC--triple number of artifacts shown and stored. Develop a catalog.

Tours and visitors: Move from an average of three special tours per week (Fall 80) to three special tours per day, plus a large number of ad hoc tours.

Exhibits:

Ground floor lobby - Set up with permanent exhibits.

Elevator spaces -- Established for travelling exhibits that will change.

Stairwell -- Established with a time line of the history of computers -- with computer portraits and appropriate artifacts starting with 1936 to the present day.

Corridor to cafeteria -- Expansion of pre-computer computing device exhibits.

TX-0 and Whirlwind exhibits

enhanced and documented. TX-0 should run with demonstration programs that are documented with video-tape before it is once more decommissioned.

Software - incorporated and explained in exhibits.

Computer art. The Cohen mural, painted in 1980, will be complemented by a second mural in 1982, and a piece of computer generated and user activated music in 1981. Art will be added on a yearly basis.

Viewing room on triangular office with full set of 10 one-hour video tapes of pioneer computer lectures and a number of 10-15 minute audio-visual user-activated tapes including the Whirlwind film, the EDSAC film, the logic talk, the calculator talk, the LDP talk, and a film on how the Cohen mural was made.

Museum store will have moved from the lobby desk to the second triangular spaced room and will serve the visitors and Marlboro working population with books, audio and visual tapes, replicas of calculating devices, photographs, slides, postcards, posters, wall charts, and various computer history and computer user articles.

Events:

Quarterly pioneer computer lecture series will conclude with the tenth machine and the second series will feature pioneering software efforts.

Yearly event on computer and the arts.

Yearly event honoring a DEC history-making object, e.g., the April 80 VAX party. Other candidates: 20 years of 36-bits or 12-bits; or CAD; 10 years of RSTS, RT11, M, the LA's, VT's, Disks, DECnet.

Alumni gatherings for the TX-0 and PDP-1 to run programs and do video tapings.

Bi-annual event with publication of each DEC Press book in the history series.

Occasional scheduling for meetings for educational groups, eg., Sept. 27th meeting of ASTC committee preparing an exhibit on "The Computer in the Pocket." Suggest CBI board meetings, and other groups hosted by museum.

Gordon Bell, Keeper
Gwen Bell, Assistant Keeper

To kgf staff, dudley
Subject: An interesting, immediate product: Designing High Quality Software

Lou Cohen has been engaged in teaching various software quality courses for the last several years with a great deal of success. The software comes out faster, has fewer bugs, meets specs, and requires less maintainence. While his teaching has been confined within a company to a very large number of hardware, vlsi and software engineers, he has a following outside too. The world is starting to ask him to give the course(s) full-time outside.

I propsed that he form a TRAINING COMPANY within Encore to do this. He has a partner, perhaps who'd attend to some of the administrative aspects. The two of them might take on the whole training for dollars bag, and get going now. The investment is such that we could get a payback in a month or two. Also, it's something that the sales force could sell.

Like any disciple of Demming's, he has a certain fervour and zeal. He's thinking about it, and before proceeding with us at all would like to understand if we are committed to quality from the top, down. Thus, everyone has to take the course, which we'd give for 1/2 to 1 day on the weekend. I agree with him!

The courses he envisions:
1. Introduction to Quality (ie. Demming) 3 days...
2. Introduction to Sofware Quality or Software Quality Workshop 2 days
3. Introdctuion to Inspections (for quality) 2 days
4. Overview (all 3) in 1/2, or 1 day
5. Combined course in 3 to 5 days

This could be started up within a month, requires only the printing of some course materials and an edited videotape from the Demming course. 15 Walnut could house the lectures. There's the usual logistics, PR, Sales and Advertising.

I think it presents an interesting and unique opportunity as our first deliverable product. What youse think?
.
9/20/78 Wed 14:31:15

Type up GB 3x5 card for 9/26 and leave on his phone monday. Clip PS memo & Marriot invitation to it. Other backup for 9/26 also attached here, but don't give to GB.

Check Ulf/Leng on GB going to Leng's staff--what time (hopefully around 7:30 as he does have his Jungle meeting). Where--Marlboro is probably best.

9/26 he is at PK3 all day--it is a tight schedule, so don't schedule anything else that day.

Marilyn Arbuckle has made all the arrangements for Monday. If you have any questions, she said she would handle it.

mj

Subject: **Let's Now Go Get the Low Cost Alphanumeric Terminal You Killed**

To: Carl Gibson, ML5-2/M11

Date: 10 OCT 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Congratulations on killing the above terminal! You have succeeded when I failed in being able to stop the expensive IPG terminals that are nowhere near their sales plan, and create and perpetuate what will ultimately be an abortive, but is a low volume, high cost interface.

Having failed to stop the PDP-14, nearly all the graphics scopes (with little or no software or way of using them) and many other losing basically CSS products outside of CSS, I envy your lethal ability. Much corporate money and pain to our users would be saved if you can impact your secret to me.

Unfortunately your action on this product is opposite to my feeling and given the history of IPG products, I believe you are again wrong. The product is basically right, necessary for our users (not necessarily for us to build) and will become a fundamental part for use. The price will decline based on the LEDs and the cost, due to lower power, the small interface, and basic simplicity. The only condition that you could be right is that the product is so basic that it will be in such high volume to become a commodity, and hence we can buy them very cheaply as components. But then we still have to resell them and tailor them; however, with commodities we end up selling the system and someone gets the terminals so we do need some control, and it would be nice to get the profit too.

Basically in your decision I don't think the real users are identified very well because you don't have an understanding or view of what users do or could do with our computers (especially if we make TRAX go!).

My belief about high volume use:

1. TRAX will spawn an incredible demand for terminals because all transactions need to be captured. The easiest way is to give every "transaction maker", i.e., person, their own terminal. We'd program the multidrop protocol.

2. We would use it universally as lower cost consoles on all peripherals (e.g., Mass storage drives and subsystems) and computers (remote consoles).

3. Perhaps the most interesting use is as a standalone computer! Here the users would do all the things that require alphanumeric i/o. There are a number of these uses and each would be sold as specialized calculators are now. Here we'd need a plugable rom and special keypad to do the "tailoring".

4. As an appendage to a phone doing a number of control and data entry tasks. Here some non-volatile memory is probably also required.

Since there isn't an internal product interest, and since it is clearly a commodity like thing, and since we could probably use them internally as products, should we get some outside? Who (e.g., TI)?

Q. Can we handle the market?

A. It's big and vast, and soon to be totally semi-vendor dominated with their attendant agressive development, lots of $ in development, lower profit, and faster turnaround. They may be too fast moving and too low profit to compete with.

Q. Is it safe to say that we should either get our act together here, or forget about this market?

A. The problem may be that tomorrow's microprocessor is today's minicomputer, and by not participating we may lose if we aren't able to continue to convince our customers they need our high overhead support versus the dedicatedness of the micro. In essence, we're to SiValley as IBM is to us.

Q. Have we missed the opportunity by either offering our small microprocessor (e.g., the 8) or dominating by packaging other microprocessors (e.g., 8080, 6800, 9900)?

A. Not clear it's lost yet...although it's fading rapidly. If we'd employed the module business to hold it, buyers may have moved to the semi-vendors to eventually get chips...not just software, boxes, and boards.

Q. What's not together?

A. We only have a product at the high end sum-of-boards level, and also at the system level (11V03), with no way to beat the cost (the expensive chips, bus, and green blocks) at lower levels of integration. It protects low end of mini-box, but is miles away from micro market of boards and chips.

Q. Why not use the 8 at the low end to go against INTEL, et al.

A. I don't know; but, since we don't sell chips we could steer users to INTERSIL. Also, I still fail to see why we don't permit WD to sell 11 chips. Does anyone else know why we don't?

Q. What would an aggressive market/product posture look like?

A1. Selling. Significant self-selling catalogs. Application engineers at the chip level. We would put on microprocessor courses including video/cassettes to get the info out widely. The universities and technical school training market has to be addressed so they do the education/selling like they did with minis. A recent survey showed we had only 5% activity in universities and trade schools and were a recognized micro. SiValley vendors are selling that we aren't a micro, but a mini!

A2. Software - Here we are doing nothing, but waiting for Silicon Valley to hire our people, build forces and attach us. We could build a superset of PL/M...following INTEL, or we could move people to Fortran, BASIC (not very good) or Pascal! We must have a product/direction! I don't have an opinion.

A3. Chip level products - We don't sell here now. We would offer 8, 11 as chips and work with both INTERSIL and WD to be high quality chip suppliers to the world...or we can try to kill them like we've been acting! More significantly, we have to either have compatibility with INTEL or Motorola at the bus level, or agressively go after the 1 chip interfaces needed to build small systems. These 1 chip interfaces include: UARTs (including DDCMP support), floppy controllers, display generators, digital i/o, and analog i/o so that a user can build a system up from chips easily.

A4. Board-level products - Our option list is sparse compared to semivendors and the box vendors (MITS, Prolog). We probably have to consider board relayout to get over green blocks and large pin count that limits us. Also, we could supply all processors (8, 11, 6800, 8080) on boards! For now, we should migrate to a Q-bus only to get volume with Q-Unibus conversion! Let's use the OEM channel to get volume for our end-user lines.

A5. Systems/Box level - We're doing a lot (e.g., 11V03, Boxes, Krypton) but probably have to do more! More would be:

1. Design/Debug system. Appropriate interfaces so a user could design and debug his system in the same way INTEL has ICE-8080.

2. Manufacturing Test Systems. This is a new idea! We would support users who build with our chips, boards, and boxes so they could test their systems in manufacturing!

A6. Applications-level products - In essence we need a testimonial (e.g., LSI-11 in a suitcase) that one can build products at this level. What are some alternatives?

A7. Organization - I believe the development groups are sufficiently diffused (Teicher, Moffa, P/L's) and defocussed (e.g., Teicher has many levels-of-integration as his responsibility). Similarly, there is not clarity in the marketing.

<u>Q vs Toby</u>
I'm still for the "management bounding" terminal for the Fonz based on the Q-bus approach instead of TOBY. Two new reasons beyond my earlier memo (see attached):

1. We're doing the VT103 already. That gets us well on the way. Otherwise we duplicate products.

2. There are/will be some useful fall out modules of using the Q-bus approach.

<u>White Tornado</u>
Please, please, let's make the VT162 be done with the White Tornado. This gets us volume and 1 less product. Also the WT costs less than the VT162.

Jerry Witmore has interest in a low cost <u>Basic</u> terminal. WT is pretty good. Can he use it?

To really get low cost <u>with</u> Mass Storage, the TU58 "cached" by a few CCD chips is best. Let's do this and really get a high performance, low cost terminal to beat out the floppy-based ones.

Proposal for a LOW END TEAM (LET)

PROPOSAL
Form an integrated marketing, engineering and manufacturing team for >100K/year, <$2.5K, CT, VT and LA products and components.

CHARTER
The team will develop, build and market our current terminals, and evolving computing terminals, including stand alone Word Processing products (ie. 278), and possibly other low cost products (eg. 11/23). Within the group there would be clear segmentation and responsiblility for the kinds of terminals, computing terminals and applications.

Market/Product Priorities:

1. Protect terminals video (VT) and printer (LA) market.
2. Enhance DEC-host systems via CT's, VT's and LA's.
3. Stand alone word processing
4. Workstations for DEC and non-DEC systems.
5. Small business systems.

MOTIVATION: PROTECTION OF TERMINALS AND 16-BIT PLUS EXPANSION
The group is predicated on the fact that we must move rapidly to support our terminal base that will be totally eroded in TWO years

by personal computers! It is also essential to provide an aggressive alternative to our 16-bit, shared systems. WE MUST MOVE FAST AND UNINCUMBERED!

Similarly, the shared, group-level systems must focus on lower costs too, but with support for our conventional RSTS, RSX-11 and RT systems which are characterized by larger size, sharing and more support. The 16-bit Group must concentrate on competitive, 16-bit boards, boxes, and systems for our oems and end users.

Low end (personal computer products) have one user for each computer sold, versus being timeshared with dumb terminals. They are much higher performance in terms of user interface, and they are customer installable by non-computer users. Eventually, clustered systems may offer capabilities similar to our current, shared sytems... we'll worry later.

RELATIONSHIP TO OTHER PRODUCT LINES
All other product groups may take the low end (personal) products at transfer cost and market them as appropriate (eg. bundled into systems, in quantity) on a case by case basis. Unique software or hardware would usually distinguish the products.

RELATIONSHIP TO OTHER ENGINEERING GROUPS AND PRODUCTS
Most resources will be directly controlled. The group would typically contract projects with the semiconductor, mass storage and software groups. Similarly, Word Processing software that would support the OFFICE Program would be done by the OFIS group.

The group would be responsible for providing competitive terminals and personal computers to the various computer groups according to clear, architectural specifications.

Proposed Organization

WF                  x        x      x
Phoenix                      x      x
```

(Terminals and computing terminals are in three plants. They are fed by lsi, modem, board and mass storage plants.)

```
PRODUCT LINE COUPLING
TPG                 x        x      x
WPS                 x
Technical groups (especially graphics, rt)                  x
             x
```

?
Commercial groups (especially forms, graphics)? x

(TPG might be the highest volume channel, but with the change to Computing Terminals from VT's, all VT/LA selling product lines will end up selling CT's. Furthermore, applications programs will evolve to the terminal and be an alternative to current, shared systems.)

SERVICE COUPLING
The hardware service techniques are common. CT introduces software support not present in dumb terminals.

SUBJECT: I WANT HELP TOMORROW ON THE LOW END; ALSO SOFTWARE FOR IT

Pursuant of our discussion tonite, and considering where we are
on this critical project, I hope you can work on it tomorrow with me in lieu of going to the seminar. There are a number of issues relating to the disk availability, its interface, and getting the right resources on the project (ie not too many and not too few).

Will talk with you tomorrow.
gordon

ps

Dick,
You and I should go over the software options... cause there are really a lot we can go for in the short term. This entails getting together with BJ (but let's keep this outside
of the hardware project as there isn't a need to interact with
it!). To name a few of the options:
1. get Ollie Stone really working to acquire for the 11 low end on pdt
2. get Thissel to buyout and/or find a way to get oems helping
3. Jake and Dibol on the 11 which he is using on PDT-150
4. PDT as a down line load, that Gil Steil has done
5. Packaged RT things like Basic, or interactive Fortran
6 Word processing that is being done for the new terminal
7. other p/l specific stuff.

Somehow we have to focus this effort around collecting and then marketing. Maybe the store is the vehicle and we can do it now using our 7500 pdt150s we have in inventory! (Note our 20VT200 with t&e floppy is exactly equivalent to the PDT150
we have in inventory. We need some creative packaging and ways of distributing. Let's get these together and go see Stan about moving what we can demo.

(See Distribution)

Why not this policy for semiconductors? (Basically it's the Make vs. Buy issue)?

0. Overall, if we can buy it, do so. Only make (design and manufacturing) what we can sell, not what we can buy! See the attached.

We have far more needs and opportunities than we can build proprietarily, therefore, we must chose carefully, and leverage to get semiconductor and semicomputer companies to do as much as possible.

1. We want proprietary parts only where we must have them - in the CPU part mainly because they're to sell (e.g. Tiny, Fonz, LSI-11) and not available outside; or to get unique performance (MCA); or cost/performance (COMET). Get others to make our processor chips (e.g. Jaws, 6120) when we can.

2. We need to be competitive in several technologies or else it impairs competitiveness at the systems level. It would be nice to excel in one technology and acquire the smallest number of processes in

other technology areas.

3. We must use external parts from Semicomputer companies* whenever possible (e.g. Comm. options, floppy controllers).

4. We should get (build or buy) special interface chips so we can use standard peripheral parts as much as possible to get the lowest cost systems; and

5. We must get as many proprietary parts as possible to be

done externally (e.g. disk parts), giving up proprietariness (unless it's the 11 or VAX-11 Architecture) when necessary to get cost, availability and a good supply.

6. We must go to fast turn around design to get cost reductions only when 4 and 5 aren't available.

7. We must keep a good watch to determine our competitive position (cost, performance, or cost/performance). If we are clearly failing by falling further behind in an area, we must act. For example, in the low end we can consider: doing more, getting outside proprietary, or switching to a non-DEC ISP (especially when we don't rely on or need our software base).

*A Semicomputer company (e.g. Intel, Xilog, and TI?) is a company that predominately supplies semiconductor parts that are computers and computer options selling at chips, board, box and system level. They feed OEMS that often compete with us (e.g. Apple, Tandy, Olivetti).

SUBJECT: AN AGGRESSIVE VT AND SET OF LOW COST CT PRODUCTS FAST!

We would like to meet Friday morning at 8:15 to begin to address how we are going to get an aggressive set of low end terminal and computing terminal products. Please come, together with no more than a couple other technical persons.

At the Operations Committee Woods on Tuesday and Wednesday, we looked at the Product Strategy and position in the Terminals and Computing Terminals. We are concerned with our competitive ability, and would like to go for an aggressive product introduction schedule to address ALL the competitive holes and issues surrounding the products we are building. The concerns:

1. A low cost VT100 replacement based on the computing terminal components (monitor and keyboard). This would be a VT100 and hopefully upgradeable to a VT125. It should have a modem as

an option. It would most likely not be based on a Tiny, nor would it be programmable.

2. A package with power supply for a small computer board, or perhaps 2 boards at the most, that would be used to build:

2a. The lowest cost and best 11 system to execute the OBM!

2b. CAT ... Z80 with option for 6120 or Tiny.

2c. A board for the 278 SW.

3. SW that will run OBM and CTAB competitively:

3a. OBM and CTAB files must be identical and OBM must be layerable on CTAB

3b. CTAB must provide a basis for layering PL SW, eg. COBOL.

3c. We must be able to use CT as a VT125

3d. We must show that the OBM/GOM development group is properly organized and motivated, given the seperation of the groups. We should address architecture, PM, the direction, etc.

The package for the CT25 will be reported on Oct. 5. The other items will be discussed at the Oct. 15 Woods. Item 3 will be discussed on Nov. 2.

The schedules for the products are:

VT100R	July 1, 1982
CT25	Nov. 1982 (concurrent with the Office software)
CT278	asap, negates need for RX50 repackage
CTCAT	no goal until ROBIN is introduced

ALL PREVIOUS PLANS ARE STILL IN PLACE! We are entering an intensive period of phase 0/1 to EXPLORE, DEFINE AND BREADBOARD
SEVERAL ALTERNATIVES FOR EACT OF THE ABOVE.

On Friday Morning, We would like to meet with you and several of
your technical designers to discuss the above 3 items. I expect
that items 1 and 2 will take until 11 am. Then I would like to
discuss items 3.

TO: see "TO" DISTRIBUTION

DATE: THU 3 SEP 1981 22:02 EST

FROM: GORDON BELL
DEPT: ENG STAFF
EXT: 223-2236
LOC/MAIL STOP: ML12-1/A51

SUBJECT: INTELLIGENT AND COMPUTING TERMINALS FOR OC WOODS

Ken wanted to go through the whole list of products in this low end space and conceivably add these:
vt 50/52, vt100, vt101...vt131/132 (feel like losers)

11/03, 11/23 rx and rl, Shoebox.

The object is to find out whether any of them made money. We should also understand why they have not made money as one could safely predict they haven't. Perhaps the only exceptions are the CSS products that have achieved low volume, but are priced high in a product price controlled environment.

The attached memo gives a listing of the various attempts, and while we might spend a great deal of effort precisely defining the failure, I don't think it is worth doing it on anything but a qualitative basis. In addition, we should be aware of the tremendous need for software and the perception that we are going to supply software forever when we put out a new system. This is clearly why we have trouble selling 8's... and why putting out a system that would also run 11 code might just make the system really saleable, independent of whether we ever supplied any software for the 11.

Potentially we have a new zoo of operating systems which we will be obliged to support and enhance:

PDP-8
- wps
- dibol for running business packages

PDP-11
- RT/Dibol
- RT/for programming environment
- CTAB based on M for CT ... which really looks competitive
- UCSD Pascal (recall that this was originally written for the 11)
- UNIX- also available for the 11 and we should make sure it will run on future hardware. While it runs on a Fonz, it really would prefer a J.

Z80
- CP/M ... can we confine our software to what we can just simply convert and run so that we do no programming, but merely publish what's available.

I would like to limit our exposure and have a pretty clear policy on the programming environments we support.
Specifically:
PDP-8
 all applications in DIBOL. Do enhancements if wps 278 can
 support them via sales. This will depend on the reception to
the product announcements of OFFICE.
PDP-11
 CTAB will be the main basis, and provide programming environments
  for BASIC, UCSD Pascal, FORTRAN, and DIBOL
 RT (support only)
 UNIX-make sure it runs well on all 11's now and forever
 UCSD Pascal- make sure it runs well, but try to encourage
  the support on CTAB instead
Z80
 Only convert (not program) available programs on a pay as you
  go, business basis.

Right now we're off inventing two new systems for the lower end below CT, in addition to the system we've been calling ROBIN, which uses the Z80 and runs CP/M. Both of these use the Tiny, and while I don't understand who would buy either of them yet, I'm more concerned about what base system they'd run. Perhaps the UCSD Pascal is the best alternative, since it is potentially the smallest and least general and therefore might run well there. One system is the VT200 and the other, called CAT, or TRIAD, capable of running all 3 environments of Z80, PDP-8 and PDP-11 (Tiny type). CP/M is the only general purpose environment... and since it's so poor, we would ensure that these systems wouldn't be used for anything but terminal and fixed applications. It's clearly not a system for the small business person (due to primary and secondary memory size).

All in all, I feel very, very bad about these later two products from a systems viewpoint. As a terminal, the VT200 is really vital! Somehow, I'd do anything to get it to also be a video option for CT! What's the chance of this?

SUBJECT: UURGENT PROBLEM: RESPONSIBILITY FOR LOW COST SYSTEMS

For our disussion at GVPC:

Independent of whether I have be able to help build better low
end personal computing terminals, historically we have tried and
generally have done poorly (market share,
profitability,quality).

PRODUCT HISTORY
The products arena, over the past 6 years and currently:
VT8/E (Reuters), VT14(originally GM for PDP-14)
VT30, 31, etc. by CSS for weaving, mimic diagrams, tv
VT15,GT40, GT60, Megatek (lab and engineering graphics)
VSV11 (Graphics and Image) LDP, now CSS
VT20,21,71,171, etc. for Typeset also Tektronix based
LA36/BSR, LA36/TU60, LA120/TU58 (AT&T), LA44, VT134

PDT130, PDT150 (for ADP)
Minc, Mini-Minc, TLC
Gigi, Gigi 1.5
VT103 (TPG)
DS315

WHY IT HAPPENS

Our structure and the basic P/L Bill of Rights (which I do not advocate changing), created the problem. Some of the forces:

- .Customers specialized need (Caused 6)
- .Perceived specialized market need (caused about 20)
- .Perceived general purpose, high volume opportunity (5)
- .The components are available, and it's about the only piece of hardware that a P/L can afford to engineer
- .They are fun to start. It is the one product that can be built according to the classic model: marketing specifies and engineering builds it
- .The market is perceived to be sufficiently different that no gp system can be built (Apple disproved this!) ... hence no common system was able to be defined
- .The engineering budget was not large enough to cover this evolving part ... for example, the whole WPS P/L had to be started up to start the eng. investment
- .Poor engineering leadership to recognize need, and propose it

SOLUTION

Now that we have recognized the problem, let's solve it.

- .Technology is changing making engineering cost higher, product costs lower, and unprofitabity clearer
- .We are doing a system to cover many of these areas
- .Near term, Engineering is taking responsibility for 278
- .Engineering will operate "modified Golden Rule":
  - .Will operate with Business Plan and Phase Review

.Will get an outside assessment of product viability

.Review the current terminal and PC's ... there are lots more lurking losers. Put the $'s in low end PC's!

SUBJECT: OC WOODS DISCUSSION AND ACTION ITEMS

LOW END was the main topic. We want to continue winning with lower cost competitive terminals (and also getting the high functionality VT200) AND we want to get a lower cost CT for the OFFICE products that are coming. The goal is to have the strongest possible CT offering. There's a seperate memo on this.

We discussed the issues on the Office and CTAB software vis a vis compatibility and have to report back on our plan. In the review on Thursday evening with the developers, I think we may be ok. The critical issue now is make sure the goals are right and then support the plan! I think it is quite good and we can win, assuming a few of the details are reconciled. We have more

compatibility of languages, files and interfaces than any competitior. Furthermore, the OFFICE specs look great and we can
win there too! But we have to implement.

Personal Computing Clusters and various Servers are not yet moving fast enough. Why can't our hot M team to get into this?

PRODUCT RESPONSIBILITY AND PROFITABILITY IS TO BE IMPLEMENTED:
.one person must be responsible for a product, and
.Engineering has the profit responsibility for a product.

We must stop introducing products that have below average profit
... because we are responsible for product success (ie. profit)!
In the event products are planned (or have no plans) which violate the profit goals, we must ask the Operations Committee
for guidance as to whether to introduce. We must review:
.VT278, pending and ideas(278T, 278RL, 278 Mini floppy, CT278)
.11/23 RL package
.CTs in all the desired versions
.Robin

PRODUCT AND PRODUCT AREA REVIEWS. There is a proposal that there
be a major review of all products and product areas. Note that,
Jack Shields' staff reviews the service plan for the 50 majors.

Ward McKenzie agreed to co-sponsor a review of the 16-bit products from chips to systems.

Marcus was concerned about not being informed of the move to Reading of the Office Program. We screwed up and have to report
back to OC on this now regarding the status. BJ's plan is

ON!

We got the offer of support from Ken, Julius, Si, Win and Ted to
discuss the importance of CT and OFFICE with the development groups. Avram and Bruce, feel free to schedule any of us to talk
about the importance of these programs.

LOW END MASS STORAGE AND REMOVABILITY IS OF MUCH CONCERN! Grant
must lead us through the morass of possibilities. We have lost
the low end COEM business by high markups, but I'm still concerned about getting the straight story here about total cost
(including DEC storage and transshipment, FOB charges, handling,
portability, high cost of backing up with either floppies or RL's, etc.) of alternatives. How viable are the RL's? What are
we going to do on the CT?

Subject: **LOW END DIRECTION DISCUSSION WITH STAN**

To: Dick Clayton, ML12-2/E71
Bruce Delagi, MR2-1/M64

Date: April 20, 1979
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

CC: Mike Gutman, ML3-6/E94
John Kevill, ML3-6/E94
Andy Knowles, ML10-2/A52
Stan Olsen, MK1-2/C36
Stan Pearson, ML12-2/E71

Stan would like us to be the volume, leader and build products for retail outlets. This would be >100K systems/year in 4 years and aiming at low, entry cost, with decreasing average selling price. He'll put the market plan in place, but he wants a clear statement of the products (entry, average and maximum) vs. time for the next 4 years. <u>Could you put together (plot) this set of systems (vs. time)?</u> Then we should get together.

This would be in terms of a table giving the (really part of Redbook) components (CRT, printer, processor, mass store, communications options, and software) versus time.

In our planning we need a better interconnect and packaging strategy so that each component can be evolved relatively independently so as to gradually decrease these system prices. Such a strategy would address: where the computer is packaged; boundness; keyboard on printer or not; how the pieces connect to each other; communications and modems; etc.

Some of the questions we discussed:

1. Will videotape/videodisk be a product in this time?

2. Can Gigi be made available in high volume to effect lower entry cost?

3. Will Pascal be a standard? Should we adopt it? How do we have propriety SW with it?

4. Transition from 8 to 11? Is it possible? Will the 11 go into the

store?

5. Is the VT100L useful at getting lower costs?

6. Can bubbles or CCD be used with tape (TU58 or successor) to lower entry cost?

7. Is it necessary to build low end hard disk?

8. Can RL02 be sold to add on to all low end systems to further get us in this market?

9. Will all these be CRT-based?

10. Should we have low cost printers without keyboards for these systems?

The Japanese did what seems like an incredibly clever thing in developing a low power gate array. They simply use only a fraction of their regular large gate array that has a heat sink. This means only one part, one design system etc. Can we learn from them? (Let's not develop the smaller bipolar gate array -- have everyone use the current one.)

Can the ECL array be used in a similar way?

Fujitsu has bipolar arrays. Can we use them? They also have 8ns RAMs.

SUBJECT: LOWER COST SYSTEMS ARE LIMITED BY DISK ELECTRONICS

It seems like the systems we are coming out with in CSD are above the 16K nu charter limit because they use the DEC traditional boxes within boxes, backplane and cabinet approach which organizations reinforce. Would it be better to partition the Low end to systems that are mounted in the terminal or in the disk? It bothers me to see the vt 278 use the same kludgy disk system package and electronics in this day and age. Part of the problem here is that there is no lsi work in the disk area, nor do we use standard chips because they are incompatible with our bus...hence, we are stuck with using msi just like we did about 5-7 years ago.

Would you guys get together and see what can be done here to get us in a more competitive position? (Even IBM's recent Intelligent terminal is smaller)

Let's not have the 278 in the current package.

Grant, would you look at what is being done to get us into the 4th generation as measured by our logic design capabilities?

Follow Up: 8/20/79

In talking to some of the troops in the mill doing LSI design, they suggested that we (management) get on the stick and help the morale at WX. Their concern was that we built a building in Hudson, yet the WX folks aren't going to get into it for quite some time and we keep delaying the day. Also, these designers are separated from the other designers on a chip who are in the mill. Also, there is no cafeteria, it has been a temporary facility, etc. Can we do anything to help out here besides being understanding and appreciative? Should we try to find a place in the mill until Hudson?

follow up 1/2/79

Jack asked me to note this prior to the January Operations Committee review. My concerns right at a time we're capacity-bound:

1. Will we have a problem moving from Worcester and Westboro to Hudson?

2. Why bother to do higher volume manufacturing for LSI-11 and Fonz inside? Let's get these manufactured outside.

3. Don't we need better (reasonable) engineering turn-around? Our profits in this area get made by short turn-around and time to market, not manufacturing cost.

4. Right now we need Fonz chips in numerous groups and this conflicts with manufacturing capacity. How can we get them?

5. Fonz is doubly (triply?) frustrating with a third (fourth?) pass on the design. Can we get reasonable tools to avoid two (three?) extra passes? The SQUID chip is expensive (outrageous) too. I see us going nowhere except out of business because we can't afford the designs.

Again, let me reiterate. The designs (and quick turn-around) are the big leverage on products and profit. I don't care if we make a single chip.

- VAX SBI Memory Board, Digital Equipment Corp, 1976, (D164.80).
- VAX Star 64K MOS Memory Array, Digital Equipment Corp, 1976, (D165.80).
- VAX Proto-type UBA, Digital Equipment Corp, 1976, (D166.80).
- VAX Test Tapes, Digital Equipment Corp, 1976, (D167.80).
- VAX Logic Module, Digital Equipment Corp, 1976, (D170.80).

This board was an experiment in fine line routing (8 mil conductors and spacing). The logic is the 11780 UMD Module. It is significant in that it was the best routing solution that the top automated p/c vendors in the country (Algorex Data Corp) could achieve. (The production version of the module was done in-house, using 15 mil conductors and spaces.) It contributed toward influencing DEC to adopt fine line as a standard and was used extensively in developing the process which eventually came to be used for the 11750.

- VAX poster signed, Digital Equipment Corp, 1976, (D171.80).

MINC, (Modular Instrument Computer) Digital Equipment Corp, 1975, (D155.80).

Word length: 16 bits

Memory size: 32,768 words

Speed: Approximately 200,000 single instructions per second

Clock rate: 3 Mhz

Instruction set Processor: PDP-11(LSI-11)

Arithmetic element: Data path on an LSI chip, 8 general purpose registers

Instruction format: Double operand, multi-mode, 16 bit instructions

Power consumption: Approximately 500 watts

Size: Roll around cart (24"x30"x40")

Component Count: 4 LSI chips forming the LSI-11 processor, 300 MSI and LSI chips for memory and peripherals

Project start: August, 1975

Packaging model demonstrated: August, 1976

Running system demonstrated: August, 1977

Product announcement: October, 1978

First shipment: December, 1978

Number produced: 1500 annually

Input-Output: Real-time plug-in modules for analog, digital event processing and signal conditions. Graphics CRT. IEEE 488 and serial communications lines.

Software: Real-time and graphics BASIC. Optional languages and facilities available on PDP-11.

Use: Science-based discipline computation, including general purpose programming, mathematical modeling, graph plotting, laboratory management. Real-time use including data acquisition, signal processing or experiment control.

Achievements: Improved human interface as scientific and laboratory computer through software, modular hardware and documentation. Improved cost and performance per cost of ownership by portability, higher mean time between failures (MTBF), customer installation, built-in service and diagnostics, and direct phone link to factory for information.

Date: MON 27-NOV-78 22:09:05 EDT
Subject: Anothehr higher priority project

LSI VAX chip looks more important to me for two reasongs: 1. When I see the
MINC and the software it needs to/could use that will come from what else is
being done, the chip seems essential This sort of systems is really needed
to get rid of the limits that plague these single user systems like the HP
and IBM personal machines. VAX won't have he limits.

2. To build the really reliable systems, we do need chips so as to use
/build them in either checking or voting mode. Getiing a zero cost machie is
important. This would really change the approach we are having to go with in
HYDRA.

Date: 30 OCT 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

In order to get a start on our Wednesday meeting, here's my concerns:

1. The process looks out of control and I'm frightened. Bill has had to step in to manage this, and the former good guys are doing meanial work. Independent of their capabilities as managers, there is a major problem in recruiting in this area, and I worry about things that will guarantee an exodus of people. Similarly, I don't like the thought of overloading Bill this way. He has to be free to lead us out of the morass.

2. Comet chips. How are we going to get them? Need we bother? Why not just get the outside vendors such as TI to do it and we won't have to fool with them?

3. Overall, I can't see us as getting very good in the process domain because we don't sell MOS chips competitively. By buying from INTEL we're constrained to be several years behind. If you look at the channel width vs time and where our products sit, we're getting worse! There's no end in sight or no way to get back on the curve. This is the situation we were in with disks several years ago too (and aren't out of yet). Here, could you please bring a plot of this situation, to either allay or confirm my fears?

4. The design group and interface with the rest of the engineering users is poor and I think basically wrong. No successful semi manufacturer separates process, circuit, cad, logic, and architecture so organizationally and physically as we do.

5. The LSI engineering effort is busily building a collection of processes, some of which they believe in and want to do, and some of which they are merely coerced into doing (eg. gate arrays) and they feel beneath them. I think we have a large catalog of processes and no products for them (also because of the mystique we've managed to put up around the notion of LSI). Here I'd like a table which shows the processes versus time and the entries would be the products built with each of the processes. The entries would also contain how much we've spent for the processes and how much we spent to get each product, given the process. PLEASE BRING THIS ONE ON WEDNESDAY.

Mini-sermon: The way we make money in engineering and manufacturing is by selecting a process or a basic architecture and doing repeat designs.

6. Training and obtaining LSI designers is an important part of the group effort and I don't believe it has been recognized as such. We have been unsuccessful at getting, retaining and training people. This ought to be trivial as we have very bright people, and they can easily learn this kind of design, given the proper environment. Could you please bring a table of skills versus time, showing the people we've gained and lost by name in the various areas?

7. There was some clear disowning of the problems associated with the Motorola MECL array as being proposed for the Dolphin. Since the chip is to be second sourced internally, I don't understand the remoteness. The attitude is "see, Motorola is in trouble and will fail and they're having trouble just like us". The group had not communicated the concern with Ulf and the large systems group.

There are probably other issues, but I'd like to start with these as a means of really getting control of our destiny in this essential area. I want to help and everyone concerned with hardware does too. It is time to let some of us get involved in helping.

Subject: **LSI VAX: How, Where and When**

To: Distribution

Date: 18 OCT 78
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

follow up 11/1/78

Craig and I discussed the above last weekend. Now, I'm concerned with the possibility of milling inactivity. Frankly, it is pivotal to the strategy and I want us to settle a whole bunch of issues...quick!

The goal for the project should probably be:

> a small number of chips processor, permitting us to build small systems that can be embedded in terminals and be used at the same level as Fonz level systems we are now working on. (Such systems would become the terminus nodes in distributed processing systems and alternatively, powerful stand alone systems.)

Organizationally, I want something out of this project like we seem to be getting with both Comet and Dolphin, but with much better performance in the semiconductor area vis a vis the meeting of commitments. I note that in the case of Dolphin, the technology isn't even within DEC. To me this means a small, dedicated crew working together (geographically and in the same group) on:

1. selecting the technology, and then
2. getting the architecture
3. circuit design
4. CAD tools
5. logic design, and then when close to completion
6. working with customers to apply it.

For starters, this means to me the selection of a leader and the early exploration of 1 together with feasibility. Craig is already going on the architecture, and we need the focus now that a project would bring so that he can be more effective and really move! This also requires deciding who's going to be responsible for it within OOD.

I certainly have prejudices on things like moving quickly to CMOS, if necessary, in order to get the power down, speed up. Also, it need not be that small, as we are not competing at the chip level (i.e., cost isn't that important). It does have to have a small channel in order to get the density (and speed...which we should want). Using Intel technology worries me because that allows them to keep up exactly one generation behind them! Instead of doing the CMOS-11 at Harris, is VAX a better choice?

What are your thoughts on this project (see attached also)?

Bob, will you please frame the proposals so we can get moving in a "+" direction?

BOTTOM LINE

We're wasting our time (and much money) in the low cost timesharing systems like 23, 24 and NOW MICRO 11, as history has shown. The small (low cost) business computer market area will be the lossiest. I think the market has rejected them on a totally rational, economic basis. UNLESS we consider the total system economics, and get a complete market/product plan, we're going to lose again. Unfortunately, in the NEW Digital, no one will ever know that we're off a factor of 10 in a product plan, and we'll continue to invest.

Note that 11/23 and 11/24 were forecasted at 1.9 and 2.0 Billlion dollars. The actual appears to be something like 1/10 this amount! Being off by an order of magnitude is pretty poor.

Ken got a task force that gave a bit of insight, and other folks tried to analyze it too (including me). I suspect we'll forget the fact that this work was done and will be organizing another one in the near future to replicate the work or try and understand why Micro 11 ain't making its numbers. To me, the responsiblity for plans are clear: Gutman for Micro 11 sold alone, and any market group (eg. Small Business) when it's sold with applications software).

HERE'S WHY WE GOT A PROBLEM
While the "SuperMicro" is a possible computer structure of the 5th Generation, I believe it is far from obvious how it will be achieved and maybe even whether it will exist due to market infeasibility.

I'd suggested that we rename the Micro 11, SuperMicro 11 (especially when J's in it) to reflect the fact that it's Microprocessor based, but it behaves a Minicomputer of the previous generaton. Note the
price decline AND STYLE OF USE evolution versus generations (time):

```
1965-70        1972-75            1983

PDP-6/10 ---> 11/40...11/70 ---> Micro 11  (timesharing
decline)
(Central)      (distributed)     (now personal level)
400K            100K-250K          10K-20K

6600                 780           Scorpio   (6600 was Super
of '65)
(Central)      (distributed)      (operated at personal)
3 Million         250K               50K

LINC                 Apple
65 (40K)              78 (3K)
```

MY CURRENT PREMISE

1. There are several kinds of computing styles (and support economies):
 .super/mainframe- cared for by a staff
 .distributed mini- cared for by a staff or very knowledgeable person
 (requires several k$ to install a new piece of software)
 .personal- simple, user software installable. >100k units sold.

2. In the low end, boxes, busses, cables, etc. and vanity boxes are all irrelevant unless they impact a single individual's ability to buy, move and somehow get operational a given machine. Software costs dominate. We have 3 PC's to penetrate the market, IBM has one!

3. Micro 11 and supermicro 11 (the j) will be added to our list of marketing failures, because we have a general purpose system (derived historically via RSTS). It's unclear why anyone would want a low cost gpts except in a school where labor's free. Such a system is characterized:
 .can program it to do anything
 .low volume, (<5k per year)
 .lots of ad hoc softare written to take advantage of gpts, requires
 experts (fellow users ala Decus), or oems to install it.
 .typical installation is 1/2 day per package (like the tap), lots
 of training to use, lots of manuals (>1 foot of shelf for system)

4. Applications for micro11 are pretty much irrelevant for end user because the installation and use were designed for an economy based on 100K-400K. Application of such software is a major re-write.

USE OF SMALL COMPUTERS IN SMALL BUSINESSES

I don't think anyone's made any money serving this market so far for various reasons. Micro11 will be then next failure because:

1. economics are right (see above)
2. product ain't right (see above)
3. the range of tasks are too hard to do, and the users won't pay to learn to be computer people. This is similar to the

reason why home computers stay in the closet, and people ask what do you do with them?

HOW WILL THE SMALL BUSINESSES BE SERVED?
Personal computer clusters are the way to attack it because all these users will start with a simple computer that does NOT do their whole job, but does a few functions. It will be something they feel comfortable with, and they can learn with. Also, the human interfaceis better. It probably won't be centered on WPS because they don't have much correspondance, but it could use the list processing of WPS to do report writing and to send out bills and pay bills. (This would give them a simple accounts receivable/payable system.)

BUT WHY DOES IT SEEM TO BE WORKING IN EUROPE?
I think the price of the systems are just enough higher due to delays in introduction/use to allow the system work. The system will work for systems above 23's, but probably not below! Also, the market may not have all the clutter we have vis a vis personals, etc.

IS THERE ANYWAY TO GET DECENT VOLUME ON MICRO 11?
I still say get some FIXED application and flog the hell out of it. The only one I've seen is the bounded WORD 11 (Mary Jane and I tried this about a year ago). Also, the EDU folks might be able to bundle something useful.
.

<dispo/date>SAM, CC:PAUL GUILBAULT - 5/11/81
<message>THIS LOOKS USELESS FOR **OUR** PURPOSE. WHAT DO YOU THINK? I SEE **NO** PROPOSAL.
<answer>GORDON, YOUARE RIGHT IN THAT THERE IS NO SPECIFIC PROPOSAL **NOR** ANY DATA TO INDICATE QUALITY IF MCODE COMPLICE. THIS IS CLEARLY A LONG SHOT. IF PAUL IS INTERESTED I'D PROPOSE HE:
1) GET SO PERFORMANCE DATA ON GENERATED MCODE.
2) SEE IF JRS PLANS TO DEVELOP CODE GENERATIONFOR 750 & 730 TOO. THIS **COULD BE OF INTEREST TO DEC** IF THEY COULD TARGET CODE TO 730, 750, & 780. - 5/19/81

<message>I DOUBT IF THERE ARE REALLY ANY SURPRISES. IF WE FIND THEM, LET'S UTILIZE THEM. WHAT DO YOU THINK THE SURPRISE IS? IT'S PROBABLY TIME TO STOP EDUCATING THE EDUCATORS HERE.
<answer>FROM BILL STRECKER:I THINK THEIR WORK IS INTERESTING BUT NOT SURPRISING. THE REDUCTION IN MEMORY TRAFFIC DUE TO THEIR PROCEDURE CALL/REGISTER MECHANISM IS IMPRESSIVE - BUT IS A MULTIPROGRAMMED SYSTEMS WOULD RESULT IN THE SAVE/RESTORE OF 140 REGISTERS ON 2 CONTEXT SWITCHES. THEIR RESULTS SHOULD BE GENERALIZED TO MORE GENERAL PROGRAMMING ENVIRONMENTS WITH SOME CARE: THEY HAVE LOOKED AT SMALL PROGRAMS USING ONLY A LIMITED NUMBER OF DATA TYPES. INVESTING IN A MORE COMPLEX ARCHITECTURE TO SAVE 50 PERCENT IN PROGRAM SIZE MAY BE A BIG WIN IN ALL BUT THE SMALLEST SYSTEMS. - 4/21/81

SUBJECT: MAIL PRODUCT LINE

I apparently missed a M/C meeting in which we agreed to have the WP PL put in 12 systems of Electronic Mail as a test case to various corps.
I think this is a terrible mistake for two reasons: the current products are in reasonable trouble , coupled with the growth and promises of profit this year; and I strongly disbelieve in WP as a PL, versus it being a generic tool (like Fortran, or Cobol, or DECnet) that every P/L group needs and should should be permitted to sell. If it isn't too late, I think we should re-review this.

SUBJECT: PLEASE HELP IN THE MAKE BUY SPACE

I view we are going headlong to make all the mass storage devices except mag tape, where we don't have enough engineers to
be able to make a proposal. I don't understand this in regard to
commodity like devices such as floppy, except that people say no
company can supply our needs. We have a big unquenchable thirst
for products to support the varied systems, but there isn't
anything like enough factories or people to do the devices,

hence
we'll either not go out with a product (as in the case of
built
in fixed media devices based on the early 14" and soon to be
8"
winchester products), or we will be too expensive as in the
case
of the floppies as we see too little too late. We won in
the
marketplace by initially buying out floppies, but since then
we
have been consistently late and/ or expensive or not there
with
the product.

The two areas that are of especial concern are the removeable
prodcut that requires a new technology, pack,ie the works and
is orthogonal to the Winchester and RL tech that we have
there
and feels like it could easily be supplied by CDC as a
displacement for the RM03 (the reason is cost, but most of
that's smoke due to the interconnect); and the low end where
numerous floppies, cheap tapes and 8" Winchesters are
required.

How can we get an aggressive buy out alternatives to the
in house makes that are inevitable with our strong mfg / eng
combine?

What DEC SELLS not what it BUILDS is the more important issue for continuing success. In a rapidly changing industry where technologies can quickly become obsolete, it is essential that DEC maintain flexibility and not become over committed to any particular technology or process. As we make more and more of the items we sell, we become more rigid. Opportunities in the marketplace can be delayed or lost forever. Opportunities to cost reduce by building more inside will stay with us. The following guideline is intended to help us focus on these issues.

1.DEC wants to build unique products that offer specific advantages to its customers. Profitability alone is not sufficient.

2.High ROI by itself is no reason to build anything (e.g., it robs resources from other, more essential projects).

3.The general rule should be, if we don't make it now, buy it.

4.Proposals to build must explicitly demonstrate that:

a.project will result in a quantum jump in technology or

b.needed to introduce (or confine) a vital technology to DEC or

c.present or developing vendors are unable to supply demands of ON-GOING high production item.

5.All proposals to build should address and be screened by at least the following criteria:

a.DEC's forecasted needs exceed the volume of at least the smallest economically viable vendor.

b.DEC's engineering resources to accomplish task is at least comparable to vendor.

c.Incremental NOR/employee will be above the corporate average for the effort. [We should strive to increase "PRODUCTIVITY".]

d.Hardware products can be sold through the Components Group. [The product is inherently good enough to stand on its own.]

e.ROI analysis of not only the results of pursuing the project but the corresponding results when using the vendors part.

f.Level-of-integration of the project. [We should tend to increase level-of-integration-focus on MAKING what we sell--NOT what we BUY.]

g.The resulting incremental NOR to development cost ratio compare with Corporate NOR to total engineering ratio budgets. [Won't become an engineering sink.]

6.We must have a "buy out" advocate to test analysis (in Manufacturing, Purchasing, and Engineering?).

7.Proposals to "make" must be explicit with respect to the level-of-integration covered (i.e., which parts). "Making" is not a carte blanche licensing to make everything.

MESSAGE ID: 5191028948

SUBJECT: ENGINEERING MANAGEMENT PROBS 0 AND 1; ONE DATA POINT

GB4.S1.32

Probs 0 and 1 are:

0. Simply deciding what to do and then managing to do it

1. Engineering with a Quality Design Methodology

On Sunday I rode back from San Francisco with an engineer who'd been out of a good engineering school for two years. The engineer was disillusioned and was thinking of changing fields because so little was getting accomplished in their life. We commiserated because their group is so near the bottom in #0 (organization, direction) and #1 (capability).

He's never shipped a product, and went into A/D because the development group takes forever to introduce products into manufacturing. (Are we using A/D as a refuge so that people can get work done and feel a little bit good, even though the work may not really go anywhere?).

We also talked about the enjoyment of school because one worked so hard and achieved clear goals. (Bruce Delagi, at Stanford, says he's working twice as hard and enjoying it more . . . Bruce has never been a piker.)

Their project has changed by several factors of two over the last weeks, and the only real direction is that it be cheap, perform well and get to market fast. Another group has a project that may

overlap
with theirs and both shoot at and hide from one another.

Even though their education is broad, they're now pidgeon-holed as
being analog because they did a circuit. The desire is to do analog -
digital logic, software and how they work together (architecture).
Considering the other lament -- the group is unfamiliar with using the
computer (and programming) to solve problems, this is a shame. (I
think we want people who can span this great range including
electromechanical control.

He was on the west coast to look at gate arrays, but the group is
scared because they can't do the same old cut-and-try, ECO to death,
find it and fix it in DMT engineering that's their trademark. We

agreed formal training was absolutely necessry. A major problem is
they don't know they need it and they're scared to go do it. This
real concern is the fact that the group has worked or are looking to
leave because they think the management's really poor. Personnel's
taking a survey about how people feel; but he doubted people were
secure enough to tell the truth even though morale's so low.

The
complaint was that a buyout was being considered and this is no
challenge.

Given all this, the group's moving to an isolated building and everything will be worse. It can then be transferred to NOD probably.

I recruited for a really exciting project. I sure want to keep good
engineers as long as they can go someplace where they feel good and
are productive. If you know of competent people who are working on
dumb projects and don't want to be managed by clods or work with dull
people, I'd like to help place them.

SUBJECT: LET'S GET THE AGREEMENT WITH MANCHESTER SIGNED

GB5.42

I'll sign an agreement that says we pay them a royalty on a per machine basis IF we use their machine commercially, as it is designed.
The agreement is limited to a maximum of $500K for all the machines we sell, as I understand it. The agreement ought to be on a

reasonable
per cent of each system. This is clearly the right thing to do!

Let's start using common sense in this dealing:
we don't want to turn what is basically a good relationship into a
fight among contract officers;
the amount of money involved is trivial and highly limited according
to what we will EARN from the endeavor.

Let's get the contract signed and get on with the work.

Gordon
PS
I'll be accessible in California if we can't work this out.

MANUAL AGE

Although the study of mathematics is very ancient, the objects that ad to the birth of the computer are very sparse until the early venteenth century, when the craft generation starts.

Coins, beads, stones, and rope were used both for simple lculations and recording keeping. Thus they appear as both antecedents memory and calculating devices that separated and developed in the ghteenth century. The artifacts in the llection are relatively late representatives of the simple devices, ed in simple cultures and backwaters through the twentieth century.

The abacus is one of the earliest known computing devices and the rst hand-held calculator. It postdated the invention of the decimal stem by the Egyptians circa 3000 BC. The Greeks and Romans built and ed the abacus based on Hindu-Arabic numerals. Unlike earlier notations d devices using stones and marks, the abacus utilizes positional tation, including the representation of zeros, differences, with pabilities for multiplication and division. The Chinese abacus has ads in groups of 5 and 2, representing decimal digits. The Japanese rst modified this to 5 and 1 and then 4 and 1, a system known as bi-inary representation that was also used in early electronic digital mputers such as the IBM 650 (ca 1955).

In the operation of the abacus, a single register machine, the ving of the beads also immediately provides the answer.

Abacus, 22x16x3 cm,
Wood, 9 Digit, (B93.80).

Abacus, 2x4x6 cm,
Green, Marble and Brass, 9 Digit, (B95.80).

P Abacus, 29x14x2.5 cm,
Wood, 13 digit, (B172.81).

Soroban, 4x11x29 cm,
(B26.79).

Soroban, 10x2x40 cm,
Wood and Bamboo, 21 Digits, (B94.80).

Counting beads are simplified form of an abacus often used r teaching or given to children as a "learning" toy. Versions of unting beads are used for score keeping in such games as pool and thus ten form a simple, large scale, graphic, erasable memory and simple der.

Counting Beads,
27x19.5x1 cm, 10 digit, Red, Black, and Green Beads, Wood and

Metal, Paint worn off beads, beads missing on top, (B141.80).
Counting Beads,
37x2x44 cm, red and black beads, wood and metal, 9 rows by 10 digits, (B178.81).

FOLLOW-UP: 10/5/79
GB0004/57

Given:

1. The situation in Springfield vis a vis their ability to handle the growth and new products.

2. Lack of orders on TS04 and TU77.

3. Pertec.

Let's:

1. Withdraw these products.

2. Only introduce the CSS-based STC 6250 drive.

What do you say?

SUBJECT: MANUFACTURING A/D AND MANUFACTURING ENGINEERING

I attended a review of our Technical Managment Committee,
TMC,
composed of A/D managers where the plans were presented.

I am really concerned about the incredible lack of planning
and direction and co-ordination within manufacturing and
don't
see how we can possibly survive.

The problems were everywhere:
.a network to be able to get information to the plants
.networking within the plants (or anyway to help them either
 individually or collectively, given the strong lack of
 centrality of anything). This is why our Order Entry is
 so screwed up as it crosses plants and product lines.
.testing methodology and testors
.modern materials and product flow using on line computers
 (Here, I understand we buy mostly in a hodge podge fashion,
 but now we are also developing this both in Don's group and
 under Steve Gutz. This seems crazy.)

.a program to reduce product introduction times
.physical interconnect appears to be headed nowhere!
.automation in general, especially the standards to interconnect
 assembly line components

I'd like to see a strong, engineering effort applied to driving this across manufacturing. Much would take the form of
standardization, but there would have to be real leadership too.

Can't we learn from the current product line fiasco where we see massive waste and non-professionalism because everyone was told to be independent and do their own thing?

SUBJECT: MEETING TO LAYOUT MANUFACTURING PRODUCT APPROACH

I think your suggestion of a Woods of 1+ days sound fine to look
at the approach to getting these products. We should start by
asking Roger to send us the literature of his products and the

strategy he's on now.

You, Jack (as mfg and eng person), me (as engineer and arch of distributed systems) and Cady (as responsible business person)
should be the nucleus. Some others:

Steve Gutz, the engineering manager
Hansen, as manufacturing person and person who has to be the guinea pig. The basic approach we are advocating is to buyout software in a clearinghouse fashion and to run it internally. Note, as a side-effect we get a shot at moving manufacturing to be CAM oriented. I want direct transfer of information from CAD to factory and this means both LANs (Ethernet) and a global net like the links between engineering sites. Here, I see a structure with a PWB/logic plant, for example, to be: three interconnected networks (on 1 EThernet): EDP, shop floor control including any automated movement, electrical design information update to inserters, testors, pwb makers, etc. In addition, a board shop would be under computer control.
Metzger, as contractor to a very large amound of CAM for Mfg.
??, as EDP facilities and standards co-ordination. Here, a network person has to exist so that any exchange is possible.
No way can this be done bottom-up by plant.
Dick Clayton, who's looking at various forms of control and automation (materials handling) within plants.
??, as person doing electrical standards for CAM part especially aimed at test.

Anyway, this would be double pronged... looking at our own computing in depth to solve mfg plants for others. I think this is the way to go! (We should also buyout all the software.)

Since HP and Univac are the biggies in this area, we should have an easy time at the market.

GVPC: EXT: 223-2236
LARRY PORTNER LOC/MAIL STOP: ML12-
1/A51

SUBJECT: MANUFACTURING MARKET: WILL IT BE THE NEXT MARKET WE COVET?

I'd like to figure out a way to stop the hand to mouth existence
we travel in deciding about products and market areas. For example, Our ability to identify and move in WPS and PC's has been abyssmal! We have a good group in Engineering and Manufacturing that is dedicated to making products that we can
use internally. Similarly, Roger is on a course that looks like
it could win in the manufacturing world. HP currently looks the
best in this regard with their commitment to using their own products internally. IBM may have a similar stance.

IBM is very active in this effort, and is now starting to market
a robot. HP is commiting to both AI products and to robotics.
Their culture won't let them not go after the state of the art.

I think Sam is probably right in that this area looks like a comer. Also, we need to have product expertise in Knowledge Based Systems, particularly if the Japanese are going to be there in the 5th Generation. (There's also the question as to whether we will want to be in the home with a computer, or have a computer in a briefcase, etc.)

Is there a way to be rational about new product areas?

(I see no slack for anything, given the over commitments in engineering to existing, and past products... no matter whether
they are going to make money or not.)

Surely there's a better way to live.

SUBJECT: JOHN BIRK; ROBOTICS PERSON

I've talked with John today to follow up the offer we made him Friday; as
I understand it, Bob Glorioso talked with him today also.

He has at the 95% level decided to leave the Univ. of RI and go to the other
company. I think he has made the decision for a few reasons:

1. Other company has a clearer commitment to Robotics than DEC. This
is measured in $, size of group he'll manage, etc.
2. Other company was earlier with their offer.
3. California looks better than Mass. at the end of this hard

winter.
There is an outside chance DEC may still come out on top and I suggest we keep the offer open for the coming weeks.

The troubling aspect of this to me is watching IBM, HP, and a raft of other companies getting into mfg. automation. It looks like we will be trying to play catchup in mfg. automation in a few years like we're trying to play catchup in office automation today.

Subject: Manufacturing-Engineering Interface

To: OOD,
Win Hindle, ML10-2/A53
Jack Smith, ML1-4/A54

Date: 1/28/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Jack and I discussed the above in the context of a discussion with my staff at a recent jungle meeting. We agreed that some sort of formal communications link might be useful. One of the possibilities would be to have the chairman of the Manufacturing-Engineering Committee attend Jack's Staff Meetings on a somewhat regular basis. In this way, we could get a coupling that is now more one way via Jim Cudmore...although Jim would certainly continue to be a part of OOD.

Subject: **Volume and Market Domination**

To: Irwin Jacobs, Julius Marcus, OOD, OC, EBOD

Date: 19 SEP 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1
Ext.: 2236

follow up

10/03/78

This is the first creative idea (see attached) I have seen to get volume and market domination since the Distributors and since the DCG terminals sales. I support the need and say let's get the channel. A trip to Japan convinced me that we want to be a manufacturer at a high growth rate! I've a lengthy essay on this but the meat is:

> We (the U.S.) with all our law and business school training take the easy way out by buying manufactured goods from Japan. The ROI on this is enormous and there is no risk, because all we have to do is be good purchasing agents and distributors...and we dignify it by calling it marketing. Fortune further writes up these people as great business leadership. Many manufacturers have gone this way (RCA, GE, Chrysler), because it's a pain to think of product ideas, develop them in detail and manufacture them competitively. Also the government hassles you all the way.

While in the short term, when the Japanese start competing with us, we could simply buy their products and add on as much as they let us (their goal is to get the greatest amount of added value). The strategy doesn't work in the long term because:

1. Distribution is fundamentally the fatty part of the organization ...thus it is easy to form a lean and mean one when the need's there.

2. If all U.S. manufacturers do this (and they seem likely to, given their laziness) then there is no export of goods to pay for the Japanese products unless we

are effectively able to sell them all the land, manufacturing and people resources in the U.S.

(Any wonder why the dollar isn't worth anything overseas since this <u>paper</u> is all we're exporting?)

The point is: DEC must become a high volume manufacturer. We'll lose if we just fool around with a lot of low volume products and take their high costs while we try to pursue the diverse set of needs through the various channels (e.g., stores, big and little companies and governments, all possible uses, with all possible computing styles). TI will beat us, and so will everyone else. This implies a high growth in such an area. Given, too the sales department is limited in their ability to hire and train salespeople, there is no other alternative:

<u>Damn It -- get the business outside through another channel!</u>

How can engineering help you?

(You also might get some help from manufacturing too. I suspect Andy would concur and help.)

Digital **Interoffice Memo**

Subject: **Market Maturity versus Geography**

To: Marketing Committee
Product Line Managers
Ron Spinek

Date: 25 OCT 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.:

2236

CC: Ken Olsen

Having recently visited with different users for applications (markets) in a number of different locations (e.g., Europe set, West Coast, Boston Area, Pittsburgh), it's very obvious that there are significant time delays among the markets and among the various locations. There appears to be of the order of up to 5 years...and in some cases, a transient market might even disappear. Furthermore, I believe the dominant factor differentiating the market may be geography not market area.

Rather than wandering around in this market-geography space could we agree on a simple function for roughly predicting markets (based on part performance) and then parameterize it in these two dimensions?

The standard DEC model is:

$$\text{MKT Size (in Millions)} = (4/.04) \times 1.41^{t-1961}$$

i.e., we gross 41%/year or double every two years, (the PL birthright), were about 4M in 1961, and have about 40% market share.

Could it be first refined on a per P/L basis to reflect:

1. Growth rate

2. Exponential limits (i.e., saturation), eg. Try

$$y = L/(1-ae^{-bt}) \text{ (Pearl Curve?)}$$

or

$$y = Le^{-b(e^{-at})} \quad \text{(Gompertz Curve?)}$$

3. Time delays due to geography.

Although I have to believe in products as being the dominant factor in a market, and that marketing may be an art, should we move a slight direction to transform it into a respectable, quantitative discipline?

GB:ljp

LONG TERM MARKET/PRODUCT GOALS

1. PROVIDE A COMPATIBLE SET OF DISTRIBUTED COMPUTING PRODUCTS SO A

USER CAN COMPUTE (IN A TRANSPARENT FASHION) IN ANY OF THE

FOLLOWING STYLES AND SIZES WITHOUT REPROGRAMMING (OR EXTRA WORK):

- **AS SINGLE USER WITHIN TERMINAL**
- **SMALL, LOCAL SHARED SYSTEM FOR A GROUP**
- **LARGE SYSTEM SERVING SEVERAL GROUPS**

2. BECOME MORE APPLICATIONS ORIENTED.

3.   PROTECT EXISTING BUSINESS COMING UNDER ATTACK BY SPECIAL SYSTEMS

(E.G., RSTS) IMPLEMENTED BY 21-BIT MICROS (E.G., INTEL 8086).

4.   PROVIDE CURRENT USERS OF EXISTING SYSTEMS (E.G., 8'S, 10'S, AND

20'S) WITH COST-EFFECTIVE HARDWARE TO PROTECT THEIR SOFTWARE

INVESTMENT.

MESSAGE ID: 5171520445

SUBJECT: MARKETING ADS CONTENT

Sorry my previous message had the wrong attachment which I erroneously pulled out of my EMS file. Please attach this message to the one I sent you about 2 hours ago.

Having cooled off from the last message which was really aimed at having Julius get us a decent market plan for his area together with a set of ads, and having just re-read this one in which I swore off trying to help Julius market, I've decided that my previous comments show too much patience with everybody!

Ken,
Why don't you demand an office marketing plan (and ads)?

Julius,
Why don't you produce a plan that is fit for execution?

We have been in a morass in this area and need Spencer and Benton and Bowles merely to figure out what the hell we are doing!

Julius,
Why not sell your boat and get back to work and get this out?

Love,
Gordon

PS
This is really a selfish message. Will you guys start selling the office things because with the kinds of thoughts I've been having recently about things to build, I really am going to need
a lot of money to have this kind of fun? ... and I like to have
fun.

MESSAGE ID: 5166445656

SUBJECT: RE: COMMERCIAL MARKETING

You're right, I may be the problem in trying to tell the customers about our products, but I figure saying something is better than saying nothing. Maybe a little advertising directed at specifics would help. Last week I wanted to help write an ad but I couldn't find anyone in MK to talk to since they were all at the show AND there weren't even any products they sell. Since I can't ever find any people to help, or anyone there that understand products, I don't think I'm the product. I've instructed the engineers to help them on the ad because we've got some pretty exciting products and neat product messages in terms of productivity.

This is probably my final attempt to help the commercial group, but I do offer them a set of 15 or so hard hitting ads:
1. Range of compatible Data Processing products from PC's to VAX.
2. Range of compatible Transaction Processing products.
3. Range of compatible WP/office/Decset products.
4. Integration of DP, TP and office.
5. Interconnectivity via Local Area Nets and remote Lans

6. Local Area Nets for interfacing to other nets and systems.
7. Datamanagement integration
8. Distributed datamanagement (a big knockoff)
9. VMS environment for the most productivity in SW development
10. Applications languages for productivity
11. Applications (10/11 would cover the outside SW)
12. Office environment compatibility (physical design)
13. Customer installability and serviceablity for pc and group machines
14. Multiple channels and ways to by and source
15. Field support of all kinds.
16. Largest 3rd party source of hardware/software

I offer some people to help write them who know the details.

For example, in the other end of MK, Bob Daley gave me a presentation of DBMS, which is truly spectacular and its use in Transaction Processing. My ad would say:

VAX: Transaction Processing at the lowest cost, highest performance and covering the greatest range of use

TP would be defined, together with a typical task so that a novice would understand.

The computers used to do TP would be shown with their prices. There would be 2 graphs: Performance (in transactions/sec) versus the number of users ; and cost/user versus users for all the configurations.

There would be text describing the story. The novice would learn a lot and we would become known as a hot company in this area. It would be an extremely powerful ad and I think read by people who want to learn more about computing and who want to buy them too. We would also become known too.

If this doesn't work, then let's hire a super IBM type marketer like just recently became president of Prime. They're doing well and so is Wang with these types, so probably that's a better answer. We sure need to do something to get some business from prime, wang, hp and ibm.

WPS USERS - Leave HP mode and type <CR>

SUBJECT: RE: COMMERCIAL MARKETING

You're right, I may be the problem in trying to tell the customers about our products, but I figure saying something is better than saying nothing. Maybe a little advertising directed at specifics would help. Last week I wanted to help write an ad but I couldn't find anyone in MK to talk to since they were all at the show AND there weren't even any products they sell. Since I can't ever find any people to help, or anyone there that understand products, I don't think I'm the product. I've instructed the engineers to help them on the ad because we've got some pretty exciting products and neat product messages in terms of productivity.

This is probably my final attempt to help the commercial group, but I do offer them a set of 15 or so hard hitting ads:
1. Range of compatible Data Processing products from PC's to VAX.
2. Range of compatible Transaction Processing products.
3. Range of compatible WP/office/Decset products.
4. Integration of DP, TP and office.
5. Interconnectivity via Local Area Nets and remote Lans
6. Local Area Nets for interfacing to other nets and systems.
7. Datamanagement integration

8. Distributed datamanagement (a big knockoff)
9. VMS environment for the most productivity in SW development
10. Applications languages for productivity
11. Applications (10/11 would cover the outside SW)
12. Office environment compatibility (physical design)
13. Customer installability and serviceablity for pc and group machines
14. Multiple channels and ways to by and source
15. Field support of all kinds.
16. Largest 3rd party source of hardware/software

I offer some people to help write them who know the details.

For example, in the other end of MK, Bob Daley gave me a presentation of DBMS, which is truly spectacular and its use in Transaction Processing. My ad would say:

VAX: Transaction Processing at the lowest cost, highest performance and covering the greatest range of use

TP would be defined, together with a typical task so that

a novice would understand.
The computers used to do TP would be shown with their prices.
There would be 2 graphs: Performance (in transactions/sec) versus
the number of users ; and cost/user versus users for all the configurations.

There would be text describing the story. The novice would learn a lot and we would become known as a hot company in this area. It would be an extremely powerful ad and I think read by people who want to learn more about computing and who want to buy them too. We would also become known too.

If this doesn't work, then let's hire a super IBM type marketer like just recently became president of Prime. They're doing well and so is Wang with these types, so probably that's a better answer. We sure need to do something to get some business from prime, wang, hp and ibm.

SUBJECT: MASS STORAGE AND BUILDING LOW END PRODUCTS

It's very clear that this area is going to and should be heated up and our planning assumptions reviewed again. Frankly, I don't think that the plans are worth a damn there, starting with the idea of building mini-floppies and going up to the AZTEC because they do not recognize the commodity nature of these products. (This includes mini-floppy follow-on, Maya (we have a solid record of having NEVER made a reasonable tape in terms of performance, cost, profitability, etc.), RD52, and now AXTEC due to large number of emerging alternatives.)

I don't think we can depend on Ken's enthusiasm for the RL02 to carry the day. Everyway I look at it, the RL02 costs: direct, FAT due to arcane way of producing the products, size, high service costs, inability to get a small enough system, etc. In this later regard, you should note that even with steep discounting, the 23 is only making 0.1 of its plan, and I don't think that major discounting is going to help much at all. Note the plan of 192K RL's total versus the 64K we've shipped seems incredulous.

We all have to REREAD and understand the Engineering Strategy Overview. The 5th Generation means major transitions in the product set and the way we engineer and produce products. Much of the organization outside of the VT's and CT's haven't

gotten
this message as we judge by their response. This is going to
the challenge this year.

It's going to be a lively new year.

Subject: **Rules of Thumb for Mass Storage Cost/Systems Price and Component Cost Reductions (for Red Book)**

To: OOD, Senior Product Managers,
Andy Knowles, ML10-2/A52
Mike Tomasic, ML12-2/E71

Date: 3/28/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

<u>Relationship Between Mass Store Cost and System Price</u>

We have been tossing around the relationship between mass storage subsystem cost and system price of a factor of 10 because of a markup of a factor of 4 and the fact that the mass storage represents 2/5 (40%) of the entire system. This has been quoted as if it were like the Second Law of Thermodynamics, or an experimental constant like the speed of light. It ain't. Note:

1. Assume mass storage susbsystems of 2200, 1600, and 1100.

2. Rule of thumb would say, we can only market systems at 22K, 16K and 11K. This would imply other costs of $3300, $2400, and $1650. Now assume, the 1100 disk is not available for some reason.

3. We could market systems at either 11K (the original target system price) + 4.4K = 15.4K; or 11K + 2K = 13K...both of which are under the implicit 22K or 16K, while still maintaining

the 4 markup.

4. Alternatively, we could market systems based on either mass storage subsystem at 11K, but taking lower markups of 11K/(1650+1600) = 3.38; or 11K/(1650+2200) = 2.86. For example if the mass storage is bought out, while the markups are substantially lower, the return-on-investment may be much, much higher due to the fact that design and manufacturing tool up investments aren't required.

<u>Relationship Between Component Cost and System Price</u>
Unlike the case of mass storage where we believe a relationship exists, there is a need for some guidelines (rule of thumb) as to when we need a new component in order to achieve a lower cost system. In this case, we may spend several million dollars to build a brand new, one-chip processor, only to find that it has a negligible effect on the cost of the system. Alternatively, the same money spent to reduce a common interface, or get a lower cost mass storage system would be better. Since, we don't have a total planning system, it is imperative that the groups chartered to carry out the designs act responsibly by targeting the use a priori.

As an example, consider:

1. There is an available processor that costs $100. A new processor-on-a-chip is proposed that cost 1/2 as much, $50.

2. We build several things, terminals which cost about $500, and small systems which nominally cost $1000 to $2000.

3. The $50 cost premium means that these systems could otherwise be built for $550 and $1050, reflecting a 10% and 5% cost premium. It isn't clear that in these systems, a 10% premium will mean very much in the marketability, especially since we don't have channels of distribution oriented to these lower priced systems.

This type of cost reduction activity doesn't seem worthwhile according to the make versus buy guidelines we have tried to establish in the past, and that are attached. As a minimum, we should not do a cost reduction of the type given in the above example unless we get a 20% to 30% cost reduction! Is this a good guideline?

Subject: Mass Storage for personal VAX

Your note indicates that you have concluded that AZTEC is the best productw
without stating what the selection metrics were. We would like to take a shot
at your requirements and would appreciate a statement of your goals and
requirements.

I note that the HP300 uses a 14 inch hard disk and floppy

loader/backup. It is
highly unlikely that an 8 inch disk could be costper megabyte competitive. I
believe that we can be technology competitive to HP on either 8 or 14 inch. 14
inch offers THREE times the recording area (= to capacity) at perhaps a 10 %
cost disadvantage.

I also believe that RL01 imbedded servo technology can be cost effectively
applied to floppy media. This could yield 3 to 5 megabytes at significantly
higher performance and equal or LOWER media cost than multitrack large 3M
cartridges.

By concentrating on larger floopies we also get a terminal type mass storage
systems device. The TU5900 certainly can't fill this bill. Let's minimize
our technology space and maximize utilization of each product!

I agree with Grant. Furthermore, we probably have to use what's coming at
that time...although now is clearly the time to influence it. What are the
requirements? Do we need removability or very much removability?

Subject: Our meeting on storage next week

Mary Jane: Please hand deliver to Bob Jack, Mike Riggle and Mike Gutman next
week before our meeting.

I view you people are spending all your time bickering about charters and not
doing work. Your people are sulking because they feel the same way you do.
There have been some past bad decisions that were made in both areas inin
selecting vendors (Pertec and ISS) and in underestimating prduct development
t that have blown the budget to hell. The comment I've heard about this that
one group is being penalized because of the stupidity of o another one is
really bad! Of course, we don't have that much money to spend, however, it
is being covered by Portner.He doesn't complain about your poor decisions.
The decisions have already been made, and we haveto live with them, build on
the errors, cut the losses however we must...the key thing is are we on the
right product path now??? [The next time I hear the word that Colorado or
whoever is apaying for the mistakes of Peyton, I will insist that we get a
new manager in Colorado. It is true, just as Colorado is alos paying for the

poor selection of ISS as a vendor...and that is a hell of lot more serios
mistake that the people who are now in Colordo made before leaving. The
point is that we are one family, and when a member takes the food money and
goes out on a binge, we're all going to be mighty hungry.]

There is a real competitive threat out there now, unlike we've ever had before
in IBM, because for once they have chased all their competitiors out of the
high end (eg Univac and Honeywell, etc) and are now coming down to take care
of us. And based on our past performance we will crumble. The big problem
will be the competitive situation in the mass storage area.

The real reason I don't want to/ am reluctant to increase funding in this area
is you and the product area. Giving that we could do all the projects on
the list, we would really fail, because they are both too late, and I think
too weak. You are all up tight about charters too intra mass storage, and
you have taken on charters outside of your past domain in a product like HSC
and this will eat into a budget like you've never seen before...because it
has an almost unbounded software component.

Help is needed and I think the system's groups represent a place where you
can get some of it. They too don't want to fail because of poor components.
Similarly, there is the outside, which based on our past record is not a
solution becuse we have picked the wrong vendors. However, some combination
of both of thes is needed, given the problem (competition) we see looming

ahead.

Maybe I'm naive, but I see that IBM has only 4 mass storage products to cover
this whole range...the 1 Mbyte floppy for getting in and out of systems; the
50 and 600 mbyte fixed disk systems and the 8xxx tape for backup. Also,
according to recent results, they may be going for density in bubbles (a
breakthrough may have happened) to cover as a system device down in the low
end, and enabling them to use floppy or some other device as the removable
media.They will no doubt offer a pile of more products for there large
systems, and I'd believe these would be in the archival are plus maybe
andother disk. (Note unlike us, these disks are seperated by factors of 50
and 12...ours currently are seperated in no increments or factors of 2, 3, 4
at the most). Also we have no way to get out of the products in production.
This is easy!! We propose it and get approved by the Marketing Committee!!!!

We can spend a little time about the charters at our meeting, but I want to
know how/ where you are going to get help from? What products do we/ will we
have to survive against IBM? How can we cut done on what we are doing and get
the quality up?

EMS   5-MAR-79

18:37:02 570 1

To: John Kevill

CC: John Meyer

From: Gordon Bell

Date: MON 5-MAR-79 18:37:02 EDT
Subject: Disks

We had a very heated discussion today in regard to disks. The perception is
that we have been screwed again by the disk group by not having competitive
products. Jack Shields casme to the rescue in saying that we decided to have
low end products (RL) versus finsish the large disk we bought from Telex and
have a big disk. His perception is that we (enginering) have operated
according to plan and there have been no surprises.   To a certain extent
he's right, but the problems we had in tape and in the RP07/8 have recently
blown any old strategy that was probably ok, ... to hell.

Win would like a discussion of how we are going to get somewhere in this
area. At that time, I didn't raise the issue that the discussion is
premature until we had the Redbook cycle complete. Let's get together quick
and meet with Win. The disucssion might take the 2 part form: Past an and
anything we might learn; and the future. Julie throws out the
ireelevant...buy someone so ask Henry to   say who'e for sale and how much
they would cost.   This is a follow onof my memo to the group last week. I
view we have done a series of dumb things each year (eg. making RK07 packs,
maybe ts04, having a redundant rk06/6 and RM03; chosing ISS; chosing Pertec;
and wehave no room for any errors in plan, product selection, execution,
etc). Here it might be appropriate to look at the state of the plans versus
cexecution for the last 3 years.

EMS 18-MAR-79
14:10:55 530 1
To: John Kevill
CC: John Meyer
From: Gordon Bell
Date: SUN 18-MAR-79 14:10:55 EDT
Subject: Prioritizing the issues and helping in mass storage

I have spent some time thinking about a whole range of issues. I want you to
get a list of the problems so we can start to address them on a one by one
basis. It is increasingly clear that the management depth is a big one, and
I am going to push to have you segment the business acccording to size so that
a single development manager wont' have cover such a big dynamic range. I.e.
let's draw a little table of disks/tape and size (3 bands), giving us 6
entries with products in each. Tell me who is responsible in each of the
boxes or set of boxes. If we get two more managers, then who's going to do
what? John Meyer, this recruiting has to get really high on your list for
recruiting...John has been doing it so far and he's got to delegate!

Intellectually we need to have someone help Gutman. I think Bob Steingart
who works for Tomasic could do it. I want to update the whole Sills charts
to se how we are doing after 2 years. By the way,. let's get Grant to
compare the spending profile in the R80 with that of the lRL01 and RK06/7 to
see (have him face directly) just how long it takes to get something done,

given the breadboard state that things afre in.   Reality can be obtaine by
facing history! I have these charts if you don't, but I think we must have
them to navigate and help your managers be realistic.

By adding more managers who report to you responsible for other size ranges,
it will be possible to have a second manager in CX. With this, I have no
worry about putting more (eg hi end buyout in CX.) there.

Post v N Computing: A 10 YEAR, DIRECTED RESEARCH PROGRAM AND NATIONAL FACILITIES AIMED AT PARALLEL PROCESSING

A Draft Outline*
&
Invitation For A Proposal(s)**

Gordon Bell, DEC

George Clark, Harris

Bruce Delagi, DEC

Sid Fernbach, Consultant to CDC

Bob Lillestrand, CDC

Red Phillips, Univac

13 August 1982

* Substantive references to previous and ongoing work and

bibliographic references have been omitted. While we believe the general direction is correct, specific tactics such as the applications to focus on, will be subject to change with the final proposal(s). We now solicit both conceptual and detailed critiques.

** The final proposal must come from the program group dedicated to produce the results. Thus we solicit:

- o sites
- o individual researchers and a program director
- o applications and other research projects

TABLE OF CONTENTS

1. Some Critical Global Questions
2. Why use CDC's Advanced Flexible Processor?
3. Rough Budget

OVERVIEW

This proposal began as an exercise by positing a computing environment we believe is attainable in 10 years based on parallelism uncharacteristic of the single, von Neumann machine and then asking ourselves:

> Are we doing anything significant to understand and build this environment?

The result was overwhelming:

1. most industrial research appears to be aimed at incrementally improving today's products and processes; while

2. academic research is aimed at basic research and the mechanism of getting grants, producing papers and Ph.D's.

The objective of this program is to develop the technology and build next generation computers by establishing several National Laboratories for computer science and engineering research within the U.S. military, academic and industrial community. This technology is essential:

1. for defense;

2. to improve the declining computer and semicomputer part of the U.S. Information Processing Industry which now constitutes and supports much of our economy directly and via exports; and

3. as a basis for much of the 21st Century Industries.

The declining technology position in the computers and semicomputer industry is a national crisis. As such, this necessitates these unique aspects of the program:

1. collaboration among national science, defense,

university and industrial applied research, often called technology, in a fashion not unlike the VHSIC program;

2. National laboratories so that limited machine and people resources can be shared, unlike the VHSIC program;

3. a large, fast network including access both for experimentation and to extend the program to other research sites;

4. construction of prototypes by industry for evaluation within the research community;

5. technology transfer by industrial residents at the laboratories;

6. tighter coupling of application (need), architecture, construction and use by co-location in order to rapidly engineer, build and test ideas. This speeds up migration of ideas to use by applying engineering resources earlier.

These facilities will be the hub of a goal directed research program aimed at new VLSI-based, highly parallel computing structures. Parallel processing systems, including: specialized processors and hardware algorithms, multiprocessors, multicomputers, dataflow and high speed local area network based meshes will be built and evaluated. Evolutionary projections show a performance increase in processing of only a factor of 3 (Fig. 1) to 11 (Fig. 2) over the next 10 years. In contrast, the Japanese Fifth Generation Research Project, is aimed at producing high speed and parallel computers with a factor of 100 to 1000 more computing power for conventional and Knowledge Based computing systems by 1990 (Fig. 2).

Another major goal of the program is VLSIzation, the ability to transfer an algorithm, simulated within the computing environment, to VLSI limited only by the foundry time in much the way programs are currently compiled. By it's nature, this structure adds inherent parallelism to computing. The national facilities would also support the goal that computers would do a substantial part of the VLSI design. Research in the parallel computing structures we target will rely on accomplishment of these goals.

A new computer generation is marked by concurrence of technology and needs causing a new computing structure and resulting in new use. We believe this driving need is for the ability to transmit, store, and process (understand) the same information as people, including voice, natural languages and images. Images are a major data type of this research program because of the links with people. The research need is driven both by hardware and technology and by the potential of Knowledge Based Systems requiring much higher performance. These must be coupled with signal processing to assimilate voice and images.

The program would be organized in 3 phases, covering roughly a decade, in order to focus the work in a timely fashion. Generations have historically taken 7-10 years and consist of two periods: specification and construction; followed by use and evaluation. The immediate installation of the most powerful, high speed network of general purpose computers would start the program in the use and evaluation phase. Results based on application of this facility would then be applied to produce new VLSIzed computing structures by the end of this first phase. The second phase would apply these newer structures, forming the basis for new designs in the final program phase.

MOTIVATION FOR THE PROGRAM

The U.S. lead in the combined Information Processing Industries is now declining relative to Japan. While there are many reasons for the decline, these are noteworthy and represent the motivation for this program:

1. The U.S. (and World) funding for basic and applied research is large. This mechanism produces far more results than can be applied.

2. There is NO U.S. effort or policy aimed at systematically examining the basic research results and refining them so they can be applied to products. The cost to do applied research on even a small fraction of the basic research is usually far greater than the original work and is well beyond the scope of a single company or a laboratory. Furthermore, most laboratories doing research can only carry ideas to the paper stage because of the engineering nature of the final stages to build and test the idea. Thus, overfunding research relative to applied research means a "spilling" of knowledge that forms the basis of a significant industry.

3. U.S. companies have not worked collaboratively to develop these technologies because of legal and cultural reasons.

4. U.S. industry has been especially short sighted in its funding of this phase of research. Now, many short term, mundane product opportunities (eg. another Z80 + CP/M based personal computer) exist to attract resources resulting in further decline. This is further fueled by the venture capital market and increased R&D tax credits which in turn produce even more mundane products.

5. An inadequate supply of people and equipment exist to carry out the work in industry and the research organizations.

6. A research program aimed at parallelism requires interaction and co-location with a user community.

We marvel at the effectiveness of the Japanese collaborative research programs and believe we must emulate them. Both France and the U.K. have established programs aimed at the next computer generation. Note the past and present programs in the Information Processing area:

1. Pattern Information Processing- voice and vision

2. VLSI- improved processing characteristics (eg. 64K and 256K rams resulted in a 2 year lead over U.S. industry)

3. Supercomputers- high speed technology

4. Optoelectronics- just established

5. Standard Minicomputer for NTT- Fujitsu, NEC and Hitachi

6. Fifth Generation Computer- Fujitsu, NEC, Hitachi, Mitsubishi, Matsushita, Oki, Sharp. ICOT Lab and 10 year program were established. The first phase builds Relational Database and Prolog machines.

7. Local Area Network standards as part of the Fifth Generation.

8. Next generation research and technology program.

THE RESEARCH PROGRAM CONTENT

RESEARCH OBJECTIVES

This work is undertaken with the expectation that the confluence of the disciplines of parallel processing applied to image processing, and knowledge engineering, and implemented using VLSI will prove fertile. It, and the resulting VLSIzation process, that of first understanding specific algorithm and tasks and then VLSI'ing them, may well be a major characteristic of the next generation computing systems, which the Japanese call the Fifth Computer Generation.* The establishment of a quasi-competitive, but coordinated program of research using common research facilities is intended to stimulate a national understanding of such systems and their potential application.

The work is aimed at a fundamental understanding of parallelism and its application to a class of problems critical both to the growth of the computer industry in this country and to the maintenance of a preeminant US position in intelligence based military systems.

ESTABLISHING AND USING THE FACILITIES: PHASE ONE

The short term focus will be on installing and applying parallel approaches to image procesing and logic/circuit/process simulation problems, especially dataflow. We think it is vital to understand the range of dataflow from theory to practice across a wide range of applications. In its simplest form, dataflow can be viewed as a formalized, generalization of pipelining that is conventionally used for graphics and image process. In its more general form, dataflow looks appealing for logic simulation, signal routing, and conventional array processing type tasks where a great deal of parallelism exists, but cannot be exploited due to the difficulty of expressing algorithms in conventional languages. It is indeed possible that dataflow-specific machines <u>will not</u> exist, instead dataflow languages will enable programs to be written for large, multiprocessors. The centers will be based on a high performance local area network to interconnect the central machines, including:

- supercomputers,
- experimental machines (dataflow and conventional multiprocessors and multicomputers), and
- the CDC AFP.*

The AFP will operate with <u>fixed microprograms</u> to simulate several computer structures including dataflow computers. This will enable researchers to begin now and to understand the limits and use of dataflow architecture, for example. These efforts must be put to the test of representative applications in order that the tradeoffs discovered be relevant to solve.

* One of us (GB), believes that the current generation, number 5, is based on powerful personal computers interconnected via local area networks. The Japanese are working on the sixth generation, beginning in the late '80's.

It is essential to have real applications on which to "benchmark" various designs. The following applications cover some of the possible important military and industrial problems: scanning electron microscopic image enhancement, automated assembly inspection, target identification, digital system design and construction (eg. logic simulation, routing and IC signature analysis). The actual applications should be made firm with final proposal.

While the initial results have focused on using a dataflow architecture to examine its limits, the network and facilities we envision are much more extensive and will be used as alternative ways of computing.

PROGRAM DEVELOPMENT OF THE CENTRAL FACILITIES

It is expected that the central research facilities will be enriched further over time by including, as additional research tools, the fruits of the aspects of this program particularly focussed on realizing more powerful forms of processor interconnect and process (or operator based) intercommunication. It is expectd, further, that several realizations of parallel solutions to specific application image processing problems will be implemented (in VLSI) and included in the central research environment.

UNDERSTANDING PARALLELISM: PHASE TWO

In the middle phase of the program here proposed, the principle results will include a deep understanding of the dimensions and metrics that describe the space of parallel computing - costs, performance, programming expense, and reliability. The proposed facilities provide a rich set of alternative realizations for parallel computing - ranging from tightly coupled multiprocessors to conventional Local Area Networks. We do not believe that the kind of interconnect for switching is a particularly fruitful area of study because it is really an economic issue that shifts with technology, regulation, market demand, and supply. Thus, the goal is to provide various structures for evaluation and use very rapidly, but not to research the interconnect possibilities!

END POINTS

Expert systems and knowledge engineering efforts are expected to yield their most important results in the last phase of the program. Significant milestones are established throughout the research effort: discerning the computational (and data management) primitives underlaying current rules-based expert systems languages, establishing an effective integration of image and symbolic information into a knowledge base (consistent with the data management primitives noted above), realizing a VLSI implementation of a highly parallel, post von Neumann computer structure for expert systems, trying it out on (say) a SEM analysis problem, a fully automated VLSI design, and finally on an expert system for (semiconductor) process/crisis management (or threat evaluation and reconnaissance mission). These will, in turn, provide the understanding needed for a second VLSI implementation of the expert system engine above.

SINE QUA NON

As a necessary ingredient of effective VLSI implementations supporting the research goals of this program we need the 1990's VLSI equivalent not merely of the Guttenberg Press but of the linotype machine and the automatic typesetter. The process would be completely controlled by an individual or small group. The most important element of this program then is the development of the capability for (fully) automated VLSI circuit design from representations of parallel algorithms simulated on the parallel computing facilities proposed. At first, this will likely be by means of both conventional supercomputers and the dataflow machine simulators running at the central facility.

The automated design capabilities will be made to stand the test of real use in VLSI implementatins of (at least one) dataflow machine. The design of this machine will be based on the measurement and analysis of simulated dataflow machines running applications as noted earlier. These design capabilities will be also tested in VLSI realizations of IC signature analysis dataflow algorithms and the mobile object identification and tracking projects implemented previously. The culmination of efforts in image encoding and compressions will be a special purpose VLSI processor chip that provides full motion video-conferencing within the bounds of a 56 Kbps phone line, for example.

A FACILITY TO UNDERSTAND AND EXPLOIT PARALLELISM

New computer applications usually result from having new, higher performance computers allowing solution of problems that previously were computationally intractable. Performance increases in computing come from two sources: technology improvements and increased parallelism. This program is aimed at understanding and exploiting parallelism to gain performance.

VLSI contributes to parallelism in two ways.

> First, commodity processors allow the low cost construction of the most cost effective systems. That is the Mips/chip of microprocessors far outstrips the densest, high performance ECL gate arrays.
>
> Second, VLSIzation is an inherently parallel process - standard algorithms are off loaded.

To date, attempts to improve performance through highly parallel structures has been relatively disappointing. We believe the major reason for this lack of progress is the high real and personal cost to build and evaluate parallel structures. This program supports systematic research and development on the following alternatives. In this regard, we posit this fundamental hypothesis: <u>in order for a new computer structure to be attractive to a user, and hence ultimately developed and exist, it must offer an order of magnitude improvent in performance over his current method of computation.</u>

SPECIALIZED PROCESSING (AND VLSIZATION)

Historically, an order of magnitude or more speed improvement has resulted from looking at the execution times of particular work and then building hardware to carry out the function. VLSIzation is a realization that this evolutionary process exists and is an attempt to formalize the process.

Some examples of "off-loading" using special function hardware:

1. Floating point hardware versus a software interpreter

2. Channels, I/O Processors and I/O Computers versus interrupt and hardwired I/O

3. Display processors

4. Array Signal Processors

5. Front end (communications) and back end (disk, file and database) computers

A need, resulting from a computation on a particular kind of data occurs.

This need is then a requirement for a new computing structure. The function is then "off-loaded" in specialized hardware that operates in parallel with the general purpose computer.

By having a general purpose, very high speed system, the resulting, specialized structures can be totally simulated before they are committed to VLSI designs. In this way the designer can interact with the structure in a quickly iteractive fashion instead of waiting at each iteration for fabrication and system (re) integration.

MULTIPROCESSORS

Every time a new computer class is formed, there are strong arguments to build multiprocessors for performance reasons. Invariably, others build higher performance Uniprocessors at the same time and deliver more power via the strictly sequential approach. Multiprocessors were proposed by the early 60's, with Burroughs probably delivering the first one (B5000). By the early 70's Burrough's, CDC, DEC, GE, IBM and Univac had all built 2 - 4 processor multiprocessors. Unfortunately, these were either used in an asymmetrical fashion, or at most they were used in an ordinary multiprogramming environment. In no cases was parallel processing of a single task provided.

In 1966 Lehman investigated parallel processing of a single task with a 16 procesor multiprocessor and showed that for various tasks speed-ups were possible. By 1975 two 16 processor systems were built by BTL and at CMU. The CMU system was predicted on the 11/40 minicomputer, as a way to afford the construction, and speed-ups of up to 10 were observed in various algorithms.

CDC's Advanced Flexible Processor is an ideal machine to investigate the use of multiprocessors and multicomputers since the interconnection among the computers is via very high speed local links (ultra LAN) and shared memory. It can be used in many ways, including:

1. a 16 computer multiprocessor;

2. a 16 processor multiprocessor;

3. a fixed, intrpreter for particular structures (eg. dataflow); or

4. a particular, dedicated pipeline processing configuration (eg. image processing).

Several laboratories are building systems with up to several hundred microprocessors.

LLL is building a multiprocessor, the successor to the S1, with 16 supercomputer class processors. As soon as the processor's available, it should be extended to the multiprocessor case for evaluation, since the processors are both tightly coupled and have very fast inter processor communication mechanisms. This should be within the next three years.

DENELCOR is offering a 64 processor multiprocessor which requires investigation. We strongly recommend the installation of this machine in the facility in order to work on the multiprocessor problem.

Recently, Schwartz, et al at NYU has proposed the Ultra-Computer, a multiprocessor with up to 16,000 VLSI microprocessors. Just as soon as we can operate a reasonable number of processors together, construction should begin on this very large multiprocessor.

It's safe to say that one can produce conventional parallel processors which should be able to deliver up to a factor of four, for specially coded programs. A factor of 10 is possible, but there has to be a significant amount of research to make this automatically possible. Studies continue to indicate vast amounts of parallelism in algorithms that we have no way of exploiting.

We believe that the optimistic (Fifth Generation) projection for computing power speed-up over the next decade could be accomplished simply and entirely by parallel processing using multiprocessors and not by semiconductor and packaging technology if a significant effort were applied! Undoubtedly the dataflow language is an important part of this effort to represent, control and thereby exploit this form of parallelism.

MULTICOMPUTERS

Very little has been done formally with arrays of tightly coupled multicomputers where independent computers (Pc-Mp pairs) operate independently and communicate with one another by sending messages. By 1980, CM*, a multicomputer system based on the LSI-11 microprocessor with 5 clusters of 10 computers was constructed, and speedups of up to 30 were observed for particular problems, including speech recognition. Because there is less interconnection among the computers, it is more difficult to predict the performance: the algorithm has to be carefully partitioned across computers rather than distributed in memory.

In addition to AFP, we believe that other multicomputers should be constructed and used, particularly those with several hundred computers. Here, we would support the construction of several, (say 6) different multicomputer alternatives.

DATAFLOW ARCHITECTURES

Although many dataflow computers have been proposed, only a half dozen computers have been built. The performance of dataflow computers is not understood, although the use of dataflow graphs and languages to express parallelism is promising. In particular, dataflow appears to be most useful in expressing signal processing operations. For example, the AFP is programmed using a dataflow-like representation for image processing tasks. Individual computer modules can be assigned to various processing stages of say a digital filtering task. The AFP also appears to be ideal to simulate static dataflow architectures and their application. It would be microprogrammed to be a general purpose dataflow machine using separate computer modules in a functional fashion: matching store, switching, processing, and i/o.

ULTRA-, FAST-, AND CONVENTIONAL LOCAL AREA NETWORKS

Local Area Networks, LANs, are systems which normally allow the physical distribution of functional, server components to cover a local geographical area (eg. a building, or campus). The functional servers roughly correspond to various parts of a shared system: person servers (computing workstations/terminals), file servers, print servers, and communicatins servers. The communications is via message passing protocols. While the curent 10 Mbit/sec LANs are relatively slow, they are well matched to today's, slow terminals, personal computers and for intercomputer networking.

Researchers have also posited that LANs can be used to provide high performance, parallel processing. We too believe higher speed LANs are the backbone interconect architecture for new computer structures. The higher speed, 100 Mbit/s LANs will be the basis for interconnecting functional computers in a hierarchy as shown in the facilities section (Fig. 3).

We view the Ultra-LAN as a major architectural component and standard for truly fast, highly parallel structures of this next generation. Note that the ring that interconnects the AFP provides transmission at about 2 Gbits/sec for each computer node connected for the tightly connected computers. Thus, the AFP would be used for some studies of this type of LAN-based architecture.

The purpose of the hierarchy of three LANs is summarized:

Ultra-LAN	2 Gbits x p	AFP's processor intercommunication; as first basis for an ultra-LAN architecture
Fast-LAN	100 Mbits	Facility computer intercommunication and center to remote sites, forming a single cluster
LAN	10 Mbits	Individual workstations to form centers

PARALLEL PROCESSING FOR KNOWLEDGE BASED SYSTEMS

It has not been widely agreed that Knowledge based Systems can exploit parallelism. For Rule Based Systems, it is believed that many rules can be evaluated in parallel. The research will be aimed at first answering the question, and then simulating and evaluating the resulting structure. AFP might be used to simulate such a structure, provided this approach looks worthwhile.

THE RESEARCH PROGRAM FORM

ORGANIZATION, DIRECTION AND RELATIONSHIP TO ONGOING RESEARCH

A program office, together with a board of directors would contract the research in a fairly structured fashion. While research of this type is not commonly done today in computer science, we believe it can and must be done effectively by a joint industry and computer science research laboratory efort. <u>Industry can be effective at providing facilities and systems</u> that have been traditionally absent from the research laboratories. In effect, this is the major motivation for the proposal.

A major goal of the research project is to provide a large infusion of computing systems to support existing, more basic and unstructured work, including robotics.

The purpose would not be to change the nature of the existing unstructured research to be highly focused and goal directd, but rather to provide additional resources so that both the structured project and unstructued work could co-exist and complement one another.

The centers would be aimed at very similar research targets in order to get the benefit of "friendly competition". Similarly, several approaches would be examined within a center. This approach was successful in the mid-70's in speech research and should be the "model" direction. However, the speech research resulted in few, commercialized industrial or military applications, because the research coupling between academic and industrial research was poor. Unfortunately, the final transfer phase of research was terminated before the program ended.* It is this gap between basic research and applications research that the program is fundamentally addressing. It is interesting to note that NEC had an advanced development operating separately, but concurrently with the ARPA program. The result is that NEC provides recognition products.

We would hope that a better model to follow is VHSIC. It is crucial that the participants be able to exploit the technology for commercial and military applications propitiously. Unlike VHSIC, we believe that the work should be done at a few sites with movement of personnel.

THE PROGRAM OFFICE

The fabric of this research is a fairly close weave. The environments are, indeed, established anticipating that unexpected leverage and collaborations will yeild significant results not included in the program plan. However, it is precisely the existance of a structured program and the interrelation of its several work flows that will enable this to occur. The program office is responsible for the successive development of the fabric using resources as it can find them and coordinating efforts so work can easily build upon what came before.

* Personal communication with Allen Newell and Raj Reddy at CMM.

The program office will set adequate standards so that ideas meet no unnecessary boundaries between the workers and the worksites in this program. Early, stable agreement on the common rules, language, workstation, the network and the general computational support structure will be among the most important contributions of the program office, the goal is to use this commonality of interface to allow pyramiding of work - being careful not to pyramid risk.

The program uses applications to test ideas, and uses realizations of those ideas to build the next generation applications. It even uses these applications themselves to acomplish future generation realizations fueling the next cycle. The central facilities are the place that application tools for realizing ideas, the realizations themselves, and the applications for testing ideas all come together. This must all flow forward rather than bottleneck into a deadlocking interdependencies. The opportunity and expectation for people to build on each others work as it becomes available is the key. In the natural uncertainties inherent in this ambitious program of research, there must be enough alternative paths so clever people can use their wits to find a critically helpful piece of another's work or another's facility wherever it may turn up.

The program office must have the ability to facilitate the construction of important engineering breadboards so that systems can be rapidly built and evaluated. We envision utilizing the industrial sponsors for this breadboarding.

The program office is deliberately kept small to force most standards to be developed collaboratively with the groups doing the work. The program staffing for the parallel computing facilities is very light in the expectation that site personnel will be provided by the host institution. The Budget Table, Appendix 3, provides a more detailed breakdown.

PROGRAM BENEFICIARIES

The program was conceived in order to improve this flow of basic and applied research into industrial research and eventually into products. The main beneficiaries are those who use these ideas to eventually build products. Products will not come directly from this program.

On the other hand, virtually everyone will benefit by the program:

1. the U.S. technology will be drastically improved - thereby improving defense and the economy;

2. the researchers will be more effective and productive by having more meaningful work;

3. certain research will be published; and

4. researchers will still migrate from the coupled programs, being attracted by venture capital, and build higher technology products.

TRANSFERING THE TECHNOLOGY

The most effective means of technology transfer is through the transfer of people. Program sponsors will each have the right to place people in each project of the program. It is expected that assignments be for a three year interval and that the assigned person return to the sponsoring organization prepared to produce the competitive products of the late 80's.

To insure a co-operative working environment among the members of a project team, intellectual property rights for the work done as a team using the facilities of the host institution will be controlled by the policies of the host institution. However, each program sponsor will have the right to a non-exclusive license at reasonable terms.

A major part of the transfer will occur when the sites and industry collaborate on fabricating a design that a site has specified.

With VLSIzation, chips produced as part of a research project would be licensed to the sponsors. The "rights" to chips and software produced as part of a research program are indeed not clear at this time and vary among the institutions. This area would have to be worked out between the institution and the program.

Other mechanisms for technology transfer include sponsor access to prototypes, distribution of published technical reports and invitations to program seminars.

Seminars will be held quarterly for program sponsors with invited speakers from universities, government and industry.

In inviting speakers the organizers of the seminars will have the freedom to draw on the wide range of topics encompassed by the program, including:

- Pattern and image processing applications
- A. I. algorithm research
- Multi-processor architectural developments
- CAD/CAM software systems
- VLSI design process advancements

FACILITIES

HIERARCHIES OF AREA NETWORKS

The program would be organized around at least central research computation centers containing a variety of production and experimental computing systems (nodes) interconnected via 100 Mb/s links and forming the central facility for a hierarchical set of closely coupled, high performance, local area networks. The centers will be linked to several campuses via the highest available links so that they could be used in a clustered fashion "as if local" computation centers.

Each site would contain supercomputers, AFP's and experimental computers.

ARPA-NET II

In effect, we're proposing ARPA-net II. This must come into operation relatively soon, to be used to interconnect the more remote research to the centers. High bandwidth, such as several video channels would be needed to avoid limiting the interaction between sites. Here, the goal would be to provide only millisecond delays between processes operating on separated machines.

VLSIZATION FACILITY

Since the projects would be designing many VLSI chips, the facility would need a way to build state of the art VLSI chips from mask design. this could be acomplished by a multi-year committment of appropriate existing capacity to the needs of the program.

LOCATION

The program would start immediately and be coupled to existing computer science and computer engineering research facilities and programs. Facility selection is strictly on the basis of the intensity and quality of work in VLSI, image processing, parallel computing and AI. Either Lawrence Livermore or Berkeley Laboratories would be ideal sites for the computation center which would link to Stanford, SRI, and UC/Berkeley. MIT, MITRE or Lincoln Laboratory could be the basis of an East Coast facility. Los Alamos has the largest network of supercomputers and support computers including storage and image production. If a central site were Los Alamos, this would force the development and installation of high speed links to other sites.

APPLICATION CENTERS

The following very imcomplete list of application centers is included as an example of how work would be contracted by the program office to expertise centers throughout the country.

DELIVERABLES

The work encompassed is broken into three classes shown in the Deliverables Table. Within each class there are families of projects and finally the projects themselves. The program runs about ten years broken into rough phase transitions at the end of 1985 and 1989. The work in the first phase puts the research environment and work standards in place and develops the first generation tools and applications. The second phase includes several machine realizations that use the tools and runs the test bed applications. In this phase, the research facilities are enriched with the machines realized by program efforts. These are in turn, the base of the second generation tools and applications. Finally, the third phase provides refinements and solves the hard problems that depended on the new understandings generated in the first two phases of the program.

MOTIVATING SUMMARY

The motivation for this approach is timeliness and effectiveness:

1. THE RESEARCH PROGRAM SHOULD START NOW

2. WE NEED COUPLING OF INDUSTRIAL R&D AND APPLICATIONS WITH COMPUTER SCIENCE RESEARCH

3. WE CAN BUILD ON EXISTING RESEARCH PROGRAMS AND COMPUTERS

It is essential that we start now on the research program, as our computer science research has been drifting these last few years as both industry and computer science research have both gotten large, diffused, and independent of one another. Significant industrial research outside of IBM, Bell Labs and Japanese companies is non-existent and there is no coupling of basic and industrial research. For example, we believe there is better coupling of Bell Labs work to the Japanese computer industry via NTT's, ECL, than between Bell Labs and the U.S. Information Industry. Furthermore, both the academic and industrial research communities are now poorly coupled to real applications. We believe that program focus of some of the existing research efforts into a goal directed system will enhance their productivity and enable the continuation of a vital Information Industry for the 21st Century.

APPENDIX 1

SOME CRITICAL GLOBAL QUESTIONS (AND ANASWERS)

1. Why is the establishment of national facilities the correct way to attach the parallel problem?

.

No single lab now has critical mass or focus in anyone area - currently all resources are difused.

.

The lab(s) and programs operate together to do the work.

.

Users, architects, and builders must couple.

2. What impact will this proposed program have on existing research facilities? Programs?

.

The intent is to build on, and <u>extend</u> current facilities by additionla resouces. We believe that this program is close enough to some of the existing.

2

a. What about the extra space required for these facilities?

. We don't know.

3. How will this effort help the basic problem of a shortage of qualified researchers?

- It is hoped that a "program" will stimulate the demand to produce more researches over the long term.

- Short term, the focus should increase everyone's effectiveness.

- We hope to apply industrial researchers to the problem that are now difused and often operate as a sub-critical mass.

4. Who is supposed to benefit from this proposal and in what specific ways?

(See Section on Program Beneficiaries)

5. Is there a nationla crisis and exactly what is it?

(See section on Motivation for the Program)

6. What evidence do you have to support the level of funding which is projected as being adequate to achieve the goals?

This is really a draft outline for concrete proposals. From this we expect specific sites to be established and operated in very targetted areas: such as parallel knowledge based systems, high performance parallel processing and parallel image processing.

7. What, exactly is the overall objection of the program?

(See the first sentence of this document)

APPENDIX 2

WHY USE CDC'S ADVANCED FLEXIBLE PROCESSOR?

The AFP has demonstrated high performance in digital image and signal - processing tasks. For example, a processor system can transform the every co-ordinate of a million point picture in 1/30 second. Several systems are in operation today. It includes various support software including simulators.

Traditionally, we design, build and then use. A machine as fast and general as AFP would require at least 5 years to build. By using the current AFP as a general purpose research tool, we can gain at least 5 years on starting such a program from scratch. To illustrate, consider the several data-flow projects that could use AFP today to simulate architectures. Since we need to evaluate these architectures by using them, we could understand the benefits and drawbacks of these machines five years (or so) sooner by adopting the AFP as a hardware simulation base.

The CDC AFP provides a very fast, flexible, microprogrammed set of up to 16 computer modules for experimenting in various parallel computing structures of various type. A single, AFP microprogrammed processor provides the following capability:

. 20 to 800 Mops in 16 parallel, 16-bit arithmetic and logic units

. Microprogrammed control

. Access to 32 Megaword (256 Megabyte block oriented memory)

. 2 X 1 Gbits/sec communication with neighbors in ring

A flexible multiprocessor and multicomputer structure are both provided since, the sixteen processors can be interconnected both to a common 32 Megabyte memory and to adjacent processors.

The AFP can thus be used as a <u>tool</u> to study several different computer structures that we believe are much of the basis of the next generation.

Because AFP is so highly parallel, including having functional units with side effects, we believe it will not be imcroporgrammed to any great extent.

The mode we envision is that it would operate in several configurations, with fixed microprograms to behave as:

1. Set of microprogrammed pipelined, functional units within each processor. Four units can be initiated every 20 nanoseconds, although an average of seven units operate in parallel for most problems. Because of the difficulty of programming this highly parallel structure, the most important benefit, or side-effect will be understanding in how to do it effectively. Because the microprogramming so heavily pipelined, we believe a better understanding of dataflow techniques for expressing algorithms will result from the use. Nearly all high performance machines are pipelined; hence, we believe AFP is a good vehicle to get a better understanding of pipelining.

2. 16 processor multiprocessor with shared memory and very fast interprocessor intercommunication. Here, the processors will be programmed to be particular ISP, such C. If C could become the basis of the machine, then UNIX could be run.

3. Set of 16 Computer Modules microprogrammed for particular functions. AFP was designed to be operated in this mode for image processing.

4. A dataflow computer. This is a special case of item

3 whereby particular computers are programmed to behave as the various functionla units of a dataflow computer.

5. A set of special, parallel processing architectures using individual, microprogrammed processors as the functional units of the particular structures. In this mode, AFP turns out to be a very good emulator of relatively complex VLSI chips.

6. An experimental Ultra-LAN based architecture. To examine how computers can be coupled effectively and work together on a task, the AFP looks like an ideal for study.

APENDIX 3

ROUGH BUDGET

The program expenses are estimated at approximately $18M/year running from 1982 through 1989. Equipment is expensed as delivered. In general two or three "competitive but collaborative" groups are charged with each project family.

YEAR 1

Program	# Expenses Sites Manpower	Heads (ea.site)	Total ($M) Heads Equip

GB3.S7.3

Post v N Computing: A 10 YEAR, DIRECTED RESEARCH PROGRAM AND NATIONAL FACILITIES AIMED AT PARALLEL PROCESSING

A Draft Outline*

&

Invitation For A Proposal(s)**

Gordon Bell, DEC

George Clark, Harris

Bruce Delagi, DEC

Sid Fernbach, Consultant to CDC

Bob Lillestrand, CDC

Red Phillips, Univac

13 August 1982

* Substantive references to previous and ongoing work and bibliographic references have been omitted. While we believe the general direction is correct, specific tactics such as the applications to focus on, will be subject to change with the final proposal(s). We now solicit both conceptual and detailed critiques.

** The final proposal must come from the program group dedicated to produce the results. Thus we solicit:

o sites

- individual researchers and a program director
- applications and other research projects

TABLE OF CONTENTS

1. Some Critical Global Questions
2. Why use CDC's Advanced Flexible Processor?
3. Rough Budget

OVERVIEW

This proposal began as an exercise by positing a computing environment we believe is attainable in 10 years based on parallelism uncharacteristic of the single, von Neumann machine and then asking ourselves:

> Are we doing anything significant to understand and build this environment?

The result was overwhelming:

1. most industrial research appears to be aimed at incrementally improving today's products and processes; while

2. academic research is aimed at basic research and the mechanism of getting grants, producing papers and Ph.D's.

The objective of this program is to develop the technology and build next generation computers by establishing several National Laboratories for computer science and engineering research within the U.S. military, academic and industrial community. This technology is essential:

1. for defense;

2. to improve the declining computer and semicomputer part of the U.S. Information Processing Industry which now constitutes and supports much of our economy directly and via exports; and

3. as a basis for much of the 21st Century Industries.

The declining technology position in the computers and semicomputer industry is a national crisis. As such, this necessitates these unique aspects of the program:

1. collaboration among national science, defense, university and industrial applied research, often

called technology, in a fashion not unlike the VHSIC program;

2. National laboratories so that limited machine and people resources can be shared, unlike the VHSIC program;

3. a large, fast network including access both for experimentation and to extend the program to other research sites;

4. construction of prototypes by industry for evaluation within the research community;

5. technology transfer by industrial residents at the laboratories;

6. tighter coupling of application (need), architecture, construction and use by co-location in order to rapidly engineer, build and test ideas. This speeds up migration of ideas to use by applying engineering resources earlier.

These facilities will be the hub of a goal directed research program aimed at new VLSI-based, highly parallel computing structures. Parallel processing systems, including: specialized processors and hardware algorithms, multiprocessors, multicomputers, dataflow and high speed local area network based meshes will be built and evaluated. Evolutionary projections show a performance increase in processing of only a factor of 3 (Fig. 1) to 11 (Fig. 2) over the next 10 years. In contrast, the Japanese Fifth Generation Research Project, is aimed at producing high speed and parallel computers with a factor of 100 to 1000 more computing power for conventional and Knowledge Based computing systems by 1990 (Fig. 2).

Another major goal of the program is VLSIzation, the ability to transfer an algorithm, simulated within the computing environment, to VLSI limited only by the foundry time in much the way programs are currently compiled. By it's nature, this structure adds inherent parallelism to computing. The national facilities would also support the goal that computers would do a substantial part of the VLSI design. Research in the parallel computing structures we target will rely on accomplishment of these goals.

A new computer generation is marked by concurrence of technology and needs causing a new computing structure and resulting in new use. We believe this driving need is for the ability to transmit, store, and process (understand) the same information as people, including voice, natural languages and images. Images are a major data type of this research program because of the links with people. The research need is driven both by hardware and technology and by the potential of Knowledge Based Systems requiring much higher performance. These must be coupled with signal processing to assimilate voice and images.

The program would be organized in 3 phases, covering roughly a decade, in order to focus the work in a timely fashion. Generations have historically taken 7-10 years and consist of two periods: specification and construction; followed by use and evaluation. The immediate installation of the most powerful, high speed network of general purpose computers would start the program in the use and evaluation phase. Results based on application of this facility would then be applied to produce new VLSIzed computing structures by the end of this first phase. The second phase would apply these newer structures, forming the basis for new designs in the final program phase.

MOTIVATION FOR THE PROGRAM

The U.S. lead in the combined Information Processing Industries is now declining relative to Japan. While there are many reasons for the decline, these are noteworthy and represent the motivation for this program:

1. The U.S. (and World) funding for basic and applied research is large. This mechanism produces far more results than can be applied.

2. There is NO U.S. effort or policy aimed at systematically examining the basic research results and refining them so they can be applied to products. The cost to do applied research on even a small fraction of the basic research is usually far greater than the original work and is well beyond the scope of a single company or a laboratory. Furthermore, most laboratories doing research can only carry ideas to the paper stage because of the engineering nature of the final stages to build and test the idea. Thus, overfunding research relative to applied research means a "spilling" of knowledge that forms the basis of a significant industry.

3. U.S. companies have not worked collaboratively to develop these technologies because of legal and cultural reasons.

4. U.S. industry has been especially short sighted in its funding of this phase of research. Now, many short term, mundane product opportunities (eg. another Z80 + CP/M based personal computer) exist to attract resources resulting in further decline. This is further fueled by the venture capital market and increased R&D tax credits which in turn produce even more mundane products.

5. An inadequate supply of people and equipment exist to carry out the work in industry and the research organizations.

6. A research program aimed at parallelism requires interaction and co-location with a user community.

We marvel at the effectiveness of the Japanese collaborative research programs and believe we must emulate them. Both France and the U.K. have established programs aimed at the next computer generation. Note the past and present programs in the Information Processing area:

1. Pattern Information Processing- voice and vision

2. VLSI- improved processing characteristics (eg. 64K and 256K rams resulted in a 2 year lead over U.S. industry)

3. Supercomputers- high speed technology

4. Optoelectronics- just established

5. Standard Minicomputer for NTT- Fujitsu, NEC and Hitachi

6. Fifth Generation Computer- Fujitsu, NEC, Hitachi, Mitsubishi, Matsushita, Oki, Sharp. ICOT Lab and 10 year program were established. The first phase builds Relational Database and Prolog machines.

7. Local Area Network standards as part of the Fifth Generation.

8. Next generation research and technology program.

THE RESEARCH PROGRAM CONTENT

RESEARCH OBJECTIVES

This work is undertaken with the expectation that the confluence of the disciplines of parallel processing applied to image processing, and knowledge engineering, and implemented using VLSI will prove fertile. It, and the resulting VLSIzation process, that of first understanding specific algorithm and tasks and then VLSI'ing them, may well be a major characteristic of the next generation computing systems, which the Japanese call the Fifth Computer Generation.* The establishment of a quasi-competitive, but coordinated program of research using common research facilities is intended to stimulate a national understanding of such systems and their potential application.

The work is aimed at a fundamental understanding of parallelism and its application to a class of problems critical both to the growth of the computer industry in this country and to the maintenance of a preeminant US position in intelligence based military systems.

ESTABLISHING AND USING THE FACILITIES: PHASE ONE

The short term focus will be on installing and applying parallel approaches to image procesing and logic/circuit/process simulation problems, especially dataflow. We think it is vital to understand the range of dataflow from theory to practice across a wide range of applications. In its simplest form, dataflow can be viewed as a formalized, generalization of pipelining that is conventionally used for graphics and image process. In its more general form, dataflow looks appealing for logic simulation, signal routing, and conventional array processing type tasks where a great deal of parallelism exists, but cannot be exploited due to the difficulty of expressing algorithms in conventional languages. It is indeed possible that dataflow-specific machines <u>will not</u> exist, instead dataflow languages will enable programs to be written for large, multiprocessors. The centers will be based on a high performance local area network to interconnect the central machines, including:

- supercomputers,

- experimental machines (dataflow and conventional multiprocessors and multicomputers), and

- the CDC AFP.*

The AFP will operate with <u>fixed microprograms</u> to simulate several computer structures including dataflow computers. This will enable researchers to begin now and to understand the limits and use of dataflow architecture, for example. These efforts must be put to the test of representative applications in order that the tradeoffs discovered be relevant to solve.

* One of us (GB), believes that the current generation, number 5, is based on powerful personal computers interconnected via local area networks. The Japanese are working on the sixth generation, beginning in the late '80's.

It is essential to have real applications on which to "benchmark" various designs. The following applications cover some of the possible important military and industrial problems: scanning electron microscopic image enhancement, automated assembly inspection, target identification, digital system design and construction (eg. logic simulation, routing and IC signature analysis). The actual applications should be made firm with final proposal.

While the initial results have focused on using a dataflow architecture to examine its limits, the network and facilities we envision are much more extensive and will be used as alternative ways of computing.

PROGRAM DEVELOPMENT OF THE CENTRAL FACILITIES

It is expected that the central research facilities will be enriched further over time by including, as additional research tools, the fruits of the aspects of this program particularly focussed on realizing more powerful forms of processor interconnect and process (or operator based) intercommunication. It is expectd, further, that several realizations of parallel solutions to specific application image processing problems will be implemented (in VLSI) and included in the central research environment.

UNDERSTANDING PARALLELISM: PHASE TWO

In the middle phase of the program here proposed, the principle results will include a deep understanding of the dimensions and metrics that describe the space of parallel computing - costs, performance, programming expense, and reliability. The proposed facilities provide a rich set of alternative realizations for parallel computing - ranging from tightly coupled multiprocessors to conventional Local Area Networks. We do not believe that the kind of interconnect for switching is a particularly fruitful area of study because it is really an economic issue that shifts with technology, regulation, market demand, and supply. Thus, the goal is to provide various structures for evaluation and use very rapidly, but not to research the interconnect possibilities!

END POINTS

Expert systems and knowledge engineering efforts are expected to yield their most important results in the last phase of the program. Significant milestones are established throughout the research effort: discerning the computational (and data management) primitives underlaying current rules-based expert systems languages, establishing an effective integration of image and symbolic information into a knowledge base (consistent with the data management primitives noted above), realizing a VLSI implementation of a highly parallel, post von Neumann computer structure for expert systems, trying it out on (say) a SEM analysis problem, a fully automated VLSI design, and finally on an expert system for (semiconductor) process/crisis management (or threat evaluation and reconnaissance mission). These will, in turn, provide the understanding needed for a second VLSI implementation of the expert system engine above.

SINE QUA NON

As a necessary ingredient of effective VLSI implementations supporting the research goals of this program we need the 1990's VLSI equivalent not merely of the Guttenberg Press but of the linotype machine and the automatic typesetter. The process would be completely controlled by an individual or small group. The most important element of this program then is the development of the capability for (fully) automated VLSI circuit design from representations of parallel algorithms simulated on the parallel computing facilities proposed. At first, this will likely be by means of both conventional supercomputers and the dataflow machine simulators running at the central facility.

The automated design capabilities will be made to stand the test of real use in VLSI implementatins of (at least one) dataflow machine. The design of this machine will be based on the measurement and analysis of simulated dataflow machines running applications as noted earlier. These design capabilities will be also tested in VLSI realizations of IC signature analysis dataflow algorithms and the mobile object identification and tracking projects implemented previously. The culmination of efforts in image encoding and compressions will be a special purpose VLSI processor chip that provides full motion video-conferencing within the bounds of a 56 Kbps phone line, for example.

A FACILITY TO UNDERSTAND AND EXPLOIT PARALLELISM

New computer applications usually result from having new, higher performance computers allowing solution of problems that previously were computationally intractable. Performance increases in computing come from two sources: technology improvements and increased parallelism. This program is aimed at understanding and exploiting parallelism to gain performance.

VLSI contributes to parallelism in two ways.

First, commodity processors allow the low cost construction of the most cost effective systems. That is the Mips/chip of microprocessors far outstrips the densest, high performance ECL gate arrays.

Second, VLSIzation is an inherently parallel process - standard algorithms are off loaded.

To date, attempts to improve performance through highly parallel structures has been relatively disappointing. We believe the major reason for this lack of progress is the high real and personal cost to build and evaluate parallel structures. This program supports systematic research and development on the following alternatives. In this regard, we posit this fundamental hypothesis: <u>in order for a new computer structure to be attractive to a user, and hence ultimately developed and exist, it must offer an order of magnitude improvent in performance over his current method of computation.</u>

SPECIALIZED PROCESSING (AND VLSIZATION)

Historically, an order of magnitude or more speed improvement has resulted from looking at the execution times of particular work and then building hardware to carry out the function. VLSIzation is a realization that this evolutionary process exists and is an attempt to formalize the process.

Some examples of "off-loading" using special function hardware:

1. Floating point hardware versus a software interpreter

2. Channels, I/O Processors and I/O Computers versus interrupt and hardwired I/O

3. Display processors

4. Array Signal Processors

5. Front end (communications) and back end (disk, file and database) computers

A need, resulting from a computation on a particular kind of data occurs.

This need is then a requirement for a new computing structure. The function is then "off-loaded" in specialized hardware that operates in parallel with the general purpose computer.

By having a general purpose, very high speed system, the resulting, specialized structures can be totally simulated before they are committed to VLSI designs. In this way the designer can interact with the structure in a quickly iteractive fashion instead of waiting at each iteration for fabrication and system (re) integration.

MULTIPROCESSORS

Every time a new computer class is formed, there are strong arguments to build multiprocessors for performance reasons. Invariably, others build higher performance Uniprocessors at the same time and deliver more power via the strictly sequential approach. Multiprocessors were proposed by the early 60's, with Burroughs probably delivering the first one (B5000). By the early 70's Burrough's, CDC, DEC, GE, IBM and Univac had all built 2 - 4 processor multiprocessors. Unfortunately, these were either used in an asymmetrical fashion, or at most they were used in an ordinary multiprogramming environment. In no cases was parallel processing of a single task provided.

In 1966 Lehman investigated parallel processing of a single task with a 16 procesor multiprocessor and showed that for various tasks speed-ups were possible. By 1975 two 16 processor systems were built by BTL and at CMU. The CMU system was predicted on the 11/40 minicomputer, as a way to afford the construction, and speed-ups of up to 10 were observed in various algorithms.

CDC's Advanced Flexible Processor is an ideal machine to investigate the use of multiprocessors and multicomputers since the interconnection among the computers is via very high speed local links (ultra LAN) and shared memory. It can be used in many ways, including:

1. a 16 computer multiprocessor;

2. a 16 processor multiprocessor;

3. a fixed, intrpreter for particular structures (eg. dataflow); or

4. a particular, dedicated pipeline processing configuration (eg. image processing).

Several laboratories are building systems with up to several hundred microprocessors.

LLL is building a multiprocessor, the successor to the S1, with 16 supercomputer class processors. As soon as the processor's available, it should be extended to the multiprocessor case for evaluation, since the processors are both tightly coupled and have very fast inter processor communication mechanisms. This should be within the next three years.

DENELCOR is offering a 64 processor multiprocessor which requires investigation. We strongly recommend the installation of this machine in the facility in order to work on the multiprocessor problem.

Recently, Schwartz, et al at NYU has proposed the Ultra-Computer, a multiprocessor with up to 16,000 VLSI microprocessors. Just as soon as we can operate a reasonable number of processors together, construction should begin on this very large multiprocessor.

It's safe to say that one can produce conventional parallel processors which should be able to deliver up to a factor of four, for specially coded programs. A factor of 10 is possible, but there has to be a significant amount of research to make this automatically possible. Studies continue to indicate vast amounts of parallelism in algorithms that we have no way of exploiting.

We believe that the optimistic (Fifth Generation) projection for computing power speed-up over the next decade could be accomplished simply and entirely by parallel processing using multiprocessors and not by semiconductor and packaging technology if a significant effort were applied! Undoubtedly the dataflow language is an important part of this effort to represent, control and thereby exploit this form of parallelism.

MULTICOMPUTERS

Very little has been done formally with arrays of tightly coupled multicomputers where independent computers (Pc-Mp pairs) operate independently and communicate with one another by sending messages. By 1980, CM*, a multicomputer system based on the LSI-11 microprocessor with 5 clusters of 10 computers was constructed, and speedups of up to 30 were observed for particular problems, including speech recognition. Because there is less interconnection among the computers, it is more difficult to predict the performance: the algorithm has to be carefully partitioned across computers rather than distributed in memory.

In addition to AFP, we believe that other multicomputers should be constructed and used, particularly those with several hundred computers. Here, we would support the construction of several, (say 6) different multicomputer alternatives.

DATAFLOW ARCHITECTURES

Although many dataflow computers have been proposed, only a half dozen computers have been built. The performance of dataflow computers is not understood, although the use of dataflow graphs and languages to express parallelism is promising. In particular, dataflow appears to be most useful in expressing signal processing operations. For example, the AFP is programmed using a dataflow-like representation for image processing tasks. Individual computer modules can be assigned to various processing stages of say a digital filtering task. The AFP also appears to be ideal to simulate static dataflow architectures and their application. It would be microprogrammed to be a general purpose dataflow machine using separate computer modules in a functional fashion: matching store, switching, processing, and i/o.

ULTRA-, FAST-, AND CONVENTIONAL LOCAL AREA NETWORKS

Local Area Networks, LANs, are systems which normally allow the physical distribution of functional, server components to cover a local geographical area (eg. a building, or campus). The functional servers roughly correspond to various parts of a shared system: person servers (computing workstations/terminals), file servers, print servers, and communicatins servers. The communications is via message passing protocols. While the curent 10 Mbit/sec LANs are relatively slow, they are well matched to today's, slow terminals, personal computers and for intercomputer networking.

Researchers have also posited that LANs can be used to provide high performance, parallel processing. We too believe higher speed LANs are the backbone interconect architecture for new computer structures. The higher speed, 100 Mbit/s LANs will be the basis for interconnecting functional computers in a hierarchy as shown in the facilities section (Fig. 3).

We view the Ultra-LAN as a major architectural component and standard for truly fast, highly parallel structures of this next generation. Note that the ring that interconnects the AFP provides transmission at about 2 Gbits/sec for each computer node connected for the tightly connected computers. Thus, the AFP would be used for some studies of this type of LAN-based architecture.

The purpose of the hierarchy of three LANs is summarized:

Ultra-LAN	2 Gbits x p	AFP's processor intercommunication; as first basis for an ultra-LAN architecture
Fast-LAN	100 Mbits	Facility computer intercommunication and center to remote sites, forming a single cluster
LAN	10 Mbits	Individual workstations to form centers

PARALLEL PROCESSING FOR KNOWLEDGE BASED SYSTEMS

It has not been widely agreed that Knowledge based Systems can exploit parallelism. For Rule Based Systems, it is believed that many rules can be evaluated in parallel. The research will be aimed at first answering the question, and then simulating and evaluating the resulting structure. AFP might be used to simulate such a structure, provided this approach looks worthwhile.

THE RESEARCH PROGRAM FORM

ORGANIZATION, DIRECTION AND RELATIONSHIP TO ONGOING RESEARCH

A program office, together with a board of directors would contract the research in a fairly structured fashion. While research of this type is not commonly done today in computer science, we believe it can and must be done effectively by a joint industry and computer science research laboratory efort. <u>Industry can be effective at providing facilities and systems</u> that have been traditionally absent from the research laboratories. In effect, this is the major motivation for the proposal.

A major goal of the research project is to provide a large infusion of computing systems to support existing, more basic and unstructured work, including robotics.

The purpose would not be to change the nature of the existing unstructured research to be highly focused and goal directd, but rather to provide additional resources so that both the structured project and unstructued work could co-exist and complement one another.

The centers would be aimed at very similar research targets in order to get the benefit of "friendly competition". Similarly, several approaches would be examined within a center. This approach was successful in the mid-70's in speech research and should be the "model" direction. However, the speech research resulted in few, commercialized industrial or military applications, because the research coupling between academic and industrial research was poor. Unfortunately, the final transfer phase of research was terminated before the program ended.* It is this gap between basic research and applications research that the program is fundamentally addressing. It is interesting to note that NEC had an advanced development operating separately, but concurrently with the ARPA program. The result is that NEC provides recognition products.

We would hope that a better model to follow is VHSIC. It is crucial that the participants be able to exploit the technology for commercial and military applications propitiously. Unlike VHSIC, we believe that the work should be done at a few sites with movement of personnel.

THE PROGRAM OFFICE

The fabric of this research is a fairly close weave. The environments are, indeed, established anticipating that unexpected leverage and collaborations will yeild significant results not included in the program plan. However, it is precisely the existance of a structured program and the interrelation of its several work flows that will enable this to occur. The program office is responsible for the successive development of the fabric using resources as it can find them and coordinating efforts so work can easily build upon what came before.

* Personal communication with Allen Newell and Raj Reddy at CMM.

The program office will set adequate standards so that ideas meet no unnecessary boundaries between the workers and the worksites in this program. Early, stable agreement on the common rules, language, workstation, the network and the general computational support structure will be among the most important contributions of the program office, the goal is to use this commonality of interface to allow pyramiding of work - being careful not to pyramid risk.

The program uses applications to test ideas, and uses realizations of those ideas to build the next generation applications. It even uses these applications themselves to acomplish future generation realizations fueling the next cycle. The central facilities are the place that application tools for realizing ideas, the realizations themselves, and the applications for testing ideas all come together. This must all flow forward rather than bottleneck into a deadlocking interdependencies. The opportunity and expectation for people to build on each others work as it becomes available is the key. In the natural uncertainties inherent in this ambitious program of research, there must be enough alternative paths so clever people can use their wits to find a critically helpful piece of another's work or another's facility wherever it may turn up.

The program office must have the ability to facilitate the construction of important engineering breadboards so that systems can be rapidly built and evaluated. We envision utilizing the industrial sponsors for this breadboarding.

The program office is deliberately kept small to force most standards to be developed collaboratively with the groups doing the work. The program staffing for the parallel computing facilities is very light in the expectation that site personnel will be provided by the host institution. The Budget Table, Appendix 3, provides a more detailed breakdown.

PROGRAM BENEFICIARIES

The program was conceived in order to improve this flow of basic and applied research into industrial research and eventually into products. The main beneficiaries are those who use these ideas to eventually build products. Products will not come directly from this program.

On the other hand, virtually everyone will benefit by the program:

1. the U.S. technology will be drastically improved - thereby improving defense and the economy;

2. the researchers will be more effective and productive by having more meaningful work;

3. certain research will be published; and

4. researchers will still migrate from the coupled programs, being attracted by venture capital, and build higher technology products.

TRANSFERING THE TECHNOLOGY

The most effective means of technology transfer is through the transfer of people. Program sponsors will each have the right to place people in each project of the program. It is expected that assignments be for a three year interval and that the assigned person return to the sponsoring organization prepared to produce the competitive products of the late 80's.

To insure a co-operative working environment among the members of a project team, intellectual property rights for the work done as a team using the facilities of the host institution will be controlled by the policies of the host institution. However, each program sponsor will have the right to a non-exclusive license at reasonable terms.

A major part of the transfer will occur when the sites and industry collaborate on fabricating a design that a site has specified.

With VLSIzation, chips produced as part of a research project would be licensed to the sponsors. The "rights" to chips and software produced as part of a research program are indeed not clear at this time and vary among the institutions. This area would have to be worked out between the institution and the program.

Other mechanisms for technology transfer include sponsor access to prototypes, distribution of published technical reports and invitations to program seminars.

Seminars will be held quarterly for program sponsors with invited speakers from universities, government and industry.

In inviting speakers the organizers of the seminars will have the freedom to draw on the wide range of topics encompassed by the program, including:

- Pattern and image processing applications
- A. I. algorithm research
- Multi-processor architectural developments
- CAD/CAM software systems
- VLSI design process advancements

FACILITIES

HIERARCHIES OF AREA NETWORKS

The program would be organized around at least central research computation centers containing a variety of production and experimental computing systems (nodes) interconnected via 100 Mb/s links and forming the central facility for a hierarchical set of closely coupled, high performance, local area networks. The centers will be linked to several campuses via the highest available links so that they could be used in a clustered fashion "as if local" computation centers.

Each site would contain supercomputers, AFP's and experimental computers.

ARPA-NET II

In effect, we're proposing ARPA-net II. This must come into operation relatively soon, to be used to interconnect the more remote research to the centers. High bandwidth, such as several video channels would be needed to avoid limiting the interaction between sites. Here, the goal would be to provide only millisecond delays between processes operating on separated machines.

VLSIZATION FACILITY

Since the projects would be designing many VLSI chips, the facility would need a way to build state of the art VLSI chips from mask design. this could be acomplished by a multi-year committment of appropriate existing capacity to the needs of the program.

LOCATION

The program would start immediately and be coupled to existing computer science and computer engineering research facilities and programs. Facility selection is strictly on the basis of the intensity and quality of work in VLSI, image processing, parallel computing and AI. Either Lawrence Livermore or Berkeley Laboratories would be ideal sites for the computation center which would link to Stanford, SRI, and UC/Berkeley. MIT, MITRE or Lincoln Laboratory could be the basis of an East Coast facility. Los Alamos has the largest network of supercomputers and support computers including storage and image production. If a central site were Los Alamos, this would force the development and installation of high speed links to other sites.

APPLICATION CENTERS

The following very imcomplete list of application centers is included as an example of how work would be contracted by the program office to expertise centers throughout the country.

DELIVERABLES

The work encompassed is broken into three classes shown in the Deliverables Table. Within each class there are families of projects and finally the projects themselves. The program runs about ten years broken into rough phase transitions at the end of 1985 and 1989. The work in the first phase puts the research environment and work standards in place and develops the first generation tools and applications. The second phase includes several machine realizations that use the tools and runs the test bed applications. In this phase, the research facilities are enriched with the machines realized by program efforts. These are in turn, the base of the second generation tools and applications. Finally, the third phase provides refinements and solves the hard problems that depended on the new understandings generated in the first two phases of the program.

L

MOTIVATING SUMMARY

The motivation for this approach is timeliness and effectiveness:

1. THE RESEARCH PROGRAM SHOULD START NOW

2. WE NEED COUPLING OF INDUSTRIAL R&D AND APPLICATIONS WITH COMPUTER SCIENCE RESEARCH

3. WE CAN BUILD ON EXISTING RESEARCH PROGRAMS AND COMPUTERS

It is essential that we start now on the research program, as our computer science research has been drifting these last few years as both industry and computer science research have both gotten large, diffused, and independent of one another. Significant industrial research outside of IBM, Bell Labs and Japanese companies is non-existent and there is no coupling of basic and industrial research. For example, we believe there is better coupling of Bell Labs work to the Japanese computer industry via NTT's, ECL, than between Bell Labs and the U.S. Information Industry. Furthermore, both the academic and industrial research communities are now poorly coupled to real applications. We believe that program focus of some of the existing research efforts into a goal directed system will enhance their productivity and enable the continuation of a vital Information Industry for the 21st Century.

APPENDIX 1

SOME CRITICAL GLOBAL QUESTIONS (AND ANASWERS)

1. Why is the establishment of national facilities the correct way to attach the parallel problem?

- No single lab now has critical mass or focus in anyone area - currently all resources are difused.

- The lab(s) and programs operate together to do the work.

- Users, architects, and builders must couple.

2. What impact will this proposed program have on existing research facilities? Programs?

- The intent is to build on, and <u>extend</u> current facilities by additionla resouces. We believe that this program is close enough to some of the existing.

2a. What about the extra space required for these facilities?

- We don't know.

3. How will this effort help the basic problem of a shortage of qualified researchers?

- It is hoped that a "program" will stimulate the demand to produce more researches over the long term.

- Short term, the focus should increase everyone's effectiveness.

- We hope to apply industrial researchers to the problem that are now difused and often operate as a sub-critical mass.

4. Who is supposed to benefit from this proposal and in what specific ways?

(See Section on Program Beneficiaries)

5. Is there a nationla crisis and exactly what is it?

(See section on Motivation for the Program)

6. What evidence do you have to support the level of funding which is projected as being adequate to achieve the goals?

This is really a draft outline for concrete proposals. From this we expect specific sites to be established and operated in very targetted areas: such as parallel knowledge based systems, high performance parallel processing and parallel image processing.

7. What, exactly is the overall objection of the program?

(See the first sentence of this document)

APPENDIX 2

WHY USE CDC'S ADVANCED FLEXIBLE PROCESSOR?

The AFP has demonstrated high performance in digital image and signal - processing tasks. For example, a processor system can transform the every co-ordinate of a million point picture in 1/30 second. Several systems are in operation today. It includes various support software including simulators.

Traditionally, we design, build and then use. A machine as fast and general as AFP would require at least 5 years to build. By using the current AFP as a general purpose research tool, we can gain at least 5 years on starting such a program from scratch. To illustrate, consider the several data-flow projects that could use AFP today to simulate architectures. Since we need to evaluate these architectures by using them, we could understand the benefits and drawbacks of these machines five years (or so) sooner by adopting the AFP as a hardware simulation base.

The CDC AFP provides a very fast, flexible, microprogrammed set of up to 16 computer modules for experimenting in various parallel computing structures of various type. A <u>single</u>, AFP microprogrammed processor provides the following capability:

- 20 to 800 Mops in 16 parallel, 16-bit arithmetic and logic units
- Microprogrammed control
- Access to 32 Megaword (256 Megabyte block oriented memory)
- 2 X 1 Gbits/sec communication with neighbors in ring

A flexible multiprocessor and multicomputer structure are both provided since, the sixteen processors can be interconnected both to a common 32 Megabyte memory and to adjacent processors.

The AFP can thus be used as a <u>tool</u> to study several different computer structures that we believe are much of the basis of the next generation.

Because AFP is so highly parallel, including having functional units with side effects, we believe it will not be imcroporgrammed to any great extent.

The mode we envision is that it would operate in several configurations, with fixed microprograms to behave as:

1. Set of microprogrammed pipelined, functional units within each processor. Four units can be initiated every 20 nanoseconds, although an average of seven units operate in parallel for most problems. Because of the difficulty of programming this highly parallel structure, the most important benefit, or side-effect will be understanding in how to do it effectively. Because the microprogramming so heavily pipelined, we believe a better understanding of dataflow techniques for expressing algorithms will result from the use. Nearly all high performance machines are pipelined; hence, we believe AFP is a good vehicle to get a better understanding of pipelining.

2. 16 processor multiprocessor with shared memory and very fast interprocessor intercommunication. Here, the processors will be programmed to be particular ISP, such C. If C could become the basis of the machine, then UNIX could be run.

3. Set of 16 Computer Modules microprogrammed for particular functions. AFP was designed to be operated in this mode for image processing.

4. A dataflow computer. This is a special case of item 3 whereby particular computers are programmed to behave as the various functionla units of a dataflow computer.

5. A set of special, parallel processing architectures using individual, microprogrammed

processors as the functional units of the particular structures. In this mode, AFP turns out to be a very good emulator of relatively complex VLSI chips.

6. An experimental Ultra-LAN based architecture. To examine how computers can be coupled effectively and work together on a task, the AFP looks like an ideal for study.

APENDIX 3

ROUGH BUDGET

The program expenses are estimated at approximately $18M/year running from 1982 through 1989. Equipment is expensed as delivered. In general two or three "competitive but collaborative" groups are charged with each project family.

GB3.S7.3

22 November 1982

Mr. Joe Traub
450 Riverside Drive
New York, N.Y. 10027

Dear Joe:

Enclosed is a much revised version of the project called Alpha Omega which we submitted as part of MCC (Microelectronics and Computer Consortium/ Company). It is now called Post von Neumann Computing.

Since the original proposal, I visited Japan's ICOT (Fifth Generation) laboratory where 40 researchers are at work defining an architecture that they expect to build within two years. The construction will be done by the companies as an engineering task. It's very clear to me that we (the U. S.) has to move rapidly on a program along these lines, if we expect to design and build competitive systems in the late 80's.

The proposal is now a framework for establishing specific, detailed proposals for sites and other facilities (eg. ARPAnet II). Furthermore, the program is predicated on a unique organization that has not been used since WWII.

I would like your comments at this stage before the proposal has wider circulation. Please do not circulate outside your organization.

Sincerely,

Gordon Bell
Vice President, Engineering
Digital Equipment Corporation

Bruce Delagi and I led a group from CDC, Univac, and Harris to define a research program on parallel computing for use across a large array of problems including AI. This is a program which we believe must be executed in order to do the basic work necessary to produce machines to compete with those produced by the Fifth Generation Computer Program.

CALL FOR COMMENTS ON THE DRAFT PROPOSAL

Please call or EMS me for a copy of the research proposal. Bruce is going to give a seminar at Hudson on it and we'd like to get your comments on how the proposal can be improved either by narrowing or widening the scope.

CALL FOR PEOPLE WHO WOULD LIKE TO WORK ON THE PROJECT

Now, we would like to carry the proposal into the next phase by having the group who are going to carry out the work write the detailed research proposal/plan.

If you would like to work on this, please let me know now. Individuals are needed.

We are looking for someone to head the program. Any candidates?
(Please forward message as appropriate).

SUBJ: YOUR SUPPORT FOR JOINING MCC, AN R&D CONSORTIUM

TO: OPERATIONS COMMITTEE Date: AUGUST 2, 1982
PEG From: Gordon Bell, Jack
Smith,
Arnold Goldfein Grant Saviers
Peter Christy Dept: Eng. Staff
Henry Crouse MS: ML12-1/A51 Ext:
223-2236
Bruce DeLagi EMS: @CORE

CDC has been leading an effort to define an R&D consortium aimed at doing the work necessary to allow our companies to build future competitive products. The U.S. is producing much research in the universities and other organizations. This work is "open" to the world, and the Japanese have operated a number of programs that take this basic research and move it into a pre-production research phase by corporate, government (MITI) funded consortia (eg. NEC, Fujitsu, Hitachi, Oki, Mistubishi, Sharp, Matshusta). The scarcity of people and money requires collaboration!

The Japanese focussed development MITI/industry consortia programs include:
1. VLSI (now terminated) that resulted in semiconductor process (eg. 64K, 256K ram)
2. Pattern Information Processing (speech and video chips).
3. Supercomputers (started two years ago). Fujitsu just announced being number one here.
4. Optoelectronics, just announced
5. Minicomputers for NTT, just announced with Fujitsu, NEC and Hitachi.
6. The Fifth Computer Generation (40 person lab operating).

The MCC projects which we could be involved with are:
1. An International Office, aimed at technology assessment.
2. A CAD/CAM development program aimed at standardization and interchange of electronic and semiconductor CAD/CAM data.
3. Advanced interconnects.

4. Software productivity.
5. Semiconductor factory automation.
6. Parallel Architectures for the Next Computer Generation.

Engineering has participated in task forces which have broadly defined these programs. For example, Bruce Delagi and Gordon led the group called Alpha Omega which has defined a research program aimed at the Next Generation. Various laboratories and government funding agencies now are interested in supporting it, and 4 companies want to join in this.

We believe DIGITAL MUST join this consortium and become a member of several groups (eg. 1, 3, and 6 above) to save our scarce resources, to get the work done and to establish the standards and technology for the future. CDC, Univac, NCR, Motorola, Mostek, National, Harris and GE look like first pass members.

Attached is a description of the enterprise and its operation. Can we have your support for becoming a member of MCC?

SUBJECT: MORE ON MCE PRESENTATION BY CDC

MCE was started by CDC as a joint effort with the first meeting being attended by CEOs by many computer and semiconductor companies. Since then, the support to look at consortia has progressed more rapidly and more positively than I expected.

Task forces from various companies went off and explored whether it would be worthwhile to do research, a/d or standards settings in these areas.

Bruce and I led a group aimed at a 10 year research program, called Alpha Omega which would let us build really large ai machines that would compete with the Japanese.

The group likes Alpha Omega. In addition, there seems to be useful work that can be done in building a CAD workstation and in A/D for packaging especially in standards. Programming productivity was explored to no avail. An effort at automating semiconductor processing is being explored.

Tomorrow, Jim Lacey, Phil Arneson VP's of CDC are going to be here to present where we are. Bob Price (not the president) is running the co-ordination.

This is not a CPI-type endeavor, but a consortia much more like Ethernet, or in some cases like the SRC (Semiconductor Research Consortia).

DEC will continue to support MCE on the basis of need from each of the groups. The need has to be based on our need in each area. That's why you're requested to come. We want to explore this together.

Not only do I need your counsel and feedback on this endeavor, but it can't happen without your belief that we need it!

PLEASE JOIN US at 10:30 through lunch.

MOTIVATION FOR ALPHA OMEGA

The U. S. lead in the combined Information Processing industries is now declining relative to Japan, and potentially to France and the U.K. While there are many reasons for this decline, these are noteworthy and represent the motivation for this program:

1. The U. S. (and World) funding for basic and applied research is large. This mechanism produces far more results than can be applied.
2. There is NO U. S. effort or policy aimed at systematically examining the basic results and refining them so they can be applied to products. The cost to do applied research on even a small fraction of the basic research is usually far greater than the original work and is well beyond the scope of a single company.
3. U. S. companies have not worked collaboratively to develop these technologies because of legal and cultural reasons.
4. U. S. industry has been especially short sighted in its funding of this phase of research, especially in light of the many short term, mundane product opportunities (eg. another Z80 + CP/M based personal computer).
5. An inadequate supply of people exist to carry out the work in industry and the research organizations.
6. A research program aimed at parallelism requires interaction and co-location with a user community.

We marvel at the effectiveness of the Japanese collaborative research programs and believe we must emulate them. Note the past and present programs in the Information Processing area:

1. Pattern Information Processing- voice and vision
2. VLSI- improved processing characteristics (eg. 64K and 256K rams)
3. Supercomputers- high speed technology
4. Optoelectronics- just established
5. Standard Minicomputer for NTT- Fujitsu, NEC and Hitachi
6. Fifth Generation Computer- Fujitsu, NEC, Hitachi, Mitsubishi, Matsushita, Oki, Sharp. ICOT Lab and 10

year program established. First phase builds a Relational Database and a Prolog machine.

7. Local Area Network standards as part of Fifth Generation.

The entire industry is a set of relatively loosely coupled 4-6 stage pipelines consisting of: basic and applied research at the universities and research organizations; industrial research aimed at discovering, refining and applying the basic research to produce feasiblity models for products; advanced product development; product development; and product enhancement. The main set of pipelines and pipeline stages include: an ensemble of interacting and internicine military organizations and suppliers; IBM, ATT, and world computer and semicomputer suppliers.
Bob Price, Director, Microelectronics/CAD, for CDC; Bruce Delagi and myself will present the MCE program.

OBJECTIVES

This work is undertaken in the expectation that the confluence of the disciplines of parallel (image) processing, knowledge engineering - expert systems and vlsi implementation will prove to be a fertile ground. Further, it may well form the necessary ground on which to establish the foundation of the fifth generation computing systems. We need this as a nation, in order to retain our industrial and military leadership. The establishment of a coordinated program of research and common (slightly competitive) research facilities is intended to stimulate a great deal of bootstrapping to develop an increasingly broad and deep national understanding of such systems and their potential application.

The work is aimed at a fundamental understanding of parallelism and its application to a class of problems critical both to the growth of the computer industry in this country and to the maintenance of a pre-eminant US position in intelligence based military systems.

Comment from Bob Price: Review of strawhorse business plan for MCE - 1st introduction.

On Saturday, several people from LASL visited us and we talked about the negative gap in our technology with Japan for Supercomputers. While we don't build them, the technology and ideas invariably feed the main line and ultimately VLSI. Large machines too are vital in the design of VLSI chips today. Note:

Dr. Robert Ewald
Computing Division
Los Alamos National Laboratory

Dear Bob:
Thank you for the presentation to the Alpha Omega MCC team members on Saturday on the position of the Japanese in supercomputers and the need for a strong research program on parallelism along the lines of our draft Alpha Omega report. We were delighted to review LASL's facilities and computer science and engineering research.

Various proposals to establish a national facility have come before government committees, but I've never supported them because they've been too vague and weren't based on a need. In writing the Alpha Omega proposal, the urgent need for a large effort with critical mass and focus on parallelism became clear.

Personally, I was really gratified to learn of the possiblity of having focussed research at a LASL managed institute in both VLSI and supercomputing, together with the fact that you might support LANs at other sites with computing. This is the only real ray of hope I've seen to date since I became a member of SRC and MCC. I want to encourage you to proceed as rapidly as possible to approach both SRC and MCC to propose the establishment of such a facility. In this regard, I hope you can present your cursory proposal to SRC this month. Hence, I'm sending a copy of this letter to Erich Bloch and Larry Sumney, the Director.

Thanks again for the personal efforts of you, Billy Buzbee and Byran McCormick. I intend to accept your offer to present the supercomputer data to a local audience as soon as I return from Japan.

LASL has a fine record of building competitive, timely hardware. I think we have an urgent need for your help again.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

FROM: GORDON BELL
SUBJECT: COLOCATION WITH HPP CENTER, PALO ALTO

GB4.S1.36

The Heuristic Programming project (HPP) is moving to a separate laboratory facility on 701 Welch Road, very near the Stanford campus. They might offer us temporary space, provided we eventually locate near them.

Ed Feigenbaum is proposing an Institute as Center for HPP which would be supported by government and industrial sponsors. Sponsors would send people there for 3+ years. This would be somewhat "open" along the lines of ICOT, but it would not be freely open ala a university.

Ed suggests that we (Alpha-Omega) locate nearby and have a few people who would be jointly in both laboratories.

Bob Kahn, ARPA, has promised the center and PARAVAN support starting in October.

It would seem this is exactly the opportunity we're looking for.

Bruce Delagi is proposing a parallel VLSI architecture project for knowledge based systems (PARAVAN). A draft copy of the proposal is available from me.

Let's discuss this Friday.

Enclosure

Pat McCormick

I have known Pat McCormick since July, 1972, when she worked as an architectural designer for my home and office. Subsequently she came to work at Digital, responsible for remodelling 1.5 million sq. ft. (formerly woolen mill buildings built in the late 1800's through early 1900's) which house engineering and some manufacturing. She was in our Facilities Planning Group on a corporate wide basis.

She successfully interfaced with the various groups who occupy space and operated within various cost and other design constraints. Overall, the space has been significantly upgraded. This has included the design of our own very highly portable partition system prior to the recent availability of satisfactory externally manufactured systems. Here designs were significantly lower cost and we still build them. The work has been widely cited, and a brochure is enclosed describing the mill which shows some before and after photos.

Overall, she was effective in bringing about change in an environment that is suspicious of architects. Despite this concern about the architectural profession, she has operated effectively as a professional and I encouraged her to pursue a degree. Hopefully your program is flexible enough so that she can get credit for experience/accomplishments and take the necessary courses while continuing work.

May 2, 1978

Dr. Jack McCredie
Vice Provost for Computing
Carnegie-Mellon University
Schenley Park
Pittsburgh, PA 15213

Dear Jack:

It was good to talk with you last week in regard to the CMU-DEC interaction. I'm sorry that there has been a strain in the relationship, but am delighted that the 2050 is now performing well and that you are delivering so many terminal hours to your users. The long time to get the machine up is inexcusable.

In regard to the numerous DEC salespeople who refer customers to visit CMU, I am asking that Ulf discuss this directly with you to get a better arrangement so that you aren't spending so much time. Frankly, I believe we should get a videotape of the CMU systems and this should answer many of the questions for potential visitors.

As to what would make a good research project, I am quite excited that you would take our various DECnet components and interconnect all the computers on campus (10, 20 VAX, 11s on RT, M and Unix). Connecting the commercial front office computers would be interesting too. It would be of interest to know how difficult this is, and how you go about such an undertaking. Although we sell systems for such a network, it is yet to be a standard product because special software and complex hardware is still required. I'd like to know just how this is done and what performance and benefits you really get out of the network.

I saw the VAX-11/780 in chemistry and was pleased as to how well things had gone there.

Again, thanks for discussing the situation with me. I don't believe any of us really are bent on taking advantage of CMU or taking the relationship for granted. We want to continue what has been a unique relationship.

Sincerely,

Gordon Bell

SUBJECT: RE: TASK FORCE MEETING MICROELECTRONICS PACKAGING

We're attempting to form a research consortium with several companies. The feasibility depends on whether we can establish significant programs. Please attend. I don't think we need to discuss our plans. The purpose is to devise a research program that would help us build better products. The goal is to not duplicate research and A/D. Also we may want to use this group to drive some standards. Please call Bruce Delagi too.

SUBJ: TASK FORCE MEETING MICROELECTRONICS PACKAGING

This memo is from George Katronge.

I received a call from Mr. Mike McGuire of Harris Semiconductor. He invited me to sit-in on a Task Force meeting on Microelectronics Packaging scheduled for April 21st in Melbourne Florida. He mentioned that you had recommended that I participate as a member of this task force.

My understan ding is that this is a task sponsored by computer Microelectronics Technology Corp., a research

consortium which
DEC is a sponsor/member.

1. Can you provide me with some background.

2. Should I attend this meeting?

3. If we participate, how open can we be about our plans,
strategies, etc.

Other representatives at the up-comming meeting include:

Marshall Andrews - Harris
Jim Geers - Signetics
Kent Hansen - Motorola

ALPHA OMEGA: A 10 YEAR, DIRECTED RESEARCH PROGRAM AIMED AT IMAGE, KNOWLEDGE BASED, AND PARALLEL PROCESSING

[committee and authorship]

OVERVIEW

GOAL AND TIMELINESS

By January 1983 we must establish several National facilities as part of ongoing computer science research and start to operate a goal directed research program aimed at high performance computing based on parallelism and new computing structures made possible by VLSI. Evolutionary projections show an increase of only a factor of 3 (Fig. 1) to 11 (Fig. 2) over the next 10 years (Fig. 1) for scientific processing. For example, the Fifth Generation Research Project is aimed at producing computers with a factor of 100 to 1000 more computing power for conventional and for Expert computing systems by the end of the decade (Fig. 2).

The need for research is driven both by the hardware technology of VLSI, networks and by the software technology of Knowledge Based Systems, together with signal processing of voice and images. A new generation is the concurrence of technology and need causing a new computing structure whereby new uses are possible. We believe the need is the ability to transmit, store, and process (understand) the same information as people, including voice, natural lanaguages and images. Images are the central theme of the research program.

In order to continue to supply state of the art computing to the world, we believe it is necessary to have a research program aimed at building and understanding parallel processing systems of all kinds (specialized processing, multiprocessors, multicomputers, and large computing meshs based on high speed local area networking). The target is image processing and knowledge based systems.

A major goal of the project is the ability to transfer a parallel algorithm, simulated within the computing environment, to VLSI limited only by the foundry time. These facilities would also support the goal that computers would do a substantial part of the VLSI design.

The program would be organized into approximately 3 phases covering roughly a decade and would begin now with the installation of the most powerful, high speed network of general purpose computers. In this way, results based on use can be applied to produce VLSI by the end of the first phase. The second phase would use these newer structures, forming the basis for new designs in the final phase.

FACILITIES

Hierarchies of Local Area Networks Around Centers

The program would be organized around at least two research computation centers containing a variety of experimental computing systems (nodes) interconnected via very high speed links forming a hierarchical set of closely coupled, high performance, local area networks. The centers will be linked to several campuses via 100-300 Mbit fiber optic links so that they could be used in a clustered fashion "as if local computation centers". Since ARPA-net II is coming into operation relatively soon, it can be used to interconnect other, more remote research to the centers, although the intensity of interaction would certainly be less due to the limited bandwidth.

CDC's AFP, A Key Element of the Center

The centers would contain a large, fast, tightly coupled multi-processor, manufactured by CDC called the Advanced Flexible Processor networked with general purpose and special purpose computers. Because of its speed, microprogrammability and extensive interconnectivity, the AFP will be used to simulate various computer structures.

VLSI Design

Since the projects would be designing many VLSI chips, the facility would need a way to build state of the art VLSI chips from mask design.

Location

The program would start immediately and be coupled to existing computer science and computer engineering research facilities and programs. Facility selection is strictly on the basis of the intensity and quality of work in VLSI, image processing, parallel computing and AI. Lawrence Livermore Laboratory would be an ideal site for the computation center which would link to Stanford, SRI, UC/Berkely and Lawrence Berkeley Laboratory. MIT and Lincoln Laboratory could be the basis of an East Coast facility.

ORGANIZATION AND DIRECTION

A program office, together with a board of directors would contract the research in a fairly structured fashion. While research of this type is not commonly done today in computer science, we believe it can be done effectively by a joint industry and computer science research laboratory effort. <u>Industry can be effective at providing facilities and building hardware</u> that has been traditionally absent from the research laboratories.

The purpose would not be to change the nature of the existing unstructured research to be highly focussed and goal directed, but rather to provide additional resources so that both the structured project and unstructured work could co-exist and complement one another.

A major goal of the resarch project is to provide a large infusion of computing systems to support existing more basic and unstructured work, including robotics.

The centers would be aimed at very similar research targets in order to get the benefit of "friendly competition". Similarly, several approaches would be examined within a center. This approach was successful in the mid-70's in speech research.

MOTIVATION FOR THE APPROACH

The motivation for this approach is timeliness and effectiveness:

1. THE RESEARCH PROGRAM SHOULD START NOW
2. COUPLING OF INDUSTRIAL R AND D WITH COMPUTER SCIEN RESEARCH
3. BUILD ON EXISTING RESEARCH PROGRAMS AND COMPUTERS

It is essential that we start now on the research program, as our computer science research has been drifting these last few years as both industry and computer science research have both gotten large, reached critical mass, and become independent of one another. It is also the intent that the program focus some of the existing programs into a goal directed system.

It should be noted that by using the current AFP as a general purpose research tool, <u>we can gain at least 5 years</u> on starting such a program. Traditionally, we design, build and then use. A machine as fast and general as AFP would require at least 5 years to build. For example, several data-flow projects could use AFP today to simulate architectures. We now need to evaluate the architectures by using them.

A FACILITY TO UNDERSTAND AND EXPLOIT PARALLELISM

New computer applications usually result from having new, higher performance computers allowing solution of problems that were computationally intractable. Performance increases in computing come from two sources: technology improvements and increased parallelism. AO is aimed at understanding and exploiting parallelism to gain performance.

To date, attempts to improve performance through highly parallel structures has been relatively disappointing. AO supports systematic research and development on the following alternatives.

SPECIALIZED PROCESSING ATTACHED TO A CONVENTIONAL UNIPROCESSOR

Historically, an order of magnitude or more speed improvement has resulted from looking at the execution times of particular work and then building hardware to carry out the function.

Some examples of "off-loading":

1. Floating point hardware versus a software interpreter
2. Channels, I/O Processors and I/O Computers versus interru
   and hardwired I/O
3. Display processors
4. Array Signal Processors

A need, resulting from a computation on a particular kind of data occurs. This need is then a requirement for a new computing structure. The function is then "off-loaded" in specialized hardware that operates in parallel with the general purpose computer.

By having a general purpose, very high speed system, the resulting, specialized structures can be totally simulated before they are committed to VLSI designs. In this way the designer can interact with the structure in an iterative fashion instead of waiting for fabrication and the slow system integration process.

MULTIPROCESSING

Every time a new computer class is formed, there are strong arguments to build multiprocessors for performance reasons. Invariably, others build higher performance Uniprocessors at the same time and deliver more power via the strictly sequential approach. Multiprocessors were proposed by the early 60's, with Burroughs probably delivering the first one (B5000). By the early 70's Burroughs, CDC, DEC, GE, IBM and Univac had all built 2 - 4 processor multiprocessors. Unfortunately, these were either used in an assymetrical fashion, or at most they were used in an ordinary multiprogramming environment. In no cases was parallel processing of a single task provided.

In 1966 Lehman investigated parallel processing of a single task with a 16 processor multiprocessor and showed that for various tasks speed-ups were possible. By 1975 two 16 processor systems were built by BTL and at CMU. The CMU system was predicated on the 11/40 minicomputer, as a way to afford the construction, and speed-ups of up to 10 were observed in various algorithms.

Current Research Needs
Recently, Schwartz, et al at NYU has proposed the Ultra-Computer, a multiprocessor with up to 16,000 VLSI microprocessors. Several laboratories are building systems with up to several hundred microprocessors. LLL is building a a multiprocessor with 16 supercomputer class processors. DENELCOR is offering a 64 processor multiprocessor which requires investigation. CDC's Advanced Flexible Processor can be programmed to behave as a conventional 16 processor multiprocessors computer.

It's safe to say that one can produce conventional parallel processors which should be able to deliver up to a factor of four, for specially coded programs. A factor of 10 is possible, but there has to be a signficant amount of research to make this automatically possible. Studies continue to indicate vast amounts of parallelism in algorithms that we have no way of exploiting. Notice that the optimistic projection for computing power speed-up over the next decade could be accomplished simply and entirely by multiprocessing, and not by semiconductor and packaging technology if a signficant effort were applied!

MULTICOMPUTERS

Very little has been done formally with arrays of tightly coupled multicomputers. By 1980, CM*, a multicomputer system based on the LSI-11 microprocessor with 5 clusters of 10 computers was constructed, and speedups of up to ? was observed for particular problems, including speech recognition. Because there is less interconnection among the computers, it is more difficult to predict the performance because the algorithm has to be carefully partitioned across computers rather than distributed in memory.

CDC's Advanced Flexible Processor is an ideal machine to investigate the use of multicomputers because the interconnection among the computers is via very high speed local links (ultra LAN). AFP is described in detail below.

DATA-FLOW ARCHITECTURES

Although many data-flow computers have been proposed, only a half dozen computers have been built. The performance of data-flow computers is not understood, although the use of data-flow graphs and languages to express parallelism is promising. In particular, data-flow appears to be most useful in expressing signal processing operations. The CDC AFP has been programmed using the data-flow representation; and individual computer modules can be assigned to various processing stages. The AFP also appears to be ideal to simulate static data-flow architecture and application. It would be microprogrammed to be a general purpose data-flow machine using seperate computer modules in a functional fashion: matching store, switching, processing, and i/o.

ULTRA-, FAST-, AND CONVENTIONAL LOCAL AREA NETWORKS

Local Area Networks are systems which allow the physical distribution of functional, server components to cover a local, geographical area (eg. a building, or campus). The functional servers roughly correspond to various parts of a shared system: person servers (computing workstations/terminals), file servers, print servers, and communications servers. The communications is via message passing protocols. Researchers have posited the notion that LANs can be used to provide high performance, parallel processing. While the current LANs are relatively slow (10 Mbits/sec), they are ideally matched to today's, slow terminals and personal computers. In the future, we believe higher speed LANs are needed, and can form the basis for interconnecting functional computers in a hierarchy as shown in the facilities section (Fig. ?) providing 100 Mbits. Also note that the ring that interconnects the AFP provides transmission at about 2 Gbits/sec for each computer node connected for the tightly connected computers.

The purpose of the hierarchy of LANs is summarized:

Ultra-LAN	2 Gbits x p	AFP's processor intercommunicatio
Fast-LAN	100 Mbits	Facility comput intercommunication and center to remote sites, formi cluster
LAN	10 Mbits	Individual workstations to centers

PARALLEL PROCESSING FOR KNOWLEDGE BASED SYSTEMS

It has not widely agreed that Knowledge Based Systems can exploit parallelism. For Rule Based Systems, it is believed that many rules can be evaluated in parallel. The research will be aimed at first answering the question, and then simulating and evaluting the resulting structure. AFP could be used to simulate such a structure, provided this approach looks worthwhile.

WHY USE CDC'S ADVANCED FLEXIBLE PROCESSOR?

The CDC AFP provides a very fast, flexible, microprogrammed set of computer modules for experimenting in various parallel computing structures of various type. A single, AFP microprogrammed processor provides the following capability:

250 to 800 Mops in 16 parallel arithmetic and logic units

Microprogrammed control
Access to 32 Megaword memory
2 x 1 Gbytes / sec communication with neighbors in ring

Sixteen processors can be both interconnected to a common 32 Megabyte memory and to adjacent processors in a ring structure, providing both a very flexible multiprocessor and multicomputer.

The AFP can thus be used as a tool to study several different computer structure problems:

1. Microprogramming of 16 pipelined, functional units with the processor. Four units can be initiated every nanoseconds. Because of the difficulty of programming th highly parallel structure, the most important benefit, or sid effect will be understanding in how to do it effectivel Because the microprogramming so heavily pipelined, we belie a better understanding of dataflow techniques for expressi algorithms will result from the use.
2. A 16 processor multiprocessor with shared memory and ve fast interprocessor intercommunication. Here, a processor wi be programmed to be a particular ISP, such as one capable interpreting some language effectively (eg. C).
3. A set of 16 Computer Modules programmed for particul functions. AFP was designed to be operated in this mode f image processing.
4. Microprogrammed as a Dataflow Computer. This is a speci case of 3 whereby particular computers are programmed to beha as the various functional units of a Dataflow computer.
5. Special, parallel processing architectures usi individual, microprogrammed processors as the functional uni of the particular structures. In this mode, AFP turns out be a very good emulator of relatively complex VLSI chips.

January 15, 1982

Dr. Lowell Wood
Lawrence Livermore Laboratory
P.O. Box 808-L-276
700 East Avenue
Livermore, CA 94550

Dear Lowell:

The petition letter to stop the MCF began to look like a hopeless morass given the large government-industry effort.

I did not send the file containing the letter and its response to anyone until now. I do not intend to send the petition letter to anyone, but you're welcome to a copy of the attached file as it now stands to use anyway you want.

I still regard the MCF as a major waste of what should be our most precious and talented designers. Since we (the U.S.) are manpower limited, the effort spreads us thin and means we don't build competitive (with the Japanese) products. In the past, having relatively obsolete military machines may have been unimportant because the Russian computer technology was very bad.

With VLSI, the ability to copy chips, and the flow of technology, I view we are going to wind up with the situation where the Russians are using standard U.S. designed microprocessors, such as the Motorola 68,000 or Intel 8086, running UNIX. This will put the U.S. military at an instantaneous six year lag in computers!

Good luck in your attempt to influence the MCF direction.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

GB:mal
ID#GB3.S1.69

We believe the MCF (Military Computer Family) approach to procuring a military computer is wrong. The standardization, architectural and procurement requirements can be better met by adopting virtually any existing, commercial architecture or even several architectures.

The probability that the MCF approach can result in a machine competitive with available commercial systems is low.

a. This has been the case historically in every military design effort.

b. The military can't match the level, diversity and speed of industrial development.

c. It is unlikely that even an advanced concept can become available before it is out moded by standard commercial products. This may put us in a militarily precarious position. Ironically, our Russian counterparts use U.S. architectures and do have access to world-wide semiconductors.

d. The quantity-price relationship will make MCF substantially more expensive than any other commercial design.

Furthermore, the MCF carries a great risk of standardizing on one or more inferior design. Carrying out this project will be a significant drain on our scarce computer scientists and engineers.

The objectives of standardization are laudable, however these objectives can be clearly and simply met by standardization on an existing, commercial architectures supporting a DOD Standard High Level Language versus the development and subsequent procurement of a new and unique architecture.

Respectively,

ULF FAGERQUIST
BILL MCBRIDE @MR16

SUBJECT: MARKETING COMMITTEE AGENDA ITEM--1/21/80

I'M VOTING NO HERE.

Under no circumstances should we say anymore about 2080 than we have already widely stated! We can repeat the party line, "We are working on a 20 follow-on with several times (targeted 2-3 times) the performance and less price (target of 1/2) to be shipped in the next 3 years".

There has yet to be a good design review for the Phase 0 -> Phase 1 transition!

MESSAGE ID: 5181684364

SUBJECT: RE: DINNER WITH TOM MCWILLIAMS

We didn't get into the issue of the machine. They are still enthusiastic about the machine and think that it is no problem. If there is a major problem, and the machine will never work, I didn't get behind the facade. They have a very convincing story about the machine, and appear to be resolved to finish it, including going ahead with the full machine.

The goal is to make about 6 of the 25K chip ones, then move to build the Mark III, a very tightly packed one where they put 25K chips on 50 boards, on 1/2" centers, on double sides ala cray, on 15" water cooled boards (250/side). I saw the boards and said we'd like to work with them on packaging... which we badly need. This means a Venus could go down to 10x10x10 cube, and with 2 zif connectors on the edges, could get the delays down by over a factor of 2 over venus. With the MCAIII, this could be quite a decent machine IF we can make a Venus I.

The Mark IV is put the whole processor on a wafer... by 87.

I was impressed that the I box ran in such a short time from power up time.

I said that you think that for simple benchmarks the machine done there will compute very fast. Tom really went after the

benchmark issue, cause there's so much there for transcendentals,
vectors, matricies, LISP,... ?, and mP's. In the interest of CS, I want to see the machine run badly and see how close to a cray they come. Whether, after they have a Pc running, they will want to go on is still an issue. I assume that if they get this one running at 80ns, then they will want to go on with the program. I don't see how they can alter their course unless the machine fails to work, but at least to the outside world, they are not ready to remotely admit that it has any problems.

I'm about to write a letter of encouragement to them, but will wait till after your meeting to send it. It's clearly the best way to get Tom to come. I think you ought to make an offer of Titans to them for mP work. Also, it would be worth

getting Tom's input on a non-disclosed basis. Somehow, we need to get him to your lab gradually.

He's now working on Scald III, to do the scaling of the IIA to get it to the new packages. This is precisely the work we need now on Venus and Nautilus... Is there a program that can convert these designs into different packaging and logic? (I think clearly yes, but the only question is what form is needed to express the initial design such that a program has a chance.) This is critical to our future. It's probably largely AI based, and it's the second highest priority Ai program I know of.

I offered to give 50% off on a 4 processor 784 so that they could start to do mP software work before they get their machine.
This offer was made to George Michaels and Tom thought it was a terrific idea. Also, the CS guys under George are ecstatic

too, since they could also do their dataflow simulation on it too,. Does it make any sense for you to install a 784 there that they could compute on? (It would solve some of their logistics problems, but it might not really get them hooked the way they need to, to get the work done.)

Command >

MECHANICAL GENERATION

The second pre-computer generation started about 1810 and was brought about by the change from handcraft to mechanical technology. Two machines establish the beginning of the period: the Jacquard loom and the planimeter. In the 1790's Joseph Jacquard integrated a design based on the ideas of Bouchon, deVaucauson, and Falcon, for an automatic harness controlled by punched cards connected to an endless roll that would mechanize fancy weaving. This was shown at an exhibition in Paris in 1801 and by 1812, ten thousand Jacquard looms were in operation in France alone (Strandh, p. 195). The planimeter, the first instrument for directly measuring an area bounded by an irregular curve, appears to have been invented by the Bavarian engineer J. M. Hermann in 1814. It was improved by Lamule in 1816, and constructed in 1817 (Pugh, 1975). With the need for surveying and recording land ownership, the planimeter rapidly came into widespread use.

Analog calculating devices flourished in the mechanical generation. Specialized slide rules were spawned for a wide variety of uses: by revenuers to calculate tax on alcoholic beverages, lumbermen for cordage, printers for paper quantity, and traders for interest rates (Turner, 1980). A company still exists in the North of England that makes specialized slide rules. Although the technology is based on a previous generation and two-three part analog calculators do not need mechanization, they were improved by industrialized forms of production.

Mechanical digital calculators had their beginnings within this generation and flourished in the next. In 1820, Charles de Colmar, an insurance agent, experimented with a four-function calculator, but it was not built or distributed until the 1850s. The invention of practical mechanical calculators began in the last ten years of the century when Baldwin, Burroughs, and Felt were in business in the U.S., and Odhner had started his company in Russia. Then in the next generation, they became embedded in Western office procedures and practices.

ANALOG CALCULA
(described in the Craft generation)

2-3 PART

LEVEL REFERENCE

The use of analog devices for calculating differences often depended on the analysis of a position in reference to ground or horizon position. The simple gunnery level with its few moving parts has evolved to sophisticated analog circuitry guiding missiles.

Gunnery Level, Swift & Anderson Inc., ca 1910, Lead,
Brass and Glass, (B66.80).

INTEGRATOR

Integrators are analog calculators that perform the mathematical integration function. The two-three part mileage readers are indeed very primitive forms of this phenomena. In calculus, integration is carried out by continuously summing up rectangles whose height is represented by the value of a function and whose width approaches zero. The infinite sum of all of these results is a value that represents the area under the function. In an integrator this process is duplicated by means of a wheel sliding on a rotating cone or disk. As the function increases, the wheel is slid further out on the disk, making it spin faster to account for the greater area under the function.

"Morris's Measuring Instrument", Morris, 5.5d x1 cm, Metal, Paper, Cloth, Glass, (B128.80).

Map Measure and Compass, Tacro Inc., 7x3.5x.5 cm, Chrome, Paper, Glass, (B129.80).

<u>Map Mileage Reader</u>, Depose H.C., 12x3.5dx.5 cm, Metal, Paper and Glass,, (B140.80).

<u>Map mileage reader and compass</u>, SELSI, ca 1930, 11x3.5x.5 cm, The handle also serves as a pencil, (B152.81).

<u>MULTIPLE PART</u>

DRAWING INSTRUMENTS

PANTOGRAPHS

The pantograph is a device mechanically changing the scale of a drawing, speeding up engineering processes whole insuring reasonalbe accuracy. The pantograph was invented between 1603 and 1605 by the Germany astronomer, Christoph Scheiner, and greatly improved in 1743 by the Parisian craftsman, Claude Langlois (L'e Turner 1980). The devices usually consist of four brass bars, jointed in pairs, one pair being twice the length of the other. Under the joints are small castors, and one long bar has a tracing point, and a short arm has a pen held by a sliding head that is set to the ratio required. On the other long bar is a pivot point in the form of a heavy brass disc. While the invention occurred in the craft generation, significant use was not possible until machine tooling increased precision.

INTEGRATOR

PLANIMETERS

Instruments for directly measuring an area bounded by an irregular curve are based on an idea developed by the Bavarian engineer, J M Hermann, in 1814. The first commercially successful devices were made by Ernst of Paris. In 1851, John Sang of Kirkcaldy invented and made a "platometer" resembling the planimeter of Ernst.

Their operation is based on continuous integration. A curve is traced using the pointer, with the area read off on the dial after the complete perimeter has been traversed. As the pointer is moved the rollers that measure distance on the conical shaft calculate the product of the vertical distance times the horizontal distance. As a curve is traversed in a clockwise direction, the top area is integrated in a positive direction. On the return trip the integration is negative and the net value is provided.

P
"<u>Platometer</u>", J. Sang, ca 1860, 9x15x37 cm, Brass, (B6.76).

<u>Planimeter</u>, The A. Leitz Co., ca 1900, 2x4x28 cm, German Silver and Steel, (B49.79).

This instrument for measuring the area of any plane figure was invented by Professor Jacob

Amsler in 1856. It is a proportional instrument in that the unit can be changed by altering the radius of the tracing arm.

Use. The weighted point is fixed and the tracing pointer guided exactly once round the outline of the figure whose area is to be measured. The difference of the readings on the graduated roller before and after this operation gives the area of the figure in units dependent on the setting of the tracing arm.

OTHER

INTEGRATING DEVICES

?M?

"Directions for Making a Machine to Solve Equations", Rowning, J., 1768, 22x18x2 cm, (B48.79).

This

work describes the first analog computer designed to solve algebraic equations of the n'th degree expessed in the form y = a + bx + cx2 + dx3 + . . . + qxn . It was completed in 1768 by Rowning based upon the graphical method invented by A. deSegner in 1751. In 1770 an actual machine mechanized to the second degree was presented to the Royal Society, but apparently no longer exists. Rowning's instrument consists of a number of adjustable straight bars, or "rulers," centred and combined together in such a way as to occupy progressively the various positions in accordance with deSegner's graphical construction. Movement in two directions at right angles to one another is secured by means of two pairs of racks and pinions. The curve is drawn by a pencil on the underside of a piece of pasteboard supported by two adjustable bars.

Use.

Segner's method consisted in finding, by graphical construction, the values of y for various assumed values of x, plotting the curve, and reading off the values of x at the points where the curve intersected the axis of x, thus obtaining the real roots of the equation. The impossible or imaginary roots were indicated by the points where the curve approached and reached from the axis of x, without reaching it.

"Lowry-bowyer Telemeter", Lowry Mfg. Co., ca 1900, 15x78x7 cm, Aluminum and Wood, (B53.80).

A version of the classical trigonometer signed and dated "THE LOWRY MFG. CO./BOSTON, U.S.A./PAT. 1887, '92, '96". It has two four and a half inch compass bearing dials, one fixed at the end of the twenty-six inch long graduate slotted base plate, the other sliding, and each with graduated pivoted arms of 18 3/8" radius. It was intended for the analog solution of the plane triangle knowing two angles and included side, two sides and the included angle, or three sides. Thus it was useful for problems both of navigation and gunnery.

DIGITAL CALCULA

The Digital Order, Class Calcula has five families: single register, two register, three-four register, complex and programmable. The abacus, a single register, manually operated, portable calculator, was not challenged until the development of equally portable and inexpensive electronic pocket calculators. Abacus-type machines have been unique because with a skilled, accurate operator, they could carry out diverse and complex functions, including long mulitplication and division. They had the characteristic of all single-register machines, i.e., the only record of the operator's input was the current result on the single register. The dual calculator Sharp-Elsi Mate, with both a soroban and a four-function electronic calculator, was manufactured to preserve a culture, i.e., to teach children to use a soroban and not to use the calculator. If abacus-like machines are so extraordinary, why in fact were mechanical calculators ever invented? Probably, because of the likelihood of human error, and desire for simple aids with some kind of memory to check the human operator.

The Pascaline (1645) is the first of the mechanical, single register calculators. All machines using the Pascal-wheel principal subtracted by adding the one's complement of the total. Two register calculators, developed in the late nineteenth century, were characterized by using the keyboard as one register and using bi-directional wheels for direct subtraction.

Three and four register calculators were derived from Leibniz's concept of a stepped-wheel mechanism allowing an improved automatic carry, thus multiplication and division. Otto Steiger's Millionaire, a heavy brass machine based on purely mechanical principles, also had the first fully automatic multiply. Millionaire production came to a halt in the nineteen-thirties, when these machines were kludged with key punches and motors in an unsuccessful effort to meet the growing competition of electric motor-driven machines.

In the 1870s, both Frank Baldwin and Wilhelm Odhner developed a compressed version of the stepped wheel device with one large wheel and all operations based on its rotation. Machines of this type were widely distributed in Europe under the names Odhner and Brunsviga. The principal was most refined as the Curta, produced through the nineteen-sixties.

In 1911, when Baldwin was old enough to retire he met Frank Monroe and they started the Monroe Calculator Company (Chase, 1980). The Monroematics, electric calculators, were among the first electrified automatic machines.

Four-function electronic calculators are the general-purpose calculators of the nineteen-eighties: school children and people balancing their check books have become about as attached to their calculators as to their watches. The inexpensive four-function electronic pocket calculator has replaced almost all other forms of analog and digital calculators.

Complex digital calculators stem from the Difference Engine, outlined by Charles Babbage in the eighteen-twenties and built by Scheutz later in the century.

SINGLE REGISTER

Three kinds of mechanisms divide this family into three genuses: Pascal wheel; Pascal strip; and keyed wheel. The original machine was based on a toothed wheel driven by a stylus. Pascal's bulky machine with its long teeth was replaced by many streamlined variants. As teeth on the wheels became more compressed the volume of the machine was taken up by the diameter of the wheels themselves, giving rise to the Pascal strip -- simply an elongated circle. From the nineteen-thirties to fifites, the Pascal strip family provided a portable, cheap and, relatively widely used alternative. However, key punch equipment is faster and more accurate for the average office worker. Dorr E. Felt was the first person to patent and manufacture a key-punch variant of the wheel, the Comptometer, marketed mainly for the growing bureaucracy of turn-of-the-century industry.

PASCAL WHEEL

THE

PASCALINE

P

Pascaline replica by Roberto Guatelli, 1645, Bronze, (B150.81).

A replica of the first mechanical adding machine.

Use. The dials show the French monetary unit, the livre, which was divided into 12 deniers, each subdivided into 20 sols. The essential part of the machine was its decimal carry; each toothed wheel moved forward one unit (one-tenth of a revolution on each wheel except those of deniers and sols) when the previous wheel had completed one revolution. Subtraction is based on complementary numbers revealed by moving the strip at the top of the calculator.

p

VARIOUS REFINEMENTS

"Addometer", Reliable Typewriter & Adding Machine Co., USA, 1x5x30 cm, Brown with red and white dials and yellow numbers, Metal, Case, Instructions, Stylus, and Calculator, (B179.81).

"Addometer" Reliable Typewriter & Adding Machine Corp., 1x5x30 cm, Black, Metal, (B85.78).

"Addometer" Reliable Typewriter and Adding Machine Corp., 1x5x30 cm, Dark Gray, Metal and Fiber, (B96.80).

"BRI-CAL POCKET ADDING MACHINE", BRI-CAL, 1900, 12.5 cm diameter, Black, Metal, Loaned by Dick Rubinstein (X13.80).

"Quixsum Adding Machine Model C", Precision Adding Machine Co. Inc., ca 1930, 7x18x48 cm, (B38.79).

The Quixsum is a good example of how the stepped wheel principle of Pascal can be used to operate any special measures, not necessarily base ten. In this case it adds English units of feet and inches.

Use. To add a number to the register, the appropriate digit is dialed. The result is displayed in a notch at the top of each wheel.

"SEE CALCULATOR", Selective Educational Equipment Corp., 1968, 18x4x1 cm, (B31.79).

A small replica of the Pascal-type adder made to illustrate the mechanism.

P PASCAL STRIP

"BABY CALCULATOR", ca 1950, 1x8x6 cm, Tin, (B76.80).

"BABY CALCULATOR", 14.5x7.5x7 cm, Black, Gold and Red, Metal, (B149.81).

"B.U.G. Calculator", ADDI-COSMOS, 4.5x20.5x4 cm, Brass, Steel, Wood, fabric, (B131.80).

"EXACTUS", ca 1950, 7x11x.5 cm, (B36.79).

A linear form of the simple Pascal two function calculating device that uses complement arithmetic.

Use. Addition or subtraction is carried out by dialing the numbers starting with the least significant. A carry is performed by moving the final digit around the corner to the next linear register.

KEYED WHEEL

All machines in this category are derived from the invention of Dorr E. Felt who helds an 1887 patent (#371,496) for the machine. In 1884, at age 22, Felt, a machinist, conceived his idea while watching the ratchet-feed motion of the planer that he ran. He wrote: "Watching the planer-feed set me to scheming on ideas for a machine to simplify the hard grind of the bookkeeper in his day's calculation of accounts. I realized that for a machine to hold any value to an accountant, it must have greater capacity than the average expert accountant. Now I know that many accountants could mentally add four columns of figures at a time, so I decided that I must beat that in designing my machine. Therefore, I worked on the principle of duplicate denominational orders that could be stretched to any capacity within reason. The plan I finally settled on is displayed in what is generally know as the "Macaroni Box" model. This crude model was made under rather adverse circumstances. The construction of such a complicated macine from metal, as I schemed up was not within my reach from a monetary standpoint, so I decided to put my ideas into wood. It was near Thanksgiving Day of 1884, and I decided to use the holiday in the construction of the wooden model. I went to the grocer's and selected a box which seemed to me to be about the right size for the casing. It was a macaroni box, so I have always called it the macaroni box model. For keys I procured some meat skewers from the butcher around the corner and some staples from a hardware store for the key guides and an assortment of elastic bands to be used for springs. When Thanksgiving day came I got up early and went to work with a few tools, principally a jack knife. I soon discovered that there were some parts which would soon require better tools than I had at hand for the purpose, and when night came I found that the model I had expected to construct in a day was a long way from being complete or in working order. I finally had some of the parts made out of metal, and finished the model soon after New Year's day, 1885." (Felt in Turck, 1921) He produced eight finished machines before September, 1887, and two were immediately put into service for training operators.

One of the first trained operators, George W. Martin wrote Felt on November 6, 1887, "...in accordance with your request I have called on as many businessmen as I will have time to call on owing to the fact that the Gas Co. has written for me to come to work next Monday morning. The names and addresses are as follows: Sprague Warner and Co., Michigan Avenue and Randolph Pelkin and Brooks, Lake and State Streets, Melville E. Stone, Editor, of the Daily News, and the Freight Auditor of the C.B.&Q RR. These Gentlemen are very much please with the machine and say they will give it a trial as soon as you put it on the market." (Turck, 1921, p. 71)

According to Turck, "significant proof of Felt's claim as the first inventor of the modern calculating machine is justified by the fact that no other multiple-order key-driven calculating machine was placed on the market prior to 1902." (Turck, 1921, p.75)

Use. For each digit a push button from 1 to 9 is selected which rotates a Pascal-type wheel with the corresponding number of increments. Numbers are subtracted by adding the complement (shown in smaller numbers). The carrying of tens is accomplished by power generated by the action of the keys and stored in a helical spring, which is automatically released at the proper instant to perform the carry. Through effective marketing and training of skilled operators versed in complement arithmetic at Comptometer Schools, these machines became the workhorse of the accounting profession in the first part of the century. They never successfully advanced into the electro-mechanical era, but remained purely mechanical, two-function adding and subtracting machines.

COMPTOMETER

P

"Comptometer" #505, Felt & Tarrant Mfg Co., ca 1895, USA, Walnut, Brass & Other Metals, (B174.81).

An early Comptometer with the springs showing on the upper keys. The keys are molded differently on alternative rows to give the operator a "feeling" of relative location. The walnut cabinetry and tooling was clearly a hand-made.

"Comptometer", Felt & Tarrant Manufacturing Co., 1914, 37x28x15 cm, Green, Metal, (B9.76).

"Comptometer", Felt & Tarrant Mfg Co., ca 1920, 36x22x15 cm, Bronze, Metal, (B57.80).

COMPTOMETER COPIES

"Burroughs" Burroughs Adding Machine Company, ca 1920, 15x30x25 cm, Black, Metal, Complement Arithmetic Nine Digits, (B22.78).

"Burroughs Calculator", Burroughs, ca 1910, 18x23x30 cm, Black and green, Metal, 11 Digit, Stands on legs at a tilt for ease of operation, (B155.81).

"Plus" Bell Punch Co. Ltd., 15x30x40 cm, Green, Metal, Model #909/C/V/504.929/A, (B81.80).

An electrified modification of the Comptometer.

TWO REGISTER

TAB INDICATOR

"Adding Machine", Wolverine Supply and Manufacturing Co., ca 1950, USA, 10x15x23 cm, Red, blue, and cream, Tin, (B167.81).

"American Adding Machine", American Can Company, ca 1920, Black, Metal, Digits worn, (B137.81).

Essentially a Pascal-like single register machine, only the digits are grooved and stay in place showing the entry (a second register) until they are cleared.

"American Adding Machine", American Can Company, ca 1920, USA, 22x22x19 cm, Black with green, Metal, Rusted and worn, (B180.81).

KEYED WHEEL

One register is formed by the depressed keys, in contrast to the single register comptometer type where the keys are on springs. The other register is the accumulator. In many cases, these also started as printing and adding machines. The first practical machine resulted from William S. Burrough's patent of 1892. Prior to this a number of machines were patented and experimented with, particularly the patents of Henry Pottin (No. 312,014, 1885) and William S. Burroughs (Nos. 388,116 and 388,118, 1888). Like the comptometer type, until the adaptation of Wm. E. Swalm's patent of 1910 (No. 1,028149), complement arithmetic was used for subtraction. In 1907, Burroughs sold 13,314 adding and listing machines, and with 58 different styles of Burroughs (including comptometer copies) claimed to be the leading producer in an ad in the February 1908 issue of Office Appliances Magazine.

<u>3-4 REGISTER</u>

STEPPED WHEEL

In 1820, Chevalier Charles X Thomas de Colmar designed and introduced the first multiplication machine made commercially available for general sale. Although it was not patented until 1851, the main features of the 1820 design remained unaltered. The mechanism has three parts, concerned with setting, counting, and recording respectively. Any number up to 999,999 may be set by moving the pointers to the numbers 0 to 9 engraved next to the six slots on the fixed cover plate. The movement of any of these pointers slides a small pinion with ten teeth along a square axle, underneath and to the left of which is a Leibniz stepped wheel. The Leibnix wheel, a cylinder having nine teeth of increasing length, is driven from the main shaft by means of a bevel wheel, and the small pinion is thus rotated by as many teeth as the cylinder bears in the plane corresponding to the digit set. This amount of rotation is transferred through one of a pair of bevel wheels, carried on a sleeve on the same axis, to the 'results' figure wheel on the back row on the hinged plate. This plate also carried the figure wheel recording the number of turns of the driving crank for each position of the hinged plate. The pair of bevel wheels is placed in proper gear by setting a lever at the top left-hand cover to either "Addition and Multiplication" or "Subtraction and Division". The "results" figure wheel is thereby rotated anti-clockwise or clockwise respectively.

<u>Use</u>. Multiplying 2432 by 598 may be performed as follows: Lift the hinged plate, turn and release the two milled knobs to bring all the figure wheels to

show zero; lower the hinged plate in its position to the extreme left; set the number 2432 on the four slots on the fixed plate; set the lever on the left to "multiplication" and turn the handle eight times; lift the hinged plate, slide it one step to the right, and lower it into positon; turn the handle nine times; step the plate one point to the right again and turn the handle five times. The product 1,454,336 will then appear on the top row, and the multiplier 598 on the next row of figures.

"Arithmometer", Chevalier Charles Xavier Thomas de Colmar, ca 1850, 10x18x58 cm, Brass, (B3.76). *p*
"Tates Arithmometer", C & E Layton, 10x17x58 cm, Brass and Wood, (B82.80).

This machine, which is of the Thomas type, embodies the modifications patented in 1884 and 1903 by S. Tate, who in 1883 was the first in England to manufacture this type of calculating machine. His patents were later taken over by C. and E. Layton.

"BUNZEL", Thomas-type arithmometer, Bunzel Mfg, Vienna, ca 1910, Wood, Metal, (B143.81).

AUTOMATIC STEPPED WHEEL

MILLIONAIRE

The Millionaire was invented in 1893 by Otto Steiger and was the first direct multiplying calculator to be commercially successful. Between 1894 and 1935, 4,655 millionaires were sold.

Use. One turn of the crank automatically multiplies the accumulator by a single digit specified by a pointer in the upper left hand corner of the machine. The pointer is reset for each digit in

the multiplier until the computation is complete.
P
"<u>Millionaire</u>", EGLI & CO., 1903, 17x52x28 cm, Brass, 6 Digit, (B1.75).

"<u>Millionaire</u>", EGLI & CO., ca 1910, 18x29x76 cm, Brass 10 Digit, (B17.78).

"<u>Millionaire</u>", Hans W. Egli, 18x29x76 cm, Brass, 8 Digit, (B91.76).

"<u>Millionaire</u>" #272, HANS W. EGLI CO., ca 1900, Switzerland, 18x29x76 cm, wooden case, brass calculator, 8 digit, wooden stand, case, and calculator, (B161.81).

ROTARY

The German patent of W. T. Odhner, 1891, was acquired by Messrs. Grimme, Natalis & Co., and was embodied in a machine known as the "Brunsviga".

<u>Use</u>. Although the machine performs multiplication by repeated addition as in the Thomas type, the use of the Odhner wheel instead of the Leibniz toothed wheel led to a more compact design. The Odhner wheels fit very close together on the axle on the back. A setting lever, the end of which projects through a slot in the cylindrical portion of the cover plate, forms part of each wheel. If a lever is set against any figure (1 to 9) of its slot, a corresponding number of pins are made to project from its wheel. When the operating handle is turned, these pins gear with small toothed wheels of the product register, which in turn gear with the number wheels in front. The product register is mounted on a longitudinally movable carriage arranged in front of the machine, which carries a second counter for

registering the multiplier or the quotient. The handle is turned in a clockwise direction for addition and multiplication, and counter-clockwise for subtraction and division.

p

"Trinks-brunsviga" Trinks-brunsviga, ca 1940, 15x12x36 cm, (B80.80).

This example is a further adaptation of the Brunsviga and sits on a wood board that was part of a disappearing desk top.

"DE TE WE" Harmann Manus, Gift of Declan and Margrit Kennedy (D190.80).

"Original Odhner", Odhner, ca 1920, Grey, Metal, (B135.80).

"Curta" Contina Ag Mauren, 10d x 12 cm, Black, Metal, (B87.79).

The Curta is the ultimate example of the rotary mechanical calculator. Its small size requires better manufacturing technology than any other mechanical calculator. Model I had an 8 digit input setting, 6 digit counter, and 11 digit accumulator. Model II had an 11 digit setting, 8 digit counter, and 15 digit accumulator. Prior to the electronic calculator, the Curta was the only four-function portable calculator and as such was especially popular for use at car rallies.

CONTROL

CARD-CONTROLLED - LOOM

The origin of punched card program control can be traced to 18th century developments in the French silk weaving industry.

In 1725 Basile Bouchon, the son of an organ manufacturer, devised a perforated tape control for weaving ornamental patterns. Before then, draw looms were operated by two people, one to control the shuttle, and the other to control warp threads by means of cords. A row of perforations across a tape automatically selected the warp threads in Bouchon's loom, reducing the assistant's task to that of pressing the mechanism against a set of needles that sensed which holes had been punched.

In 1728 Falcon, a master silk weaver in Lyons, constructed a loom replacing the perforated tape with a row of connected punched cards. His loom used several rows of needles so that four hundred or more cords could be controlled. At Falcon's death in 1765, about forty of his looms were in operation.

In 1746, Jacques de Vaucanson, the celebrated inventor of automata, designed the first draw loom to function completely automatically. While this innovation was significant, the use of a perforated cylinder rather than a row of cards was retrogressive.

In 1804 Jacquard commercialized and improved de Vaucanson's fully automatic loom utilizing the punched cards of Falcon. Each card carried an individual pattern line. Mounted on a belt, the cards wound over a prism shaped like squared cylinder which revolved with a ratchet system. To extend a pattern, more cards were added, so that complex non-repetitive patterns could be created on the loom.

By the 1830s, thousands of examples of Jacquard looms were operating in France. It is then understandable that Charles Babbage in 1836 chose to use Jacquard mechanisms as program-control devices to direct the wheels and gears in his Analytical Engine.

P

"Jacquard Loom Mechanism", ca 1805, 16x36x40 cm, Wood, Brass, and Steel, Paper Cards Added by Peter Delehar, (B117.80).

A rare and important contemporary model of the first loom device invented by J. M. Jacquard (1752-1834) for use in the French silk weaving industry. The loom was automatic. Patterns in fabric were generated by programmed punched cards.

TRANSDUCTION

COPIER

"The Edison Mimeograph No. 1", A.B. Dick, ca 1900, 13x33x43 cm, Wood Case and Frames, (B78.80).

TYPEWRITER

The typewriter evolution belongs within the taxonomy as these machines were adapted to become I/O devices.

The first patent for a "writing machine" was granted to Henry Mill in 1714. (Science Museum 78) Starting in 1829 a number of Americans produced a variety of writing machines. The first commercially successful machine was manufactured by E Remington and Sons in 1874, based on the invention of Christopher L. Sholes.

The Type Writer was not quickly adopted, and its name did not suggest its labor-saving virtues. The salesmen finally struck descriptive paydirt through the simile: "The Type Writer is to the pen what the sewing machine is to the needle" (Sutherland, 1981). The four-row Type Writer keyboard, with the most commonly used letters emplaced for the left hand -- just as it remains --, was present on the Remington built Sholes Type Writer. The machine that went on sale in 1874, was finished in gleaming black, embossed with hand-stenciled flowers and portraits of ladies, equipped with a sewing-machine-style table, with foot treadle for cariage return and line spacing. Since the printing was done on the bottom of the cylinder instead of the front, the typist who wished to inspect writing-in-progress was forced to raise the carriage on its hinges for a look. In 1878, the "Perfected Type Writer No. 2" was a simpler, functional machine. By 1881, the typewriter proved a commercial success and the Remingtons hired a small team to build a sales force. Then in 1886, when difficulties in the gun business as well as other activities brought the Remington Arms Company into banckruptcy, the men who had developed the typewriter sales organization set up a new firm, Remington Typewriter Company. A number of rivals appeared, but only the Underwood Company and the Wagner Typewriter Company, which built similar sales organizations succeeded in becoming major competitors. (Chandler, 1977). According to Alfred D. Chandler, Jr.,

> "The Remington experience underlines in a dramatic fashion the necessity of creating an extensive marketing organization to sell a new office machine in volume. ... As the experience of all the new mass-produced machinery companies emphasizes, they could sell in volume only if they created a massive, multiunit marketing organization. all their products were new, all were relatively complicated to operate and maintain, and all relatively costly. No existing marketer knew the product as well as the manufacturer. None had the facilities to provide after-sales service and repair. Few were willing to take the risk of selling on installment, a marketing device which these machinery makers had to invent. Nor were outsiders abole to maintain close control over collections, essential to assure a continued cash flow on which the financial health of the enterprise rested. Finally by using uniform slaes techniques, bringing together regularly members of a nation-wide sales force, and comparing the activities and performances of the many different sales offices, the single, centrally controlled sales department was able to develop more effective marketing techniques. It was also able to obtain a constant flow of information on the changing shifts in demands and customer requirments. ... The economies of speed and scale, and their national, often global, marketing organizations gave the pioneering firms an impressive competitive advantage and so made it easy for them to continue to dominate their industries" (Chandler, 1977, pp 308-9).

The typewriter stayed remarkably stable in design through the first half of the twentieth century. New ideas, such as the daisy wheel, that were to become part of the electro-mechanical typewriter associated with computers, were only tried out as toys in this era. The large corporations, listening to their customers (who were essentially conservative -- not innovative) saw no reason for any kind of retooling or rethinking. Thus, in the mechanical generation one sees percursors of the typewriters of the seventies and eighties built as not-very-well-engineered toys.

P
"Bennett", 27x12x4 cm, Black with Yellow Letters, Metal, (B142.81).

Very compact with three positions for the keys and a wheel device. Small sized ribbon and removable carriage.

"Bing No. 2" Bing, ca 1930, 15x28x38 cm, 1926 patent pending, (B43.80).

"Corona No. 3", Corona, ca 1920, 23x25x12 cm, Black, Metal, Carriage folds up over Keyboard, (B63.80).

"CORONA FOUR", Corona Typewriter Co., Inc. Groton, NY, ca 1920, 26x31x11 cm, Black, (B154.81).

"Dial Typewriter", MARX, ca 1950, 15x15x30 cm, (B75.80).

"Favorit 2" Adler, ca 1940, 36x28x11 cm, Black, German Keyboard, (B67.80).

"Featherweight Blickensderfer", Blickensderfer, ca 1900, 25x30x13 cm, Aluminum, 501 Special Stamped on Base, (B116.80).

The "Blick" was the first typewriter intented to be readily portable. It was designed by Georges Blickensderfer and patented in 1890 and first sold in 1893.

Use. Each key had three positions, upper and lower case and a figure that positioned three levels of the printing wheel.

"Junior Typewriter", MARX 28x13x18 cm, Gray and Blue, Tin, Bent & Rusty, (B101.80).

"Molle No. 3", Molle Typewriter Co., 25x28x33 cm, Black, Metal, (B65.80).

"NOISELESS TYPEWRITER", The Noiseless Typewriter Co., ca 1915, 30x30x30 cm, Black, Metal, Text typed on the machine. Loaned by Ed Luwish (X5.80).

"The New Simplex Typewriter No. 1", Simplex Typewriter Company, ca 1920, USA, 22x12x6 cm, red, yellow, and black, wooden base with metal, cardboard case and typewriter, (B165.81).

The simplex is a small, inexpensive, home typewriter that only holds paper less than seven inches wide. U.S. patent numbers 1138427, 1204912, 1521408, 1865288, 1869426, and 1957373.

Use: From the Directions for Operating in the case: "First: Hold the machine with rack side toward you. Push carriage to the left to starting point. When doing this see that dog does not catch in rack. Insert paper between rollers from the front. Put finger on key of letter desired and swing it into notch in rim of typecase near the dog: Press downward to print. To make a space without prining, press down on any key near to but not in the notch. To ink apply only a drop of ink to each pad with the end of a matchstick or toothpick. Be careful not to bend the pads down so far as to prevent them from springing back into position. Use only Simplex Ink which will be supplied at 10 cents per tube, cheap ink destroys the face of the type. Do not oil. If keyplate sticks take a rag moistened with vaseline and hold against underside of keys at the notch and twirl type plate around a few times. If the carriage does not move forward freely, apply a little vaseline to the carriageway where it rubs. Caution! Keep oil or vaseline away from rubber type and ink pads. Oil will swell and destroy the letters."

"Simplex Portable Typewriter Special Demonstrated Model S" Typewriter , Simlex Typewriter Co., Inc., ca 1930, USA, 24x8x16 cm, Green and red, Metal, (B166.81).

"Underwood Typewriter No. 5", Underwood, 22x30x30 cm, (B15.76).

Last Date: 1/18/80
Revised Date: 1/30/80

Our current performance versus our plan has reached an all-time low; while there are many reasons, including how the commitments themselves are established, this conclusion is unmistakable!

Are the root problems:

omanagement attention at the top levels of the organization?

oproject management expertise at the middle management level?

o review procedures at the organizational level?

oviable planning processes for ascertaining our ability to perform before the commitments are established?

o doing state-of-the-art work with an inadequate technology or understanding base?

The solution to most of these problems must reside within each organization. It is inconceivable that the Office of Central Engineering (OCE) can solve these problems, we belive establishing real accountability at all levels of the engineering organization is the only way.

We must begin to measure Engineering Management against their plans! This would not be the only metric; we still expect quality, innovation, and the appropriate degree of risk, but a significantly greater proportion of our development activities must produce the promised capability, product cost and quality **on schedule**. The December 17 management system package is a start in this direction.

At our next dinner meeting (February 12) can we discuss the details on how to deal with our schedule performance and resulting loss in credibility?

Subject: **Meeting with Ken: Our Philosophy, Keeping People, Charters (and Diletantes)**

To: OOD

CC: Ken Olsen, ML10-2/A50
Shel Davis, PK3-1/C21

Date: 9/25/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-2236

Follow-up: 11/1/79

Our Philosophy

I think we ought to go through the exercise of trying to write up, on a page what it is we have that's unique. Bruce really frightens me because either: he doesn't understand that all engineering processes pretty much look alike and only differ by the environment which encourages drive, motivation, brightness, ability to communicate and perform better; or we are totally average, and have only a few significant products by having at least a good enough environment to permit a few great people to build an occasional great product, otherwise everything is average. In any case, I would like to get your input and then write down a draft of the DEC Engineering Philosophy.

On Losing People

Let's also write down our thoughts on keeping some of the critical people we have now. Let's do a case-by-case post mortem (so to speak) and build a model including: Kevill, Gourd, Hughes, etc. Anything we do philosophically or organizationally or in human resources planning should address whether these people might have stayed or not.

Charters and Diletantes

As we address the charters, it occurs to me that we might just have a problem because of some of our openness: namely, we encourage testing and review of all sorts of things, including R and D, new busses, etc. What happens is that some of the doers are often tempted to do what all the reviewers want, and only the really skillful developers know when to say no.

Another factor which I especially understand is being able to be a diletante, go to everyone's review and work on every project (except my own). Given the organization where all of OOD has clear charters, plans, and is busily executing the plans, I believe there are only two diletantes (Larry and I and possibly some people in the TD and Research Groups), and I really worry that many of our project workers are not able to say no to requests to be on every possible review or new project (especially in the definition phase). On several recent occasions, I know I've seen people that should be at home, rather than being in what amount to be peripheral reviews. Hopefully only a few people are doing this, but it's an easy trap because we have an incredible number of really interesting projects going on.

Dear Louise:

Enclosed are copies of the publications Gordon referred to.

I understand you already have a copy of the Engineering Orientation Manual. As this is "Company Confidential" material, please return it when you are finished.

Thank you,

Mary Jane Forbes

Digital **Interoffice Memo**

Subject: **Clarifying Responsibility (Drive?) for Memory Hierarchies**

To: OOD
Jim Bell
Bill Demmer
Mike Gutman
Bob Peyton
Grant Saviers
Bill Strecker
Mike Tomasic
Steve Teicher

Date: 5 OCT 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1
Ext.: 2236

The Stratton Mountain meeting presented the dilemma of who's in charge of memory hierarchies.

Those not directly responsible: R&D (although they can be asked, coerce, comment), any task force, any committee, any planning group, and me (except ultimately).

Fundamentally, providing the hardware hierarchy is the responsibility of Dick Clayton generally and the system managers or hardware system managers.

1. VAX - Bill Demmer
2. LSI-11/Krypton - Steve Teicher
3. 11/34-11/70? - Dick Clayton?, Mike Tomasic

4. System 10/20 - Ulf

If the task proves to be as simple as attaching to/or being a part of:

1. Primary memory - Mike Gutman
2. Secondary memory - Grant Saviers
3. Tertiary memory - Bob Peyton

Then, they are responsible. It's clear Mike Gutman is responsbile for availability of semiconductor or magnetic bubbles. For a simple software solution with "CCD disks", then Mike, Larry and Dick are on the hook.

Jim Bell and Mike Gutman were to get with Dick to get us started here.

Although this memo is awful specific, I don't mean to be that careful or let anyone shirk their responsibility.

Subject: **Memory Hierarchy Costs**

To: Distribution

Date: 4 OCT 76

From: Gordon Bell

Dept: OOD

Loc.: ML12-1

Ext.: 2236

F/U 10/12

The application of CCD (and possibly bubbles) depends on the certainty of the price relationship between main memory (e.g., MOS) and CCD's.

Dean Toombe at TI promised me this, also I talked with Gelback (Intel) and Tom Longo (Fairchild) about this, and they agreed.

Can we "collect" on these promises now to get memory hierarchy design going?

Loc.: ML12-1 Ext.: 2236

follow up 5/24/78

The crude, but accurate, price erosion model I've been using since 1975 is simply driven by main memory cost and price.

It is:

System price ($) per byte of main memory

$$= 3 \times 5 \times 8 \times .005 \times .79^{t-1972} \times \text{no. of bytes}$$

$$= .6 \times .79^{t-1972} \times \text{no. of bytes}$$

<u>where</u>

3 is markup (roughly)
5 is fact that about 1/5 of system is primary memory
8 is 8 bits/byte
.005 is cost of a bit in 1972
.79 is 21% price decline per year for memory
1972 is base year

Some system prices at various times using the model:

Bytes	1978	1980	1982
1	.146	.091	.057
8K	1.2K	745	467
65K (Qbus limit)	9.6K	5.96K	3.7K
256K (Ubus limit)	28.3K	23.9K	14.9K
1M	153K	95.4K	59.8K
2M (11/74 bus limit)	306K	190.8K	119.5K
8M	1,225K	763K	478K

Some concerns:

1. How do we get enough applications for the larger systems our salesmen are selling? [Note the system price we sell has been increasing -- maybe because of the salespeople we hire.]

2. Can we/should we provide cost-effective enough processors to balance these larger memories? [Note, Gene Amdahl has maintained that 1 inst/sec. requires 1 byte of primary memory.]

3. Can we think of selling systems down in the $10K and below range? [Note in 1982 a 256 Kbyte system will only sell for $14.9K, whereas a 65 Kbyte system will sell for $3.7K!]

4. Will the more expensive multiprocessor and multicomputer systems help the revenue/sales problem while providing much greater RAM and expandability that we can sell? [Note that a duplex computer costs only slightly more than twice the above machines.] [Note, isn't this what IBM is up to in providing multiprocessors?]

With the next version of M+ being oriented to the 11/74 mP, I believe our subsequent 11 hardware in the Unibus area should also support them. This design in the 11 area should be as easy as adding additional memory. I'd hope that new processors can use the 11/74 multiport memory -- this also gets the mips up in line with the memory size.

Subject: **Memory Price Disparity on 20 and VAX**

To: Bill Demmer, John Leng, Jack Shields

CC: Marketing Committee,

Date: 10 MAY 78
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

Ulf Fagerquist

I just talked with Jack McCredie at CMU and he was considering an upgrade on a 2040 to get to a 2060 as the cheapest way to get performance.

He asked whether he should switch to VAX given:

2060	175K	2.3 Mbytes
VAX	88K	2 Mbytes

The service is also twice as expensive on the 2060.

He's confused given a comment by John Leng that our memories are corporate wide.

```

This is neat. Your last one was a whopper though. Other groups might try it (e.g. Term/PC, Computer Systems, Comm./nets; PPPI, Semis/micros, Software) if it can be tuned to save us time. We are inundated in news now and this can help (e.g. I read or scan about 40 journals, magazines, per month).

How about trying to make it better? How about producing an abstract or digest of the news, getting it down to six pages maximum?

Put one paragraph or sentence/article. Put any tables in that are relevant that have data. Arrange them into priority order or keyed somehow. Make the full article available via EMS request.

SUBJECT: RE: MERCURY

I have been the advocate of getting Hg off the CI, without any success. Tonite, it was clear why it is a very interim step:

We must have NI on the high performance machines (i.e Venus, 780, the 2080), simply because there is no way to transfer data at high speeds between the next level machines such as Comet or 780 or personal VAX's or other machines that have files by going through mercury, because it will be a fundamental
bandwidth limiter.   In the past, my arguments have centered on distributing the Comm. around the building and the fact that the NI is where we want our ultimate Comm, and hence doing Hg on CI is just an interim thing.

Now, I can prove that what we are doing is interim, cause we must do NI on all machines.   So, given that we as usual assume we have infinite resources, and besides we have little
confiidence in our ability to do the job in a straightforward fashion, but instead have to do a lot of incremental jobs which we will forever have to support, then it is clear
DO THE WRONG THING, get Hg on CI if you think you can and then let's do it right the next time around.

Good luck.

PS
Any idea where we get all the bucks for the interim projects?
Any idea when we get to the long term?

Any idea who's going to do the A/D so that we can get the right product?
...
Gordon

SUBJECT: RE: MERCURY ON NI

I think we could get Terry to help or I suspect Mickey Smith knows. I know that an 11/34 will front end a 10/20, and that the aggragate data rate (average) is very low, and I suspect the peak is too, given the response time of the Operating System. The input case where there are only a few characters,
where NI is bad (20 bytes of overhead) doesn't bother me, and on output, I can't see it being a limit. Say that we all could
use 2400 baud lines (I can't tell the difference between 1200 and 2400 because I can't drive the system that fast). This would mean that NI would support 4000 terminals at 2400 baud. A VAX supports 25-100, a 10/20 30-200, hence, I see no problem
at all in NI being easily able to handle say 50 or so VAX 780's
or 10/20's. The bottleneck looks like the system (ie just handling the load that a terminal implies), and the next bottleneck might be Mg (how many bits/second do you think it will deliver?). I don't see NI as being anywhere near the limiting bottleneck. This also co-incides with the Xerox observation that the peak rates observed on their 3 mbit Ethernets are somewhere around 300k, even with several hundred
nodes including some concentrators I believe.

NI isn't the limit that I can see at all. This will make the common front end to all the systems that the 10/20, DECnet, and
VMS and Hydra groups have commited to. So let's go ahead with
it.

Subject: Mercury Communications Subsystem

Thank you for your recent comments on this. Here are some answers to your
questions.With regard to 64Kb, YES, we would like to provide 32K or 64K bytes
at FCS with capability to replace the 16K chips with 64K chips when they
become available and thus expand to 128K or 256K bytes. The DECSYSTEM-20
people want this for COMNETS software and George Plowman would like it for a
general purpose network node. With regard to DEC dataway , we have been
talking with John Holz and he is interested in building a line card for DEC
dataway and programming the microcontroller (11ISP) appropriately. If we have
any problem there, it's that they are too anxious to use Mercury!(i.e. they

want it before FCS). Withe rega rd to PUSART, YES, but... For present design
purposes we are using a UART and a USRT to give us an async/sync line card,
but as soon as PUSART is available, we intend to use it to save space and $.
At present, it looks like that will be around FCS, however, so we will start
with the UART/ USRT combination. The modularity of the Mercury design is such
that we would o only have to redesign a double board (5x7) to do that, so that
is not a problem. Frankly, since weintend to use FONZs, Tinys, and other
"not-quite- here-yet products", I'd just as soon wait on PUSART to keep the
number of unknowns in this project under control. With regard to multiple
Mercuries on one ICCS, YES, definitely. For cost goals, we would like to keep
the cost to $100 per line so that we are in the DZ11 with KMC11 area, offering
better packaging, performance, RAMP, etc. for the same price. With regard to
ICCS power cost, etc, YES, we see that as a possible problem and are pursuing
two avenues. 1) the lastest ICCS thought is "make it cheaper" and 2) we are
looking at methods of connecting the Mercury directly to low end COMETs and
Nebulas , particularly Nebulas, without ICCS level of in erconnect.

Again, thanks for your interest and let me know if you have any other question
----

Date: MON 5-MAR-79 19:04:19 EDT
Subject: Mercury and the Interconnect (Wayne's Status Report)

Pete, give a copy to John Gilbert too.

I'm glad the review of Mercury went well. It feels we really need it!

Is it possible that Mercury should be connected by the Local Area Network
Interface instead of ICCS? This would be a lot cheaper, possibly it would
not handle the data rate, but it could be much more remotable? Note if this
interface is used...it would presumable alread exist as a connection to
other computers, and hence maybe woudn't be needed as a special one. This
would eliminate one expensive piece of hardware on minimal systems.

John, why not make an interface that has like 8 intrfaces to it and uses a
single board...even though it would use several slot spaces in mercury? It
seems like we always have this option.

I'm concerned about the mercury software. Can I urge you in HYdra to go
after Doug McClure who's now working on MInnow and who did the ANF10, and
which by all accounts is about 3 years ahead of DECnet in terms of capability.
He shuld be working in DECnet, probably but couldn't get along with the former
head of programming there (who's since left)..

As a seperate issue, I'm too distressed that the Merimack hardware folks
don't attend the important interconnect meetings. This is indicative of the
whole interconnect area...which is going to take a lot of much tigher
management with some required participation and results and not a lose,
federated, research project with no schedule, etc. and no clear resposnsibility for hardware, software etc..

Command:
The Research Assistant reports to the Exhibit Coordinator and the Programs Coordinator.

Exhibits Area

A. The assistant aids with cataloging new pieces for the museu. See accessioning   for more procedural details.

1. catalogs each new piece on B list (=Bell), D list (=DEC) or X list (=from other sources) recording relevant information as name, manufacturer, donor, etc.

2. send acknowledgment letter (form letter on Jamie P. floppy)

3. send contract for donation or loan (form on Jamie P floppy)

4. send thank you (form on same)

B. Work on potential acquisitions

1. Follow up by phone, letter if word of potential new piece is received

2. Get more information, pictures, history if possible

Other Areas of Assistance

A. Tours
1. conduct tours
2. compile tour information for future use

B. Store
1. work in store when needed
2. prepare slide collections for future sale

C. Special Projects

For example, researching names of famous mathematicians and others for Spitbrook Conference Rooms naming

Floppies used:

Meredith: slide collection and list of people/addresses who requested information on slides, and date of response

Store: list of all books in store, flea market items, posters, etc.

Jamie P: correspondence, form letters for accessioning

B list: collection pieces loaned from Bells

D list: collection pieces from Digital

X list: collection pieces from other sources

10/20

MESSAGE

THE GENERAL PURPOSE (MAINFRAME) TIMESHARING MACHINE DECSYSTEM 10 INTRODUCED

TIMESHARING; DECSYSTEM 20 IS EVEN BETTER AND MORE USER ORIENTED.

MARKET

MAINFRAME GENERALITY THROUGH THE LANGUAGES AND APPLICATIONS THAT HAVE

EVOLVED OVER ITS 15 YEAR LIFE. TIMESHARING. SPECIFIC SOFTWARE THAT

IT HAS (E.G., MULTI-TERMINAL APL).

BASIC HARDWARE STRATEGY

. SUPPORT EXISTING CUSTOMER BASE WITH BETTER PERFORMANCE AT LESS

COST (BETTER FIELD INTEGRATION) AND MORE RELIABILITY

. IF 2020 SUCCEEDS, BUILD A BIGGER BASE AT ITS PRICE LEVEL

. DON'T ENTER LOWER COST, NEW PDP-11 COMPETITIVE MARKET

BASE OPERATING SYSTEM

. NO O/S ENHANCEMENTS, ONLY IMPROVED PERFORMANCE, RELIABILITY AND

INTERCONNECTIVITY IMPROVEMENTS

. PROGRAMMING IN DEC COMPATIBLE LANGUAGES

COMMERCIAL LANGUAGES/APPLICATIONS

. USE AS GENERAL PURPOSE MAINFRAME

. COBOL WOULD BE 11 COMPATIBLE

.   ENCOURAGE APPLICATIONS (E.G., BUSINESS ANALYSIS) THEN MARKET

<u>TECHNICAL LANGUAGES/APPLICATIONS</u>

.   SELL. DON'T ENHANCE

.   ENCOURAGE APPLICATIONS (E.G., MILITARY COMMAND AND CONTROL);

THEN MARKET

<date>8/20/80
<name>GB & GKB
<tel#>RE THE 2 REQS. BECAUSE OF THE "STATE OF THE CORP" WE HAVE TO ASK BY MEMO TO GO OVER THE BUDGET (MUSEUM) BY 10K. NANCY BERTRAND SAYS BECAUSE OF THE "STATE OF THE CORPORATION" IT MAY NOT GO THROUGH. HOWEVER, WE DO HAVE A PERSON BUDGETED IN 383 FOR FY81. BECAUSE OF ENGINEERING'S "STATE OF THE BUDGET" SHE DOESN'T THINK YOU, GORDON, OR LP WOULD WANT TO TRANSFER 10K OUT OF ENGINEERING (WHICH IS BUDGETED) INTO G&A. NO MATTER HOW YOU LOOK AT IT, THE IMPACT IS ON THIS OFFICE OR 383 SO SHOULD WE: NOT HIRE, GO AHEAD AND USE THE BUDGETED MONEY, ASK TO GO OVER BUDGET IN 69F, CUT SOMETHING ELSE IN 69F (I DON'T SEE HOW WITH THE LECTURE PLANS) TO ACCOMMODATE THESE REQS?

I VOTE TO HIRE 3 MONTHS, 383, AND GO FROM THERE. I MADE IT VERY CLEAR TO THE 2 I INTERVIEWED THAT THESE WERE UNFUNDED JOBS AFTER THE 3 MONTHS. THAT WE WERE GOING TO CLEAN UP THE BACKLOG AND SEE WHERE WE WERE. IT WAS POSSIBLE THEY WOULD

BECOME PERMANENT BUT THAT WOULD BE DETERMINED DURING OR AT THE END OF THE 3 MONTHS. IF THEY WANTED TO TAKE A FLYER WITH US, WE WOULD TAKE A FLYER WITH THE JOB.

<name>MJ
<tel#>
<subj>MJ called this morning: The following are comments she heard at DECUS. Otherwise she is having a ball! 4,000 registration!

"A lot of controversey over DECWORD for example:

o Why just running RSTS?

o What about VAX and RSX11M?

o We know you have a 2 yr contract with DPD what are you going to do when that runs out?

o Word 11 first urged us Word 11 users to go to DEC. Now they are saying they are going to enhance their product and we feel we are caught in the middle knowing full well you have this 2 yr contract.

o When I say a lot of controversy I mean it is a BIG HASSLE here. Really putting us on the spot and not too gently!

o Many, many requests for a hard disk on DEC MATE. One OEM from Australia is holding up a big order hoping for word that the hard disk will come along otherwise he is going to have to sell them a WANG.

Telephone Messages -- September 21

1. Neil Dadd, (Insurance Product Line) 8-264-5473 in Merrimack, called. Re: A customer visit (Connecticut General) on the 28th in Merrimack. He wants to know if you would be available to give a 1/2 hr. presentation on "Computers in the Future". You have a 10:00 staff that morning and two meetings in the afternoon at 2:00 and 4:00.

Also, there is a follow-up meeting on the 28th from 2:00 to 5:00 in the R&D conference to last Tuesday's meeting which you are invited to attend if you get a chance.

2. Jan (John Leng's secretary) called. There is no chance to schedule you for tomorrow morning's meeting. It has been left as it was for the 6th of October.

3. FYI -- Sam Fuller called to let you know that Tom Knight (from MIT) will be in Tewksbury tomorrow at 1:30 to discuss the CHAOSnet.

4. Ralph Drury, 426-0130 (Boston) called to discuss Systems Engineering with you. He will call back Tuesday if you don't get a chance to call him between now and then.

5. Do you need to see/sign the United Way memo written for you by John Meyer before it goes out?

6. Dr. Bruce Merrifield, VP of Technology for Continental (Can) Group, called. Re: a personal matter. (212) 551-7321 -- New York

7. Bruce Arden (609) 452-4640 called. Re: 1980 IFIPS.

MJ -- Messages

Sept. 21

1. Ann in TOPAZ X3-2442 called to confirm Gordon's trip arrangements. They are as follows:

October 1
TWA flight 117
Leave Boston 7:45 AM
Arrive Denver 11:11 AM

October 3
United flight 743
Leave Denver 6:30 PM
Arrive SF 7:53 PM

October 5
TWA flight 32
Leave SF 8:30 AM
Arrive Boston 4:40 PM

The tickets can be picked up at the mill on September 27th and the Hotel information (directions, etc.) will be attached.

The Hotel reservation is a guaranteed late arrival at the Holiday Inn in Livermore. It is $26 a day plus tax and subject to change as of October 1.

2. Please call Ann Peskin -- no message.

Messages 9/22

1. Pete van Roekens (8-247-2603). Re: Needs your approval for a job offer to a software person for Hydra.

2. Tom Hastings 8-264-6767 in Merrimack. (Home phone (617) 646-5098.)
Re: Would like make a job offer to a software engineer (Steve Lionel) for the VAX Common Run Time Group to do the Library Project Fortran Release. He has been interviewed by the

Fortran group and by Tom and they all have good feelings about hiring him. There are already four people in the group doing basic and cobol and this person would do the Fortran.

3. Dawn Boyd (Denver office (303) 773-6535, X205). Re: Needs to know if "The PDP-11 Family and the VAX11/780 for a Large Address Space" is the right topic for your speech there. Needs to know by Monday.

MJ -- Messages

Sept. 22

1. Gene Gross X4834. Re: Needs to set up a meeting (30-45 minutes) with Gordon to discuss Service Function Management.

2. Tom Hastings 8-264-6767. Re: Susan Jackson did all the typing for Tom's group while they were in the mill. When the group transferred to Merrimack, she didn't want to go so she's looking for a job here in the mill. Any suggestion? Tom said she's very good on the word processor and also knows runoff.

Dear Professor Metropolis,
Los Alamos

I was intrigued reading your article in the January issue of the ANNALS and want to make a few comments. You will note that I haved signed the letter with two titles -- I am in fact enjoying my role as the "keeper" of the Digital Computer Museum. We plan to document as much history as possible so that it will become somewhat real to the new generations of computer specialists and users who did not know early machines. We have TX-O up as it looked at MIT in the late 50s, parts of Whirlwind, a collection of pre-computing devices, and benchmark DEC machines. When you are in this area, I would be delighted to arrange a tour of the Museum for you. (You might keep in mind a museum lecture by George Stibitz on May 8 and our "opening" September 22.)

Bell and Newell is now being revised and I would like to apologize to you for the MANIAC mistakes. It should be caught in this next edition. I particularly enjoyed reading the section on MANIAC and would very much like to have some parts and copies of early photographs of the installation for the Museum. Perhaps you could help me in locating and acquiring some.

I particularly liked figure l, and the taxonomic tree of the evolution of program control modes. I was wondering however, why you credit the Manchester Mark I prototype as one of the first computers to be run with a dynamically modifiable stored program?

Although you omitted reference to Atanasoff, it was clear to the patent office that he did have something to do with computation. Do you have a good reference or historical evidence as to just what his contributions were either to the stored program concept or to circuitry? Similarly, references to Dirks were missing. Any reference works here?

Again, I enjoyed your article.

Cordially,

Gordon Bell
Vice President, Engineering
Keeper, Digital Computer Museum

SUBJECT: MANUFACTURING/ENGINEERING SEGMENTATION AND COUPLING. WHAT NEXT?

I got sort of a weak approval and support to pursue the thinking
on segmentation that I gave at the OC Woods. Shel was to be a moderator/catalyst with Jack and I. Jack, Larry and I met on this once and given that Jack is moving toward a similar segmentation, we agreed to be supportive on two fronts:

Bill Hanson is most likely to do the Systems job, now spread across the request commit, cpu, general manufacturing and FAT organizations. As such, our various systems by size managers will work on how to best align and support. Given that there are 3 of them, then one of us will act as a focal point. Now,
Pete Van Roekens is working on a list of our joint problems and
how to best connect (clear, still seperated, but aligned, and have knowledge of what the other group is and what their processes
are).

We are giving a clear message to Thompson and Holman to get their collective acts together with respect to what belongs in manufacturing engineering (processes, CAM), in engineering (products and technology and CAD), and what is in the specific
product engineering groups and what belongs in the plants.

Have read Jack's notes on how he is proposing to organize and find there is really pretty good agreement of what I proposed as a segmentation (really aligned with product).

Smith proposed org.	Bell model
Components	Semiconductors and Physical Interconnect
Mass store	Mass store divison with direct sales
Terminals	Terminals and terminal based systems with direct sales
	A group to handle comm and networks
Systems	Small, medium and large groups
Staff and brain trust	
Far East	
External mfg.	

Fundamentally, I support the two changes and want us to push forward on the coupling of terminals and terminals based systems among manufacturing, engineering and appropriate parts
of the marketing groups. Also, I would hope that they can be encouraged to relocate out of NE in the long term, starting
a co-location soon as a method of encouraging coupling and segmentation.

There is also a question of helping take some of the load off manufacturing so that we can get organized to be a high volume
supplier. Currently, we have a number of low volume and special
products and the Field Service plant mixed in with the high volume part. Given that the Japanese are coming, I think it is essential to at least put these in a seperate categorie so that the Components, Terminals, Mass Storage and Systems groups
are pure, lean and mean! Traditionally, these other efforts simply take time (say only 5 or 10%) that might better be used
in longer range planning. Perhaps a better writing of CSS and
TPL charters to handle this in what could also be a total business context is certainly appropriate. Given that Stan is so pro-division, then having him manage these as divisions might make sense (take over some of the low volume graphics, PDP-8 systems, and other low volume specials). We ought to look at what the best way to manufacture the PL low volume products too! (Perhaps a place in a FAT plant or even outside).

In this same regard, I am now scared to death of what we are doing/planning in a total manufacturing plant (1/4 billion in '81) because I don't understand how it relates to what we expect our revenue stream to be in the future. I know that we plan our engineering on the basis of future projections of revenue and it appears: OUR PROJECTIONS AND ACTUAL SHIPS ARE COMPLETELY MISALIGNED. That is, we spend engineering on

the basis of projections and we actually ship other things!
But this is minor compared to what we induce in
manufacturing.
Therefore, it is essential to spend the summer trying to get this segmentation because, let's face it the manufacturing plant and inventory is really where the money goes and we had better align by group to segment this, rather than getting
this one big ball of wax once a year that we have no understanding of in terms of how capacity and business are related.

There were a series of questions that the OC members had which
I would like to get from Steve's minutes. These ought to be incorporated in a working document which explores this set of changes. Jack has done an excellent job of listing what he
wants to preserve and what some of the goals are for what he is proposeing. Likewise, I want to state goals, constraints, and what we are trying to maximize/minimize (the objective function) in any kind of change. Currently, I hope to spend time on this in August.

Shel, I think you could also help here.

Do we want to proceed?

SECOND DOCUMENT
I spend a lot of time trying to structure what we do. For the last few years, I've been using this 4 dimensional space of: Level of integration (the what), the size (scale) of what we build; where we are in the life of what it is we are building; and the activity (or what it is we do).

SEGMENTATION DIMENSIONS
Note the 4 dimensions, which we need to continually refine and hold as our segmentation for engineering and manufacturing organizations:

Level of integration:

H/S-chips, chip carrier, module, backplane, box, cabinet, hardware system/ operating system (including files and communications), language, generic tools, application;

Hardware price of the things (components or systems) we sell:

(hand held .4-1, Terminal based 2.5-6.25, stackable 6.25-16, cabinet(s) 16-40, 40-100, interconnected cabinet 100-250-625, multiple computers using CI 250-625-1.6M);

Phase (life-time):

Basic research, Research, Advanced development, Development, Support, Enhance, and Obsolescence;
Activity:

.Component design, sometimes we call it the technology (the thing- whether it be a chip or a word processing system. We must stick with the notion that one person's system is another person's component... hence we only make components.),

.Engineering Process (how can designers use it as a component in the next highest level a design),

.Manufacturing Process (how do you make it?),

.Manufacturing test process (how do you know it works?),

.Maintainence Process (How can it be made to work over its lifetimea?),

.Market process (How do we define it during its various phases and sell it?),

.Management processes (how do we organize, manage and interface to one another to get the work done?)

TOP-DOWN APPROACH (MFG./ENG./MKT. SEGMENTS)

The taxonomy is only useful if it allows us to segment our activities. We are extremely lucky in having growth, because it is comparatively trivial to manage charters. On the other hand, left alone, there will be overlaps and underlaps in an area where the new product opportunities abound (eg. WPS, voice on packet switching networks, small systems growing into terminals). I think we ought to use the remainder of the summer to sort this out. Let me suggest two approaches: top down- we look at a cleaner manufacturing/engineering divisional structure; bottom-up, we look at overlap, underlap, and new opportunities.

Significant manufacturing-engineering (and occasionally marketing coupling). I don't want to muck in the divisional space, all I want is to STREAMLINE each group's charter and to have a clear relationship with all other groups as a buyer or seller.

This is the background thinking that led to the organizational proposal today.

SUBJECT: MANUFACTURING ENGINEERING SEGMENTATION PITCH TO YOUR STAFF

Want me to send the memo to your staff (Cudmore, Thompson and Hanson have it already)?

Also, how about a better drawn flip chart identical to the one
I gave at OC woods? (I'll provide, but let me know as I'm leaving town for 2 weeks.)
(o be used if you want it as a discussion point for your staff.)

Had a nice talk with Bill. Wonder if you want to have 3 request commit systems: let pl's buy from Systems, from mass storage (ADD-ONS ONLY), and terminals (ADD-ON's only)? Or, what about a seperate organization that is telephone, computer
only that order's stuff and tells where to ship systems, terminals,
disks etc sold as a system from the point of manufacture places
or to ship add ons. No inventory or assembly capacity... just
shipping labels making at a distance. Ultimately, this gets folded back into pls (or maybe always run as a matrix).

SUBJECT: MANUFACTURING/ENGINEERING WOODS 6/30 - 7/1

From: Gordon Bell/Jack Smith

LP1/S4/56EMS

We view clearing the air, and establishing requirements for a long-term relationship between Manufacturing and Engineering an activity of major importance. The working relationship between our two groups must be tighter and more effective particularly in the areas of strategic and operational planning.

We have planned a Woods Meeting to begin to work this set of problems
and to understand better the areas of highest impact for our joint ef
forts. This first meeting will be to frame the problem and to get
todays issues out on the table.

The meeting will be held at the Natick Hilton and will start at 4:00
p.m. Monday, June 30 and end at 4:00 p.m. Tuesday, July 1. Rooms have
been reserved for everyone but Shel Davis who only plans to stay for
the first evening.

Would you please work this meeting into your schedule?

/ma

OPERATIONS COMMITTEE:

SUBJECT: A BETTER? SEGMENTATION OF MFG/ENG/MKT(IN SOME INSTANCES)

It feels like we could have a cleaner coupling between manufacturing and engineering. Also, we need a better segmentation of product flow among the plants. There is an assumption that each major product grouping is quite vertically integrated, at least back to include modules and special packaging. Since we are stressing point of manufacture and field integration, the organization is set up to focus on this.

Although this structure is focused mainly on the Manufacturing Engineering coupling. In several cases it could conveniently extend to couple to the product lines, such that it would be possible to have a segmented business unit of manufacturing, engineering, and one or more product lines. In nearly all cases, products sold on the open market would also be sold internally as part of larger systems (eg. terminals). Note these groupings:

Group name	Customers	Suppliers
Semiconductors	MS, T, S, M, L	Ext. too
Phys. interconnect	"	
Microprocessors	Ext., S, M	Semis, Phys. I/C
Mass store (MS)	Ext.?,T, S, M, L	Semis, PIC
Communications and networks	Ext.?,PLs	Semis, PIC
Terminals and T-based systems	Ext, PLs	Semis, Phys. I/D, MS
Small	PLs	Micros, MS,
Medium	"	Semis, PIC, MS
Large	"	"

Semiconductors (M/E)
Behavior is like a semiconductor supplier! Supplies chips and occasionally a set of chips carrying out a well defined function and mounted in a single or multi-chip carrier.
.The big issue is how to segment this to get the necessary charter protection among MOS, Bipolar TTL, and Bipolar ECL?
.Also, how do we tradeoff between manufacturing and engineering resources (product ships versus new products)?

Physical Interconnect and Packaging (M/E)
This group would develop and sell this components (chip carriers, boards, modules, and back planes) to both develop groups and

to
plants. It would operate a manufacturing facility in which automation is tested and it would work on leading edge processes
that are not done in a specific product group. This might include: very low cost PI or PIP, the high performance packaging
needed in Venus/2080, and chip carriers. It would have: component development, cad development, process development, and
test development. I would like to see us try to segment this effort and see whether such a group could exist. Some questions:
.What would it include?
.How does it couple to the plants?
.To the groups it serves?
.How is it funded? (The measures of this technology are quite
clear!)
.How much of power?
.How much of packaging?
.How much is in the higher level-of-integration groups? ETC.
This is very important to look at, but very tough to do (assuming
the people are not emotional about looking at it.)

Microprocessor board and box-level components (M/E/Mkt)
Fundamentally this group would develop module-level components
for higher level systems sold through the PL. It would also sell
its components so that a Small systems group could build conventional End user and OEM products complete with disks, comm., etc. Other systems groups would buy modules.
.Should we look at it, given the opportunity of it all coming together in Hudson?

Mass Storage (M/E)
Clearly a seperate entity.
.With the purchase of new board shop, is there a way to further
clean up the interface so that modules are in their purview

too,
i.e. how can we get them to a fully stand-alone vertically integrated division and out of the rest of the M/E planning, etc.?
.Should the low end be part of the Terminals activity? (probably not, given the work needed to deal with better video, comm., intelligence and sw).
.I'm still convinced that it is desirable and maybe even necessary to sell disks on the open market to be truly good here,
.How can we get a look at this objectively?
.How can we get a better interface between disk and the systems groups to avoid building expensive, segmented sub-systems (ala floppy)?
.Getting right DM package ala the RL's?
.Dealing with what I describe as Type IV packages (where all the stuff is in one cab. and we currently need FAT)?
.Why aren't these built into the disk instead of a CPU plant?
.Taking advantage of the HSC such that this is also the high end 11 system rather than returning it to NE for FATing?

Communications and Networks
With the new interconnect structure and the increased focus on networking, it would be very good to have a strong emphasis again on these products within all parts of the organization, including the field. In some ways, the product strategy lessens the product focus need because all products must have built in connections. There will be more emphasis in terms of: communications concentrators ala Mercury (part of Hydra and other products), Hydra itself is structured this way, Gateways to IBM, x.25, and the phone companies, and voice switching. Electronic

mail systems per se might be sold through this channel. This group would supply standards to other systems and products per
se.
.What is the best way to provide this focus?
.What is its product charter?
.How are M and E coupled?
.Is there a need for a better PL focus?

Terminal and Terminal Based Systems (M/E/MKT)
This one is clear I hope. I'm deadly afraid of seperating dumb
and smart and intelligent, cause they are just a few Kilobytes of
RAM away from one another and differ by whether there is secondary memory or not. In the not too distant future, I see
the convergence of all our current dumbs to have local intelligence and sufficient secondary memory, versus being all
dumb. This follows the Xerox and Datapoint models to a certain
extent. At any rate, the customers are: all systems, Terminals
PL, most of WPS, and Retail.
.How can these best be coupled to form a business unit?
.How to segment into various price and function ranges? .
.How to integrate the base software?
.The applications software?
.Is there a need to have the mass store as part of the group?

System groups (M/E)
Currently this is a disaster by every conceivable measure:
inventory, cost, time to get something to market, forecasting,
order processing. Jack's edict that we are not going to have any
more FAT, but instead are going to ship from point of manufacture
beginning in year ?, is the beginning of what should bring about
this change. We still must deal with the turning of the

corner
of what we produce as components and what some customers and
PL's, believe is an ala carte approach to building systems.
The
interconnect fully supports this approach! Some of the
questions:
.How many, and what is the segmentation? (by type, $-amount,
architecture, technology?)
.How is the corner turned so that PL's "feel" their
inventory?
.What are the rules to deal with "specials" ... which I think
are
minimum?
.How to plan the transition associated with the products and
back
up if there are any slips?

Diagrammatically, the product flow, through the various M/E
and
possible M/E/Mkt groups to PLs would be as follows:

```
Semis    PIP (lead technology only, not dominate supplier)
!        !
--------------------
!        !         !
MS+PL?-x Micro+PL-x!
!        !         !
----------------------------------------
!        !         !         !         !
T+PL?-x  C/N+PL?-x S         M         L
!        !         !         !         !
----------------------------------------
         !
         OEM and End user PL
         !
         x
```

x = customer

This is hardly meant to be final, but is rather something we
might
discuss from. I think it would acccomplish better interfaces

and
more autonomy among the groups.

What you folks think?

Hopefully it might help in the Woods discussion on
Wed./Thur.,
although it only deals with trying to segment a small part of our world. Again, please don't take it as final. (There is another memo that deals with the various dimensions I use to work on segmentation.)

Mr. Michel Gouilloud
Schlumberger Ltd.
277 Park Avenue
44th Floor
New York, New York 10172

Dear Michel:

The Clipper Chip discussed at the April 11 meeting, at Fairchild, with Howard Sachs and Tony Ley is extremely impressive and may have the potential to make Fairchild a significant, microprocessor supplier. The group has rightly returned to a simple, hardwired design versus relying on a complex Instruction-set Architecture, requiring a large microprogram. This is a result of increased primary memory speeds relative to logic speed, microprogram memory and cache memories. The design is along the lines of the IBM 801, Berkeley RISC, Stanford MIPS, Pyramid, Ridge and other efforts. Since other semicomputer manufacturers have apparently not reached this conclusion yet, it is essential that Fairchild continue in utmost secrecy until the chip is much further along with first silicon!

Their estimate of a factor of 4.8 x a VAX 780 is quite conservative. Speedup variability will be experienced with benchmarks because of the long pipeline and comparatively slow floating point. Simple benchmarks will be much faster and floating point intensive benchmarks such as Whetstones may have less speed-up because the floating point is not proportionately faster than a 780.

The design is along the lines of designs I've been discussing with two potential Encore companies, including the notion of an onchip ROM for more diagnostics and often used subroutines. In this regard, it is vital to have a much, much closer look including the behavior of the pipeline with the compiler produced benchmarks, before the design is fully completed. Howard and I have been discussing the memory management structure, which I hope can be made identical to the I/O computing channel. This would end up more like VAX and better support UNIX.

I am also excited about Encore exploiting the chip for systems. It would be totally complementary to Fairchild, thereby increasing the probability of success of the chip in the marketplace. I would like to move as soon as possible on the company while a systems user can still act to check and potentially simplify, the chip.

Sincerely,

Gordon Bell
Chief Technical Officer

SUBJECT: TASK FORCE ON A COMPETITIVE MICROPROCESSOR

Several of us met today and outlined this scenario:

The strategy of waiting for the VAX to come down in cost to meet
the 11 is basically inadequate because the 11 is also too large
and uncompetitive with the 68,000. Unfortunately, the 68,000 is
rapidly emerging as the 32-bit standard. Thus there is a
non-converging gap in time and price! Using VAX as Scorpio
constrains us to a "chip cost" of over $1K in '85 or $200 in '84
with an 11. Anyone will be able to have a "better than 11"
system right now at much less cost, thereby causing erosion of
the 11 base. At the same time, in 85 the 68000 will have evolved
to be competitive with VAX, but at 1/10 the cost.

INDUSTRY OVERVIEW IN THE MID-'80'S
There are an emerging set of industry standard micros and
peripheral chips which are virtually identical to the Unibus
options of the previous decade, including: communications, mass
storage, voice i/o, analog signal processing, raster scan video,
etc. that will enable ANY garage shop to put together a specific
collection to solve a particular problem and hence address any
market as a systems supplier. Systems for every conceivable
function will proliferate in much the same what that there are a
plethora of hand held calculators for accounting, bio-rhythmns,
computing, dieting, ... etc. Furthermore, our OEM business will
be in jeprody as customers try to become independent of any

ISP
and use commodity hardware (NI, 68,000, Wini's, etc.) and commodity, portable software (UNIX, CP/M, etc. Also, conventional systems are shrunk to a small number of chips.

OUR ALTERNATIVES

0. Hope It Goes Away (Flat Micros Business). We remain basically uncompetitive at the board level, we ignore the chips business (except perhaps licensing others to build it, the result would mostly be to target our base), and we only worry about the 11 for existing users. VAX is used for larger systems.

1. License the industry and standardize a new MicroVAX chip. Time to market of 2 years to the chip. Instant availability of development systems in the form of present VAX systems. This is a subset of the VAX ISP that is constrained to fit on one chip and drive industry standard peripherals. It would be built by one or more semiconductor companies. It would be suitable for us to build systems and anyone to build a controller at any level they chose. Software would be the control mechanism to prevent system competitors.

2. Defacto strategy. Do nothing and little by little adopt the 68,000 for various applications and eventually evolve into full support of user programmable systems.

2A. Aggressive, defacto strategy. Embrace the 68,000 and work with Motorola to get it to be the DEC 68,000 with full

support of
VAX data types such that we could provide a VMS environment for
programs and data to not know the difference.

Which one we chose depends on what we want to be in the '80's.
Rather than worrying about this end, we must develop what
products would look like in scenarios 1, 2, and 2A. In all three
of these scenarios, I have no worry about our viability or what
we sell. (Scenario 0 and 2 may preclude us from some businesses,
however.) Scenario 1 and 2A could be quite supportive of our
product strategy which is:

"A range of compatible products such that a user can chose to
compute at a personal, departmental or mainframe level without
reprogramming. This means compatible files (data types),
languages, human interfaces, etc. all interconnected."

Roy is going to head a task force of Dave Cutler, Bill Strecker,
and Bob Supnik to examine the two main alternatives in terms of
the ability to be compatible with existing VAX software, the
competitiveness of the chip and board components, the design
effort and time, what the MicroVAX subset would actually be (or
what a DEC 68,000 would be), and put together the skeleton of the
two scenarios.

From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.: 2236

F/U 10/6

Stan has (correctly, I believe) suggested that the DS31 (i.e., Stan's name for VT52 with 16K CMOS 8 in base with floppy) only be sold for fixed applications where there is absolutely NO Programming outside of the first time...and the system is wholly defined by a user manual of say less than 25 pages (including how it's diagnosed). Reading this manual and/or sales brochure (if there be one) should let the buyer see if he wants one...or wants to try one. The program should be in DIBOL and be less than 10 pages. The use of the system has to be significantly easier to learn than DS310W! There should be 0, 1, or 2 options.

In visiting Kodak to look at their Xerography technology, we found what seems like a great application currently (marginally) served by an $8K Olivetti dual tape system. Either Kodak would sell the system OEM or they would give them our brochure (to order by mail).

The application provides the index for one or more rolls of microfilm (3,000 images) so that it may be somehow retrieved. Such a device is an absolute necessity, although people have used paper systems. Thus, the market is defined by several hundred thousand microfilm reader systems in existence plus the new ones Kodak and others sell. Mary Jane has such a system for my own microfilm files, but it runs on a 10 (with no 10 time), and ends up on paper which I search, versus asking the computer.

To remind you of the microfilm system modus operandi:

1. Documents are first microfilmed sequentially with a seq.#. At this time any indicees are built. The most useful are: source, destination(s), title, date, keyword(s) and one can have many indicees.

Here the computer sits next to the camera, and the operator enters the relevant fields per document. (One could envision having the computer control the camera so that sequence # errors don't occur.)

2. The microfilm is developed and the original documents flushed.

3a. One sits at computer CRT, and does a retrieval by typing in the relevant fields. Normally this is by a secretary (since bosses can't or won't admit they type). If there are multiple hits, then there may be either hard copy of the microfilm at the reader/printer; or the operator may give out a possible hard copy (optional) of the hits, so the end user may further select before hard copying the film. (In the later case, a VT52 with copier or LA36 is useful.) On modern microfilm units the computer can also direct the reader-printer.

3b. The process is the same except that there is no hard copy, and the whole thing is more interactive.

4. There may be "reports" i.e., listings of each area or film if a hard copy unit exists.

5. There may be utilities to merge subject/date indicees so that the system works across many rolls of film. One floppy holds about one roll. This would not be needed with the simplest system. But it would require two floppies instead of one.

How does this approach sound?

How could these "applications" be done and sold?

How do the above rules for fixed applications sound?

I enjoyed the interaction with the MPD Staff and I was pleased to see the exchange with Dick and Bill too. The group should be congratulated for getting expertise quickly so that we can build great products. Although the glamour is mostly with FONZ and COMET, the chips for the disks will really help us competitively.

I look forward to continued productivity there. Hopefully, we can continue and get better coupling so as to do the right products in a timely fashion.

SUBJECT: RILEY'S COMMENTS ON THE 11, 16- AND 32-BIT MICROS

Note Jim's comments via Roy. We had Jim make this survey and it should be distributed and presented to both PEG and the OC.

There are 3 scenarios beyond our usual do nothing now and then panic or wring our hands when it's too late. They are:

0. Do nothing. Make our stand in the systems business; don't plan on a big chip and board business.

1. Build a VAX subset that will fit on a chip that could be available in two years. This could be used in chip and board market, but a version of VMS could also run on it.

2. Get Motorola to modify the 68000 to support our data types so that a compatible system could be made that would run our languages, file systems and give the same result.

3. Steve believes we can make a smaller and earlier than Scorpio product. He wants to look at this.

Engineering has asked Roy to lead a task force to examine these 3 alternatives as to functionality, time to market, price, competitiveness, etc. Dave Cutler, Supnick and Strecker are

SUBJECT: NOTES FROM RILEY DEBRIEFING

Jim Riley summarized what he thought were some of the key points from the interview assignment.

PDP-11

1. Software is the big advantage. No software, little interest.

2. The primary customer from a semiconductor vendor standpoint would be the current DEC customer base.

3. PDP-11 is an old architecture and is not competitive for new design wins.

4. Unanimous comment that the 32 bit prospects are exciting and a totally different ball game than 16 bits.

5. Almost a general consensus that DEC selling PDP-11 chips would be a non-event in the semiconductor industry. The industry would understand the need to protect the current PDP-11 base. This move on DEC's part would have minimal impact on our current relationships with our semiconductor suppliers.

6. All agreed that the PDP-11 was anywhere from 2-5 years late to compete in the 16 bit chip market.

7. Does DEC really want to feed potential DEC system competitors by selling at the chip level? Would it be worth it?

8. Not clear what the upgrade path would be from 16 to 32 bits.

Some of the minutes from the general discussion are as follows.

Independent of DEC or the semiconductor industry the 8086 will become the industry 16 bit software standard. The single event to make this happen is the IBM personal computer. Jim indicated that Dataquest knows of 16 Japanese firms that are preparing to produce IBM look-a-likes for the personal computer. Therefore, the entrepreneural software community will be driven to write software for the 8086 because it will have the highest number of machines in the field.

The discussion of potential 16 bit partners really centered on Harris, G.E., maybe Synertek. In general most of the 16 bit affiliations have been made. Fairchild is uncommitted but Jim feels they may be ineffective. A key decision on selecting a partner is what does DEC expect. The alternatives are to go for a company that has a strong aggressive sales force or one that is strong technically and could provide additional development dollars. That's DEC's decision to make.

Jim's opinion is that DEC probably could market the 16 bit machine by itself. He does not think that a second source is required if DEC markets the chip due to the security of DEC as a corporation. This approach would allow DEC to technically control the market and gain some practical experience that could potentially be applied to a decision to market 32 bit chips.

In terms of design wins, Dataquest believes that there are approximately 500 per month 16 bit new design wins. Currently they feel that there is a 3 to 1 advantage towards the Intel 8086. T.I. seems to be holding steady at about 25 per month.

The 32 bit market is completely a new ball game. Some of the quotes from the interviews are: 1. "DEC can be a standard", 2. "32 bits is an explosive opportunity", 3. "Intel could be wiped out", 4. "The window is 2 years to make a decision".

Jim feels there is a definite linkage between 16 bits and 32 bits. If DEC declares itself to eventually be in the 32 bit chip market the 32 bit ball game would be over. In addition, by announcing DEC's intention to be solidly in the chip microprocessor marketplace, with both 16 bit and 32 bit follow-ons, many customers would elect to go with the PDP-11 and wait for the VAX versus selecting the 68000. This could be a key factor to maintaining the 16 bit market.

Jim's opinion is that the Japanese are squarely aimed at dominating the 32 bit market at the chip, board and system level. He feels this is a 20 year project on the part of Japanese, and the U.S. industry (semiconductors and systems) have to get together to head off this threat. This represents the most compelling motivation for a major U.S. semiconductor supplier and systems company to join forces.

If DEC elected to market 32 bits at a chip level, our vendor selection is anyone we want except Intel and T.I. It is quite conceivable that Motorola would be a willing partner in the 32 bit marketplace with DEC, and would make an unbeatable combination.

In terms of controlling the marketplace from a brokering

dilemma,
it's generally agreed that the controlling factor is software.
However, in Jim's opinion, no one has developed a good second source arrangement to control software licensing. This would be new ground. There are few symetrical joint ventures between a world class systems company and world class semiconductor company.

There was considerable discussion about hardware independent software. The question being; what advantage is a unique hardware architecture, if indeed the trend is to develop software applications that are transportable from one 32 or 16 bit machine to another. It's the writer's opinion that the concept of totally transparent hardware and migratable software is not a reality. Particularly in the 32 bit market where there are no hardware or software standards established (VAX being the most notable exception). A single company controlling both the hardware architecture and software architecture is a decided advantage. There will continue to be significant optimization between hardware architecture and software architecture in the 32 bit domain, which can best be managed in a timely way by single company.

There was no identified follow-up activities. General concensus is what's missing is a way to model a strategic decision to sell chips (16 and 32) against the potential implications to DEC's long term business.

STATE OF WORKSTATIONS AND PC TODAY
The bad thing about getting well is that although my body's better, my pshyche takes over. Thinking about how we've spent the last 3 or 4 years getting a decent PC based on the 11 and VAX is the most depressing thoughts one can have about our engineering. Getting a competitive Workstation or Personal Computer based on MicroVAX appears well outside our technical or managerial capability.

I've had time to read about our architecture in the terminals and workstation areas, and I'm concerned. The VS100 clearly gets a runner-up PARC East Award (greatest contribution to science and least to the company). The PRO should also get one too. I'm pretty sure that neither of these devices are going to provide cost-effective, highly interactive, Personal Computer capability. The PRO is simple and cheap enough, but the address space and overhead to transfer data from applications to it is unacceptably SLOW... alas very low performance/cost! The VS100 is not cheap, and its performance just has to be the pits, based on:
.layers of host overhead including various terminal emulators
.a thin link to transfer data between the host and big, dumb terminal
 (This will really go to hell when one thinks about a color version.)
.the inability to couple an application directly to the terminal in a
 responsive fashion
.a generally roccocco hardware and software architecture requiring

massive interpretation and memory (mainly affects cost)

We seem to have taken every idea from communications protocols on layering and used them. We have gone around the wheel of reincarnation twice.

Bottom Line
Unfortunately, this means we will not be able to compete either on a cost or performance basis with: Apollo, PERQ, Masscomp, Sun Workstations, IBM's 9000, HP's 9000 and 9825, Silicon Graphics, etc. all of which give a Nebula-Comet class computer and offer high resolution graphics with fast response between the application and the screen. Many of these offer both black and white and color. This will be a direct loss in the technical market.

OUR RESPONSE
Wait for MicroVAX to build the bounded VC100 (a 1-2Mbyte, Microvax, bit map graphics, etc. terminal coupled to Ethernet). Use Low Cost Nebula with the one board version of the VS100.

MY PROPOSAL
Assume the VC100 will be a key product for personal computing for the technical and business (analyst) user.

Build a Qbus CRT controller that will be used with Seahorse I and II and allows us to get a small, low cost PC/Workstation on the market in the shortest time.

This is essential to build now because:
.We must define a suitable architecture for graphics that couples the
 user programs to the screen. VS100 ain't it, although we can learn
 from it! We are building Personal Computers, NOT one user computers
 which have dumb terminals connected to them!
.We must build something NOW, before we try to build the ultimate, bounded product, the VC100. We will want both bounded and unbounded (Qbus) versions for the market. This is one of the errors on PRO.

.Bounded products are neat, but somehow our customers want flexibility
 to add storage (and use it stand alone), real time i/o, printers, etc. Rarely are bounded products successful, however.
.Low Cost Nebula and the one board VS100 are still a factor of two
 more expensive than what I'm proposing based on Seahorse I.
.I don't believe Low Cost Nebula and the VS100 will be very much
 better than a VS100 with a fiber optic link in terms of performance,
 even if our customers will pay the high price.
.I want a PC that looks like a PC. LCN is neat, but still a big box.
.We need the hardware now to get the software ready for the high volume that could materialize (if we have the software).
.We have to have a product now, given the ones we are fielding. I
 want to have this a year+ earlier than the VC100!
.

MESSAGE ID: 5191028986

SUBJECT: 68,000 LANDSLIDE, AND THE MICROVAX WINDOW

GB4.S1.30

I talked with several customers (and friends) on a West Coast trip which caused several concerns:

1. Both the computational user (labs, business, universities) and AI user believe the game's over, and the 68,000's won. Apple, HP, IBM, Sunworkstation, Apollo, Masscomp, Charles River, Fortune, etc. etc. are all providing PC's. A new company starts up every day to build another one. HP has a great product set, for example. The 68020 with paging will be the final blow. UNIX is/will be the operating system just like CP/M was in the low end.

2. I said we'll win with MicroVAX because we have an upward compatible range and all the systems. People are skeptical because:

    . UNIX is free or low cost. VMS is not.
    . There are many more possibilities for products and DEC can't do them all.
    . DEC isn't in the PC business and won't be able to respond.
    . VMS compatibility will not let us move fast enough.
    . Our past performance is poor. they don't see us.

I really would like to win and MicroVAX is the only shot I see at getting a leadership product. Specifying and managing our MicroVAX products just has to be Engineering's Number 1 product problem if we want to preserve our traditional market and get any new market.

Alternatively, we can wait for IBM to make a good PC here using

the
68,000 and then provide the same capability later and rely on our
manufacturing and marketing strength. Also pray that TI and the big
Japanese firms don't cut the price.

5195710512

SUBJECT: A MICROVAX PLAN TO TAKE CARE OF CUSTOMERS?

GB5.27

Your question:
"Can we take care of our customers' needs for 32-bit
machines with
your new conglomeration of micro-VAXs?"

We have no choice, but it's tight. Note the product
schedule:
Seahorse I (Cutler's machine) 1/84
Seahorse II (Jesse's microVAX) Q285
BI (Q3 85 is the earliest... 2 years from now)

I think we need all of these systems to come off on schedule,
and then
we have a chance of meeting our customers' needs. The Qbus
CRT
controller to make Seahorse I a PC is absolutely critical, so

I'm
delighted that we have a responsible person now.

The original complaints of building the Seahorse I are diminishing, as
people see the early time to market as critical to both holding the
base and going after new 32-bit users. I hear complaints that the
machine is too slow, but I'm not worried (because I think these
systems are disk limited anyway) given that MicroVAX is coming and the
fact that we can tie this into a network of VAXen for higher
performance processing.

MICROVAX PC ON THE QBUS (1/84)
Being able to ship a MicroVAX PC in 1 year is critical because it is
what is really going to make us compete with Apollo, HP (9000 and
their 68,000-based system), IBM Lab PC (68,000), their evolving Intel
based PC, and the machine they may market based on their proprietary
801. A MicroVAX should be able to compete nicely with these.

The critical component that's been added, but is not yet fully spec'd
is a Qbus CRT that we drafted Cathy Learoyd and Stocky to do, because
it allows us to build a MicroVAX PC/Workstation (whatever the
difference is). It's critical both as a diskless and RD52 base
because it gets VAX down in physical size, form factor and noise level
to fit into an office and become a PC psychologically... somethin we
can't do with our usual Rack/Stack Cabinets. (Note my VAX PC in
building 12.)

The other reason it's critical to get a MicroVAX PC out is the
software. We should have learned our lesson from the PRO... it's non
trivial to take a shared operating system and convert it into a PC
based system. So far, I like the plan and thoughts that Dick Hustvedt
has produced, so we have a chance. Anyway, there's OUR software: the
PC part, the distributed function that lets a PC really tightly
connect to a service or another PC. AND there's USER software:
migraton of an application into a PC, and the distribution over a
network to the degree it's not transparent. Here we want a PC to
access a compute server because that's what we have to sell that's
unique.

I think this PC is what our Technical users, including OEMs want.
It's a nicely matched PC with expansion capability to do control,
robotic, vision, etc. applications. (It's bus is awfully light duty
to be competitive, but that'll have to do for now.)

MICROVAX AS A SHARED MACHINE
We aren't really doing very well selling these machines now (Micro 11,
the low end 11's, and the 730), so I'm not sure how this will fare.
It just may be that the market it responding favorably to the PCs and
is demanding what looks like a more responsive machine with a
flashier, larger screen. I've made suggestions on how to make a 240
"appea" more like a PC in terms of responsiveness.

MICROVAX/SEABOARD FOR REAL TIME and OEMS

Cutler will produce a super product. This should get us back into the board and real time market. OEMs should love it, and some of our applications Product groups could make nice products too.

SHORT ANSWER

Jesse Lipcon, the QBUS MicroVAX Project Engineer has written down a Q-bus MicroVAX Vision/Strategy that encompasses the critical customer needs. Now that we're on target to get a PC based on MicroVAX (and Cutler's Seahorse I), we address what I think is the most critical need. We should review the overall plan and Roy Moffa should embrace and broadcast it as the product direction. We should all swear that we're going to deliver our respective pieces, and then we should all simply do it.

The BI is also quite critical to get us a modern, high performance, high reliability, large address space, competitive bus to beat Intel and Motorola. The Qbus (circa 74) will have to hold us until then.

SUBJECT: QBUS CONTROLLERS FOR MICROVAX (AND PRO?) PC'S

GB5.28

Several of us met last week and came to the following agreement regarding getting a MicroVAX PC based on Seahorse, and what the VC100 might look like. We had several areas of concern (i.e.) disagreement and voids.

We're going to meet on Thursday and make sure that we're in sync to get this hardware (Bob, I trust you'll be there). I'll be away in May, and have incredible expectations that the detailed design will get worked out. Also, we need a meeting scheduled for review in early June, because I want to make sure we're going to make it with the product.

The 3 days of meeting were both frustrating (there's not a common set of terms), but productive (if we follow through).

AGREEMENT ABOUT HARDWARE AVAILABILITY

0. We must have a Qbus CRT controller option from the terminals group
to make a Seahorse I based Personal Computer at FCS, Jan.

1984.

1. The first pass definition of VC100 is:
    . it's a terminal that computes, replacing the VT100 in popularity. Should be on everyone's desk and cost <1,000
    . MicroVAX chip, 1 Megabyte; optional memory of 1 to 2 Megabytes;
    . 15" crt with 480 x 800 pixels; a pointing device
    . NI, no mass storage
    . Area copy and any other display functions that fall out of display processor chips;
    . direct bit map addressing by MicroVAX

2. A simple, bit map board will be made available to the VMS group ASAP for implementing (breadboarding) WGA/SDA as part of VMS. The board should be useful too as the PRO PC video.

    . 15" CRT with 480 x 800 piexels; a pointing device
    . direct bit map addressing by Seahorse I over the Qbus
    . any options such as area move, but without impacting schedule

3. A VS100 compatible board, but only necessary for use in driving a low resolution CRT as described above. This would permit the current software in the 68,000 and VAX to be used directly thereby providing the WGA without the need for the software rewrite in VMS.

In addition, the board will provide bit map addressing from the host!

4. We must get experience and provide a user base now with VS100, VS300 and LCN/WS. Currently it is similar to PRO as a non-performer due to the time to call system functions. In addition, it

has many
software layers and interpreters (see below).

Brian Croxon will provide a VS100 to the VMS group by May 9, 1983 so
they can evaluate the VS100 and begin to assist in the implementation
that will improve performance, modifying WGA/SDA as needed.

AGREEMENT ABOUT ARCHITECTURE AND STANDARDS

0. We need a basic architecture whereby all applications run on all
implementations, although physical limits will impose certain limits
on applications. There appears to be a significant investment in
terminal and architectural interface software being done on WGA/SDA:

- SDA/WGA- applications programs can call them directly
- VT100 emulator- a virtual display can be a VT100
- REGIS - DEC's very own line graphics standard used as a guideline for implementing the VT125, Gigi and VT240 (I hope)
- TEKTRONIX 4014- very old line drawing crt
- GKS (Graphic Kernel System) - Draft international standard. This is the level above NAPLPS, a device level standard.
- PLP/NAPLPS (for the device)- Presentation-Level Protocol (or North American version)- Is probably what will end up for PC's
- Sig-graph's CORE standard- Another attempt at a standard. Not clear where it is with respect to use or needs.

1. WE HAVE A WORKING AGREEMENT THAT THE USER INTERFACE IS WGA/SDA,
(Hank, please explain the relationship of the two)
WORKSTATION GRAPHIC

ARCHITECTURE/ SYSTEM DISPLAY ARCHITECTURE.

DGA WILL BECOME WGA/SDA.

WGA/SDA CAN BE MODIFIED USING THE NORMAL ARCHITECTURE CONTROL PROCESS!
(Hank is the holder of them.)

2. A competitive PC must have a window orientation with the ability to
have multiple processes drive seperate Virtual Displays.

PROBLEMS THAT REQUIRE RESOLUTION (I.E. A VOID OR CONFLICT)

0. Who is the system manager for MicroVAX PC around Seahorse I? the
VC 100? (It's not too early to think about this, but we don't need the
usual gargantuan staff.)

1. The structure for a PC with respect to:
    1. Hardware to do area copy (probably no argument); area copy with
       special functions;
    2. Extra processor to actually interpret display commands versus
       having the user's processor do them directly in a PC; This is
       why two Qbus boards are being built at this time.
    3. Access by an applications program for it to generate true
       images; This implies or requires that the host processor be
       able to access the various images (i.e. Virtual Displays and
       physical Frame Buffers) directly.
    4. Applicability of various specialized chips in light of need to
       have memory access to the physical image;
    5. How to do color; and need for color option in the PC or VC.

2. Can we possibly offer and support all the protocols and architectures? Won't this will totally confuse and difuse the applications writers? Can't this be lead under Jim Cudmore now that the Workstations hardware group is there?

3. I'm quite concerned about the large number of layers of software, resulting in incredible overhead and loss of performance. In the case of the VT100, one more, non-trivial translator operates. For example:

- a VS100 application program generates a text string for a VT100
- the string is translated to a WGA/SDA compatible string
- the operating system is called as a QIO
- the string is moved to the VS100
- the string is interpreted by the VS100 and output

We must really get the performance (load) understood in each of these translators, interpreters and system calls. There's NO DATA!

NEXT STEP
We're going to meet on Thursday at 2, in the museum, for further resolution and ratification of the specifications and schedule.

I would like to invite Jim, Bob and Sam. Can you come?

SUBJECT: CLEAN UP THE MILL CAMPAIGN!

Ken's probably right on here. The environment does have a lot to do about thinking. Si, maybe you made a mistake in not moving to Hudson. I feel the same engineers work better there... but it may be my imagination. The mill was great at one point before it got messy and when we were young, lean, and mean and had to prove to the world that you didn't have to be IBM to build computers... or there was another way to compute. Lately, the high technology image is shiny buildings
(Del Thorndike commented we probably couldn't hire engineers in Silicon valley if they had to live in the old Mtn. View disk facility.)

Given that you are already changing the way people view their job, let's surprise Ken by working this environmental question. I'll come around some Friday afternoon if we want to have a house cleaning. Let's give all the old terminals and computers and test equipment to Dick Eckhouse to give to the universities. It seems the old 8 lab is probably the worst, but Larry and I should walk through the mill and write notes to the various persons. Alternatively, we might have a general clean up one day complete with posters.

MJ,
Please get the clean up campaign rolling.

SUBJECT: JAPANESE/QUALITY

Everything we read about the Japanese says that they are primarily interested in quality. Everytime you see a picture of their facilities, they are absolutely immaculate. Maybe one way to emphasize quality would be to get our facilities clean; insist on them being clean and absolutely immaculate. Some parts of this mill are a disgrace. The first floor of building one looks like a pig pen. Some of the Engineering facilities, particularly in the Terminals area, are a disgrace. How could we get good engineering, good manufacturing, and in any way, emphasize quality, when our facilities are so dirty, so messy, and so unbusinesslike.

SUBJECT: MILL WALK-THROUGH

We should do this once a year at every site. There were lots of
really good projects, but I'll focus on the problems:

POOR A/D FLOW MANAGEMENT

I'm scared about our "technology" development centers. I never liked
the concept and the results are disastrous, since the use is decoupled
from the development which is done in a vacuum. Note, Henk and Will
who both pushed the concept are "long gone from the crime."

I must insist that no A/D be done outside a development group when a
single manager has the responsibility of both A/D + D. The PS A/D
group has no way to flow results into the various PS groups -- just
feet away because organizationally they're 6 - people away!

The acoustics group seems decoupled and is likely to be completely out
of it in Andover.

Why do we have both Sci Cards and Applicon for Analog? (This seems
crazy) Is the CAM support Group, independent of Dick Gonzales? Is
there too much support?

Let's go back and have two (not three) packaging groups: for
everything except large systems; and for MR + Nebula. This would get
more resources if Dick managed it. Here, Gonzales has great desk and
underdesk packaging the Scorpio and Nebula retry should use. . . to be
compatible with our nifty furniture.

Do we have enough coupling in our CRT work across: ALB, ML,
Workstations, CRA, and CSS?

Subject: Priorities in systems and minc

Having heard the minc presentation and at the same time reading and having
read the blurbs about the HP products I conclude that we have higher priority
products than toby becaause: 1. WE have a sales problem in this area anyway
and a bit lower cost won't do a hell of a lot for us, particualrly in the PLs
where we sell only 1's. They want functionality. 2. Minc needs higher
performance and 3. Extensions for signal processing but mainely 4. a BASIC
that can support > 65K or multiple proceswses note that HP basicas all go to
a larger address space and they alsll 5.Have their operating systems in ROM
6. Mainly we need graphics so baasd that even our customers are asking for it
and even our marketing people are asking you, so we know we need it and the
then we need 7. all graphics has to have a hard coyp I?O system and
possibley a 8Digitizer and of course while these are stand alone computers,
the one thing to segment us from the riff-raff is 9. High sped
interconnections so that we can network and pre-process in a nice fashion.
Even our customers are saying that too. I want a very high speed one so as to
handle the LDP problem. 10 Getting the RL02 and successors on the system is
needed too. Alternatively we could go down, based on some caching on a tu 58.

Given that the lifetime of the products we are working with

is only oing to be
a couple of years, I say it i{s essential to use the q bus at 128K and then
even evolve it to beyond this size and to get the products out quickly in
bound systems , based on a et of mo set of modules, not a particular new
scheme for interconnect that will a have to be changed for every
product/generaltion. While you say do TOBY (the answer to the questionI
asked as to what it looks like is given in the pages of the document you gave
to me) I question why we can blow this kind of money except to keep the
commercial group happy and to find your cpu packaging people something that is
easy to do and provides a challenge. I wish they ere challenged by items
1-11 above. I would like to minimize our proliferation of new interfaces
here , not like we have done with the Q (although now I certainly say build
on the dual or quad system and go.

If you really think there is some nice systems to bind, then package some of
the collection of options on a couple of quads in a compativle way...to save
interface cost. The green blocks aren't the problem and they will turn out to
be your friend

Give me some more data and let's talk.

SUBJECT: CONGRATULATIONS ON DROP SHIPPING MINC FROM WF

And the FAT reduction by getting it out of WM. I appreciate all the effort that went into changing the manufacturing organization so that this was possible. I trust our customers are happier too, with higher quality products.

I must admit that I didn't think this was possible...and even though we didn't write down a bet, I certainly owe you and the key people in Manufacturing some sort of celebration.

Minnow: Let's Go Ahead. Central Engineering Is Stopping It Now. -- **NOT SENT**

From a marketing, business, strategy viewpoint, my position has not changed on Minnow. It is still painfully clear that we shouldn't, especially since the forecasts have dropped and that the 2020 doesn't seem to be bought. I assume, however, that we will do it because it will be coupled to the Data Services business, which will have a very high revenue forecast. Furthermore, we have never passed up incremental businees, or left a customer stranded when we implied a commitment.

I like Minnow! There are concerns about its boundnesss and our ability to say with certainty that a tape, or some other option won't be required that will force continued changes to it and the system software it requires. These problems can be corrected, and it will approach looking like a 2020, but it can still be a good money maker.

The issue which I have unsuccessfully communicated is that we, Central Engineering, do not have the resources, charter, or will take the responsibility for this product. We implement high volume products within the strategy. Minnow is neither high volume, nor within the strategy.

Effective now, I have instructed Ulf to spend no more engineering effort on Minnow. However, we will make available people who will help in the transfer of the design, or transfer people to design Minnow to any product line or product group who wants to engineering, manufacture, or market it. Since it is proposed as a single product line product, it might be wise to have it part of their organization, especially since the customer base expects follow on products. TPL has done a fine job in making the PDP-14 successful, and this would be a clear moneymaker for CSS. I would support either of these groups in taking on the work.

We are aggressively working on high end 32 and 36 bit machines in Marlboro so that they become a mainline, high volume engineering group. Their charter is to continue the relatively constant price, higher performance follow-on line, until it is more effective to use VAX. Our priorities are to improve the reliability of the KL, to move and establish the design of 32 bit products in Marlboro, and to define the structure of the KL replacement built around the common base VAX components. The charter does not include doing, product line specific, high or low volume, low cost systems. Any incremental effort spent on tangential work now detracts from this main charter and mission.

follow up 12/4/78

While we're fooling around here, blowing hardware and software resources in the mini territory with Minnow, indications are that IBM will be coming in with its hot, new series to regain territory from Amdahl and the new low end 370 plus-compatible vendors. But more important to us, they could get back the low end 370's:

1. the 10/20 displace; and

2. the central control that VAX threatens by having either much more cost-effective 370's (e.g., 20 M.PS for $1.8 M) or hot low end 370's to use as distributed computing the way that VAX/780 is used.

Let's use our scarce hardware/software resources for the gate array 10/20/VAX and for the CAD to bring it in in time!

Subject: Today

Thanks for the presentation. I hope we atr slmost there. I am sorry to be
s so adamant about the postition as to why we are not doing just one more
project (ie Minnow). It is quite simple. It is another 10% to manage these
u next 2 years, and I am not going to let us do it. We are committing to a
much more aggressive machine/schedule and much better than Dolphin. Also, it
has a big software component. Although these constitute a major program,
the VENUS project was just (possibly erroneously) moved to be done in
Marlboro...making Marlboro responsible for a major part of the corporate
revenue. (more than when we decided to do it...which at that time only
included Minnow, and no follow-on 10/20 for 2060.
Already, I heard than
George had to ask wheteher we cold get x, out of a 2020.
This is nonsense.
The VENUS team is still up in the air. He has one

responsibliilty!

There seems to be some ambiguity about my posititonin this.
How can I
clarify it further?

You ignored TI. Note the TMS1000 is a 16-bit machine <u>AND</u> they have the commodity market. Their stuff goes in cars, games, appliances at the lo end. Should we watch them?

What's Taurus? D-LART?

Why aren't BI chips in your MOS list?

Are you really benchmarking chips from the outside? What's a system based on 8086/8087 cost (in chips) vs. F-11??

Are you really <u>broadcasting</u> what the possible buyout peripheral chip possibilities are? For example, could you look at cost-effectiveness, use, etc. of PUSART vs. Standard Comm?

Do you find out the new chips before they are publicly announced? Can you act as a collector/broadcaster for this? It seems like you can to much more here.

LOC/MAIL STOP: ML12-1/A51

SUBJECT: CONFIDENTIAL MINUTES OF 7/10/80 MTG.

Minutes of Bell, Portner, Meyer Meeting 7/10/80

Strategic Planning Manager Definition
Focus on longer time frame to aid A/D and help establish questions for each of the areas. More than technical: includes
tradeoffs between machines, people and make/buy. Si deals 0-3
years. This is longer (maybe out to 90). Again, doesn't do the

work, but gets the responsible groups to do it. Would try to work the Japan problem. (The Gallactic Product Strategy). Note that in writing this up, I generated the memo on the Four Dimensions to Segment our Products and Work on them. Also, the memo on the Organization Structure Proposal.

We discussed each of the organizations. This yielded some thoughts on how much time we are requiring from each member and how much they have to really do work. I did a time analysis that showed that I have only 20% discretionary time, the rest is all used up with what are either explicit or implicit meetings. This does not include my time for reading or writing or any more than a few non-scheduled meetings. WE ALL HAVE A PROBLEM HERE! The matrix organized people just have to be hurting bad. I suggest we get everyone to do a time analysis. I'll send mine around as an example. All OOD member organizations are too wide in a conventional span of control sense. Our relationship where 2 people run things in a somewhat segmented way may be necessary.

STATUS OF VARIOUS GROUPS
BJ-very wide, what's Dockser do?, should some of the systems work be with the systems groups?

MK- job scope is bigger than performance, we want more than just control, we want educator, intellectual and tool builder

Holman-coupling to Mfg? Space planning is a bitch!

SF-growing well, all used up though. Any way to get back to

technical review role? Could be valuable in A/D of new machines?
Architecture is happening.

Cudmore-group is building nicely, need a push to address some of
questions in Intel memo

Clayton-overlap with mid, needs focus on chips, and terminal
systems, opportunity to couple T and T-based Small Systems, I'd
like help in Semi strategy wrt Intel, needs architecture, A/D,
should software be in here more?, better coupling to Delagi
possible?

Demmer-lots on the plate, overlap with Small, Lots of money and
not enough output, maybe too much complexity among Hydra and
Pearson and Rodgers, who's doing MLK to 780?

Ulf-sucked A/D dry, research management, now into execution with
risks abounding, problem of interfacing to mid and to
interconnect to get the right product components, problem in the
Suvax and PBS area that frustrates GB

Grant-things seem to be happening the right way.

ORGANIZATIONAL TOPICS:
.Organizational tuning is needed: who does what wrt stategy?

.Can we better structure MSD and I/C better by breaking apart?)

.Should we put all CPU-based systems together?

.How can we better align with Mfg? (note org. proposal)

.Should we seperate all the systems planning from development to avoid the milling effect? (Can we do it without losing the commitement? How can we do it with fewer people and get better results? The situation vis a vis J is awful!

STRATEGY REVIEW

.When is the next OOD wide Program Review?

.The Rosing REview of strategy with 20-25 technical leaders is strongly recommended!

.GB discussed a System Strategy Review body to look at all Product plans wrt strategy. (Per, Rodgers, Husvedt, Sam and/or Strecker, Rosing and Jud)

.Strategy needs to be re-evaluated, in light of today's conditions of slips, etc. i.e. how are we coming?

BETTER MANAGEMENT

.No knowledge of how we tradeoff among expenses, capital, labor, space and equipment. We need to build much better tools to aid managers!

.What is job definition of Direct Report?

.What is site, function and product space decsions to fit strategy requirements?

.How can we interact with OOD members to find out what they are doing and what they need from us and how they are really doing?
LP/GB will have an organization review which is now being scheduled. Includes: space, resources, budget, organization, projects, phase transitions, EBOD/SPU interaction. Assumes Win looks at operational issues of schedules, budgets of projects.

MESSAGE ID: 5182396508

SUBJECT: RE: MIT

Agreed, things went well. But on the next visit it's more than a non-disclosure. They want a commitment of $'s.

I heard the dean say 8-10 experiments per year of heavy duty kind where they provide the resources and we supply a lot of the capital for machines. In order to get 2K machines there in 5 years, or what amounts to 10M-20M investment.

Corby said we could expect a factor of 4 price reduction in 4 years, then, we should look at price differentials of 1/4th sales price for now.

They want 100 machines there in September.

What our strategy ought to be:
Get the network business by providing an environment for internetting all their current machines so they can get started on the social aspects of computing. This would get Corby moving and get his support.

Allow that there will be a plethora of different sizes, brands, etc. The world is never going to be homogeneous ... unless we want to really try to promote VAX in a way bigger than DEC (and we're not about to do this) OR Motorola becomes a defacto standard! Thus, get them to accept this fact of life.

Sell them our brand of computing, but failing this, be open and say try before you buy. Bring in several systems and try several experiments. Coherence is a bitch, but get it through the network, not at a machine level.

Get the act structured before we get them in again.

Dear Joel:

I've known Tom since a freshman at Carnegie-Mellon. In his freshman year he single handed wrote and invented all the concepts of logic simulation. During the summer of his freshman year he came to DEC with the simulator that has become the basis of our logic simulators. He's consulted with us on CAD since then.

The work on the S-1 design and the associated CAD is superb. I've backed this work.

MIT would be lucky to get him.

SUBJECT: MIT PC

Ken just called about what MIT wants in their PC... suprise, the want it now and they want a 68,000... and they apparently want a diskless version and they want it on a LAN.

This seems to be exactly what everyone else wants... to get rid of the ridculous fiber optics and to interconnect via EN. Someday, someone is going to have to tell me how to get the speed using this contraption.

Anyway, when could we deliver a VS100 connected this way?
What's the largest memory?
How do you connect a disk to it? or do you?

What you think of this approach?

(MIT would be on their own for PC software used this way.)

Since we're having dinner with various MIT folks TODAY (when you read this on 11/16), I'd like a phone response quick as to whether we even say anything at all.

SUBJECT: PLEASE CHANGE THE ABYSMAL MIT INTERFACE

Our meeting there was appalling... and typical of a poor job on both our parts. We gave them a VAX to do LISP and we got nothing. They are producing results for Zenith, which will allow them to introduce a very, very nice personal computer which will compete with Personal VAX, assuming we ever decide that our technical computer users need a real computer and not toys.

Also, they are doing first rate work in the office research area funded by EXXON! What I heard sounded better to me than anything I had heard in this area. Clearly they are about 5 years ahead of our thinking in research in this area.

They would like something in the network area... that is, some funds to put in a net.

I don't know what to do in this area, but I couldn't be more frustrated. Let me offer some alternatives:
1. do nothing, as we've done in the past, be prepared to compete with their products as they emerge
2. get closer and track what others are doing (Zenith and Exxon so as to utilize the research) ... this would be worth doing, here, I say trade-off at least one researcher in the PBS to get this!
3. 2 + sponsor some work like the networks. Get co-ordinated about selling/research/interacting
4. 2 + get consulting from their key people and start to migrate graduate students and personnel here to help in this area.

I would like you guys to propose a plan, based on a significantly
better assessment of the situation.

SUBJECT: AN OPPORTUNITY WITH MIT WE PROBABLY CAN'T STAND

Dertouzous at MIT said that Western Digital is probably going to default on the plan to make the MIT computer NU. This is the second default after Zenith! The computer is built on a special multibus type thing and has 4 large boards along the SUN workstation lines and is Appollo size, costing 30K which MIT gets for 20K with 20Mbytes and 2 Mbytes primary memory and a 1000 x 1000 line display. The LM2, LISP machine can also plug into the backplane. This one has an Ethernet interface and of course, you guessed it, runs UNIX.

Adler of DG fame is thinking of buying them out to make it with some other company.

He asked if we wanted to make it. I said I'd get back. While it's pretty clear we probably wouldn't be interesting, there might be some useful ideas. We might have to go to LA to look at one though.

Do we want to even look or should I say thanks but no thanks?

Joel Moses
Associate Department Head
Massachusetts Institute of Technology
Headquarters Office
Room 38-401
Cambridge, MA 02139

Dear Joel:

Enclosed are some comments on Maurice.

What are his main achievements?
He is known for microprogramming (with Stringer), building EDSAC, writings on Timesharing, the first programming book, head of Cambridge department - doing the "ring", CAP.

What is his standing in Computer Science?
Highly regarded - note NAE member, McDowell Award winner.

Is he still active in research, in your opinion?
Yes. Moderately as a collaborator and support person.

Are his public lectures clearly presented?
Yes. Very clear.

Please comment, if you can, on his teaching and direct involvement with students. Students have very high regard for him as mentor and teacher.

I believe the adjunctship might have a benefit in better communication between MIT and Digital.

I know Maurice is very keen on doing this as he misses the academic environment.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

SUBJECT: MIT MEETING TO PROPOSE A PERSONAL COMPUTER PLAN

Mike Dertouzous wants the four of us to come and present a plan as to how we would equip all of, or some part of MIT with PC's. He would like to have us discuss the financing of such a venture and any quid pro quos ... because they are discussing a similar plan with IBM and HP and he thinks we ought to have some inherent synergy by being close... I concur.

Dertouzous will bring Joel Moses, Steve Ward and Corbato (the person responsible for their networking).

Could we meet together on this, prior to the meeting which is in the process of being set up?

We really need to get into some relationship like this.
MIT is one of the possible places.

SUBJECT: NEC IN NE; AND OUR POOR MIT HIGH LEVEL RELATIONSHIP

My friends at MIT continue to be impressed with Kobayashi, chairman of NEC. Kobayashi has been on other panels there and has given many insights ranging from technology to managment.

At the recent celebration of the 100th anniversary of the ee/cs
department, Dr. Kobayashi sat through the whole day and celebration, taking notes. There was discussion about the need
for engineers who could compete with the Japanese. John

Young, an MBA gave a few words I forget and left. The reason was to
demonstrate the close relationship with MIT and HP.

NEC is building a major facitity for R and D here, and I believe
they'll hire a really competent group of engineers in this area, as well as do a much better job in coupling to the MIT research
programs.

WE GOTTA DO BETTER
The key is to have very, very many troop-level working relationships such as the one between Glasser and Doberpuhl, not try to work it at the policy level with the head folks (eg. me)
who clearly aren't making it better. I did agree with Joel Moses that we would like to be a test for their Continuing Education program, but I assume neither of us will do anything. We can work with the Signal Processing Laboratory (Alan Oppenhiem) to do basic work in architecture and get another link. Similary, there's a possiblity to get the AI lab to microcode LISP to get much more out of VAX. Right now, VAX is not thought of as a particularly good AI machine, whereas the 10 still is
thought to be the best AI machine until the Lisp machine companies get enough products out.

Command >
July 28, Friday

Margaret (Bruno Durr's office) called. X2752 Re: A Data Pro excerpt Gordon sent to Bruno -- Bruno would like a copy of the entire article -- I couldn't find it.

Mike Riggle will keep a video tape from Sony an extra week or two so Gordon can see it when he returns.

July 31, Monday

Please call Susan in Treasury Services. X3431 Re: She wants to know if there was any stock activity the month of July.

(FYI) Mark Steincrouse (PMR Industrial Relations Dept.) X7182 needs a figure off the June Monthy Personnel Report for the FY 78 annual report. What he needs is the number of engineering employees -- he said he would get it elsewhere.

August 1, Tuesday

Malcolm Conway from Energetics called Gordon about some research work that Gordon was interested in -- I transferred the call to Jim Bell's office (see note 8/2/78 from Jim).

David Baker from ??DAR?? Corporation called Gordon. They are Materials Manufacturers and are in the process of buying a DEC computer -- he said the salesman suggested he call Mr. Bell because it was concerned with Research & Development. I suggested he call Jim Bell and explained who Jim is and that he was probably the Mr. Bell the salesman was referring to in the first place.

Please call Terry Potter, X9749 Re: Conference in Boston on Performance Analysis (2 1/2 days) October 24, 25, 26.

Please call Connie Schooler 8-522-2101 in Colorado Springs -- Re: memo sent a while back inviting Gordon, Lon Beaupre, and Ken Olsen to the open house there on Oct. 1 from 12-4 (Manufacturing, Engineering, Sales, and Diagnostics). Will Gordon be attending?

Please call Rich Perrin (238-2266 in Westboro) Re: He would like to set up a meeting with himself, Bill Green, Joe Zeh, Bob Kusik and Gordon to discuss the HMOS Gate Array. 1 1/2 hours would be needed sometime the week of Sept. 4th.

August 2, Wednesday

Mr. Uythoven called Re: Software Conference Speech in October -- wants GB to speak. He's going to talk to the person who recommended Gordon and see if he'll recommend someone else. If not, he'll get back to us.

Please call Dennis Kulsick, X6827 from the Corporate Sales Office.
Re: Agenda for 4 visitors from LLL Thursday, September 14 -- they would like to know if Gordon would be free for about an hour that day to see the people from LLL.

August 3, Thursday

(FYI) Gene Rosov from the Apple Hill School wanted to get in touch with Gordon -- I told him that Gordon's secretary was out and I wasn't sure of his location -- only that he was away on a business trip -- Mr. Rosov said he was going to call his home.

(FYI) Tony James from Reading England DEC office called Gordon -- he asked to be transferred to Dick Clayton and I transferred the call.

Alan Silver X2067 stopped by to inform me that Gordon, you and I will be transferring to CC 383 in one or two weeks. He'll be getting back to you about it.

Chuck Grutzius from the Washington, D.C. GIS Sales Office called Ann to set up a meeting with Grace Hopper, Gordon and Ken on October 19th. He'll be calling again when you get back to discuss it with you and Ann. (341-2279) Grace is anxious to visit as soon as possible and since Ken is away most of September, October 19th was her first free date after September.

August 4, Friday

Please call Phil Locke X5549 (MK)
Disk Products Development
Re: Official Corporate Standard -- Base Product Obsolesence vs Layered Product Obsolesence

August 7, Monday

Jim Lacey X6867 (MR) attended the Intel Seminar -- he is a senior engineer in the Peripherals Group reporting to George Hoff.

Yolanda called (8-246-2279) re: Business Product Line Untested Equipment. We have some mail regarding this -- She had a meeting with Leo Shipz and Carl Janzen. Leo will be looking into the reason why quality control is so poor in PL 41. Carl Janzen is the GIA General Manager.

Barbara Wagner X7725 needs a copy of the data quest report referred to in a memo dated June 23 from Sam Fuller to GB. (Bill Johnson's secretary)

Please call Jill in R&D -- X7682. Re: She would like to set up a meeting with a visitor from a North Holland Pubilishing Company (Wilhelm Dijkhuis) on October 30 from 9:30 to 10:30 with Jim Bell, Del Lippert, Marcie Kenah and GB. (We have mail from Jim Bell in regard to this person.)

August 8, Tuesday

Clarence Marshall from Rockwell called Gordon -- He'll call again when Gordon returns.

Susan Sacko X6778 (MR) called. She would like to set us a 15 minute phone conversation with Ed Kramer and Gordon -- is possible for him to reach Gordon before he returns?
1/24/79 Messages

1. Barbara Wollan (MIT) Re: They will be delivering the chalk board today (it is 4'x6') at about 1 or 1:15. If you have any questions, her number is 253-4665.

2. Barbara Taylor (Dartmouth College) called. Re: She would like a current abstract of Gordon for use with his presentation at the April Symposium "An

Innovation/Technology Recession?" -- Any recent awards, highlights, etc. you think he might like mentioned. I told her we could send her a current abstract but she wants the information over the phone as well.

GB9.4

Even though we've changed the nature of the company to a startup versus a turnaround company, the operational principles we discussed, but never formalized should remain.

Let me propose the first two:

1. "He who proposes, does"-- This was originated about 12 years ago by me and is used by several organizations.
2. Formal approval of plans, combined with a board (and company) who feels equally commited to and responsible for the plan.

GETTING THE PLANS

The first principle seems to be going well:

1. George's Sales/Train/Install/Service Division (we need a good name for it other than distribution) plan is going well.
2. Hydra has made a plan for delivering a high performance computer, and is clearly committed to it.

In addition, we have a number of activities aimed at getting "someone" to propose plans:

1. A product group, run by some external folks, aimed at acquiring and providing distributed system products. All the activities aimed at acquiring products will ultimately require an internal advocate to make sure that the products will work and work together.
2. Ed Fredkin's Personal Computer Products group, including accessories, servers, programs and PCs.
3. Vertical applications acquisitions group (eg. CAD). This can go very fast once we have a basic, set of distributed products.

We clearly need people who are going to propose and then implement these products for George's group.

APPROVAL OF PLANS

Hydra came forward with a product plan. I believe the product can be built along the lines (within a factor of 2) they've proposed because there are existence proofs. In constructing a most detailed agreement with the group, it must be clear that several of us believe their detailed plan can be implemented on time and within the budget.

Who's cosigning their plan in terms of specs, time and budget?

What you folks think about these principles?
        GB9.4
Subject: Momentum Discussion to kgf, pg

Ed Marinaro discussed whether we might be interested in acquiring them. Someone else is coming after them and he thinks we'd be a better fit. In the next 10 days they'll have an offer and not much time to act.

They have 100 protos in test at various places. Their value is in having a high speed workstation for business (I don't think this is a market, UNLESS it's PC compatible!). He also thinks we might use it in the technical market against Apollo (more powerful than D300) and Masscomp. He's discouraged that the VC's aren't hot on box companies now.

They've just spent a bundle (got $6M on last round) to get a manufactruing line of 90 Ksq ft. and allow them to build 1 unit every 24 minutes... they can do 400/month now at 3.5 K and with work get this down to under 2K.

They are shipping 500K in December of their old product and would ship new product in December or January. Their valuation is approximately $10-12 M.

He's coming this way and we could rendevous, but he'd really like to get us out there to look at it. (We also need to meet some of the designers and other principals.)

What I say?
.

Subject: **Monthly or Quarterly Reports and Lack Thereof**

To: OOD

Date: 1/16/79
From: Gordon Bell
Dept: OOD
Loc: ML12-1/A51 Ext: 223-
2236

I'd like to discuss this at the Jungle meeting briefly.
PLEASE BRING COPIES OF YOUR OWN, DICK'S AND LARRY'S.

Both Dick and Larry seem to be doing it right in that there is enough there plus there seems to be MBO (is this in these days?) because there's a direction of what's to be done next month. Why can't they all be this good? What should others look like?

John Meyer, I simply don't think we have any visibility of the issues of turnover. Here we need names, numbers and insight on a continuing basis.

There's also been murmurings that the Yellow Book isn't the schedule bible...and this, coupled with the declining quality and existence of the business plans, worries me.

June 11, 1984

Ms. Jacqueline Morby
TA Associates
Milk Street
Boston, Massachusetts

Dear Ms. Morby:

Last week I gave you recommendations for several fine, former DEC people in regard to a potential investment of $25M for 2/3 ownership of their company. Let me suggest Encore as a far better investment. For $25M you can own roughly 1/3. Encore's output will be about 5-10 times of what should be a good, single product company because we already have four wholly owned companies and are on our way to becoming a major computer company. Thus, Encore would give a relatively better return on investment of

2.5 - 3.5 or (5 - 10) x 1/3 / 2/3.

Also, the risk is much lower, because like you, we own multiple companies -- but we are NOT a venture capital company.

Encore "central" consists of a seasoned managment team and is responsible, through boards for wholly owned focused, yet loosely connected product companies. Encore owns a single sales and field finance company plus four product companies, with two more in the formative stage. As you may recall, Encore "central" is composed of major industry leaders with experience at Data General, DEC, GE, Honeywell, and Prime (our backgrounds, with the exception of Julius Marcus, are described in the January PPM). I don't think you'll find a comparable group at any company today outside of IBM!

Encore provides financing and wisdom in the form of an overall Product Strategy combined with tactical assistance based on much experience. We also help recruit the key management of a company. Technical help is most important and ranges from tactical review of a software module (with advice) to the entire development process. For example, we help in relationships with suppliers; eg. we were instrumental in the decision by TI to second source the National 32000 microprocessor. We helped with a difficult decision on the manufacture of a printed circuit board in just two days. (In contrast, I predict that one recent startup will be forever impeded because of a poor decision in this area.) Perhaps most important, Encore obtained a multi-100 million dollar contract for the major product distribution -- this would have been outside the reach of nearly every startup.

The final reasons to invest in Encore are its Product Strategy which guides the entrepreurial energy driven companies and their products. I was responsible, in various capacities including the period as a professor on leave from DEC, for DEC's overall products since 1960 and responsible at a detailed level for many products from the first timesharing computer and the first mini. In 1975 I led the VAX team and established the organization. As the leader of DEC's 6000 person engineering group for the last 10 years till July 1983, I have never been more enthusiastic about a <u>set</u> of products as those in the Encore companies.

Every Encore company is first rate. Each product is a leader because of increased functionality, greater performance and lower cost. Yet each can be used together in a completely compatible and synergistic fashion. Each product is innovative and competitive now (by a wide margin), but also can be evolved to the next generation and into the 90's. Although the Encore Product Strategy and current products can be described simply in a few pages, I think its better that we discuss this directly if you are genuinely interested in investing in Encore.

We have been described in various ways including being a venture capital company. But from the above description you can see that even though we borrow some of your ideas, we aren't at all because:

.our companies are wholly owned (though they needn't or won't likely be in the future); We watch 100% of one company in an industry rather than sharing in the risk of one or more companies.

. Encore "central" supplies a very tightly connected though fault tolerant product strategy, thus while a company can fail, the strategy ties them together for maximum impact assuming each will succeed;

. the entreprenurial energy driven Encore product companies develop and produce products and get rewarded in Encore equity and product royalties;

. there are two types of companies (product and distribution) for maximum management focus and economy of scale in distribution; and

.we are all full-time computer people, building a major new full-range, computer company yet founded on the principle of maximum autonomy, responsiblity and reward to independent, operational companies.

Enclosed is an essay on the computer industry which we use in our thinking and planning. It may be of interest to you.

Since the January PPM, which sketched an elegant and innovative but potentially theoretical organization and its set of products, Encore and its companies have formed and are producing at a level beyond my own expectations (my vitae is attached for your calibration). Thus, I can now highly recommend Encore. I believe you should consider us for a major investment.

Sincerely,

Gordon Bell
Chief Technical Officer

SUBJECT: SELLING TINY CHIPS WITH MOSTEK AS LICENSEE

PROPOSAL: Digital aggressively sell Tiny 11 as chips and that we license MOSTEK as an alternative

Introducing Tiny, as a chip, would give us these advantages:

. Get a new class of customer, with us as a viable supplier with a second source, including:

- Board level controllers such as comm., analog front end, speech, etc., used with other Industry-standard busses

(e.g., S100, Multibus) and other organization busses
- Controllers for small system, high volume applications
(e.g., engines, process controllers, and peripherals)
- Low end personal computers that we are not building, thus
allowing new low end software to be written on 11's (Note,
while RT-11 will operate on Tiny, our big ticket machines
require at least 128kw to operate.)

. MOSTEK will go after these new, high volume customers. Tiny
customers would have bought another microprocessor.

. Gets new customers on 11's earlier to feed our higher end

. Keeps old customers on 11's

. Prevents further erosion of market share that will be caused
by both old and new customers going to high end micros

. Really hypes the 11 and insures its success into the 80's

. Gets a new, low end development via MOSTEK, including
peripherals, and continued, one chip computers. They will
also push the hell out of performance. Our semiconductor
development is aimed mostly at our board and high end
business (e.g., Jaws).

The market is segmented, roughly according to address size and we
are nowhere near the low end of it. Microcomputers are analogous
to engines, and use is diverse (eg. lawnmowers ... jets).

BITS   CHIP STANDARDS   USES

<16	4004,8048	few chip controllers, appliances
16	Z80,8080,6800,6502,T	periph controllers, personal comps.
16+16	Tiny, 6502 (kludged)	same (Apple III)
20	8086	large micro applications, pc's
22	Fonz, Jaws, Intel 286	mini replacement chip
24	Z8000	time shared computers using UNIX, large, personal computer
32	VAX, 68000, 68000+	large computer
>32	Intel 432	"Micro mainframe"

There might be potential "fringing" of our microcomputer and systems business, but this will be small, due to the address size limit. On balance, we should get at least a factor of 10 more business than we will lose to suppliers who compete with us by supplying systems made with these components. If we can not compete with them, we would have lost the business to them anyway as they bought our processor boards!

We want the world computing on our computers, not Motorola (becoming the standard), Intel and Zilog!

Vincent Prothro, President
Mostek Corp.
1215 West Crosby
Carrollton, TX 75006

Dear Vin:

Please accept my warmest thanks for the hospitality you extended to us last week when we visited MOSTEK in Dallas and Colorado Springs. It was a great pleasure to see the openness, respect and intense interaction between the two groups of engineers. I know Henry Lemaire would have been proud of this, as one of the key founders of the relationship. You, too are clearly responsible.

We are all following-up on the various action items outlined on Tuesday. Having seen the tremendous investment required to manufacture semiconductors, I hope that we can utilize your factories in the co-operative fashion we are pursuing. I'm also excited about the possibility of licensing our microprocessor and working jointly with MOSTEK on future development in this area. A proposal has been submitted, but I don't yet have a feeling about how it will be regarded by others. Even if we won't license our microprocessor to you, let me urge you to not develop and market your Rainbow processor and to search for an alternative strategy to participate in this market. A unique architecture will take much effort to be useful and will not be used in any significant quantities due to the high support cost. The net result will be a drain of resources to both seller and buyers.

As the Keeper of the Digital Computer Museum, I look forward to receiving the important memory and calculator artifacts, for the museum. A series of three lectures, open to the public and videotaped, presenting MOSTEK's pioneering efforts in the ion implanting process, semiconductor memories and one-chip calculators, would be really great. I'll send a proposal soon on the logistics of such a museum series.

Again, thank you and your staff for the fine hospitality, I look forward to implementing last Tuesday's agreement. It will be a pleasure to have you visit Maynard and to meet other Digital officers.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Cambridge, MA 02139

Dear Mike and Paul;

I'd like to thank you and Paul for making the Moto-oka visit possible. Also, I was delighted that you could come to the reception and dinner. I learned a great deal more about the effort and the program, which I would more aptly describe as a process, by interacting with him. I'm extremely impressed by his breadth, basic intelligence and ability to run such a process.

Since you (MD) are speaking at the CDC soiree' later this month, it might be a good time to interact on how to deal with this very clear threat. My view is that they are going to be successful!

Sincerely yours,

Gordon Bell

SUBJECT: PROF. MOTO-OKA PRESENTS 5TH GENERATION COMPUTER PROJECT

4 P.M., JANUARY 28

AT MARLBORO CAFETERIA, FOLLOWED BY RECEPTION AT COMPUTER MUSEUM

PLEASE POST OR FORWARD VIA THE ENGINEERING NET

The Technical Seminar Series, normally held in Hudson, has arranged for Professor Moto-oka to come to Digital and present the goals and workplan for the FIFTH GENERATION COMPUTER PROGRAM sponsored by the Japanese Ministry of International Trade and Industry (MITI). The program is targeted at moving Japan's computer industry into the leadership position by 1990.

The workplan was developed via an extensive process encompassing members of the Japanese government, industry and universities. It is most impressive in scope (VLSI, innovative computers, and applications) and should produce many results toward the target.

Dr. Moto-oka is professor of EE and CS at University of Tokyo and received his degrees there in 1952 and 1957. His prior research included high speed circuitry, logic design automation and memory systems. He is currently working on new computer architecture, artificial intelligence and Japanese natural language processing.

I would like to urge that at least one person attend from every
development project or group. Since non-DEC persons have also
been invited, we believe there will be many in attendance. Please
RSVP only if attending, via EMS or Interoffice Mail.

Professor Tohru Moto-oka
Department of Electrical Engineering
University of Tokyo
Tokyo, JAPAN

Dear Professor Moto-oka;

It was indeed an honor to have you present the Fifth Generation Research Program to us at Digital Equipment Corporation last Thursday. We were all stimulated by the presentation.

I have reviewed your report and find it very exciting. Please accept my congratulations on organizing this effort.

Dr. Kobayshi of our Japan Engineering Center, will visit you and see how we might participate in your effort. Since we have an active program of co-operative university research, I'd like to understand if such a co-operation is possible at Tokyo University. At the very minimum, I hope you might use Digital's computers in your research.

Again, thank you. I hope to see you in Japan in the near future.

Most sincerely,

Gordon Bell
Vice President of Engineering, Digital Equipment Corporation
Professor, on leave, Carnegie-Mellon University

Dott. Marisa Bellisario September 10, 1984

Chief Executive Officer

Italtel Corporation, S.p.A.

20154 MILANO

Via A. di Tocqueville, 13

Italy

Dear Mrs. Bellisario:

I enjoyed the brainstorming session with you and your colleagues. I hope it was of value to Italtel. It was great to see such an alert organization with a strong feeling and commitment to building state of the art switching equipment. I regret that time didn't permit my learning more about your company and products, expecially the new switch. I hope you'll send me more information on the company and products.

Enclosed are several brochures on The Computer Museum. The Museum is international and cross-industry, being dedicated to the preservation of artifacts and the understanding of Information Processsing. The Museum moved to downtown Boston about one year ago, and will officially open to the public, November 14. If you're in the U. S. at the time, I hope you'll consider coming to the opening.

I would like to invite you and Italtel to become Members of the Museum. The Corporate Membership schedule is attached, and I hope Italtel can join at the $1024 / year level. In addition, the Museum would like to have various artifacts that have been pivotal in information processing. For example, Ugo just contributed the Macrodata/Olivetti computer that he believes was the first 32-bit, mini.

I hope you'll consider visiting Boston on a forthcoming trip. I would like to introduce you to The Museum, and also **discuss Encore's forthcoming products, which I believe could be very important components for switching and "added-value" services.**

Ken Fisher sends his regards.

Sincerely,

Gordon Bell
Chief Technical Officer,
Professor, on leave, Carnegie-Mellon University

SUBJECT: MSD DIRECTIONS

We had better talk. I am feeling exceedingly bad about what you are doing in MSD:
1.Nebula Jr./ given no one wants Nebula. What does it really get from a customer perspective besides a Bus to nowhere?
2.Too many little projects and no real direction. I don't think we need to spend the kind of money there for simple follow ons (or what should be) like 24, 44, Nebula.
3.BI is driving me crazy as it is a bus looking for a rider.
4.NI isn't aggressive enough and we should be using it on Hg instead of the expensive CI.
5.Want to declare future 11 direction: 23J, 24J, and put a second computer in HSC using J to get a hot 11 follow on. CX will do this. This takes very little developement.
6.Want to get lots of Nebulae as is out, so we can get on with
the software. You figure out how we get 100 with NI on them by something like January.
This is a critical problem, given that we have proceeded to

sell them to a number of universities and to our internal users
too. Now, all signs are who me? did I do that? what are we going to do?
7.Next MSD VAX is Comet follow on, and Scorpio.

8. Get DECnet to do the Hg front end on NI and get it into the IC
strategy. Stop the incrementalism that should have been done years ago to get better comm. outboarded on VAX. Let's go get NI, like we believed it is really going to happen instead of making it an advanced development effort with all kinds of alternatives.
9. Get SS a Qbus version so as to avoid the homebrew that wil emerge.
10. The Interconnect doesn't acknowledge Intel as the bus driver.
II should be it. They have a BI already in their 432 that we might use. I still suffer from the problem of why does anyone
want a BI (ie. Would you please refer to my memo on systems that are timelined out to 1990 and tell me which ones will use
it?).
11. The Interconnect doesn't acknowledge Venus or the 2080 and
solve their problems. We should not be putting the SBI on Venus,
and we should use Hg on NI as the front end to both Hydra, VMS
and the 2080 aper the Hydra agreement. Now let's get the work re-directed to goals and not have all the alternative outs
that will be used because we did all the back-ups instead of doing it right.

Somehow, your planning there is failing, given the stuff that is in process. We need a way for you to turn money back or change charters (eg. voice on NI... which I assume you are doing) rather than continue to pad the budget. This will only
get us more and more expensive projects of lower and lower

quality.

Could you please schedule a major review of all projects for Larry, Sam, Si and I ... including those in A/D?

SUBJECT: MT. FUJI SNOW JOB TO FORD BOARD: DO THEY (WE) UNDERSTAND?

It looks like they are in lots of trouble because they are still
not facing up to Japan.

The tip off as to why they are in much deeper trouble:
.The group just got back in February. A little too late to look.
.The group was "management" (versus labor) a poor dilineation.
.The automation issue is non-trivial!
.The productivity and flow models indicate a major problem in organization and industry structure not easily solved.
.The report didn't address much deeper issues like designs and car size and gas consumption.
.They conclude after enumerating a significant list of differences, that there is really no problem, all they have to do
is to attend to these details. (After all, the Japanese put on
their pants the same way they do, and cars are made the same way
the world around: materials in, cars out.)

Unfortunately, if and when they operate the way the Japanese do,
assuming they can, then I believe Japan will be in a much different place.

A friend at Stanford described his brother in law's job as a designer at Honda, US. They work every nite till 10, except Wednesday with weekends off unless they are testing cars in the desert. They have competitive car designs with Japan and Germany. The winning team has been decorated by the emperor.

I hope we can start to take them seriously. Already, they are
coming into the very low end space via the calculators to attack
what is the low end of the personal market. The only reason they
won't be seen for awhile is they need machines internally.
Therefore the exact date of confrontation can only be predicted
by looking at the economics of the situation.

We clearly have to look out and be prepared to change our ways by
understanding where we are with respect to designs, productivity,
costs and materials flow. I gave a talk to a group of robotics
experts on the Japanese topic. A person from TRW remarked, after
seeing Salem: "you guys are going to get killed". This was prior to the TRW-Fujitsu deal, so apparently his comment was based on fact.

GB1.S5.57

October 12, 1984

Dr. Craig Mudge, President
Austek Microsystems
Technology Park
Adelaide SA 5095
AUSTRALIA

Dear Craig:

I enjoyed the interaction with you and your board. The product discussion was also stimulating. The board is quite impressive and helpful; Bob Evans will also be a great addition. I hope there's some way to get Jack on the board because his wisdom about the semiconductor industry would add much.

Since I have trouble being really clear, thoughtful enough (due to slow cpu) and verbal (even though wordy) in a meeting, I'd like to take this opportunity to clarify and record my position.

My reaction then and now is in reaction to being a part of many startups over this last year as an owner, investor, advisor, buyer of product, etc. The alarming situation is that good or very good technical people in combination with knowledgeable business advisors (their board) produce such uniformly poor results. This may come from inexperience on their part, together with the model that a company is supposed to start out and lose money, even if there's nothing fundamental in their business model. I think problems come from not attending to a few key management principles:

- people
- company charter (and focus)
- profit, responsibility and control

<u>People</u>
I say: "<u>Never hire average people--you get them for free when you err.</u>" Many people hire subordinates who are intellectually subordinate. Don't let this start anywhere as it will propagate downward and end up with only morons at the working level and no communcations path upward to do many important functions, especially educating management.

You want only aggressive, bright workers who are constantly challenging the whole organization. I also don't believe you can afford <u>one</u> person in the organization who does not know the technology or industry! This view might be moderated if you get into plain old business and management problems. Expatriated Australians would seem to be a great source.

Clearly you have to hire the U. S., Australian Government and Singapore Division presidents--with full blessings from your staff and board.

People are your most important asset. Add that to your charter and constantly upgrade by forcing your staff to always hire brighter people.

<u>Company</u> <u>Charter</u>
I believe this a serious item for you and your staff to develop. I believe it should not be more than one sheet of paper, although it could have many pages of backup. It would cover your basic goals and attitudes towards: product excellence, people and profit, for example. A charter keeps people together. Don't violate the charter; change it to agree with your direction and to point out the inconsistencies of what you are doing! It shouldn't lie.

The DEC Product Strategy I wrote in 1978, describing the VAX and interconnection plan is the most comprehensive example covering a multi-billion dollar company. It was modified several times, but always stayed a page. The interpretation and discussion each year took on the order of 30 pages, including comments on products and processes. Ken Olsen told me recently that he was now personally really implmenting it...he only harassed me while I was there.

You might get Heidi Mason's company, Acquity, to look at your strategy and plan because they can ask lots of questions and clarify cloudy thinking. After one year, they are profitable, achieved their objectives and growing.

<u>Profit</u>
Let me elaborate on Plan B: "<u>Profit is habit forming.</u>"

Given that you are in a service business, there's no reason why you shouldn't be profitable from the day you make your first sale and start getting progress payments. The Australian government has been setting you up in business for the last 3+ years, so I fail to see why there is any period of unprofitability. You also have the whole country behind you. It would be crazy to not have Australia as a major market segment to start from. It would also seem you could set up a research organization for CSIRO too.

If you decide to run a profitable company, life will be enormously simple:

. The company immediately operates accoring to a steady-state business model by which it is measured and controls itself. Let me urge you to work this out, and follow it with delegation. I think the lack of a good business model which includes the P&L and Balance Sheet is at the root of the poor performance by most businesses.

. You'll be freed from the hassle of financing. This will get about 30% of your time back to do something creative... like making more money or products or even something crazy like going to Singapore.

. The orientation of the entire company will be different. You'll be unique among current supposedly successful startups! You can take the people and jobs and financing you want. The whole company will be on an upward spiral rather than a marginal, hand to mouth, frenetic operation of ups and downs where you sell investors, get money, do work and then go sell again.

. While growth shouldn't be your goal per se, profit is the only way to obtain growth and be successful. No one will fund a losing operation that grows. Look at DEC, Apple, HP and a few others who started with profitability from day one. They all make profit number one or two next to quality, and they all grow like crazy.

. Your employees and board will have much fun. I will even have fun and enjoy working with you because I know that you'll be making it, rather than being part of helping you survive. I'll show you a dozen unprofitable startup companies; none of them are having fun.

. Profit will be the organizing principle. Let the people who are going to be responsible for it, take charge. Otherwise, you'll find that every department is a cost center and will give you thousands of ideas for spending money, but none for making money. You alone will be responsible for making money, and it will not be fun. I can almost certainly guarantee that you are unlikely to ever be profitable if you start out not focused on profit. The only time the balance sheet will be positive is after a financing. In effect, other people will help you manage if you are profit based because all lines on the P&L are allocated to the profit managers.

. Profit is the basis of operational control, establishing priorities and delegating responsibility. In essence profit allows the bottom line to be managed by delegating the management of segments to others rather than delegating spending!

Management and Control
A key operational principle at every successful company can be summed up by this quote I designed at DEC in 1972: "He who plans, does." Here, the key is self-motivation, and that is the only way to get massive output.

For example, on Singapore do you really have the whole staff behind you and is an individual responsible? It would seem the individual is the one to make the plan and order the VAX and rent the building, etc. How could this possibly be done from Adelaide? Singapore cannot be your plan.

The key to the amazing growth of DEC (no company has grown this long or consistently over 25 years) was being able to motivate by having an environment for entrepreneurs who could in turn do their own thing. Your only job is to find, provide an evironment for and motivate them.

Keep the organization simple. The tree is about the only thing that works. I hate matrix management, and DEC was often wrongly accused of being unduly matrix organized, because it did use the matrix in a few places like personnel and finance. Having internal groups who sell services to others is not a matrix; don't confuse it.

You'll be full-time, leading the charge, financing, selling and attracting people (and an occasional idea). Have you delegated internal operations?

Singapore

I would like to strongly agree with Jack regarding NOT going to Singapore. I believe deals like this will always be around. It seems to:

- violate all your charter constraints (VLSI, product excellence, high cost parts, analog expertise, design synergy)

- put you in a new business--teaching

- loses money, even with their incentives, and your accounting that ignores large, allocatable charges

- detract from getting into Australia (priority #1, I hope) or the U.S. (when you find a leader)

- put enormous personal stress on the team--which will ultimately prove quite costly (I would hate to have to be responsible for this and you must get someone else to be the proposer of this plan.) I can't believe 15 guys can work 3 continents. Your team simply has no management record to carry this out yet.

. violate the fundamental management principles I described above: "He who proposes, does." That is you have no one who you trust to lead this and take responsibility for P&L. Delegating any hires of technical folks or a division president to someone else is just not done. People are your most important asset.

I would change my mind if a great, well-trained entrepreneurial engineering-oriented person with product experience could be recruited to head this division. I would assume that he could put a plan in place for profitability in the first year. This could be accpeted after you demonstrate the rest of the operation is under control.

Needless to say, I was surprised at your not withdrawing the item from the agenda and the board's approval. (I am also tired of seeing bang-bang control by boards: ok everything / fail and replace.)

Bottom Line

I hope the above comments will be useful to you and Austek. I must admit that I'd like to see you succeed with great people, products and profit. And in addition, have fun. Also, I would not object to making money on this venture, particularly if I invest any time...so my motives are not pure.

I hope these comments are useful. Please feel free to use them.

Sincerely,

Gordon Bell

CC: Ivan Sutherland

Dr. J. R. Philip, Director
Commonwealth Scientific and Industrial Research Organization
Institute of Physical Sciences
Limestone Avenue
Canberra, ACT

Dear Dr. Philip:

I would like to strongly recommend that Dr. J. C. Mudge be promoted to Chief Research Scientist Grade 1.

I have worked with Dr. Mudge since 1973 when he came to Digital to work as an engineer in the design and architecture of our computers. At Digital, he worked on a number of tasks includig those affecting the VAX architecture. He subsequently went on to be instrumental in implementing the low cost machine, Nebula, which became the 730.

I have also worked quite closely with Dr. Mudge in the compilation and writing of the book, Computer Engineering: A DEC View of Hardware Design. While I think that this book is truly unique and important, I'm probably too biassed to fully evaluate the work and worth. Over 20,000 copies of the book have been sold.

He really established the VLSI Advanced Development group at Digital and set a benchmark for what research in VLSI should be. His work was the basis for project work aimed at putting the VAX architecture on a single chip. He also spent a very productive and useful year with Carver Mead as a Visiting Associate Professor at the California Institute of Technology where he was both productive and held in very high regard by students and faculty. He is invited to speak in international conferences, and his thoughts are well respected.

In a recent visit to the laboratory in Adelaide, I had another opportunity to look at his work and leadership. Here, I am frankly surprised that he has been able to accomplish so much in the VLSI area at both this distance and with such a small team. This is impressive.

Again, let me urge you to promote Dr. Mudge to Chief Research Scientist.

Sincerely,

Gordon Bell

Vice President, Engineering, Digital Equipment Corporation
Professor, On Leave, Computer Science and Electrical Engineering,
Carnegie-Mellon University

GB4.S1.15
9 January 1983

Dr. Craig Mudge
CSIRO
P. O. Box 213
Eastwood SA-Australia 5063

Dear Craig:

Just a brief note to thank you, Maureen, Ben and your staff for the wonderful hospitality we were given in Adelaide. We especially enjoyed the Christmas brunch at your house and the opportunity to meet so many of your friends and colleagues.

I enjoyed the interaction with your staff, and only wish I knew more about VLSI. In thinking about the lab's 100K demonstration chip, I came back and threw down the gauntlet to the engineering community, and received these suggestions:

- some fraction of a VAX that is already well specified
- an existing VAX (eg. Nebula) where the goal is simply re-realization
- massive integration of a particular terminal (eg VT100) in order to achieve a one chip level
- a PDP-11 on a chip using J base
- fast Graphics accelerator
- LISP coprocessor for one of our micros
- a more advanced than TI320 Signal Processing chip

Let me urge you to engage in some sort of joint venture with us as I see it getting you PR, resources of various kinds, and credibility. The benefit to us would be direct. Also, it might be the basis of DEC coming to South Australia on an engineering basis.

If you see making the chip something of commercial value, I'm sure we can get the interaction.

The diving in FiJi was spectacular, and we especially enjoyed the S.A. provisions. We heartily recommend the Seaview, and fortunately, look forward to the cabernets, clarets and other red.

Please give my warmest regards to your family and staff.

Sincerely,

Gordon

SUBJECT: SUPPORTING AND CONSTRUCTING EXPERIMENTAL MULTICOMPUTERS

I believe we should go all out to encourage and support the construction of experimental computers by qualified researchers who have an idea and are committed to do the software and applications.
Helping Chuck Sietz feels right. Also, why not build Larry Snyder's machine at Yale?

For example, the Seitz machine is exciting for two reasons:

1. Researchers who need the machine and are committed to make it work are involved.

2. It's incredibly simple and offers a major cost performance gain (eg. for $50K parts, the performance of a Cray 1).

In looking at the design and use of new (commercial or experimental) computers, let me hypothesize:

In order for a new computer structure to be attractive to a user, and hence become a main line system, the machine must offer an order of magnitude improvement over his current computation method.

In recalling the last few years of computer systems research, it seems to me the universities have gotten slightly better at constructing hardware, but are still not up to building systems for real use. Therefore, let's build these ideas and let them program and evaluate them.

.

SUBJECT: OLEH SPEAK SOME GOOD WORDS HERE

As a user of a multiterminal system I can only say one good thing
about it. It's has good response time. And I think that the
file problem is better with lots of on line storage. Some day I
suspect we'll have a problem when we run out of space and the set
of independent secretaries that share it have to clean up the
files and garbage...or when we have a head crash and lose
files. Somehow, the 8 user wps system we are marketing
looks like a early first generation timesharing system (I
recall the PDP-6) which has the ability to lock up devices
and which seems to create chaos in the office environment.
Someone has to be the system manager (here Mary Jane is) and
this will ultimately be a full time job...especially since
the WPS200 needs more debugging (but I assume this gets
solved). Also, the system has to have dial out capability
without going to the central system. So far I'm sceptical
that the system will work like we would like to use it.

Maybe it is great for a typing pool? If so, we had better really
partition where it gets sold. Having seen the WD brochure that talks
about data processing too, I am even more sceptical that this

kind
of system can really be used.

Jack, you have a responsibility to sort this question out. I fear
you have been listening to the office manager/ data processing
manager buyers who say they want shared systems for some reason, os
say they want DP in there too (as opposed to access to DP) via the
wps terminals. The cost per terminal may be why they are saying it?
However, given my few weeks with the 200 (and ignoring the bugs), I
say get me back to an elegantly packaged wps 78 or 278 (not the knee
buster we're eventually going to come out with).

Note the personal Nebula that I'm going to get only has me, MJ, and
Sue on it, plus dial in/out (Automatic type!). I don't want to
have any of us be computer system managers. I would like Al Crawford
to link to me so I can send him files for archiving and also get
larger files from him and others.

I am now ready to do some rethinking of our direction.

SUBJECT: WPS/EMS AS A PRODUCT

I am concerned about our current emphasis with this product. I believe the market for this product will belong to whoever has the smarts to create a single user product (one for each secretary) at a price somewhere in the $2K range. Shared logic offerings usually imply sharing the printer and possibly sharing the floppy disk or TU58 with other secretaries. This pulls the secretary away from her work station and is highly undesirable. The manufacturer that solves this problem will get the spoils. Why are we working so hard to create WPS that can run as tasks in other systems? The CPU and MEMORY are the cheapest parts of a WPS system and are getting cheaper faster than any other part. We seem to be moving in the opposity direction of the distributed computing trends here.

EMS will work when we design the system in a way that makes it easy to implement in an evolutionary manner (i.e., some EMS nodes in mailrooms with machines with spoolers and fast printers).

GB1.S2.25

September 8, 1980

Dr. Harold Liebowitz
Chairman of NAE Ad Hoc Committee on Membership Elections
George Washington University
Dean and Professor, School of Engineering and Applied Science
Washington, DC 20052

Dear Dr. Liebowitz:

I appreciate being included in the membership of your committee, however, I don't recall ever being asked or agreeing to serve. Since I do feel strongly on this matter, I'll comment although I don't want to meet. I assume you'll collect inputs and make recommendations, hence I don't see why you have to meet for a day. Using your format, please note these recommendations shown in [brackets]:

1. and 2. I hope you don't spend too much time looking for an optimum number. It would seem to depend on what the NAE wants to be. This is a whole issue by itself. Given that there are people who feel that there are unworthy members of NAE based on the current criteria, then it sounds like we may have already passed the number. Optimum, would seem to depend on what the standards are or alternatively, how many are needed to carry out the academy's functions. Therefore, one might argue that it should be either half or twice as large, respectively.

Within my own specialty, computer science and engineering, I feel that based on the fifty already within the academy, [our area could have about 50% more than we have.] Furthermore, within the number that I would add, there are a large fraction that I think should already be members, based on the current criteria and constraints. This is not to say that there are non-deservers within the academy, but the priorities aren't really clear within the constraints of the current membership. Therefore, the strongest general recommendation I have is not the number, but [THE PROCESS ELECTS PERSONS IN A RANDOM FASHION <u>therefore</u> change IT!]

3. Does it matter who has the ability to nominate? We might be better off if [non-members could also nominate members!]

4.

I am less concerned about the ratio of academe, government, and industry. We should look at it, but the criteria will implicitly determine the ratio. Again, there are three other ratios that I feel much more strongly about:

4a. What should the ratio (or quota) be for a given (discipline) area?

In the case of the peer committee which I am familiar with encompassing computers, systems and control, materials as they relate to electrical circuitry, electronic circuits, and other topics covered by academic electrical engineering, I have never felt like we have done an adequate job! We have made recommendations where no one on the peer committee knew the candidate or their work or even the area. We have asked to have this split into three groups, but to no avail. Therefore, I would recommend: [restructure the peer areas such that the peers know the areas and people being recommended].

Given that we can get the right peer committees, then the problem of how many members still remains. I'd like to see the [area membership as a whole convene and recommend size]. This year I submitted a list of possible nominees to those in the computing area in order to focus on those who I think are deserving of nomination. In particular, there were cases of oversight for people who are in the over 75 age group. Also, there were several capricious over-rules by the highest level committee because candidates were from a particular organization and I felt the persons should be resubmitted as soon as possible.

At a meeting (at NAE annual meeting, or by informal network via phone or electronic mail) [under the auspices of a chairman or small sub-group an area would arrive at a list of potential nominees. This list would only be used informally, but it would tell us something about how we felt about how many people should be within a peer group. Also, by tracking this over several years, we would know how many people we believe should be added each year.] As a peer group, we must defend the criteria that causes us to believe there is an outstanding group this large. All groups would have to do this. In more mature areas with larger groups, the group should propose what it feels should be its criteria and membership needs per year.

Philosophically, do you take the number of engineers in an area, % GNP in the industry, number of papers in the area, or what? These criteria should all be known and possibly be used as guidelines, but within the framework of those proposing the membership for the area.

4b. What should the ratio (or quota) be for a given company or other large organization?

This gets really messy. For example, we have not recognized the person within IBM who made the fundamental breakthroughs in magnetic disks. This is approximately the same importance as both core and semiconductor memories, but by the closed nature of a company regarding its <u>working</u> engineers, the nomination has not been forthcoming. However, I feel that IBM is well-represented in terms of administrative engineers.

Given that a large amount of engineering is done by very large organizations (Bell Labs, GE, GM, IBM and MIT), I would like to get inputs from the organizations about how they regard the academy membership. [Also, the academy needs some guidelines here in terms of how many.] It should be part of correlating with the overall number we use for industries. Perhaps, we ask the 10 largest organizations as represented within the academy to propose a similar number based on what they think to be the criteria. I have a suspicion that several of the organizations are already doing this in a concerted effort.

We should go through an overhaul whereby [we should not accept a nomination by a member of the same organization, nor do we allow more than one recommendation to come from within! In terms of the closed balloting, I would like segmentation in terms of the organization and outside the organization!] (That is, when we find someone with a lot of yes's, I want to know whether they all came from within the organization.)

4c. and 5. What should be the ratio of engineers, engineering administrators and scientists?

Personally, I would like to see more emphasis on personal accomplishment versus engineering management. Just as some member on the ballotting writes ACADEMIC beside a nominee, someone else should write ADMINISTRATOR to warn the peer committees. I don't have a recommendation, but I do have predjudices because I rarely see the kind of leadership from these people except in budgeting and definition of processes. By the time many engineers head engineering, they are barely engineers.

I would like to [<u>not</u> change the accomplishments to be more scientifically oriented.] In fact, I believe [the criteria should be clear between individual contributor and administrator.] [For the contributor, I feel it should be two major accomplishments that have practical application, or one truly significant one (eg. APL). We should be wary of the accomplishments that are just a stream of papers that do very little unless they really structure a field.] For example, we get a stream of recommendations from one large, industrial research lab that has long since been irrelevant to electronics because the company has not made any contributions for 20 years. (It is now essentially a conglomerate that for some reason believes it should believe in research.) Thus, as engineers, there is no way their work can be useful except in a scientific capacity. Hence, the NAS should vote on them.

6. I hope you have gotten some flavor about what I think are the criteria. If you feel like the academy as a whole is floundering in this issue, then I would recommend [we do not take any more people into the academy until we sort this out! (We would have a one year moritorium with only very clear, exceptional cases looked at.)]

Hopefully this will be of some use to the ad hoc committee. Have a good meeting.

Sincerely,

Gordon Bell

NAE PANEL - ACADEME, INDUSTRY, & GOVERNMENT
INTERACTION IN ENGINEERING EDUCATION

There are comments about the overall importance of the need for coupling and direction of government help and a description of our joint program we use for research, advanced development, and in some cases prototype development.

Don't increase the level of funding for basic research because we are okay in Nobel prizes. We are losing in trade and don't precisely understand why, although it has to do with issues like understanding how to design processes and operate factories effectively that produce high quality goods. We need university help here - versus on the product!!

I don't believe we have a problem of innovation, particularly one which requires more bureaucratic process, or labs which will detract from the training of current persons to chase some new grant $'s. We do have miserable coupling of both basic research and development between universities and industries, and this should be our highest priority problem to solve...especially since our research results are being used more effectively by competitive countries for their trade.

I also conclude that we must have a separated NEF, versus NSF which deals with training and understanding engineering (directed to goods production) because the government goal set and hence funding is totally random and volatile. Also, because engineering and science are interwined we tend to believe they are connected. Breaking then apart would get better coupling than keeping them together as a single mushy mess. For starters it could be renamed, reorganized, accounted for and measured separately (also, the people could be made accountable). Several years ago it was directed at coupling with industry, and apparently now it is to be redirected to science, just when we were beginning to establish joint programs. Frankly, I don't give a damn, but it would be nice to have consistence for greater than 4 years! Do we want to win Nobel prizes or do we want to have balanced trade? Can we do both, given that a lot of people are being syphoned off into the useless MBA programs - here the abolition of business schools would probably increase productivity more than anything else? I strongly support any mechanism of coupling that is outside the government intervention and negotiation because it requires overhead time and money skimmed off of the work...that means tax credits which would favor doing work with universities. We need university help in our work if we are going to build goods effectively, and I'm interested in anything we can do to make this work.

The Digital Program

Our urgent, formal universities program has developed from random, equipment grants on the last day of our fiscal year. I still like the old, random program, but as a larger corporate bureaucracy, it is virtually impossible. Some of the best results have come from this because the effect is to put totally free, unplanned resources into someone's hands. The program, Spacewar, was written for a PDP-1 delivered to MIT on June 30, 1961. It turned out to be the father of all the space games that one currently plays with tv sets and in arcades. (Other programs came from this gift including one of the first timesharing systems, compilers, editors, and other systems programs.) We have had similar results from a machine placed at Carnegie-Mellon on June 30, 1971, when two language breadboards, APL and BLISS were written together with other software tools breadboards. Therefore, before we describe bureaucractic processes, let me recommend the element of surprise. It will probably have more payoff than anything that can be planned. As researchers learn more about business and risk avoidance, innovation will be less with these formal programs.

Our current program has been fair, and highly variable. Fundamentally, it allows us to pay for research and other work both with $'s and equipment. Because of internal accounting, a group can use what amounts to a free budget resource to "buy" work. It implicitly involves government funds for research. Because both sides believed they are getting a free lunch, there was a natural pressure to have it work. Our internal buyers are now somewhat more wary since we have asked them to report on the work just as if it had been done inside. Hence, they find that they have to really invest to get the fullest benefit. For example, the Cal Tech Silicon Structures Program requires a person there and the equivalent a person within engineering plus the direct funding to work properly - which turns out to be twice as much internal spending.

In cases where we want tightly coupled, joint programs with our advanced development, there are the expected problems of having people work intimately on something and then despite contracts, believe they must tell everyone about it immediately. Untenured faculty are really caught in this dilema. When we tend to be this well coupled, then there is also the danger of dependence, despite the fact that we don't interfere on projects that are basic research. This too causes problems when the two sides are very strong because in some situations we have had to replicate the research before we can proceed with development. We do not expect product prototypes, nor should anyone. Alternatively, when we get them, we should be smart enough to accept them...and usually we aren't due to having a good transfer process!

The universities too are now more wary, but I believe they like the change from government funding because proposals are short, sometimes verbal, and we turn them around quickly. Furthermore, one can negotiate with your reviewers without the middlepersons. Once they find out that we really do expect results, they begin to plan and deliver, something that I think has been lost in much of the sponsored government research - and in the researchers who have become more and more proposal writers and forms filler-outers instead of researchers.

Enclosure

May 18, 1981

Dr. Courtland D. Perkins

President
National Academy of Engineering
2101 Constitution Avenue, N.W.
Washington, DC 20418

Dear Dr. Perkins:

As a non-participating, non-volunteer member of the Ad Hoc Committee on NAE Membership, I want no further association with AHCOM. I also regret having wasted time as Chairman of the Peer Committee last year, since the Committee on Membership completely ignored our recommendations.

AHCOM has failed at defining the problem, gathering relevant data and proposing changes that will build a stronger NAE. Instead of "business as usual", the following issues must be addressed:

- The engineers we are electing are neither relevant nor representative of current engineering. For the NAE to be effective, the criteria for election must be changed to include the engineers on the leading edge. Since peers simply do not exist for new disciplines, then we must invent a way of making sure that the composition of the various disciplines within NAE reflects the changing field. For example, power engineering has stabilized, yet we added five more engineers this year, giving an imbalance according to every conceivable measure (demographics, current production, need, patents, publications, discovery, industry size, etc.). In contrast, NO semiconductor engineers were elected!
- Our Peer Committee recommended to COM that the Electrical Engineering Committee Peer Group be renamed and reviewed for further segmentation. COM approved this, and there was no action taken. When will this be attended to?
- The process practiced at the Committee on Membership this year failed at adding high quality choices (about 20 percent), while at the same time adding marginal members (about 20 percent). Hopefully, there will never be another COM meeting this poor. The recent exchange of letters between one of our Peer Committee members, Rolf Landauer (2/18, 3/3) and COM chairman, P. L. Thibaut Brian (2/25, 3/6) illustrated the confusion in the COM meeting on:

  - the requirements for foreign associates;
  - organizational bias;
  - grand old persons versus later greater contributions;

- respect for Peer Committee deliberations;
- right of COM to overrule a Peer Committee;
- previous professional recognition;
- previous NAE nominations; and
- discipline bias.

Our peer group had operated to solicit and review a number of high quality candidates. This came about because we had been disappointed in the quality of candidates submitted the previous year. As a result, we submitted 15 exceptionally well qualified persons to the Committee on Membership. The COM

Meeting was a fiasco, barely under control and as a result the group decided that because candidate number 10 had several controversial, anonymous statements (which have been shown to be untrue) the remaining 5 candidates were also discarded. This capricious veto eliminated six persons superior to the NAE at large, clearly superior to the COM, and well above various persons voted in that day. What I saw, was a group of engineering departments voting to sustain their own power by adding members of their own discipline.

The COM must not be given the power to capriciously reject the careful work of the Peer Committee, but should only have the ability to challenge specific candidates, not draw the line at the number from a specific discipline.

In short, there must be a process which:

. projects short and long-term yearly membership quotas;
. continually segments the professions, identifying changes in engineering and delegates the quotas to the Peer Groups;
Under the proposed, basically unintelligible scheme, new professions (e.g. computer science, genetic engineering, biomedical engineering) are still extraordinary difficult to add and declining professions (e.g. nuclear, power, civil) are difficult to contract.
. sets clear, implementable requirements to regain quality; as a minimum, the professional disciplines can be used to screen for quality so that we admit only those who have achieved Fellow status AND who have at least one major professional award. The acceptable criteria (e.g. Fellowship, specific awards) would be established a priori. The requirements such as: organization, foreign associate, previous nominations, etc. must be equally very clear.
. delegates the responsiblity to Peer Committees to get candidates who will raise the NAE standards; and
. audits, NOT REJECTS, the Peer Committee recommendations before submitting the results to NAE at large.

In conclusion, unless the NAE can change to respond to the new societal issues surrounding the information based engineering disciplines, I would strongly support a complementary National Academy for Information Engineering and Science.

Is there any chance you will take an active roll in the major overhaul of the NAE?

Sincerely,

Gordon Bell

..simpler interfaces and less overlap to reduce hassle

GB9.4
Even though we've changed the nature of the company to a

startup versus a turnaround company, the operational principles we discussed, but never formalized should remain. Let me propose the first two:

1. "He who proposes, does"-- This was originated about 12 years ago by me and is used by several organizations.
2. Formal approval of plans, combined with a board (and company) who feels equally commited to and responsible for the plan.

GETTING THE PLANS

The first principle seems to be going well:

1. George's Sales/Train/Install/Service Division (we need a good name for it other than distribution) plan is going well.
2. Hydra has made a plan for delivering a high performance computer, and is clearly committed to it.

In addition, we have a number of activities aimed at getting "someone" to propose plans:

1. A product group, run by some external folks, aimed at acquiring and providing distributed system products. All the activities aimed at acquiring products will ultimately require an internal advocate to make sure that the products will work and work together.
2. Ed Fredkin's Personal Computer Products group, including accessories, servers, programs and PCs.
3. Vertical applications acquisitions group (eg. CAD). This can go very fast once we have a basic, set of distributed products.

We clearly need people who are going to propose and then implement these products for George's group.

APPROVAL OF PLANS

Hydra came forward with a product plan. I believe the product can be built along the lines (within a factor of 2) they've proposed because there are existence proofs. In constructing a most detailed agreement with the group, it must be clear that several of us believe their detailed plan can be implemented on time and within the budget.

Who's cosigning their plan in terms of specs, time and budget?

What you folks think about these principles?

SUBJECT: EVERYTHING'S IN A NAME...LET'S USE SUPERMICRO

GB5.60

SEAHORSE
The DECwest folks were concerned about the 4 digit numbering of
Seahorse. I'm less concerned about this right now because I think the
basic machine class name isn't right yet. Scorpio would be similarly
named.

In the past, it has been important to use names to help position a
product, particularly a new one. It is also very useful when

we can
become identified as the leader with that product.

Names have evolved somewhat along these lines:

```
    super
mainframe
         midi
    mini      supermini
              micro     supermicro
                pc
```

Namely, the Supermini (eg. 780) is an evolution of the mini. It does
the work the mainframe used to do, and has the large addressing.

The Supermicro is an evolution of the micro (one chip) does the work
the mini used to do, and has large addressing. It's in a new price,
package and performance class. This also puts it in a new use class.

VENUS AND NAUTILUS POSITIONING
I don't know how we should position Venus except as a mainframe. This
would please our 10/20 customers to know that we're going to build
large machines. It would also let us price higher than the 780 it was
supposed to replace, and then Nautilus could be priced lower than the
780. I don't think there's a new class name here.

We really do need a super name.
Can you folks make the change?

"TO" DISTRIBUTION:

REID BROWN BOB GLORIOSO ROY MOFFA

to product group
subject Nancy martin

Nancy called and said she'd really like to work with us, and asked:

1. Could she review the ECC business plan? (I mentioned that for the do diligence, it's sometimes customary to have outside reviews.)
2. Do we have other consulting for us.
3. How does she go about putting together a group to build some sort of AI product? She believes that she can get a group together to do something here if we want. At the same time, a very good software engineer who's VP of SW at VTI (locally) would be interested in any job that involved a significant software product.

Her timetable is to be able to make a commitment for a permanent job by the beginning of the summer. She could be part-time till then.

.

June 2, 1982

Mr. Nicholas Tzannos
Intercontinental Air Freight, Inc.
Logan International Airport
East Boston, MA 02128

Dear Mr. Tzannos:

I'm sorry, but I don't see how we can participate in this experiment at this time, since I'm unable to come up with a rationale as to why it's relevant to us. Please send us a copy of the Nasa results.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

SUBJECT: THE NATIONAL CHIPS AS MICROVAX...

BACKGROUND
On December 1, I chartered Roy Moffa to run a task force to look at the problem of being competitive in the low end. He's worked with Cutler, Husvedt, Supnick and Strecker to come up with an aggressive set of alternatives. Jeff Kalb got us to look at National, and Ward has been a helpful sponsor.

Looking at the chart of Board, Personal Computer and multi-user System products, I think we can see that there's a big price gap caused by having the large, proprietary chips of the 11 and VAX.

1. VAX products are only in the large systems space. There's no plan to get a small processor that allows us to compete with the 68,000 at the chip, board, PC .
2. The 11 products are relatively expensive. A commodity micro is needed for lower cost products at board, controller (eg. VT200) and PC levels.

For the last few years I've maintained that the only important variable of an architecture is the virtual memory size. The fact that VAX provided 32 bits is why it's great. Similarly, a 48-bit address for the System 38 is why I worry about it. The so called 16-bit and 32-bit micros are either 17-21 bits, or in the case of a 68,000 the limit is really physical memory which is only 20-22 bits worth. Therefore, none of the emerging micros are aimed at providing what VAX gives, except the National 16032 and 32032 which have copied VAX's paging scheme. Therefore all systems, including the Hitachi and HP micros are going to have the problem of address limits. Note that Appollo did a pager for the 68,000 to get around the problem.

The 8086 is the established 16-bit standard and the 68,000 is positioned to become the 32-bit standard with Motorola, Mostek and Hitachi as the suppliers. The 68,000 with 32-bit data path is coming, but the "fix" to add paging so that it can address a large memory still isn't out in the open.

I don't think we want to let the 68,000 and the 68,000 when

it
gets fixed with a 32-bit address become the sole standard.
Clearly, we can't stop them with VAX because we don't have the
design or distribution system for chips. The 11 is inadequate in
address bits. There's an important consideration of bus
standards too as the Motorola backplane is good, but not great.
The Unibus and Qbus are clearly inadequate to compete in the
microprocessor market of the 80's.

ENTER THE NATIONAL 16032/32032: MICROVAX
It looks like we have a chance of getting back in the low end
game by using the National chip and simply defining it to be
MicroVAX for the following reasons:

1. It uses the VAX data types (byte, word, floating point and
pages). Thus, all files will be VAX compatible. A higher level
program will not know the difference whether it's computing on
VAX or on National hardware.
2. There is less work in converting our software to be machine
independent than being able to get a chip of the complexity we
need for VAX. MicroVAX for PC use is about 100 man-years.
3. As we try to make higher performance machines (eg. VENUS), the
complexity of the architecture means it cost more in time and to
develop the hardware. This directly affects competitiveness. We
are wrestling with the same issue on how to build a useful
machine for DEC in Palo Alto.
4. By having portable software, VMS would get even better and
easier to maintain.
6. By being portable, and machine independent at a higher level,
we have the opportunity to make substantial changes to the
underlying architecture for extended addressing and

protection
and make sure that all today's programs will run. If done right,
we're buying future flexibility.

The task force is suggesting an aggressive offering providing the
following:

1. Chips on the Qbus to go after board business. The software
would be an extension of Pascal and MicroPower for the real time
market!
2. Chips would be place on the CT motherboard immediately to give
us the first 32-bit Personal Computer (Hardware only). Dick
Husvedt wants to put a subset of VMS, called MicroVMS, on it so
as to run VMS programs as a Personal Computer!
3. We want to drastically increase the throughput of the bus
system. Therefore, we want to work with National and establish
BI as the new standard for microprocessor interconnect.

MICROVAX, PERSONAL COMPUTER SOFTWARE
Not everything would be converted. The goal would be to let
the programming environment be the same on the two machines.
The following languages would get MicroVAX back ends: BLISS,
Fortran, (PL/1,C,Pascal,ADA... that use the PL/1 compiler),
BASIC, ... Cobol?, Visicalc.

VMS becomes MicroVMS for Personal Computing. Here, EDT,
Mail, RTL, SORT, File utilities, debugger, DCL, Linker, and
radically different Screen manager for PC. Also, Datatrieve.

CHIPS AVAILABILITY
We could get 16032 chips now, with 32 bit data width version
called 32032 in December. The path width is irrelevant to
our needs except where it affects performance. A faster part,
the 32032A is available in early 84.

NEXT STEPS
There are lots of issues with the above. In the long run it's likely to be cheaper as we move to a higher levels. In the short run, doing products we didn't expect will cost us.

Right now I believe that we ought to figure out how to do this MicroVAX, and if it still looks good, then go ahead.

What youse think?

GB3.S5.36

Gordon Bell
Vice President of Engineering, Digital Equipment Corporation
Professor of Computer Science and Electrical Engineering (on leave)
Carnegie-Mellon University

with Gwen Bell
Social Science Editor, Pergamon Press

Computers are at the center of current industrial growth because they are tools, for modern communications and manufacturing, and components of nearly every industrialized product. For example, in the automobile industry computers, are used in design, in operating the organization, in manufacturing control, and for use within the car itself. Over the last thirty years, computers have evolved at a rate more rapid than any other object in the history of civilization. But national economic policy-making still relates to industries that change very little. Effective policies for innovative, knowledge based industries have not been formulated because the key to policy-making, the computer and its constitutent technologies have not been understood.

Although the computer industry is high technology, it is also appropriate technology. Computers do not despoil environment, degrade populations, or use undo amounts of energy. Furthermore, they are critical to the development and understanding of national and local resources. Analysis of such complex issues as the proper utilization of the Amazonian forests, the control of agricultural pests, and ecological management of wildlife, depend on computational power. Without using such tools, it is easy to make wrong choices, since the full range of alternatives are not clearly understood. But, even of greater importance, is the significance of the introduction of a computer industry in order to maximize the talents of the population.

The computer on a university campus -- and a computer science department -- are becoming as central to learning and development as mathematics and physics departments. Computer science fundamentally affects all engineering, management sciences and ultimately social sciences.

In establishing a computer industry, the foundations of the new technologically based society are laid, and the development of an information-based economy can be established. Without a computer industry any country is doomed to a backward, poor economy. Fear, greed, and strong national interests have led to policies for establishment of computer industry that have had counter-intuitive effects, slowing down rather than hastening the process because assumptions have been made based on conventional instead of rapidly evolving, high technology industrialization. In order to describe appropriate policies for the development of a computer industry, the nature of computer evolution is first explained.

The Ongoing Computer Evolution

The computer has evolved more rapidly than any other man-made object as measured by improved price for a given computer or by improved performance at a given price. By either of these measures, the rate of improvement is 20 to 30 percent per year. This means that if the price of a given system at year (t) is 1.0, at year (t+1) it will be 0.8, and at (t+2), 0.64, and (t+3), 0.51. Every 3 years, the price halves. These measures have held constant for 20 years, and do not even take into account inflation. For example, in 1970 a boxed, PDP-11/20 with 4096 word memory sold for $9,300; in 1976 a large scale integrated version was introduced that sold for $1995. This price reduction amounts to a yearly price reduction of 23% compound annually. In contrast, nearly all consumer goods, such as automobiles, have increased in price at least an inflationary rate! The consumer price index and the prices of constant function computers are plotted in Fig. 1.

Computers performance has improved roughly eight orders of magnitude during the 30 years of their life. Logic and memory technology generations mark this improvement:

1. Vacuum tubes/drum, electrostatic memory 1948-1958;
2. Transistors/core memories 1958-1966;
3. Integrated circuits core memory 1966-1974;
4. Large scale integrated circuits for processor-on-a-chip computers/integrated circuit memory 1974-1980;
5. Very large scale integrated circuits 1980-

Computers not only have become all pervasive but have affected many other rapidly evolving technologies, including semiconductors, magnetic recording, conventional electronic sub-assemblies, xerography, video display, process control and conventional communications. Computers also require "software" technologies ranging from operating systems which administer computers to conventional computer languages in which application systems are written.

Computer components are ordered by what is known as levels of integration. The highest level is the application and the lowest is the physical device used to hold or process information. The structuring of the levels in Table I starting from the top applications (use) or starting from the bottom with physical devices form the basis of developing a computer industry either through backward or forward integration, respectively.

TABLE I

LEVELS OF INTEGRATION

Application software -- a particular use;

Application components library software -- generalized parts for building various applications quite often implemented as a special language (e.g. the COGO language for civil engineering design);

Basic software -- includes standard programming languages (e.g. BASIC, COBOL, FORTRAN), data management;

network, and operating system software for building any application;

Basic Hardware System -- all the hardware of the system (e.g. an IBM 370/148);

Computer Component Hardware Options -- packages of boxes or cabinets, such as disk and tape units, terminals, memories, processing units, etc.;

Printed Circuit Modules -- holders of the semiconductor circuits;

Semiconductor circuits in a single integrated circuit array package-

the smallest physical component from which the computer is formed.

Two additional concepts are important in understanding computing: architecture and implementation. Computer architecture is the interface of a machine as seen by a program or programmer, and is an important standard because it provides the user with a constant base for writing (investing in) programs; examples include the IBM 360, and the DEC PDP-11. Although there is a temptation to change the architecture to fit the technology or the application, changes in a given architecture and among several architectures produce relatively small changes (a factor of 4) in cost or performance. Most changes in architecture have occurred by having to change the amount of memory that a program is able to access. Address size (roughly corresponding to brain cavity size) is the single parameter of architecture that must be attended to, because it is the limit on how large the computer can be.

Implementation is the building of a particular computer model, (e.g. an IBM 370 Model 158) using a specific hardware technology, that operates according to the architectural standard. It is important that there be many implementations of a given architecture over a wide price range (typically 100) so that a user may select the appropriate price and performance model for a given application. In a similar fashion, it is important to implement various models of the same architecture with evolving technologies over several computer hardware generations so that user software investment and training is protected.

Since computers can supplant every other form of information processing, storage, transmission, switching, control, and processing, broad technological expertise is required. Software engineers not only must know the subject of the application (e.g. manufacturing, civil engineering, communications) deeply and unambiguously so that it can be made algorithmic but they also must know the computer almost as well. The lack of a standard architecture requires learning different machines. But with the agreement on standards, the potential for both substantive problem and computer understanding can be greater helping to overcome the current manpower shortage of software specialists currently limiting computer use.

Policy Dimensions

Nearly all governments establish policies which they feel will allow computer industries to form and thrive. There are many alternatives ways to establish a computer industry. Three important questions usually are the focus:

Who's allowed to supply computers?
How is the supplier allowed to obtain the product?
What is the supplier allowed to supply?

Although there are a wide spectrum of answers, concentration is placed on the extremes of each dimension. A total of 2 x 3 x 3 (18) alternatives are spelled out followed by scenarios of three policies.

Who's allowed to supply computers?

From a nationalistic viewpoint, the most sensitive, political and seemingly important dimension is who will be the supplier -- foreign or multinational firms, government, monopolies, and private individuals etc. From the viewpoint of the final result, this decision is relatively unimportant except as it affects the selection of the manufacturing and computer standard policy.

Government ownership of computer industries have so far been singularly unsuccessful (e.g. the Eastern Bloc), and hence not even worth considering as an alternative. The issue of whether there be local or multinational ownership also seems less important, except as it relates to limit the ability to use a particular standard. Hence, only the two extreme cases will be considered:

P1. Free market; and
P2. Government sanctioned monopoly.

In the former case, any group who is willing to live within the various governmental constraints is free to engage in the market. A free market is likely to introduce many standards, hence cummulative learning about applications standards will be minimum, unless each product is segmented into a particular application.

A government sanctioned monopolistic supplier is often given a particular market segment. Because of the complexity of computers with many components evolving at different rates, the static nature of governmental decision making to arrive at costs and prices often mean that the equipment decided upon is not only obsolete but also more costly than newer machines. The computer industry is no exception to the rule that monopolies are likely to be most costly, with the lowest rate of evolution.

How's the supplier allowed to obtain the product?

Like all organizations, countries are especially concerned with how products are obtained. The pressure to obtain state of the art products, independent of where they originate, is seen to exacerbate national balance of payments problems. The main issue is how much of a computer should be imported and then these imports could be reduced in the future.

While it is extremely important and nationalistic to believe that, de facto, a computer should be manufactured locally. Appendix 1 spells out how a strategy of local manufacture can require more imports for component parts than if a later model product were fully imported! Hence, importing finished goods is the best alternative for many countries.

Given, that local manufacture appears feasible in terms of market, manpower and capital, then either forward or backward integration can be used to evolve to full manufacture of all levels (so far only attained by U.S. and Japan). Forward integration requires a strong technology base, and for computers has been demonstrably impossible except in the U. S.

Therefore the alternatives for Manufacturing are:

M1. Import complete products;
M2. Backward integration, starting with the user application; and
M3. Forward integration, starting with components.

What is the supplier allowed to supply? (Standards and the Product)

In the section on the On Going Computer Evolution the architecture and implementation concepts that underlie the product were described. There are three alternatives describe a range of standards control:

S1. Use established, de facto "industry standards";
S2. Design and evolve a unique, indigenous vanity

architecture; and

S3. Use any product in a non-standards fashion.

In the first case, there is a wide array of hardware and software components in the marketplace that can be potentially used (i.e. bought, copied, licensed, etc.). The standards are de facto because of their strong marketplace position and as such there is an alternative source of supply to the originating organization that provided the computer. (The so called plug-compatible industry). The temptation to build a "national computer" is so great, and the results so deleterious, that this special case is described in a section below. The third case ignores the standards question and permits free use of what ever products happen to make it into the environment. It's effect is less clear because the market can structure to automatically provide "the standards" by rejecting the non-standards.

Establishing a Computer Industry via A Forward Integration Manufacturing Approach

The conventional manufacturing approach for establishing an industry usually cuts off external supply by sanctioning various firms to operate as monopolies and builds up internal manufacturing via licenses, joint ventures, and favored manufacturers. It is a "bottom up" process. Only essential components and manufacturing equipment are imported. This approach is most successful when the evolution rate is low (i.e. automobiles, tv sets, radios) or where the ultimate goal is world market domination. However, in either case, the essential first step is the manufacture of all components, raw materials, and in some cases the equipment to manufacture components. For example, the Japanese who for 25 years have had the goal to dominate in computer manufacturing, lacked the internal manufacture of critical components (e.g. semiconductors and magnetics) as well as software technology until recently.

In essence, Japan switched from forward integration to backward integration to become successful. If Japan, or any other country, starts with the goal of internal computer manufacturing to limit imports, the flow may well become increasingly more negative due to increased reliance on critical outside component and software suppliers. For example, had a country engaged in manufacturing transistorized and MSI based calculators in 1975 with imported semi-conductor components, in 1978 it would be possible to obtain the complete calculator for less than the imported component cost because with each new generation radically different parts are used. In a similar case relating to computers, more imports of raw materials occurred to build expensive disk memories and computer systems that were obsolete on completion.

Virtually every country that has operated a protected, computer industry (except recently Japan) has paid a significant price in terms of both imports and price to users. Computing with obsolete computers, costs each country scarce resources for maintainance and operations deferring critical economic and applications gains. Only the elite company owners directly benefitting from government sanctioned monopolies have profited while the country looses both technologically and economically.

Simultaneously establishing the manufacture of the critical base components, test equipment and component manufacturing equipment for a high technology product like computers is probably not

feasible. Even manufacture of the lowest technology parts (e.g., printed circuit boards) is hazardous because these components may limit the final product as described in the calculator and computer components examples above. Manufacture of high technology components depends on the existence of all levels of integration listed above it in Table I. Neither state-of-the-art (i.e. cost effective or least cost) disks nor semiconductors are manufactured away from their design groups who require fertile environments (including large, modern computers) for innovation.

Since the critical resource for the manufacture and use of computers is educated manpower, their effective allocation has to be central to any effort in establishing a computer industry. If these limited numbers are utilized for manufacture, then there are few left to do the critical systems applications jobs that are necessary in the manufacture itself. Reversing the allocation starting at the highest level of integration and working down then establishes a firm base for local manufacture.

Establishing An Industry By An Indigenous, National Vanity Design

Most attempts to design, produce and sell computers either fail to meet their market and profit objectives or fail to be cost-effective over competitive alternatives. Worse yet only a small number of computers evolve over a long term and remain viable and available such that a user's investment in software is preserved. Vanity computers designed for special purpose (e.g. Military) have been shown to be particularly cost ineffective over their standard, commercial counterparts such that the distinction is finally disappearing. Although there are mahy reasons why military computers are so poor, one clear one is the long procurement cycle that guarantees the thechnology has moved a full generation during design and negotiations.

The temptation is especially great because the art of computer design (architecture) is fascinating. By not adopting standards untold resources are required to engage in hardware and software design that could otherwise be applied to implementing computers based on standards, or be applied directly to applications.

There is virtually no chance that a computer can become a standard without a very large user base (market) and a commitment of multiple implementation over a range of price <u>and</u> time. Furthermore the architecture must be evolved in a compatible fashion to teach the technology.

An Example of A Monopoly Based on Backward Integrated, Non-Standard Compilers

The poorest method for establishing a high technology industry is by government sanctioned, local monopolistic companies. Appendix 1 describes the scenario of such a case. Here, a monopolistic company selected a high cost, non-standard, low performance basically obsolete computer for license from a North American Company that might have failed except for its exports to its foreign "licensee". The company then promised their government the following three-year, three-stage backward integration process: importing finished goods, putting together sub-assemblies, and finally building sub-assemblies from imported circuit components under license.

After five years, the local "manufacturer" was still importing finished goods, and no progress has been made toward local manufacturing. The computer was fundamentally unable to accomplish most of the tasks that were promised. The local company has a monopoly that has cost the country roughly a factor of two or $34M in imports over the promised commitment and $50M over what could have been accomplished under a policy permitting competition which would encourage local manufacture. Also, the users have paid a factor of 5.5 times or $400M extra for equipment because of the monopoly. Also, user costs including applications programming, maintenance, and operations (e.g. power and air conditioning) are several times greater for technically obsolete equipment. Certain applications are not possible, and where possible but not available, local effort has to be expanded in doing applications.

Rather than using monopolies to establish industry, government approval of imports based on the import cost would stimulate local manufacture. The incentives to all would be clear and the system would adjust rapidly! Alternatively, simple duties of any percentage, would probably work as well, avoiding bureaucracies, hassle and loss of productivity!

Establishing A Computer Industry Via A Backward Integration Manufacturing Approach Based on Industry Standards

A policy that encourages using state-of-the-art computers to be applied in a standards-setting fashion will ultimately result in appropriate local computer manufacture. The selection of widely applicable computer standards is essential, otherwise the situation is exactly what countries that do not have a computer industry fear--manufacturer domination and non-utilitarian machines.

There are four criteria to use in the selection of the de facto standards:

1. Maximum range of applicability - germane to evolving and necessary applications. Leverage of internal resources can be gained by selecting the most appropriate machine family based on application programs.

2. The conventional metrics for cost, cost/performance, and address size. A trade-off for larger address-space may offset short-term gains in cost-performance with smaller address-space.

3. Large family range of machine models from micro to mainframe. The utilization of one family versus a variety of machine-types maximizes the learning in terms of physical implementations, architecture, and software across all system ranges from the processor-on-a-chip (often called a microcomputer), through dedicated systems for special purpose use (often called a minicomputer) and to a large, shared, central system serving many users and managed by a staff (often called a mainframe). This helps achieve a critical mass of local experts.

4. Be available from numerous suppliers in a "standards-based" fashion. Ideally, each machine in a range would be the "defacto standard" machine. A de facto standard has the following characteristics: a large fraction of installed units; well-defined system interfaces that manufacturers, users, and third-party suppliers

understand; and many supply sources so that a user can build up systems by assemblying components via numerous fashions.

Countries following a standards-setting policy are assured of having the latest models available, alternative competitive sources of supply and a method of intercommunications that has lasted and will last over time since it is understood and used by many different groups. Until Japan adopted the approach of building computers to the IBM standard, its machines were uncompetitive (even in a closed market) and were ultimately withdrawn, requiring user program conversion. The backward integration path was finally followed, interfacing with many manufacturers to license computer architecture know-how and hardware technology. Ultimate success in Japan depended on five factors: an open market; use of the industry standard; selective licenses (versus licensing the non-standards); engineering near copies in a "reverse engineering" fashion; and the growth of its large internal market.

<u>The Backward Integration Steps</u> (Top Down)

It is the "standards" approach that provides the method for backward integration into local manufacturing via the following steps:

1. Import complete systems and assign them to critical applications. This will help attract back any computer scientists and engineers attracted by the charisma of exciting problems using state-of-the-art computers who have left the country in the so-called brain drain. During this period it is important to take advantage of the training systems now developed in North America, Europe, and Japan, just as the Japanese took advantage of these systems when their industry was embryonic.

2. Enlarge applications specialties to include special systems interfaces. Special hardware interfaces could be provided by users, the applications industry, and manufacturers. This would create the base knowledge for the ultimate design and manufacture of computers.

3. User and applications industry would begin to import "standard" alternative manufactured computer options (e.g., memory modules, disks, terminals) to minimize systems costs. Systems would form from components by having local final assembly and testing. By this time a critical teaching and research mass will have been reached at a significant level internally so that the appropriate computer scientists and engineers can be attracted and held. Training, research and development will be primarily nationally based, maintaining the continual need for international cross-fertilization of ideas. However, these critical nationally attained skills are necessary since many computing applications are culture-based.

4. A secondary supplier industry would develop based on both buying lower level components (e.g., integrated circuits, disk drives) and interfacing to further reduced imports. Computer options would start to be manufactured locally both based on foreign and local designs.

5. Component manufacture may be possible when the market materialize.

If a user-directed, backward integration policy were implemented, one might see the beginning of stage two within one or two years, followed rapidly by stage three. Finally local peripheral interface designs marking stage four could occur as early as four years from the time of the policy adoption. Stage five is a Function of Market Size.

During all periods the number of computers, useful local applications, and most importantly, computer scientists and engineers, who provide a strong intellectual base for the industry, would grow. Simply trying to assemble imported, likely-to-be-obsolete components with the forward integration policy defers the applications that build up a critical mass of manpower, applications, and computers.

CONCLUSION

The different approaches toward the goal of establishing a national computer industry have varying risks, costs, and benefits as clearly outlined in the appendix. The conventional approach to establishing an industry is manufacturing-directed licensing, starting with components in a bottom-up fashion and is most risky, expensive, and has been uniformly unsuccessful for computers. The ultimate goal of indigenous design following the bottom-up approach called "forward integration" is implicitly predicated on slowly evolving standard components. In contrast, for rapidly evolving or high technologies with short component life, a "top down" user-based approach, starting with the application, categorized as "backward integration" is probably best. The computer industry falls into the second category since many rapidly changing disciplines and technologies are required for building and using computers. By initiating a policy based on the second approach a country can establish an appropriate computer industry provided it is <u>based on standards</u>. It will become self-sufficient quickly, and with less imports than by taking the forward integration approach. Futhermore, it can be shown (Appendix 1) that the forward integration approach can require more component imports than a fully assembled computer because the technology evolves so rapidly!

Backward integration necessitates the selection of one or more standard computer families. However, is desirable to <u>not</u> segment and control the market by size because emerging distributed processing systems are built more easily from a single general architecture. Furthermore, since computer prices decline rapidly, a computer characterized in one class now will enter a new class in a few years. The adoption of an "industry standard" allows rapid take-off in computational ability and the selection is based on four criteria: 1) wide range of available applications programs enabling immediate effective use; 2) cost-effectiveness and expandability as shown by various metrics including address space size; 3) availability of a family range from micro- to mainframe computer so that a small number of architectures (hopefully one), maximizes training, permits alternative computing styles to fit various problems, and results in a maximum cumulative learning curve; and 4) compatibility and accessibility through numerous suppliers for peripheral equipment and software.

Appendix 1 - Case Study of Santioned Monopoly, Free Market Import and Backward Integration Strategies

In one country a sanctioned monopoly was set up to license and manufacture what was basically an obsolete computer. The following analysis of a five year period shows, in principle, the situation and compares it with scenarios based on different policies. It neglects any user loss of productivity because of poor computers, and any import duties (since the licensee was given duty free status).

Four cases are compared:

1. Monopoly (actual) - no manufacturing was achieved and licensee only imported finished goods.

2. Monopoly (plan) - the monopoly was to have imported finished goods the first year, put together sub-assemblies the second year, and assemble the sub-assemblies from components the third year.

3. Free Market Import - No controls, are assumed. The most cost-effective system is imported.

4. Free Market Import with Backward Integration - Case 3, except a policy (e.g. duties) which gives preference to minimizing import content is instituted. In the second and third year sub-assemblies are put together locally and in the fourth and fifth years sub-assemblies are built from imported components. The base design can only be changed each two years for new components!

A summary of the results of the four cases using various costs, markups, and market data is described below:

	Total Import (M$)	Local Mfg (M$)	Cost to Users
Monopoly (actual)	78.2	0	488
Monopoly (plan)	44.2	34.0	488
Free Market Import	44.1	0	88
Free Mkt Import with Mfg.	32.0	17.2	83.3

For the study, the market is assumed to grow at 50%/year using the following units: 295 (first year), 443, 666, 1000, and 1500 (fifth year).

The following markups for sales and service are assumed:

Monopoly (actual)	6.25
Monopoly (plan)	6.25
Free Market Import	2.0
Free Market, Local Assembly	2.5
Free Market Local Assembly and Sub-Assemblies (using imported components)	3.0

It is further assumed that the following local content is possible:

Importing Finished Goods	0%
Importing Sub-assemblies	25%
Importing Components	50%

Case and Price Year	Import Cost/ Unit (K$)	Total Import Cost (M$)	Local Mfg. (M$)	User Price (K$)	Total (M$)
Monopoly (actual)					
1	20	6	0	125	36.9
2	20	8.9	0	125	55.3
3	20	13.3	0	125	83.3
4	20	20	0	125	125
5	20	30	0	125	187.5
		78.2			488.
Monopoly (plan)					
1	20	6	0	125	36.9
2	15	6.6	2.3	125	55.3
3	10	6.7	6.7	125	83.3
4	10	10	10	125	125
5	10	15	15	125	187.5
		44.2	34.		488
Free Market Import					
1	20	6	0	40	11.8
2	16	7.1	0	32	14.2
3	12.8	8.5	0	25.6	17.0
4	10.2	10.2	0	20.4	20.4
5	8.2	12.3	0	16.4	24.6
		44.1	0		88.
Free Market Import With Staged (each two years) Local Manufacture					
1	20	6	0	40	11.8
2	12	5.3	1.8	30	13.3
3	12	8.0	2.7	30	20.
4	5.1	5.1	5.1	15.3	15.3
5	5.1	7.6	7.6	15.3	22.9
		32.0	17.2		83.3

Gordon Bell
Vice President of Engineering, Digital Equipment Corporation
Professor of Computer Science and Electrical Engineering (on leave)
Carnegie-Mellon University

Two highly distinct paths for establishing a national computer industry illustrate the high costs and benefits involved in achieving this goal. The most conventional approach to establishing an industry is manufacturing-directed licensing, starting with components in a bottom-up fashion. The ultimate goal of indigenous design is usually called "forward integration" of standard, components expected to have long life-times. In contrast, for rapidly evolving, or high technologies with short component life times a "top down" oriented user-based approach with the ultimate goal of indigenous design can be categorized as a "backward integration". The computer industry falls into the second category since many rapidly changing disciplines and technologies are required for building and using computers. By initiating a policy based on the second approach a country will not only rapidly establish an appropriate computer, <u>based on international standards</u>, industry but will become self-sufficient quickly, and with less imports than by taking forward integration manufacturing approach.

Backward integration necessitates the selection of one or more standard computer families and may even have a goal of establishing and indigenous architecture and programming language to further control inputs. It is desirable to <u>not</u> segment and control the market by size because emerging distributed processing systems are built more easily from a single general architecture. The adoption of an international "standard" allows rapid take-off in computational ability and is based on four criteria: 1) wide range of applications programs enabling immediate effective use; 2) cost-effectiveness and expandability as shown by various metrics and address space size; 3) availability of a family range from micro- to mainframe computer so that a small number of architectures (hopefully one), maximizes training, permits alternative computing styles to fit various problems, and results in a maximum cumulative learning curve; and 4) compatibility and accessibility through numerous sources of supply for peripheral equipment and software.

The poorest method for establishing a high technology industry is by government sanctioned, local monopolistic companies. For example, a company selected a high cost, non-standard, low performance basically obsolete computer for license from a North American that might have failed except for its exports to its foreign "licensee". This company then promised their government the following three-year, three-stage process: putting together sub-assemblies, and finally building sub-assemblies from imported circuit components under license. After five years, the local "manufacturer" was still importing finished goods, and no progress has been made toward local manufacturing. The computer was fundamentally unable to accomplish most of the tasks that were promised. The local company has a monopoly that has cost the country roughly a factor of two or $34M in balance of payments over the promised commitment and $50M over what could have been accomplished under a policy permitting competition for users and for manufacture. (See Appendix 1) Also, the users have paid a factor of 5.5 times or $400M extra for equipment because user applications, such as programming, maintenance, and operations costs (e.g. power and air conditioning) are several times greater for technically obsolete equipment. Certain applications are not possible, and where possible but not available, effort has to be expanded in doing applications.

Rather than using monopolies to establish industry, a simple policy could help establish local industry: each computer purchased would be approved by the government based on the total import cost prior to duty. The incentives to all would be clear and the system would self adjust rapidly! Alternatively, simple duties of any percentage, would work just as well, no doubt, avoiding bureaucracies, hassle and loss of productivity!

The Ongoing Computer Evolution

The computer has evolved more rapidly than any other man-made object as measured by improved price for a given component or by improved performance at a given price. By either of these measures, the rate of improvement is 20 to 30 percent per year. This means that if a given system at year (t) is 1.0, at year (t+1) it will be 0.8, and at (t+2), 0.64, and (t+3), 0.51. Every 3 years, the price halves. These measures have held constant for 20 years, and do not even take into account inflation. In contrast, nearly all consumer goods, such as automobiles, have increased in price at least an inflationary rate!

By the end of the seventies, computers have become all pervasive including many hardware technologies, some of which have necessarily evolved more rapidly than the normal rate. Major computer components are semiconductors, magnetic recording, conventional electronic sub-assemblies, various printing and xerography, video display, human speech i/o, analog i/o for process control and conventional communications. The software technologies are even broader, ranging from operating systems which administer computers to conventional computer languages in which application systems are written. Since computers can either supplement (and in some cases supplant) every other form of information processing, the almost infinite number of applications require broad technological expertise. Information processing includes all aspects of storage, transmission, switching, control, and processing. The software specialists must know the subject of the application deeply and unambiguously so that it can be made algorithmic and they must know the computer almost as well. In all fields, we continue to see manpower and training as limiting computer use.

Establishing a Computer Industry via the Forward Manufacturing Approach

The conventional manufacturing approach for establishing an industry usually cuts off external supply by sanctioning various firms to operate as monopolies and builds up internal manufacturing via licenses, joint ventures, and favored manufacturers. Only essential components and manufacturing equipment are imported. This approach is most successful when the evolution rate is low (i.e. automobiles, tv sets, radios) or where the ultimate goal is world market domination. However, in either case, the essential first step is the manufacture of all components, raw materials, and in some cases the equipment to manufacture components. For example, even though the Japanese have had the goal to dominate in computer manufacturing for 25 years, until recently they lacked the internal manufacture of critical components (e.g. semiconductors and magnetics) as well as software technology. If Japan, or any other country, starts with the goal of internal computer manufacturing to limit imports, the flow may well become increasingly more negative due to increased reliance on critical outside component and software suppliers. For example, had a country engaged in manufacturing transistorized and MSI based calculators in 1975 with imported semi-conductor components, in 1978 it would be possible to obtain the complete calculator for less than the imported component cost because with each new generation radically different parts are used. In a similar case relating to computers, more imports of raw materials occurred to build expensive disk memories and computer systems that were obsolete on completion. Purchase by??? completion date would have been cheaper since the price halves each 3 years.

Virtually every country that has operated a protected, computer industry (except recently Japan) has paid a significant price in terms of both imports and price to users. Computing with obsolete computers, has cost the country scarce resources to design, apply, and operate. This also defers economic gains of computing and facing critical applications questions. Only the government sanctioned monopolies (often owned by a few individuals) have profited!

Simultaneously establishing the manufacture of the critical base components, test equipment and component manufacturing equipment for a high technology product like computers is probably not feasible. Even manufacture of the lowest technology parts (e.g., printed circuit boards) is hazardous because these components may limit the final product as described in the calculator and computer components examples above. Manufacture of high technology components is generally not feasible because they evolve so rapidly that they do not achieve the learning curve without a significant market; require very high cost plant and equipment which is obsolete at a rapid rate: and require a highly skilled manufacturing engineering base to manage and interface with the design engineers. It's interesting to note that neither state-of-the-art (i.e. cost effectivve or least cost) disks nor semiconductors are manufactured away from their design group.

Since the critical resource for the manufacture and use of computers is educated manpower, their effective allocation has to be central to any effort in establishing a computer industry. If these limited numbers are utilized for manufacture, then there are few left to do the critical systems applications jobs. Reversing the allocation using the skilled manpower to use computers for significant and necessary tasks will lead both to a more rapid computer population and their manufacture locally.

Establishing An Industry By An Indigenous, Local Design

Most attempts to design, produce and sell computers either fail to meet their market and profit objectives or fail to be cost-effective over competitive alternatives. Many U.S. and foreign firms who at one time engaged in manufacture no longer exist in the market. Computers designed for special purpose (e.g. Military) have been shown to be particularly cost ineffective over their standard, commercial counter parts such that the distinction has finally disappeared.

While many of the scenarios described above have particularly poor effects on all aspects of an economy, a local indigenous design is likely to have the worst effect. The temptation is especially great because the art of computer design (architecture) is fascinating. By not adopting and backward integrating, untold resources are required to engage in hardware and software design that could otherwise be applied to implementing computers based on standards, or be applied directly to applications.

Establishing A Computer Industry Via the User-Directed, Backward Integration Manufacturing Approach

A policy that encourages using state-of-the-art computers to be applied in a standards-setting fashion will ultimately result in appropriate local computer manufacture. The selection of the right computer standards is essential, otherwise the situation is exactly what countries that do not have a computer industry fear--manufacturer domination.

It is interesting to note that until Japan adopted the approach of building computers to the IBM standard, its machines were uncompetitive (even in a closed market) and were ultimately withdrawn, requiring user program conversion.

The backward integration path was followed, interfacing with many manufacturers to license computer architecture know-how and hardware technology. Ultimate success occurred by an open market, by using the standard, by engineering near copies, and by its own large internal market. The standards for computer selection are:

1. Maximum range of applicability - germane to evolving applications. Leverage of internal resources can be gained by selecting the most appropriate machine family for the key range of applications.

2. Valuation balancing the conventional metrics for cost, cost/performance, and address size. A trade-off for larger address-space may offset short-term gains in cost-performance with smaller address-space.

3. Large family range of machine models from micro to mainframe. The utilization of one family versus a variety of machine-types maximizes the learning in terms of physical implementations, architecture, and software

across all system ranges from the processor-on-a-chip (often called a microcomputer), through dedicated systems for special purpose use (often called a minicomputer) and to a large, shared, central system serving many users and managed by a staff (often called a mainframe). This would help achieve a critical mass of local experts.

4. Be available from numerous suppliers in a "standards-based" fashion. Ideally, each machine in a range would be the "defacto standard" machine. A defact standard has the following characteristics: a large fraction of installed units; well-defined system interfaces that manufacturers, users, and third-party suppliers understand; and many supply sources so that a user can build up systems by assemblying components via numerous fashions.

By using a standards-setting system, one is assured of having the latest models available, alternative competitive sources of supply and a method of intercommunications that has lasted and will last over time since it is understood and used by many different groups.

It is the "standards" approach that provides the method for backward integration into local manufacturing via the following steps.

1. Import complete systems and assign them to critical applications. This will help attract back any computer scientists and engineers attracted by the charisma of exciting problems using state-of-the-art computers who have left the country in what has been called the brain drain. During this period it is important to take advantage of the training systems now developed in North America, Europe, and Japan, just as the Japanese took advantage of these systems when their industry was embryonic.

2. Enlarge applications specialties to include special systems interfaces. Special hardware interfaces could be provided by users, the applications industry, and manufacturers. This would create the base knowledge for the ultimate design and manufacture of computers.

3

. User and applications industry would begin to import "standard" alternative manufactured computer options (e.g., memory modules, disks, terminals) to minimize systems costs. Systems would form from components by having local final assembly and testing. By this time a critical teaching and research mass will have been reached at a significant level internally so that the appropriate computer scientists and engineers can be attracted and held. Training, research and development will be primarily nationally based, maintaining the continual need for international cross-fertilization of ideas. However, these critical nationally attained skills are necessary since many computing applications are culture-based.

4

. A secondary supplier industry would develop based on both buying lower level components (e.g., integrated circuits, disk drives) and interfacing to further reduced imports. Computer options would start to be manufactured locally both based on foreign and local designs.

If a user-directed policy were implemented, one might see the beginning of stage two within one or two years, followed rapidly by stage three. Finally local peripheral interface designs marking stage four could occur as early as four years from the time of the policy adoption.

During all periods the number of computers, useful local applications, and most importantly, computer scientists and engineers, who provide a strong intellectual base for the industry, would grow. Simply trying to assemble imported, likely-to-be-obsolete components with the manufacturing-based policy defers the applications that build up a critical mass of manpower, applications, and computers.

Appendix 1 - Case Study of Santioned Monopoly, Free Market Import and Backward Integration Strategies

In one country a sanctioned monopoly was set up to license and manufacture what was basically an obsolete computer. The following analysis of a five year period shows, in principle, the situation. It neglects any user loss of productivity because of poor computers, and any import duties (since the licensee was given duty free status).

Four cases are compared:

1. Monopoly (actual) - no manufacturing was achieved and licensee only imported finished goods.

2. Monopoly (plan) - the monopoly was to have imported finished goods the first year, put together sub-assemblies the second year, and assemble the sub-assemblies from components the third year.

3. Free Market Import - No controls, are assured. The most cost-effective system is imported.

4. Free Market Import with Backward Integration - Case 3, except a policy which gives preference to minimizing import content is instituted. In the second and third year sub-assemblies are put together locally and in the fourth and fifth years sub-assemblies are built from imported components. The base design can only be changed each two years for new components!

A summary of the results of the four cases using various costs, markups, and market data is described below:

	Total Import (M$)	Local Mfg (M$)	Cost to Users
Monopoly (actual)	78.2	0	488
Monopoly (plan)	44.2	34.0	488
Free Market Import	44.1	0	88
Free Mkt Import with Mfg.	32.0	17.2	83.3

For the study, the market is assured to grow at 50%/year using the following units: 295 (first year, 443, 666, 1000, and 1500 (fifth year).

The following markups for sales and service are assured:

Monopoly (actual)	6.25
Monopoly (plan)	6.25

Free Market Import	2.0
Free Market, Local Assembly	2.5
Free Market Local Assembly and Sub-Assemblies (using imported components)	3.0

It is further assured that the following local content is possible.

Importing Finished Goods	0%
Importing Sub-assemblies	25%
Importing Components	50%

Year Price (Case)	Import Cost/ Unit (K$)	Total Import Cost (M$)	Local Mfg. (M$)	User Price (K$)	Total (M$)
Monopoly (actual)					
1	20	6	0	125	36.9
2	20	8.9	0	125	55.3
3	20	13.3	0	125	83.3
4	20	20	0	125	125
5	20	30	0	125	187.5
		78.2			488.
Monopoly (plan)					
1	20	6	0	125	36.9
2	15	6.6	2.3	125	55.3
3	10	6.7	6.7	125	83.3
4	10	10	10	125	125
5	10	15	15	125	187.5
		44.2	34.		488
Free Market Import					
1	20	6	0	40	11.8
2	16	7.1	0	32	14.2
3	12.8	8.5	0	25.6	17.0
4	10.2	10.2	0	20.4	20.4
5	8.2	12.3	0	16.4	24.6
		44.1	0		88.
Free Market Import With Staged (each two years) Local Manufacture					
1	20	6	0	40	11.8

Gordon Bell
Vice President of Engineering, Digital Equipment Corporation
Professor of Computer Science and Electrical Engineering (on leave)
Carnegie-Mellon University

The many approaches toward the goal of establishing a national computer industry have varying risks, costs, and benefits. The conventional approach to establishing an industry is manufacturing-directed licensing, starting with components in a bottom-up fashion and is most risky, expsive, and has been uniformly unsuccessful for computers. The ultimate goal of indigenous design following the bottom-up approach is usually called "forward integration" is implicitly predicated on, slowly evolving standard components. In contrast, for rapidly evolving or high technologies with short component life, a "top down" user-based approach, starting with the applicator, categorized as "backward integration" is probably best. The computer industry falls into the second category since many rapidly changing disciplines and technologies are required for building and using computers. By initiating a policy based on the second approach a country can establish an appropriate computer, industry provided it is <u>based on standards</u>. It will become self-sufficient quickly, and with less imports than by taking the forward integration approach. Futhermore, it can be shown (Appendix 1) that the forward integration approach can require more component imports than a fully assembled computer because the technology evolves, so rapidly!

Backward integration necessitates the selection of one or more standard computer families and may even have a goal of establishing an indigenous architecture and programming language to further control imports. However, is desirable to <u>not</u> segment and control the market by size because emerging distributed processing systems are built more easily from a single general architecture.

Furthermore, since computer prices decline rapidly, a computer characterized in one class now will enter a new class in a few years. The adoption of an "industry standard" allows rapid take-off in computational ability and the selection is based on four criteria: 1) wide range of available applications programs enabling immediate effective use; 2) cost-effectiveness and expandability as shown by various metrics including address space size; 3) availability of a family range from micro- to mainframe computer so that a small number of architectures (hopefully one), maximizes training, permits alternative computing styles to fit various problems, and results in a maximum cumulative learning curve; and 4) compatibility and accessibility through numerous suppliers for peripheral equipment and software.

<u>A Poor Policy Example</u>

The poorest method for establishing a high technology industry is by government sanctioned, local monopolistic companies because computers evolve more rapidly than governmental decision making processes. Appendix 1 describes the scenario of such a case. Her, a monopolistic company selected a high cost, non-standard, low performance basically obsolete computer for license from a North American that might have failed except for its exports to its foreign "licensee". The company then promised their government the following three-year, three-stage backward integration process: importing finished goods, putting together sub-assemblies, and finally building sub-assemblies from imported circuit components under license. After five years, the local "manufacturer" was still importing finished goods, and no progress has been made toward local manufacturing. The computer was fundamentally unable to accomplish most of the tasks that were promised. The local company has a monopoly that has cost the country roughly a factor of two or $34M in imports over the promised commitment and $50M over what could have been accomplished under a policy permitting competition which would encourage local manufacture.   Also, the users have paid a factor of 5.5 times or $400M extra for equipment. Also, user costs including applications programming, maintenance, and operations (e.g. power and air conditioning) are several times greater for technically obsolete equipment. Certain applications are not possible, and where possible but not available, local effort has to be expanded in doing applications.

Rather than using monopolies to establish industry, government approval of imports based on the import cost would stimualte local manufacture. The incentives to all would be clear and the system would adjust rapidly! Alternatively, simple duties of any percentage, would probably work as well, avoiding bureaucracies, hassle and loss of productivity!

The Ongoing Computer Evolution

The computer has evolved more rapidly than any other man-made object as measured by improved price for a given component or by improved performance at a given price. By either of these measures, the rate of improvement is 20 to 30 percent per year. This means that if the price of a given system at year (t) is 1.0, at year (t+1) it will be 0.8, and at (t+2), 0.64, and (t+3), 0.51. Every 3 years, the price halves. These measures have held constant for 20 years, and do not even take into account inflation. For example, in 1970 a boxed, PDP-11/20 with 4096 word memory sold for $9,300; in 1976 a large scale integrated version was introduced that sold for $1995. This price reduction amounts to a yearly price reduction of 23% compound annually. In contrast, nearly all consumer goods, such as automobiles, have increased in price at least an inflationary rate! The consumer price index and the prices of constant function computers are plotted in Fig. 1.

By the end of the seventies, computers have become all pervasive built on many hardware technologies, some of which have necessarily evolve very rapidly. Major computer components are semiconductors, magnetic recording, conventional electronic sub-assemblies, various printing and xerography, video display, human speech i/o, analog i/o for process control and conventional communications. The software technologies are even broader, ranging from operating systems which administer computers to conventional computer languages in which application systems are written.
These components are arranged in what appears to be a hierarchy which we refer to as the levels of integration. The highest level is the application and the lowest is the physical device used to hold or process information. It is the structuring of the following levels either starting from the top applicaion (use) or starting from the bottom or device phenomenon, that form the basis of either the backward or forward integration manufacturing alternatives described above. The levels of integration are:

Application software- particular instance of use

Application components library software- parts for building an application

Basic software- includes standard programming languages, data management,
network, and operating system software for building any application

Basic Hardware System- all the hardware of the system

Computer Component Hardware Options- packages of boxes or cabinets, such as
disk and tape units, terminals, memories, processing units, etc.
Printed Circuit Modules- holders of the semiconductor circuits
Semiconductor circuits in a single integrated circuit array package-
the smallest physical component from which the computer is formed

Two additional concepts are important in understanding computing: architecture and implementation. Computer architecture is the interface of a machine as seen by a program or programmer, and is an important standard because it provides the user with a constant base for writing (investing in) programs, examples include the IBM 360, and the DEC PDP-11. Although there is a temptation to change the architecture to fit the technology or the application, changes in a given architecture and among several architectures produce relatively small changes (a factor of 4) in cost or performance. Most changes in architecture have occurred by having to change the amount of memory that a program is able to access. Address size (roughly corresponding to brain cavity size) is the single parameter of architecture that must be attended to, because it is the limit on how large the computer can be.

Implementation is the building of a particular computer model, (e.g. an IBM 370 Model 158) using a specific hardware technology, that operates according to the architectural standard. It is important that there be many implementations of a given architecture over a wide price range (typically 100) so that a user may select the appropriate price and performance model for a given application. In a similar fashion, it is important to implement various models of the same architecture with evolving technologies over a long time period so that user software investment and training is protected.

Since computers can either supplement (and in some cases supplant) every other form of information processing, the almost infinite number of applications require broad technological expertise. Information processing includes all aspects of storage, transmission, switching, control, and processing. The software specialists must know the subject of the application deeply and unambiguously so that it can be made algorithmic and they must know the computer almost as well. Currently, these specialists appear to be the limit of computer use.

Policy Dimensions

Nearly all governments establish policies which they feel will allow computer industries to form and thrive. There are many alternatives ways to establish a computer industry. Rather than ennumerating all the alternative policies, the three important dimensions are control: of supplier-market, manufacturing, and architecture (i.e. standards). Roughly speaking, these are: Who's allowed to supply computers; How is the supplier allowed to obtain the product; and What is the supplier allowed to supply. Atlhough there are hundreds of alternatives for each dimension, we only concentrate on two or three, for each of the three dimensions, giving a total of 2 x 3 x 3 (18) basic alternatives. Of these, somee cases will be discussed in detail following a discussion of the three dimensions.

Who's allowed to supply computers?

From a nationalistic viewpoint, this is the most sensitive, political and seemingly important dimension. It is involved in attitudes toward foreign and multinational firms, government and private ownership, etc. However, from the viewpoint of the final result, it is a relatively unimportant decision except as it affects the selection of the manufacturing and computer standard policy.

Government ownership of computer industries have so far been singularly unsuccessful (e.g. the Eastern Bloc), and hence not even worth considering as an alternative. The issue of whether there be local or multinational ownership also seems less important, except as it relates to limit the ability to use a particular standard. Hence, only the two extreme cases will be considered:

1. Free market; and
2. Government sanctioned monopoly.

In the former case, any group who is willing to live within the various governmental constraints is free to engage in the market.

A free market is likely to introduce many standards, hence cummulative learning about applications standards to be minimum. In the later case, by some process, the government sanctions a particular organzation to be the monopolistic supplier usually to a particular market segment. The computer is no exception to the rule that monopolies are likely to be most costly: in addition, the complexity of the product clouds attempts to understand cost.

<u>How's the supplier allowed to obtain the product?</u>

Like all organizations, countries are especially concerned with how products are obtained because of the pressure to get state of the art products, independent of where they originate and hence exacerbate their balance of payments problem. Thus, the main issue is how much of a computer should be imported and then how to reduce the imports.

While it is extremely important and nationalistic to believe that, de facto, a computer should be manufactured locally, Appendix 1 shown here a strategy of local manufacture can require more imports for component parts than if a later model product were fully imported! Hence, importing finished goods is the best alternative for many countries.

Given, that local manufacture appears feasible in terms of market, manpower and capital, then either forward or backward integration can be used to evolve to full manufacture (so far only attained by U.S. and Japan). Integration requires a strong technology base, and for computers has been demonstrably impossible except in the U. S.

Therefore the alternatives for Manufacturing are:

1. Import complete products;
2. Backward integrate, starting with the user application; and
3. Forward integrate, starting with components.

<u>What is the supplier allowed to supply? (Standards and the Product)</u>

In the section on the On Going Computer Evolution the architecture and implementation concepts that underlie the product were described. There are three alternatives describe a range standards control:

1. Use established, de facto "industry standards";
2. Design and evolve a unique, indigenous vanity architecture; and
3. Use any product in a non-standards fashion.

In the first case, there is a wide array of hardware and software components in the marketplace that can be potentially used (i.e. bought, copied, licensed, etc.). The standards are de facto because of their strong marketplace position and as such there is an alternative source of supply to the originating organization that provided the computer. (The so called plug-compatible industry). The temptation to build a "national computer" is so great, and the results so deleterious, that this special case is described in a secion below. The third case ignores the standards question and permits free use of what ever products happen to make it into the environment. It's effect is less clear because the market can structure to automatically provide "the standards".

Establishing a Computer Industry via the Forward Manufacturing Approach

The conventional manufacturing approach for establishing an industry usually cuts off external supply by sanctioning various firms to operate as monopolies and builds up internal manufacturing via licenses, joint ventures, and favored manufacturers. Only essential components and manufacturing equipment are imported. This approach is most successful when the evolution rate is low (i.e. automobiles, tv sets, radios) or where the ultimate goal is world market domination. However, in either case, the essential first step is the manufacture of all components, raw materials, and in some cases the equipment to manufacture components. For example, even though the Japanese have had the goal to dominate in computer manufacturing for 25 years, until recently they lacked the internal manufacture of critical components (e.g. semiconductors and magnetics) as well as software technology.

In essence, Japan switched from forward integration to backward integration to become successful. If Japan, or any other country, starts with the goal of internal computer manufacturing to limit imports, the flow may well become increasingly more negative due to increased reliance on critical outside component and software suppliers. For example, had a country engaged in manufacturing transistorized and MSI based calculators in 1975 with imported semi-conductor components, in 1978 it would be possible to obtain the complete calculator for less than the imported component cost because with each new generation radically different parts are used. In a similar case relating to computers, more imports of raw materials occurred to build expensive disk memories and computer systems that were obsolete on completion.

Virtually every country that has operated a protected, computer industry (except recently Japan) has paid a significant price in terms of both imports and price to users. Computing with obsolete computers, costs each country scarce resources to design, apply, and operate. This also defers economic gains of computing and facing critical applications questions. Only the government sanctioned monopolies (often owned by a few individuals) have profited!

Simultaneously establishing the manufacture of the critical base components, test equipment and component manufacturing equipment for a high technology product like computers is probably not

feasible. Even manufacture of the lowest technology parts (e.g., printed circuit boards) is hazardous because these components may limit the final product as described in the calculator and computer components examples above. Manufacture of high technology components is generally not feasible because they evolve so rapidly that they do not achieve the learning curve without a significant market; require very high cost plant and equipment which is obsolete at a rapid rate; and require a highly skilled manufacturing engineering base to manage and interface with the design engineers. It's interesting to note that neither state-of-the-art (i.e. cost effective or least cost) disks nor semiconductors are manufactured away from their design group.

Since the critical resource for the manufacture and use of computers is educated manpower, their effective allocation has to be central to any effort in establishing a computer industry. If these limited numbers are utilized for manufacture, then there are few left to do the critical systems applications jobs. Reversing the allocation using the skilled manpower to use computers for significant and necessary tasks will lead both to a more rapid computer population, the basis for establishing local manufacture.

Establishing An Industry By An Indigenous, National Vanity Design

Most attempts to design, produce and sell computers either fail to meet their market and profit objectives or fail to be cost-effective over competitive alternatives. Many U.S. and foreign firms who at one time engaged in manufacture no longer exist in the market. Vanity computers designed for special purpose (e.g. Military) have been shown to be particularly cost ineffective over their standard, commercial counterparts such that the distinction has finally disappeared.

While many of the scenarios described above have particularly poor effects on all aspects of an economy, a local indigenous design is likely to have the worst effect. The temptation is especially great because the art of computer design (architecture) is fascinating. By not adopting standards and backward integrating, untold resources are required to engage in hardware and software design that could otherwise be applied to implementing computers based on standards, or be applied directly to applications.

Establishing A Computer Industry Via the User-Directed, Backward Integration Manufacturing Approach Based on Industry Standards

A policy that encourages using state-of-the-art computers to be applied in a standards-setting fashion will ultimately result in appropriate local computer manufacture. The selection of the right computer standards is essential, otherwise the situation is exactly what countries that do not have a computer industry fear--manufacturer domination and lack of the right standards.

It is interesting to note that until Japan adopted the approach of building computers to the IBM standard, its machines were uncompetitive (even in a closed market) and were ultimately withdrawn, requiring user program conversion. The backward integration path was finally followed, interfacing with many manufacturers to license computer architecture know-how and hardware technology. Ultimate success occurred by an open market, by using the industry standard, by engineering near copies, and by its own large internal market.

The selection criteria for industry standards

There are four criteria to use in the selection of the de facto standards. The first relates to the available investment of software which is very analogous to a balance sheet. The second is the goodness of the architectural standard while the third deals with the implementation range. Finally the fourth, verifies that the standard is real in the marketplace by having multiple suppliers.

1. Maximum range of applicability - germane to evolving applications. Leverage of internal resources can be gained by selecting the most appropriate machine family based on application programs.

2. The conventional metrics for cost, cost/performance, and address size. A trade-off for larger address-space may offset short-term gains in cost-performance with smaller address-space.

3. Large family range of machine models from micro to mainframe. The utilization of one family versus a

variety of machine-types maximizes the learning in terms of physical implementations, architecture, and software across all system ranges from the processor-on-a-chip (often called a microcomputer), through dedicated systems for special purpose use (often called a minicomputer) and to a large, shared, central system serving many users and managed by a staff (often called a mainframe). This helps achieve a critical mass of local experts.

4. Be available from numerous suppliers in a "standards-based" fashion. Ideally, each machine in a range would be the "defacto standard" machine. A de facto standard has the following characteristics: a large fraction of installed units; well-defined system interfaces that manufacturers, users, and third-party suppliers understand; and many supply sources so that a user can build up systems by assemblying components via numerous fashions.

By using a standards-setting system, one is assured of having the latest models available, alternative competitive sources of supply and a method of intercommunications that has lasted and will last over time since it is understood and used by many different groups.

The Backward Integration Steps

It is the "standards" approach that provides the method for backward integration into local manufacturing via the following steps:

1. Import complete systems and assign them to critical applications. This will help attract back any computer scientists and engineers attracted by the charisma of exciting problems using state-of-the-art computers who have left the country in what has been called the brain drain. During this period it is important to take advantage of the training systems now developed in North America, Europe, and Japan, just as the Japanese took advantage of these systems when their industry was embryonic.

2. Enlarge applications specialties to include special systems interfaces. Special hardware interfaces could be provided by users, the applications industry, and manufacturers. This would create the base knowledge for the ultimate design and manufacture of computers.

3. User and applications industry would begin to import "standard" alternative manufactured computer options (e.g., memory modules, disks, terminals) to minimize systems costs. Systems would form from components by having local final assembly and testing. By this time a critical teaching and research mass will have been reached at a significant level internally so that the appropriate computer scientists and engineers can be attracted and held. Training, research and development will be primarily nationally based, maintaining the continual need for international cross-fertilization of ideas. However, these critical nationally attained skills are necessary since many computing applications are culture-based.

4. A secondary supplier industry would develop based on both buying lower level components (e.g., integrated circuits, disk drives) and interfacing to further reduced imports. Computer options would start to be manufactured locally both based on foreign and local designs.

If a user-directed, backward integration policy were implemented, one might see the beginning of stage two within one or two years, followed rapidly by stage three. Finally local peripheral interface designs marking stage four could occur as early as four years from the time of the policy adoption.

During all periods the number of computers, useful local applications, and most importantly, computer scientists and engineers, who provide a strong intellectual base for the industry, would grow. Simply trying to assemble imported, likely-to-be-obsolete components with the forward integration policy defers the applications that build up a critical mass of manpower, applications, and computers.

Appendix 1 - Case Study of Santioned Monopoly, Free Market Import and Backward Integration Strategies

In one country a sanctioned monopoly was set up to license and manufacture what was basically an obsolete computer. The following analysis of a five year period shows, in principle, the situation and compares it with scenarios based on different policies. It neglects any user loss of productivity because of poor computers, and any import duties (since the licensee was given duty free status).

Four cases are compared:

1. Monopoly (actual) - no manufacturing was achieved and licensee only imported finished goods.

2. Monopoly (plan) - the monopoly was to have imported finished goods the first year, put together sub-assemblies the second year, and assemble the sub-assemblies from components the third year.

3. Free Market Import - No controls, are assumed. The most cost-effective system is imported.

4. Free Market Import with Backward Integration - Case 3, except a policy (e.g. duties) which gives preference to minimizing import content is instituted. In the second and third year sub-assemblies are put together locally and in the fourth and fifth years sub-assemblies are built from imported components. The base design can only be changed each two years for new components!

A summary of the results of the four cases using various costs, markups, and market data is described below:

	Total Import (M$)	Local Mfg (M$)	Cost to Users
Monopoly (actual)	78.2	0	488
Monopoly (plan)	44.2	34.0	488
Free Market Import	44.1	0	88
Free Mkt Import with Mfg.	32.0	17.2	83.3

For the study, the market is assumed to grow at 50%/year using the following units: 295 (first year), 443, 666, 1000, and 1500 (fifth year).

The following markups for sales and service are assumed:

Monopoly (actual)	6.25
Monopoly (plan)	6.25
Free Market Import	2.0
Free Market, Local Assembly	2.5
Free Market Local Assembly and Sub-Assemblies (using imported components)	3.0

It is further assumed that the following local content is possible:

Importing Finished Goods	0%
Importing Sub-assemblies	25%
Importing Components	50%

Case and Price Year	Import Cost/ Unit (K$)	Total Import Cost (M$)	Local Mfg. (M$)	User Price (K$)	Total (M$)
Monopoly (actual)					
1	20	6	0	125	36.9
2	20	8.9	0	125	55.3
3	20	13.3	0	125	83.3

PAPER1/8

Gordon Bell
Vice President of Engineering, Digital Equipment Corporation
Professor of Computer Science and Electrical Engineering (on leave)
Carnegie-Mellon University

Computers are at the center of current industrial growth because they are tools, for modern communications and manufacturing, and components of nearly every industrialized product. For example, in the automobile industry computers, are used in design, in corporate control, in manufacturing control, and used in the car itself. National economic policy making still relates to slowly evolving energy- and materials-based industries characteristic of the past rather than rapidly evolving technology. Effective policies for innovative, knowledge based industries have not been formulated because the key to policy-making, the computer itself has not been understood.

In establishing a computer industry, the foundations of the new technologically based society are laid, and the development of an information-based economy can be established. Without a computer industry any country is doomed to a backward, poor economy. Fear, greed, and strong national interests have led to policies for establishment of computer industry that have had counter-intuitive effects, slowing down rather than hastening the process because assumptions have been made based on conventional instead of rapidly evolving, high technology industrialization. In order to describe appropriate policies for the development of a computer industry, the nature of computer evolution is first explained.

The Ongoing Computer Evolution

The computer has evolved more rapidly than any other man-made object as measured by improved price for a given computer or by improved performance at a given price. By either of these measures, the rate of improvement is 20 to 30 percent per year. This means that if the price of a given system at year (t) is 1.0, at year (t+1) it will be 0.8, and at (t+2), 0.64, and (t+3), 0.51. Every 3 years, the price halves. These measures have held constant for 20 years, and do not even take into account inflation. For example, in 1970 a boxed, PDP-11/20 with 4096 word memory sold for $9,300; in 1976 a large scale integrated version was introduced that sold for $1995. This price reduction amounts to a yearly price reduction of 23% compound annually. In contrast, nearly all consumer goods, such as automobiles, have increased in price at least an inflationary rate! The consumer price index and the prices of constant function computers are plotted in Fig. 1.

Computers performance has improved roughly eight orders of magnitude during the 30 years of their life. Logic and memory technology generations mark this improvement:

1. Vacuum tubes/drum, electrostatic memory 1948-1958;
2. Transistors/core memories 1958-1966;
3. Integrated circuits core memory 1966-1974;
4. Large scale integrated circuits for processor-on-a-chip computers/integrated circuit memory 1974-1980;
5. Very large scale integrated circuits 1980-

Computers not only have become all pervasive but have affected many other rapidly evolving technologies, including semiconductors, magnetic recording, conventional electronic sub-assemblies, xerography, video display, process control and conventional communications. Computers also require "software" technologies ranging from operating systems which administer computers to conventional computer languages in which application systems are written.

Computer components are ordered by what is known as levels of integration. The highest level is the application and the lowest is the physical device used to hold or process information. The structuring of the levels in Table I starting from the top applications (use) or starting from the bottom with physical devices form the basis of developing a computer industry either through backward or forward integration, respectively.

TABLE I

LEVELS OF INTEGRATION

Application software -- a particular use;

Application components library software -- generalized parts for building various applications quite often implemented as a special language (e.g. COGO for civil engineering);

Basic software -- includes standard programming languages (e.g. BASIC, COBOL, FORTRAN) data management, network, and operating system software for building any application;

Basic Hardware System -- all the hardware of the system (e.g. an IBM 370/148);

Computer Component Hardware Options -- packages of boxes or cabinets, such as disk and tape units, terminals, memories, processing units, etc.;

Printed Circuit Modules -- holders of the semiconductor circuits;

Semiconductor circuits in a single integrated circuit array package- the smallest physical component from which the computer is formed.

Two additional concepts are important in understanding computing: architecture and implementation. Computer architecture is the interface of a machine as seen by a program or programmer, and is an important standard because it provides the user with a constant base for writing (investing in) programs, examples include the IBM 360, and the DEC PDP-11. Although there is a temptation to change the architecture to fit the technology or the application, changes in a given architecture and among several architectures produce relatively small changes (a factor of 4) in cost or performance. Most changes in architecture have occurred by having to change the amount of memory that a program is able to access. Address size (roughly corresponding to brain cavity size) is the single parameter of architecture that must be attended to, because it is the limit on how large the computer can be.

Implementation is the building of a particular computer model, (e.g. an IBM 370 Model 158) using a specific hardware technology, that operates according to the architectural standard. It is important that there be many implementations of a given architecture over a wide price range (typically 100) so that a user may select the appropriate price and performance model for a given application. In a similar fashion, it is important to implement various models of the same architecture with evolving technologies over several computer hardware generations so that user software investment and training is protected.

Since computers can supplant every other form of information processing, storage, transmission, switching, control, and processing, broad technological expertise is required. Software engineers not only must know the subject of the application (e.g. manufacturing, civil engineering, communications) deeply and unambiguously so that it can be made algorithmic but they also must know the computer almost as well. (Flush?) The lack of standard architecture in the past, placed the emphasis on learning different machines. But with the agreement on standards, the potential for both substantive problem and computer understanding can be greater helping to overcome the current manpower shortage of software specialists currently limiting computer use.

Policy Dimensions

Nearly all governments establish policies which they feel will allow computer industries to form and thrive. There are many alternatives ways to establish a computer industry. Three important questions usually are the focus:

Who's allowed to supply computers?
How is the supplier allowed to obtain the product?
What is the supplier allowed to supply?

Although there are a wide spectrum of answers, concentration is placed on the extremes of each dimension. A total of 2 x 3 x 3 (18) alternatives are spelled out followed by scenarios of three policies.

Who's allowed to supply computers?

From a nationalistic viewpoint, the most sensitive, political and seemingly important dimension is who will be the supplier -- foreign or multinational firms, government, monopolies, and private individuals etc. From the viewpoint of the final result, this decision is relatively unimportant except as it affects the selection of the manufacturing and computer standard policy.

Government ownership of computer industries have so far been singularly unsuccessful (e.g. the Eastern Bloc), and hence not even worth considering as an alternative. The issue of whether there be local or multinational ownership also seems less important, except as it relates to limit the ability to use a particular standard. Hence, only the two extreme cases will be considered:

P1. Free market; and
P2. Government sanctioned monopoly.

In the former case, any group who is willing to live within the various governmental constraints is free to engage in the market. A free market is likely to introduce many standards, hence cummulative learning about applications standards to be minimum.

A government sanctioned monopolistic supplier is often given a particular market segment. Because of the complexity of computers with many components evolving at different rates, the static nature of governmental decision making to arrive at costs and prices often mean that the equipment decided upon is not only obsolete but also more costly than newer machines. The computer industry is no exception to the rule that monopolies are likely to be most costly.

How's the supplier allowed to obtain the product?

Like all organizations, countries are especially concerned with how products are obtained. The pressure to obtain state of the art products, independent of where they originate, is seen to exacerbate national balance of payments problems. The main issue is how much of a computer should be imported and then these imports could be reduced in the future.

While it is extremely important and nationalistic to believe that, de facto, a computer should be manufactured locally, Appendix 1 spells out how a strategy of local manufacture can require more imports for component parts than if a later model product were fully imported! Hence, importing finished goods is the best alternative for many countries.

Given, that local manufacture appears feasible in terms of market, manpower and capital, then either forward or backward integration can be used to evolve to full manufacture of all levels (so far only attained by U.S. and Japan). Forward integration requires a strong technology base, and for computers has been demonstrably impossible except in the U. S.

Therefore the alternatives for Manufacturing are:

M1. Import complete products;

M2. Backward integration, starting with the user application; and

M3. Forward integration, starting with components.

What is the supplier allowed to supply? (Standards and the Product)

In the section on the On Going Computer Evolution the architecture and implementation concepts that underlie the product were described. There are three alternatives describe a range of standards control:

S1. Use established, de facto "industry standards";

S2. Design and evolve a unique, indigenous vanity architecture; and

S3. Use any product in a non-standards fashion.

In the first case, there is a wide array of hardware and software components in the marketplace that can be potentially used (i.e. bought, copied, licensed, etc.). The standards are de facto because of their strong marketplace position and as such there is an alternative source of supply to the originating organization that provided the computer. (The so called plug-compatible industry). The temptation to build a "national computer" is so great, and the results so deleterious, that this special case is described in a section below. The third case ignores the standards question and permits free use of what ever products happen to make it into the environment. It's effect is less clear because the market can structure to automatically provide "the standards" by rejecting the non-standards.

Establishing a Computer Industry via A Forward Integration Manufacturing Approach

The conventional manufacturing approach for establishing an industry usually cuts off external supply by sanctioning various firms to operate as monopolies and builds up internal manufacturing via licenses, joint ventures, and favored manufacturers. Only essential components and manufacturing equipment are imported. This approach is most successful when the evolution rate is low (i.e. automobiles, tv sets, radios) or where the ultimate goal is world market domination. However, in either case, the essential first step is the manufacture of all components, raw materials, and in some cases the equipment to manufacture components. For example, the Japanese who for 25 years have had the goal to dominate in computer manufacturing, lacked the internal manufacture of critical components (e.g. semiconductors and magnetics) as well as software technology until recently.

In essence, Japan switched from forward integration to backward integration to become successful. If Japan, or any other country, starts with the goal of internal computer manufacturing to limit imports, the flow may well become increasingly more negative due to increased reliance on critical outside component and software suppliers. For example, had a country engaged in manufacturing transistorized and MSI based calculators in 1975 with imported semi-conductor components, in 1978 it would be possible to obtain the complete calculator for less than the imported component cost because with each new generation radically different parts are used. In a similar case relating to computers, more imports of raw materials occurred to build expensive disk memories and computer systems that were obsolete on completion.

Virtually every country that has operated a protected, computer industry (except recently Japan) has paid a significant price in terms of both imports and price to users. Computing with obsolete computers, costs each country scarce resources for maintainance and operations deferring critical economic and applications gains. Only the elite directly benefitting from government sanctioned monopolies have profited while the country looses both technologically and economically.

Simultaneously establishing the manufacture of the critical base components, test equipment and component manufacturing equipment for a high technology product like computers is probably not

feasible. Even manufacture of the lowest technology parts (e.g., printed circuit boards) is hazardous because these components may limit the final product as described in the calculator and computer components examples above. Manufacture of high technology components depends on the existence of all levels of integration listed above it in Table I. Neither state-of-the-art (i.e. cost effective or least cost) disks nor semiconductors are manufactured away from their design groups who require fertile environments (including large, modern computers) for innovation.

Since the critical resource for the manufacture and use of computers is educated manpower, their effective allocation has to be central to any effort in establishing a computer industry. If these limited numbers are utilized for manufacture, then there are few left to do the critical systems applications jobs that are necessary in the manufacture itself. Reversing the allocation starting at the highest level of integration and working down then establishes a firm base for local manufacture.

Establishing An Industry By An Indigenous, National Vanity Design

Most attempts to design, produce and sell computers either fail to meet their market and profit objectives or fail to be cost-effective over competitive alternatives. Worse yet only a small number of computers evolve over a long term and remain viable and available such that a user's investment in software is preserved. Vanity computers designed for special purpose (e.g. Military) have been shown to be particularly cost ineffective over their standard, commercial counterparts such that the distinction is finally disappearing.

The temptation is especially great because the art of computer design (architecture) is fascinating. By not adopting standards untold resources are required to engage in hardware and software design that could otherwise be applied to implementing computers based on standards, or be applied directly to applications.

There is virtually no chance that a computer can become a standard without a very large user base and multiple implementation over a range of price and time.

An Example of A Monopoly Based on Backward Integrated, Non-Standard Compilers

The poorest method for establishing a high technology industry is by government sanctioned, local monopolistic companies. Appendix

1 describes the scenario of such a case. Here, a monopolistic company selected a high cost, non-standard, low performance basically obsolete computer for license from a North American Company that might have failed except for its exports to its foreign "licensee". The company then promised their government the following three-year, three-stage backward integration process: importing finished goods, putting together sub-assemblies, and finally building sub-assemblies from imported circuit components under license.

After five years, the local "manufacturer" was still importing finished goods, and no progress has been made toward local manufacturing. The computer was fundamentally unable to accomplish most of the tasks that were promised. The local company has a monopoly that has cost the country roughly a factor of two or $34M in imports over the promised commitment and $50M over what could have been accomplished under a policy permitting competition which would encourage local manufacture. Also, the users have paid a factor of 5.5 times or $400M extra for equipment. Also, user costs including applications programming, maintenance, and operations (e.g. power and air conditioning) are several times greater for technically obsolete equipment. Certain applications are not possible, and where possible but not available, local effort has to be expanded in doing applications.

Rather than using monopolies to establish industry, government approval of imports based on the import cost would stimulate local manufacture. The incentives to all would be clear and the system would adjust rapidly! Alternatively, simple duties of any percentage, would probably work as well, avoiding bureaucracies, hassle and loss of productivity!

Establishing A Computer Industry Via A Backward Integration Manufacturing Approach Based on Industry Standards

A policy that encourages using state-of-the-art computers to be applied in a standards-setting fashion will ultimately result in appropriate local computer manufacture. The selection of widely applicable computer standards is essential, otherwise the situation is exactly what countries that do not have a computer industry fear--manufacturer domination and non-utilitarian machines.

There are four criteria to use in the selection of the de facto standards:

1. Maximum range of applicability - germane to evolving applications. Leverage of internal resources can be gained by selecting the most appropriate machine family based on application programs.

2. The conventional metrics for cost, cost/performance, and address size. A trade-off for larger address-space may offset short-term gains in cost-performance with smaller address-space.

3. Large family range of machine models from micro to mainframe. The utilization of one family versus a variety of machine-types maximizes the learning in terms of physical implementations, architecture, and software across all system ranges from the processor-on-a-chip (often called a microcomputer), through dedicated systems for special purpose use (often called a minicomputer) and to a large, shared, central system serving many users and managed by a staff (often called a mainframe). This helps achieve a critical mass of local experts.

4. Be available from numerous suppliers in a "standards-based" fashion. Ideally, each machine in a range would be the "defacto standard" machine. A de facto standard has the following characteristics: a large fraction of installed units; well-defined system interfaces that manufacturers, users, and third-party suppliers understand; and many supply sources so that a user can

build up systems by assemblying components via numerous fashions.

Countries following a standards-setting policy are assured of having the latest models available, alternative competitive sources of supply and a method of intercommunications that has lasted and will last over time since it is understood and used by many different groups. Until Japan adopted the approach of building computers to the IBM standard, its machines were uncompetitive (even in a closed market) and were ultimately withdrawn, requiring user program conversion. The backward integration path was finally followed, interfacing with many manufacturers to license computer architecture know-how and hardware technology. Ultimate success depended on five factors: an open market; use of the industry standard; selective licenses (versus licensing the non-standards); engineering near copies in a "reverse engineering" fashion; and the growth of its large internal market.

The Backward Integration Steps

It is the "standards" approach that provides the method for backward integration into local manufacturing via the following steps:

1. Import complete systems and assign them to critical applications. This will help attract back any computer scientists and engineers attracted by the charisma of exciting problems using state-of-the-art computers who have left the country in what has been called the brain drain. During this period it is important to take advantage of the training systems now developed in North America, Europe, and Japan, just as the Japanese took advantage of these systems when their industry was embryonic.

2. Enlarge applications specialties to include special systems interfaces. Special hardware interfaces could be provided by users, the applications industry, and manufacturers. This would create the base knowledge for the ultimate design and manufacture of computers.

3. User and applications industry would begin to import "standard" alternative manufactured computer options (e.g., memory modules, disks, terminals) to minimize systems costs. Systems would form from components by having local final assembly and testing. By this time a critical teaching and research mass will have been reached at a significant level internally so that the appropriate computer scientists and engineers can be attracted and held. Training, research and development will be primarily nationally based, maintaining the continual need for international cross-fertilization of ideas. However, these critical nationally attained skills are necessary since many computing applications are culture-based.

4. A secondary supplier industry would develop based on both buying lower level components (e.g., integrated circuits, disk drives) and interfacing to further reduced imports. Computer options would start to be manufactured locally both based on foreign and local designs.

5. Component manufacture may be possible when the market materialize.

If a user-directed, backward integration policy were implemented, one might see the beginning of stage two within one or two years, followed rapidly by stage three. Finally local peripheral interface designs marking stage four could occur as early as four years from the time of the policy adoption. Stage five is a Function of Market Size.

During all periods the number of computers, useful local applications, and most importantly, computer scientists and engineers, who provide a strong intellectual base for the industry, would grow. Simply trying to assemble imported, likely-to-be-obsolete components with the forward integration policy defers the applications that build up a critical mass of manpower, applications, and computers.

CONCLUSION

The different approaches toward the goal of establishing a national computer industry have varying risks, costs, and benefits as clearly outlined in the appendix. The conventional approach to establishing an industry is manufacturing-directed licensing, starting with components in a bottom-up fashion and is most risky, expensive, and has been uniformly unsuccessful for computers. The ultimate goal of indigenous design following the bottom-up approach called "forward integration" is implicitly predicated on slowly evolving standard components. In contrast, for rapidly evolving or high technologies with short component life, a "top down" user-based approach, starting with the application, categorized as "backward integration" is probably best. The computer industry falls into the second category since many rapidly changing disciplines and technologies are required for building and using computers. By initiating a policy based on the second approach a country can establish an appropriate computer industry provided it is based on standards. It will become self-sufficient quickly, and with less imports than by taking the forward integration approach. Futhermore, it can be shown (Appendix 1) that the forward integration approach can require more component imports than a fully assembled computer because the technology evolves so rapidly!

Backward integration necessitates the selection of one or more standard computer families. However, is desirable to not segment and control the market by size because emerging distributed processing systems are built more easily from a single general architecture. Furthermore, since computer prices decline rapidly, a computer characterized in one class now will enter a new class in a few years. The adoption of an "industry standard" allows rapid take-off in computational ability and the selection is based on four criteria: 1) wide range of available applications programs enabling immediate effective use; 2) cost-effectiveness and expandability as shown by various metrics including address space size; 3) availability of a family range from micro- to mainframe computer so that a small number of architectures (hopefully one), maximizes training, permits alternative computing styles to fit various problems, and results in a maximum cumulative learning curve; and 4) compatibility and accessibility through numerous suppliers for peripheral equipment and software.

Appendix 1 - Case Study of Santioned Monopoly, Free Market Import and Backward Integration Strategies

In one country a sanctioned monopoly was set up to license and manufacture what was basically an obsolete computer. The following analysis of a five year period shows, in principle, the situation and compares it with scenarios based on different policies. It neglects any user loss of productivity because of poor computers, and any import duties (since the licensee was given duty free status).

Four cases are compared:

1. Monopoly (actual) - no manufacturing was achieved and licensee only imported finished goods.

2. Monopoly (plan) - the monopoly was to have imported finished goods the first year, put together sub-assemblies the second year, and assemble the sub-assemblies from components the third year.

3. Free Market Import - No controls, are assumed. The most cost-effective system is imported.

4. Free Market Import with Backward Integration - Case 3, except a policy (e.g. duties) which gives preference to minimizing import content is instituted. In the second and third year sub-assemblies are put together locally and in the fourth and fifth years sub-assemblies are built from imported components. The base design can only be changed each two years for new components!

A summary of the results of the four cases using various costs, markups, and market data is described below:

	Total Import (M$)	Local Mfg (M$)	Cost to Users
Monopoly (actual)	78.2	0	488
Monopoly (plan)	44.2	34.0	488
Free Market Import	44.1	0	88
Free Mkt Import with Mfg.	32.0	17.2	83.3

For the study, the market is assumed to grow at 50%/year using the following units: 295 (first year), 443, 666, 1000, and 1500 (fifth year).

The following markups for sales and service are assumed:

Monopoly (actual)	6.25
Monopoly (plan)	6.25
Free Market Import	2.0
Free Market, Local Assembly	2.5
Free Market Local Assembly and Sub-Assemblies (using imported components)	3.0

It is further assumed that the following local content is possible:

Importing Finished Goods	0%
Importing Sub-assemblies	25%
Importing Components	50%

Case and Price Year	Import Cost/ Unit (K$)	Total Import Cost (M$)	Local Mfg. (M$)	User Price (K$)	Total (M$)
Monopoly (actual)					
1	20	6	0	125	36.9
2	20	8.9	0	125	55.3
3	20	13.3	0	125	83.3
4	20	20	0	125	125
5	20	30	0	125	187.5
		78.2			488.
Monopoly (plan)					
1	20	6	0	125	36.9
2	15	6.6	2.3	125	55.3
3	10	6.7	6.7	125	83.3
4	10	10	10	125	125
5	10	15	15	125	187.5
		44.2	34.		488
Free Market Import					
1	20	6	0	40	11.8
2	16	7.1	0	32	14.2
3	12.8	8.5	0	25.6	17.0
4	10.2	10.2	0	20.4	20.4
5	8.2	12.3	0	16.4	24.6
		44.1	0		88.
Free Market Import With Staged (each two years) Local Manufacture					
1	20	6	0	40	11.8
2	12	5.3	1.8	30	13.3
3	12	8.0	2.7	30	20.
4	5.1	5.1	5.1	15.3	15.3
5	5.1	7.6	7.6	15.3	22.9
		32.0	17.2		83.3

Irwin Goodwin
National Research Council
Assembly of Engineering
2101 Constitution Avenue
Washington, DC 20418

Dear Irwin Goodwin,

I've reviewed the draft report, "Computers, Communications, and Public Policy." I have two reactions.

One. Why has it taken so long to put it out? If we really are concerned about productivity (and I am) then we as the leaders must use information technology and get out the news. This is an important report that is only growing old and obsolete. (On a final edit the word "now" might better be replaced with an appropriate date.)

Two. Why isn't the data and ideas tranferred into graphs and charts? There is too much verbiage -- most of which could have been summarized in some good comparative charts, eg., comparative size of industries -- the U.S., Japan, France, Canada, etc., the realtive use of the electromagnetic spectrum, and other concepts.

Publish it as is.

Sincerely yours,

Gordon Bell
Vice President,
Engineering

Dr. John Pasta
National Science Foundation
Office of Computing Activities
Washington, D.C. 20550

Dear John:

We have been hard at work on the Digital Computer Museum again and I'm hoping for a public opening this fall.

In the Museum, we hope to have a small shop selling informative posters, books, and educational materials related to computing. We would like to have permission to reproduce and sell the original NSF Computer Genealogy Tree as a poster. We have a large reproduction on plexi hanging in the museum and have had requests for reproductions -- both by our engineers and from faculty.

In addition, we're working on a poster to illustrate the evolution of pre-computer calculating devices, and have requested permission from the British Science Museum to sell their poster on the History of Computers.

Could you please sign the enclosed permission to reproduce the NSF Computer tree as a poster?

I'd be happy to have you see the museum sometime when you are in the area (even though it is not yet officially open) and do hope that you will be able to come to the opening, tentatively set for September 22.

Cordially,

Gordon Bell
Vice President,
Engineering

GB1.S2.44
The people: I liked Bashkow's work on the Fortran machine, however his recent activities and production of Ph.D.'s is pretty weak and unenergetic. He clearly could do the work. While Sullivan could be helpful and has done some nice work, his lack of position at Columbia and the fact that he has a business would appear to conflict (in time). Sullivan has a nice background, and if he's full time, would be valuable here. Overall, the team looks pretty weak in time...and may not even exist as a team--which is bad for this work.

There seem to be an adequate number of graduate students involved, hence it will be good training.

The earlier reference seems all right, but not exceptional.

As to the machine, there are at least two novel ideas: the interconnection scheme and the multiple virtual processors on a physical processor to be able to get around the long delays caused by the cheaper interconnection scheme. Apparently a cache was rejected since it's hard to control the distributed data. Since it's a conventional processor and since much of the traffic to memory is for programs, the cache would be valuable, maybe even necessary to avoid the constant problem they discuss of needing multiple copies of the program.

The machine design is pretty naive as described on page 31 of part I. They might clarify how they get 64K bits for 64K gates. Also the machine is awfully imbalanced, according to Amdahls constant, reflecting everyone's affinity to fix on processors. (They have only 8 megabytes of storage for 1,000 mips reflecting a 125:1 difference in the norm.) To make matters worse, they require multiple copies of programs and lots of multiprogramming (10-16 virtual processors/processor) in order for the thing to work which would imbalance the memory. Overall I think the interference could be much worse than they expect since it's possible to have a situation when all 2K processors want the same data. I'd like to see some notion of what a structure would look like physically now. A 2,000 node system for $5M might be hard to come by with its 2,000 log 2,000 cables. A back of the envelope argument as to physical size would have been nice.

The encouraging thing about having only an 8 megabyte memory is that they can easily simulate the work. However, I didn't see any reasonable entry for computer time. Alternately, they aren't getting anywhere near hardware.

Although I'm unwilling to believe their structure absolutely won't work, I do believe the more pressing problem of investigating how it would be used should be attempted before going on to propose any more details. Right now we have some structures and languages to do this with. When we finally have systems with large numbers of processors, I believe it won't resemble the proposal.

While I do strongly believe in the general approach of multiprocessors, I don't believe they will help much because the effort will keep them fairly remote from hardware, simulation, languages, and applications.

Digital **Interoffice Memo**

Subject: **Gene Amdahl's Enjoyable Talk Last Week at NATO Summer School**

To: Distribution

Date: 20 SEP 76
From: Gordon Bell
Dept: OOD
Loc.: ML12-1 Ext.:
2236

F/U 9/29

He was director of ACS, IBM Menlo Park, California, 1966-1969, and left because he could not build a large, profitable

360. I didn't find out how much of Amdahl Corporation's development was done at IBM, or how much time he spent fund raising there...but he appears to be highly ethical.

The decision to leave IBM was based on his inability to get policy changes that would permit large machines to be built. The two he discussed were: 1. The uniform allocation of overhead such that large machines could be made profitably; and 2. Poor performance internal component purchases were forced.

He claimed the high end expenses (i.e., 370/168) were less than the 158 by a significant amount because the customers were sophisticated and self-sufficient. Indeed, this group put the "independents" in business. The policy supports mid-range thrust. In fact, the support for a 145 is higher since the customers don't know what they're doing. The range is shown in the attached figure. Can we try this representation for our sales? It matches the distribution for corporations NOR.

The components supplier within IBM/Essex Junction?) was not performing acceptably to support large machines; in fact it was a marginal supplier of the 168. The System Managers had to "pay" and couldn't go outside.

Amdahl Corporation is predicated on these two policies plus the changing ratio of the processor to cover a wider range!. He doesn't see how IBM can make high end machines, nor why it would want to put him out of business. His machine provides a high end blanket for the 370. I believe he also will push multiprocessors to "extend" his range in the same way as the 168 and thereby pick up more of the high end tail in much the same way a lower price ratio for the CPU tends to "widen" the range. He is also working on other products.

His support (console) machine is a NOVA, and he's invited me to come present the PDP-11 to them...and see the factory/machines in Sunnyvale.

Who wants to go visit with me?

Do you believe his strategy is viable?

BILL DEMMER FROM: GORDON BELL
DON MCINNIS DEPT: ENG STAFF
STEVE JENKINS EXT: 223-2236
LOC/MAIL STOP: ML12-
1/A51

SUBJECT: NAUTILUS

Can we look at a set of goals that would make time to market
as
the first goal?

Bob and I discussed the fast time to market as the primary
goal
and he stated that we aren't pursuing this goal. He then
suggested that we (Bob, Bill, Don, Steve and I) might meet
and
explore these goals.

Frankly, I am deeply concerned about our strategy based on VAX.
Only the 780 seemed to come off in a timely, competitive way. Each machine we introduce has gotten later and later and less cost-effective. Nautilus and Scorpio both promise to be good, but the competition is going to be the next round of hot micros using 1 and 2 micron MOS. Already, these folks benchmark against Comet; Nebula is clearly out of it based on the fact that it's technology would have allowed it to ship two years ago had it not been for the really abysmal product and system's management direction. The sales too reflect the situation (look at the 780 and 750). We all know we need a fast processor for 780 users.

Could we consider this ordering of goals:

- .Serviceability, giving low cost of ownership
- .Time to market (<3 years for fvs!)
- .Manufacturability
- .Performance (>2.5 x 780)
- .Cost (processor approximately Comet, but could be 2x Comet)

This would mean that it would ship either concurrent with or slightly after Gemini and the next machine after Nebula.

The design for quick time to market would be done in a different way than either Comet or Venus. Certainly there would be no need to fully build it out of custom gate arrays. Use of standard, fast parts would be allowed. We are looking at a fast, National PLA (12ns) that may even be useful for Venus. Finally, it is essential that if we are going to get the design done fast,

that
it be partitionable, like the 780 so several groups can all
work
on it. (The conventions have to be clear and it means that
all
the designers needn't know the machine.) For most of Venus,
our
MCA's are really dull, and it would have been possible to
have
Motorola design them. In Nautilus's case, even though the
design
is in the gate arrays, it still behoves us to think the
machine
out so that each can be partitioned and worked on in
parallel.
This urge is the only way to get the clarity of the design
and
also the parallelism I may advocate so as to get the product
to
market asap! A design structured this way would be memory
and
table look-up (pla, rom and ram) intensive. Most of all, the
big
requirement of the design be that the team know VAX, and that
there's a very good chief designer. I trust this is Bob.

When can we have this discussion?

What do you folks think? Are there these tradeoffs? What is
the
range?

SUBJECT: DEVELOP AND MAKE OR BUY THE NAUTILUS GATE ARRAY FROM TI?

I'm delighted that the issue has come up that we are

proposing
to buy the next generation gate array from TI because it is a decision that has to get made very, very explicitly!

I support the 1/2-1 day review. At the end of it, I expect to
see us end up with a 1 page list of pros and cons, including the page of backup which gives the financial picture in terms of cash needed. It also must contain another precious resource,
the number of persons required in semiconductors as we follow the two scenarios. (Is it possible to NOT have the in house be a
second source and thereby avoid the whole issue of bringing in
the process?)

After the review between Engineering and Manufacturing, I want
to take our recommendation directly to the Operations Committee
or the Board. The issue with me is going to be what the effect is on taking another bite out of our engineering budget
by having to engineer at this level of integration... even though we started the precedent with Comet.

We should have the same concern about our capital equipment requirements as this level of integration really hits it hard and calls for an increased percentage over the past (recall that the Operations Committee approved higher capital expenses
here than based on extrapolated history).

Overall:
Let's really try to understand. I view it as mainly a financial
decision. (I would welcome some high level involvement from Al, George or Bill ... if they would want to help.)

SUBJECT: NAUTILUS: THE NEXT STEP

Let's set about asap to get the maximum learning from Venus, Rezac via the Japanese experience, Stanford S1 et al, and Comet vis a vis the CAD tools. The presentation and approach was now in retrospect clearly out of the dark ages. I believe the VLSI folks under the sponsorship of their managers are spending money in the right areas to get out of the black hole of complexity that the technology is allowing us to enter. No way, do I believe we will be able to complete the Nautlilus design, given the emphasis of the design team, and the status of the design tools. Supnick is probably the best one to start teaching this internally at this time, and perhaps Ron Melanson.

The approach has to be get the tools and discipline NOW, while the technology is being looked at, and then start the design using the tools. This may delay the design start by a year, but I'd expect the output at least two years earlier than with the approach taken.

Therefore, I'd like to see the addition of some VERY strong system programmer, right now who'll be part of the main team to carry out this function, and keep the design top down and structured.

I think we are all tired of getting into these projects and finding that the bookkeeping complexity and details of non-connected parts, etc are killing us. Comet, Venus were both this way, and Fonz ended up this way. NOW is the time to Change! We have to head for the 2 year product cycle, there is nothing stopping this, provided you have the right tools!

Let's have a session after you have the person and when you're ready to set the goals about how the design will be done.

I'd also like to interact while you're gropping with this problem too. I hope we can get together very shortly.

While it's too early to tell the results, Scorpio is being designed in this fashion. There may be the best place to start using Supnik as a guide.

This is not an optional program. No reform, no design. Am tired of seeing designers disappearing into a black hole only to reappear if they do, very tired, old and grey. There aren't that many good ones around to enter the holes.

SUBJECT: COMPUTER BASED MESSAGE SYSTEMS

Gordon,

The National Bureau of Standards has requested DEC'S participation, along with a number of other vendors (BBN, CCA, Tymenet, Telenet...), in a joint announcement of intent to adopt the specification for message format for Computer Based Message Systems developed by NBS.

The announcement does not indicate time frame for adoption. It is a public statement of future intent that will take the form of a press release and publication in a number of industry trade journels and magazines.

I have asked Bob Travis to validate whether or not he had any technical reservations about the content of the announcement. He did not since Message Router already conforms to NBS standards (to the extent that they are complete).

We would like to go ahead and participate in making this statement.
Do we have to take this to Operations Committee, or is your approval
enough?

- Bruce

follow up 7/3/78

From what I hear, we had the strongest product positions of any exhibitor. It was especially good (necessary) for the engineers involved in the creation of the products to see the reaction of potential buyers. We need more interaction of this type and I hope NCC will be an annual occurrence! (We also have to find a fall/winter forum too...DECUS?)

Especially unique were the PDT's based on the VT100 and TU58 giving us a significant system in a CRT. The VT100 and TU58 also give us a base for many future systems.

Although previously introduced, there was much interest in TRAX, VAX and the 2020. Of course DECnet permitted all the systems to communicate with one another. All of these are truly unique in their "first time" capabilities.

Please convey my thanks to the developers and Product Managers who made these introductions possible.

Grant Saviers, Bill Strecker,
Pete vanRoekens

I lost round one, the NDS breadboard was built on a home grown breadboard which I would expect to be a warmed over version of the last operating system Barry did on the PDP-15. I believed this should have been a version of M so
modified to get the interrupt latency to an acceptable time.

Now, I am more than ever convinced that the NDS system must be based on M because if we are to migrate any of the functions of M to the disk subsystem, there must be a way to use the same code and simply move it to exist in the back-end system. Although the need for the timing is clear, we must find an atlernative way to provide the M environment so as to avoid all the nonsense that will accompany another, vanity system. (This will include release, utilities, interfaces, diagnostics, another file and data management system, etc.)

When can we get this issue addressed? Bill, I look to you and Ralph to keep us from screwing this one up and compounding the problem.

Richy, can you explain too how such a system can meet these constraints?

As an aside, getting a high performance RSX-11/M is a useful, important by-product.

-Looks like too many configurations and overlap with Comet.

-Looks like a <u>good</u> plan, though, overall! (It'll be ahead of Comet.)

-Can you use Mercury/Mercury parts for communication?

-Why have TS04/R80 support?

-What about a CDC 9762 interface to various industry <u>standard</u> disks for real low ball? (Would get you to R80, to CDC drive used in the RM03, to the CDC storage module.)

-What about details on a personal machine!

-Doubt if it'll support 32 lines!! (Can you plot the price <u>vs</u> number of users plates that Terry Potter's group does -- see Paul Kampas.)

Let's go.

SUBJECT: RE: NEBULA, SUVAX, APPLE

I think we have to get the data in terms of cost performance versus the 44 and 24. I'm feeling better about using the 64K chips and getting the cost. Also, Nebula looks pretty good in terms of performance here too. We are getting this together
so we can make a rational decision.

Sorry, I didn't mean to lay Rosing blame on you. It was his shot at making 2 Megabucks and no one could stop him... nor was he especially looking.

My push to Nebula has been consistent. We have to signal the market that we are going with VAX and get them positioned. Also
we gotta get it into the low end segment so as to avoid the shift to the 22-24 bit micros (Intel, Zilog, Motorola) which has to occur. J is the last systems 11, and quite possibly we could avoid it... only using J in the terminals based products.

I want to move asap to get 11's in the personal computers only,
with a single operating system, together with support of existing
customer base (which is enormous).

A demo will be forthcoming which has a real operating system that is user installable (you or I would do it to test it) for
VAX using RL02's. This will get the cost down to where it shouldd
be, plus it will bound it from a customer installability, and maintainence standpoint. I'm anxious to try it, and will let you know how it feels.

Meanwhile, we are getting data together like crazy.

SUBJECT: GETTING SERIOUS WITH NEBULA AS A PERSONAL COMPUTER

In discussing Nebula with Lou on Friday, it's clear that it is a personal computer and for the technical OEM where the issue is VAX compatibilitly and or need for the large address space. As we make big configurations of the Nebula, it is squarely in the domain of the COMET. I have, apparently too secretly, only thought of it as the personal computer . It is to beat the hell out of the HP300 and I thought we would have found this out. Now, I say let's get serious and make it precisely this! Note, that if you go back to the strategy document, you should see that it is Nebula's role. I want to go balls out and get the product ready to announce and/or ship with Comet. The terminal we may have to use to first ship with is the VT105, but ultimately I want the VT125 followed with an upward compatible color and/or high resolution scope. I do not want to work on any terminal that must be built-in to the Nebula box because it can not be remoted!!!   (or sold on anything else!)
